Key Concepts

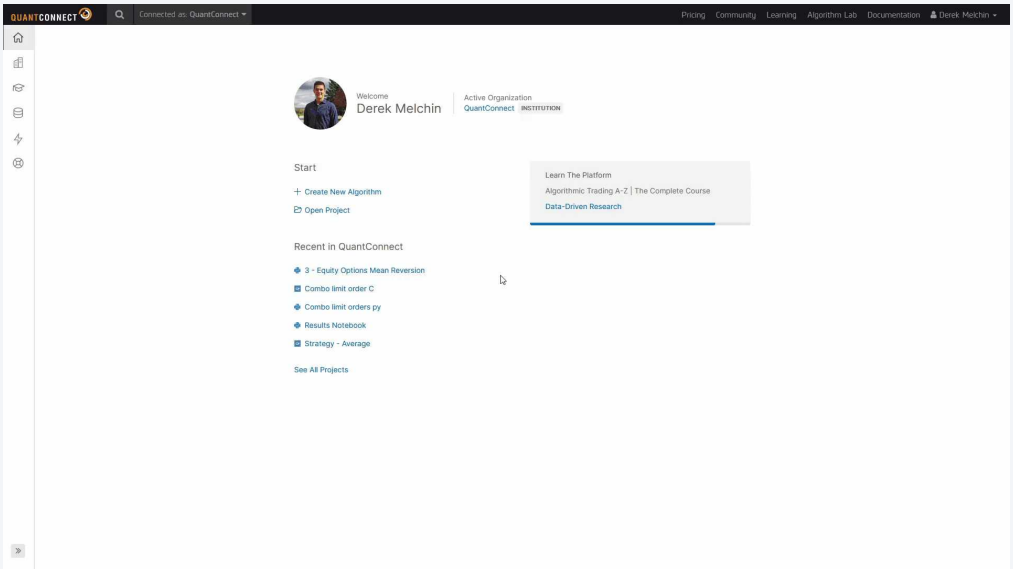
Getting Started

GET STARTED WITH WRITING ALGORITHMS

Guide through creating a project, running your first backtest, and live algo trading.



Follow these steps to create, backtest, and paper trade a new algorithm:

1. Create a new project.

The process to creating a new project depends on if you use the Cloud Platform , Local Platform , or CLI .

2. Backtest the default algorithm.

The process to backtest the algorithm depends on if you use the Cloud Platform , Local Platform , or CLI .

3. Deploy the algorithm to live paper trading.

The process to deploy the algorithm live depends on if you use the Cloud Platform , Local Platform , or CLI .

Key Concepts

Algorithm Engine

Introduction

LEAN Engine is an open-source algorithmic trading engine built for easy strategy research, backtesting, and live trading. We integrate with common data providers and brokerages, so you can quickly deploy algorithmic trading strategies. The core of the LEAN Engine is written in C#, but it operates seamlessly on Linux, Mac and Windows operating systems. To use it, you can write algorithms in Python 3.11 or C#. QuantConnect maintains the LEAN project and uses it to drive the web-based algorithmic trading platform on the website.

Since LEAN is open-source, you aren't locked-in to the QuantConnect platform. You can run LEAN with your own infrastructure, data, and brokerage connections. If you use QuantConnect, our team of engineers manage the infrastructure, you can run the latest version of LEAN with all of its brokerage connections, and you can utilize the datasets in the Dataset Market .

Your Algorithm and LEAN

To create a trading algorithm with LEAN, define a subclass of the `QCAlgorithm` class. LEAN loads your algorithm into the engine during the building and compilation process. LEAN runs an algorithm manager that synchronizes the data your algorithm requests, injects the data into your algorithm so you can place trades, processes your orders, and then updates your algorithm state.

The LEAN engine manages your portfolio and data feeds, so you focus on your algorithm strategy and execution. We automatically provide basic portfolio management and reality modeling underneath the hood. The `QCAlgorithm` class provides some key helper properties for you to use, including the Security Manager, Portfolio Manager, Transactions Manager, Notification Manager, and Scheduling Manager. The class also has hundreds of helper methods to make the API easy to use.

The Securities property is a dictionary of `Security` objects. Each asset (Equity, Forex pair, etc) in your algorithm has a `Security` object. All the models for a security live on these objects. For example, `Securities["IBM"].FeeModel` and `Securities["IBM"].Price` return the fee model and price of IBM, respectively.

The Portfolio is a dictionary of `SecurityHolding` objects. These classes track the profits, losses, fees, and quantity of individual portfolio holdings. For example, `Portfolio["IBM"].LastTradeProfit` returns the profit of your last IBM trade.

Other helpers like Transactions , Schedule , Notify , and Universe have their own helper methods.

```C#
public class QCAlgorithm
{
    SecurityManager Securities;               // Array of Security objects.
    SecurityPortfolioManager Portfolio;       // Array of SecurityHolding objects
    SecurityTransactionManager Transactions;  // Transactions helper
    ScheduleManager Schedule;                 // Scheduling helper
    NotificationManager Notify;               // Email, SMS helper
    UniverseManager Universe;                 // Universe helper

    // Set up Requested Data, Cash, Time Period.
    public virtual void Initialize() { ... };

    // Event Handlers:
    public virtual void OnData(Slice slice) { ... };
    public virtual void OnEndOfDay(Symbol symbol) { ... };
    public virtual void OnEndOfAlgorithm() { ... };

    // Indicator Helpers
    public SimpleMovingAverage SMA(Symbol symbol, int period) { ... };
}
```

Only define one algorithm class per project. To trade multiple strategies in a single algorithm, implement an Algorithm Framework design with multiple Alpha models . To be notified when you can define more than one algorithm class per project, subscribe to GitHub Issue #6968 .

Threads in LEAN

LEAN is multi-threaded and attempts to consume as much CPU as possible to perform given work as quickly as possible. The analysis engine loads data parallel and synchronizes it to generate the requested security information.

The client algorithm is plugged into LEAN, and has its events triggered synchronously in backtesting. The primary bottle neck to LEAN execution is executing client code.

In live trading, most events are synchronous as in backtesting, however order events are triggered immediately from the brokerage thread (asynchronously) to ensure the lowest latency. For example; a strategy using hourly data, with a limit order could fill between data bars. This fill event is triggered when it occurs in live trading.

We recommend using thread safe collections when possible, or locks around collections to ensure they are thread-safe.

Batch vs Stream Analysis

Backtesting platforms come in two general varieties, batch processing and event streaming. Batch processing backtesting is much simpler. It loads all data into an array and passes it to your algorithm for analysis. Because your algorithm has access to future data points, it is easy to introduce look-ahead bias . Most home-grown analysis tools are batch systems.

QuantConnect/LEAN is a streaming analysis system. In live trading, your algorithm receives data points one after another over time. QuantConnect models this in backtesting, streaming data to your algorithm in fast-forward mode. Because of this, you can't access price data beyond the Time Frontier . Although streaming analysis is slightly trickier to understand, it allows your algorithm to seamlessly work in backtests and live trading with no code changes.

Event Flow

When you deploy an algorithm, LEAN first calls the Initialize method. In live mode, the engine loads your holdings and open orders from your brokerage account to add data subscriptions and populate the `Securities` , `Portfolio` , and `Transactions` objects. LEAN receives the data from the subscriptions, synchronizes the data to create a timeslice , and then performs the following steps. Your algorithm can spend up to 10 minutes on each timeslice unless you call the Train method.

1. If it's a backtest, check if there are Scheduled Events in the past that didn't fire because there was no data between the

previous slice and the current slice. LEAN automatically creates a Scheduled Event to call the `OnEndOfDay` method at the end of each day.

In live mode, Scheduled Events occur in a separate thread from the algorithm manager, so they run at the correct time.

2. Update the algorithm time.
3. Update the `CurrentSlice` .
4. Pass the `SymbolChangedEvents` to the `OnSymbolChangedEvents` method.
5. Cancel all open orders for securities that changed their ticker .
6. Add a `Security` object to the `Securities` collection for each new security in the universe.
7. Update the `Security` objects with the latest data.
8. Update the `Cash` objects in the CashBook with the latest data.
9. Process fill models for non-market orders.
10. Submit market on open orders to liquidate Equity Option contracts if the underlying Equity has a split warning .
11. Process margin calls .
12. If it's time to settle unsettled cash , perform settlement.
13. Call the OnSecuritiesChanged method with the latest security changes.
14. Apply dividends to the portfolio.
15. For securities that have a split warning, update their portfolio holdings and adjust their open orders to account for the split.
16. Update consolidators with the latest data.
17. Pass custom data to the `OnData` method.
18. Pass the `Dividends` to the `OnDividends` method.
19. Pass the `Splits` to the `OnSplits` method.
20. Pass the `Delistings` to the `OnDelistings` method.
21. Pass the `Slice` to the `OnData` method.
22. Perform universe selection .
23. Pass the `Slice` to the `Update` method of each Alpha model .
24. Pass the `Insight` objects from the Alpha model to the Portfolio Construction model .
25. Pass the `PortfolioTarget` objects from the Portfolio Construction model to each Risk Management model .
26. Pass the risk-adjusted `PortfolioTarget` objects from the Risk Management models to the Execution model .

When your algorithm stops executing, LEAN calls the `OnEndOfAlgorithm` method .

Python Support

The LEAN engine is written in C#, but you can create algorithms in C# or Python. If you program in Python, LEAN uses Python.Net to bridge between the C# engine and your algorithm. It can be slow to move from Python to C#. If you access C# objects in your Python algorithm, it's fastest to only access them once and save a reference if you need to access them again.

Key Concepts

Multi-Asset Modeling

Introduction

We designed LEAN as a multi-asset platform with out-of-the-box support for multiple securities, so you can model complex portfolios like hedge funds.

Asset Portfolio

The portfolio manages the individual securities it contains. It tracks the cost of holding each security. It aggregates the performance of the individual securities in the portfolio to produce statistics like net profit and drawdown . The portfolio also holds information about each currency in its cashbook.

Cashbooks

We designed LEAN to be a multi-currency platform. LEAN can trade Forex, Cryptocurrencies, and other assets that are quoted in other currencies. A benefit of supporting multiple currencies is that as we add new asset classes from new countries, LEAN is already prepared to transact in those assets by using their quote currency. For instance, we added the India Equity market, which quotes assets in the INR currency.

The portfolio manages your currencies in its cashbook, which models the cash as a ledger of transactions. When you buy assets, LEAN uses the currencies in your cashbook to purchase the asset and pay the transaction fees. For more information about the cashbook, see Cashbook .

Buying Power

We model the margin requirements of each asset and reflect that in the buying power available to the algorithm. We source Futures margins from CME SPAN margins. Equity margin is 2x for standard margin accounts and 4x intraday for Pattern Day Trading accounts. For more information about buying power modeling, see Buying Power .

Examples

The following examples demonstrate some common practices for multi-asset modeling.

Example 1: BTC Spot-Crypto Future Arbitration

This algorithm demonstrates an arbitration between Spot and Crypto Future BTCUSDT using a BTC cash account. If one's price is above 0.5% of another's, we sell the relatively overpriced one and buy the counter side. To ensure the cash position is sufficient to open the buy position, we order the buy side after the sell side is filled and the cash is replenished.

```C#
public class MultiAssetModelingAlgorithm  : QCAlgorithm
{
    private Crypto _spot;
    private CryptoFuture _future;
    private decimal _threshold = 0.005m, _tradeQuantity;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the last price to set the initial price of the BTCUSDT holdings.
        Settings.SeedInitialPrices = true;

        // Simulate a cash Bybit account.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Cash);
        SetAccountCurrency("USDT", 0);
        var spotBalance = 2;  // BTC
        SetCash("BTC", spotBalance);

        // Request BTCUSD spot and future data to trade their price discrepancies.
        _spot = AddCrypto("BTCUSDT", market: Market.Bybit);
        _future = AddCryptoFuture("BTCUSDT", market: Market.Bybit);

        // Simulate the portfolio is holding BTC cash initially via BTCUSDT position.
        // Note that the performance will also be affected by the BTC performance in the default account currency.
        _spot.Holdings.SetHoldings(averagePrice: _spot.Price, quantity: spotBalance);
        _tradeQuantity = spotBalance/2.0m;
    }

    public override void OnData(Slice slice)
    {
        // Wait for the Slice to contain QuoteBar objects for both assets.
        if (!(slice.QuoteBars.ContainsKey(_spot.Symbol) && slice.QuoteBars.ContainsKey(_future.Symbol)))
        {
            return;
        }
        // If the spot price is higher than the future price more than the threshold,
        // Do arbitration by selling the spot BTC and buying the future.
        if (_spot.Price >= _future.Price * (1m + _threshold) && !_future.Holdings.IsLong)
        {
            Sell(_spot.Symbol, _tradeQuantity);
        }
        // If the future price is higher than the spot price more than the threshold,
        // Do arbitration by buying the spot BTC and selling the future.
        if (_future.Price >= _spot.Price * (1m + _threshold) && _future.Holdings.IsLong)
        {
            Sell(_future.Symbol, _tradeQuantity);
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // Order the buy-side of the arb only when the BTC is sold and USDT is obtained.
        if (!(orderEvent.Quantity < 0 && orderEvent.Status == OrderStatus.Filled))
        {
            return;
        }
        Security security = orderEvent.Symbol == _spot.Symbol ? _future : _spot;
        // Calculate the initial margin needed. We must sell the same amount of BTC to obtain sufficient USDT for
trade.
        var margin = security.BuyingPowerModel.GetInitialMarginRequirement(
            new InitialMarginParameters(security, _tradeQuantity)
        ).Value;
        // Check if USDT cash is sufficient to open the position.
        if (Portfolio.CashBook["USDT"].Amount >= margin)
        {
            Buy(security.Symbol, _tradeQuantity);
        }
    }
}
```

Example 2: BTC Spot-Future Arbitration

This algorithm implements a similar logic to the above example of an arbitration algorithm between spot BTCUSD and Future BTC using a cash account. If one's price is above 0.5% of another's, we sell the relatively overpriced one and buy the counter

side. Note that we need to calculate the future value of the Future fairly compared to the spot BTC. Also, we need to rollover any Futures contracts.

```C#
public class MultiAssetModelingAlgorithm  : QCAlgorithm
{
    private Crypto _spot;
    private Future _future;
    private decimal _threshold = 0.005m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set cash to sell Futures.
        SetCash(1000000);
        // Seed the price of each asset with its last known price to
        // avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add BTCUSD spot and Future data to trade their price
        // discrepancies.
        _spot = AddCrypto("BTCUSD", market: Market.Coinbase);
        _future = AddFuture(Futures.Currencies.BTC, dataMappingMode: DataMappingMode.OpenInterest);
        _future.SetFilter(0, 62);
    }

    public override void OnData(Slice slice)
    {
        // Get the current bar for both markets.
        if (!slice.Bars.TryGetValue(_spot.Symbol, out var spot) || !slice.QuoteBars.TryGetValue(_future.Mapped, out
var future))
        {
            return;
        }
        // Use forward price to compare to spot BTC price fairly.
        var discountFactor = RiskFreeInterestRateModel.GetInterestRate(slice.Time) * (decimal)(_future.Mapped.ID.Date
- slice.Time).TotalSeconds / 60m / 60m / 24m / 365m;
        var btcFutureFV = future.Close * Convert.ToDecimal(Math.Exp((double)discountFactor));
        // If the spot price is above the Future price by more than the
        // threshold, sell the spot BTC and buy the Future to arbitrage.
        if (!_spot.Holdings.IsShort && spot.Close >= btcFutureFV * (1m + _threshold))
        {
            Sell(_spot.Symbol, _future.SymbolProperties.ContractMultiplier);
            Buy(_future.Mapped, 1m);
        }
        // If the Future price is above the spot price by more than the
        // threshold, sell the Future BTC and buy the spot BTC to arbitrage.
        else if (!_spot.Holdings.IsLong && btcFutureFV >= spot.Close * (1m + _threshold))
        {
            Sell(_future.Mapped, 1m);
            Buy(_spot.Symbol, _future.SymbolProperties.ContractMultiplier);
        }
        // When prices converge, exit the arbitrage trade.
        else if ((_spot.Holdings.IsLong && btcFutureFV <= spot.Close) || (_spot.Holdings.IsShort && spot.Close <=
btcFutureFV))
        {
            Liquidate();
        }
    }

    public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
    {
        // Get Symbol Change Event of the Continuous Future (change
        // in mapped contract) to roll over.
        if (!symbolChangedEvents.TryGetValue(_future.Symbol, out var changedEvent))
        {
            return;
        }
        var oldSymbol = changedEvent.OldSymbol;
        // Add the new contract.
        var newSymbol = AddFutureContract(changedEvent.NewSymbol).Symbol;
        var tag = $"Rollover - Symbol changed at {Time}: {oldSymbol} -> {newSymbol}";
        var quantity = Portfolio[oldSymbol].Quantity;
        // Rolling over: liquidate the position of the old mapped
        // contract and switch to the new mapped contract.
        Liquidate(oldSymbol, tag: tag);
        if (quantity != 0)
        {
            MarketOrder(newSymbol, quantity, tag: tag);
```

```
        }
    }
}
```

Key Concepts

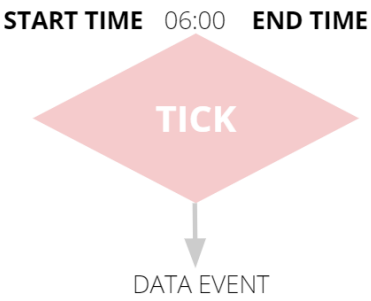
Time Modeling

Time Modeling

Periods

Introduction

Data comes in two different "shapes" according to the time period it covers: point values or period values. In QuantConnect, ticks are point values, and bars are a period values. These data formats have different properties, which control when LEAN emits them into your algorithm.



Start and End Time

Bars have a start and end time that represent the time period of which the bar aggregates data. LEAN passes the bar to your

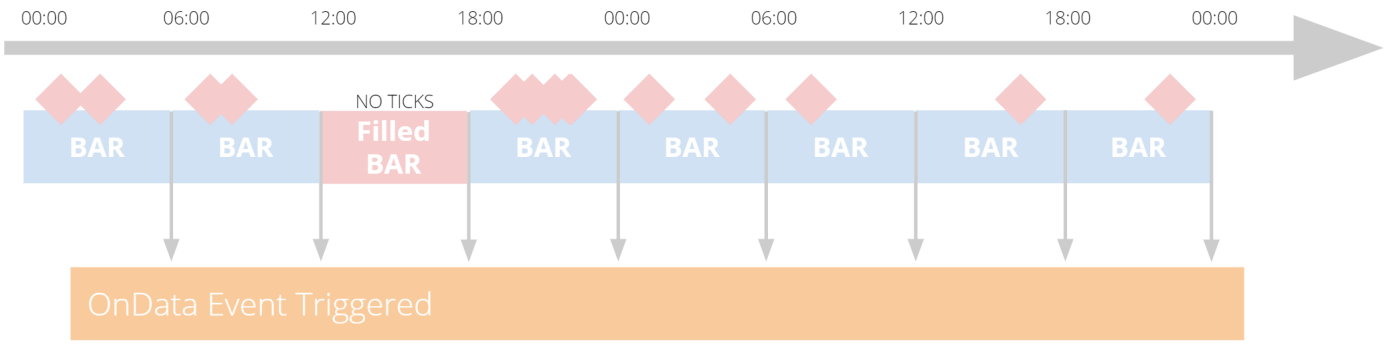
algorithm at the end time so that you don't receive the bar before it was actually available. Free online data providers commonly timestamp their bars to the start time of the bar and include the bar close price, making your research prone to look ahead bias.

Carefully consider the end-time of data to avoid one-off errors when you import the data into QC or compare indicator values across different platforms. Generally, bar timestamps can be represented as follows: `bar.EndTime = bar.Time + bar.Period`.

Period Values

Bars aggregate data across a period of time into a single object. We make this easy for you by pre-aggregating billions of raw trade-ticks into `TradeBar` objects and quote-ticks into `QuoteBar` objects.

We don't know the close of an intraday bar until the start of the next bar, which can sometimes be confusing. For daily bars, the bar will include all the ticks from market open to market close, but LEAN will emit it to your algorithm at market close. As a result, if you analyze the Friday data and then place an order, LEAN sends the order to your brokerage on Friday after the market close.



When there are no ticks during a period, LEAN emits the previous bar. This is the default behavior for bar data and it's referred to as "filling the data forward". You can enable and disable this setting when you create the security subscription.

We provide bar data in second, minute, hour, and daily bar formats. To create other periods of bars, see Consolidating Data.

Daily Periods

LEAN emits daily bars at market close or midnight, depending on your `DailyPreciseEndTime` setting. To be notified when a security has finished trading for the day, add an `OnEndOfDay` method to your algorithm. LEAN calls this method for each security every day.

```
C#
// Perform end-of-day logic for a given symbol.
public override void OnEndOfDay(Symbol symbol)
{

}
```

Point Values

Point values have no period because they occur at a singular point in time. Examples of point data includes ticks, open interest, and news releases. Tick data represents a single trade or quote in the market. It's a discrete event with no period, so the `Time` and `EndTime` properties are the same. LEAN emits ticks as soon as they arrive and doesn't fill them forward.

Examples

The following examples demonstrate some common practices for period time modeling.

Example 1: Tick Signals & Daily Bars

This example shows using a tick/pointwise signal from the Smart Insider Intention dataset while trading Starbuck's stock with daily bars. To liquidate the position after two trading days, you can count the number of `TradeBar` objects you get in the `OnData` method.

C#

```
public class PeriodTimeModelingAlgorithm : QCAlgorithm
{
    private Equity _equity;
    private Symbol _smartInsiderIntention;
    // Add a member to track the number of days until the position
    // should be liquidated.
    private int _holdDays = 0;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add an Equity asset. We will enter with a market on open order
        // and hold for 2 full days, so daily resolution is sufficient.
        _equity = AddEquity("SBUX", Resolution.Daily);
        // Add insider trade intention as the sentiment trading signal.
        _smartInsiderIntention = AddData<SmartInsiderIntention>(_equity.Symbol).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Buy Starbuck's stock whenever we receive a buyback intention
        // or transaction notification due to volatility.
        if (slice.ContainsKey(_smartInsiderIntention))
        {
            SetHoldings(_equity.Symbol, 1);
            // Hold the position for 2 days to fully digest the insider
            // intention sentiment.
            _holdDays = 2;
        }
        // Count down the holding day per each daily trade bar received.
        if (_equity.Holdings.Invested && slice.Bars.ContainsKey(_equity.Symbol) && _holdDays-- <= 0)
        {
            // LLiquidate the position if 2 days were fully counted.
            Liquidate(_equity.Symbol);
        }
    }
}
```

Time Modeling

Timeslices

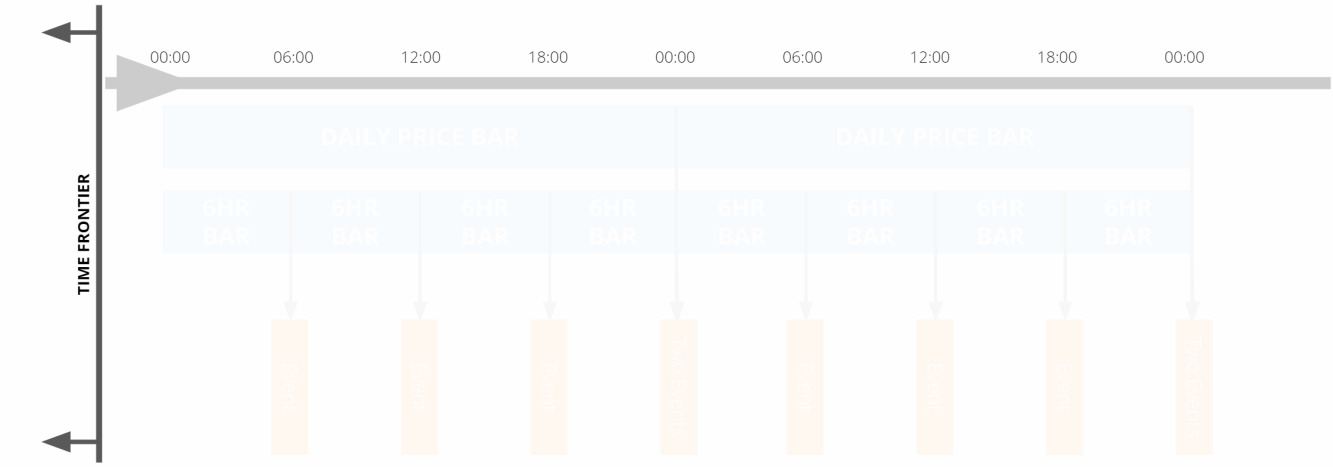
Introduction

The core technology behind QuantConnect algorithmic trading is an event-based, streaming analysis system called LEAN . LEAN attempts to model the stream of time as accurately as possible, presenting data ("events") to your algorithms in the order it arrives, as you would experience in reality.

All QuantConnect algorithms have this time-stream baked in as the primary event handler, `OnData` . The `Slice` object this method receives represents all of the data at a moment of time, a time-slice . No matter what data you request, you receive it in the order created according to simulated algorithm time. By only letting your algorithm see the present and past moments, we can prevent the most common quantitative-analysis error, look-ahead bias .

Time Frontier

If you request data for multiple securities and multiple resolutions, it can create a situation where one of your data subscriptions is ready to emit, but another subscription with a longer period is still be constructing its bar. Furthermore, if you request multiple datasets that have different time zones, your algorithm will receive the daily bars of each dataset at market close for the respective asset. To coordinate the data in these situations, we use the `EndTime` of each data point to signal when LEAN should transmit it to your algorithm.



Once your algorithm reaches the `EndTime` of a data point, LEAN sends the data to your `OnData` method. For intraday bars, this is the beginning of the next period. For daily bars, it's market close or midnight, depending on your `DailyPreciseEndTime` setting . To avoid look-ahead bias, you can only access data from before this Time Frontier. The `Time` property of your algorithm is always equal to the Time Frontier.

Properties

`Slice` objects have the following properties:

Get Time Slices

To get the current `Slice` object, define an `OnData` method or use the `CurrentSlice` property of your algorithm. The `Slice` contains all the data for a given moment in time. The `Bars bars` and `QuoteBars quote_bars` properties are `Symbol` /string indexed

dictionaries. The `Ticks ticks` property is a list of ticks for that moment of time, indexed by the `Symbol` . To check which data formats are available for each asset class, see the Data Formats page in the Asset Classes chapter.

The `Slice` object gives you the following ways to access your data:

- Indexing the `Slice` , which returns a dynamic object of your type.

  ```
  // Get the current dynamic object for the specified symbol by indexing the Slice object.
  public override void OnData(Slice slice)
  {
      var data = slice[_symbol];
  }
  ```

  With minute and second resolution data, the dynamic type is `TradeBar` for Equities and `QuoteBar` for other asset classes.

- Indexing the static properties, which returns the type you specify.

  ```
  // Get the current trade and quote bars for a specific symbol from the data slice.
  public override void OnData(Slice slice)
  {
      var tradeBars = slice.Bars[_symbol];
      var quoteBars = slice.QuoteBars[_symbol];
  }
  ```

- Calling the `Get<T>()` helper method.

  ```
  // Get trade bar, quote bar, and ticks for the specified symbol from the data slice.
  public override void OnData(Slice slice)
  {
      var tradeBar = slice.Get<TradeBar>(_symbol);
      var quoteBar = slice.Get<QuoteBar>(_symbol);
      var ticks = slice.Get<Ticks>(_symbol);
  }
  ```

Strongly typed access gives you compile-time safety, but dynamic type access can sometimes simplify coding. We recommend static types since they are easier to debug.

Check if the `Slice` contains the data you're looking for before you index it. If there is little trading, or you are in the same time loop as when you added the security, it may not have any data. Even if you enabled fill-forward for a security subscription, you should check if the data exists in the dictionary before you try to index it. To check if the `Slice` contains for a security, call the `ContainsKey` method. Note: if the `Slice` object doesn't contain any market data but it contains auxiliary data, the `slice.ContainsKey(symbol)` method can return true while `slice[symbol]` returns `null` .

```
// Check if the slice contains data for the symbol and retrieve it if it's available.
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_symbol))
    {
        var data = slice[_symbol];
    }
}
```

Examples

The following examples demonstrate some common practices for timeslices time modeling.

Example 1: 6-Hour Consolidated Bars

C#

```
public class TimeslicesTimeModelingAlgorithm : QCAlgorithm
{
    private Symbol _aapl;
    private TradeBarConsolidator _consolidator;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request AAPL data to trade it. We need a resolution denser than 6-hour for the consolidator.
        _aapl = AddEquity("AAPL", Resolution.Hour).Symbol;

        // Create a 6-hour consolidator for smoothing the noise.
        _consolidator = new TradeBarConsolidator(TimeSpan.FromHours(6));
        // Subscribe the consolidator to update with the security's data automatically.
        SubscriptionManager.AddConsolidator(_aapl, _consolidator);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_aapl, out var bar) && _consolidator.WorkingBar != null)
        {
            // Trade on a rising trend, suggested by the current close is above the past hour open
            // and the past hour open is above the 6-hour bar open.
            if (_consolidator.WorkingBar.Open < bar.Open && bar.Open < bar.Close)
            {
                SetHoldings(_aapl, 1m);
            }
            // Trade on a down trend, suggested by the current close is below the past hour open
            // and the past hour open is below the 6-hour bar open.
            else if (_consolidator.WorkingBar.Open > bar.Open && bar.Open > bar.Close)
            {
                SetHoldings(_aapl, -1m);
            }
            // Otherwise, do not hold a position if there is no deterministic trend.
            else
            {
                Liquidate();
            }
        }
    }
}
```

Time Modeling

Time Zones

Introduction

LEAN is an international trading engine, so it can operate across time zones. The exchange, your algorithm, and the data in your algorithm can all have different time zones.

Exchange Time Zone

Exchanges are located in different areas, so they can have different time zones. To get the time zone of the exchange that a `Security` trades on, use its `Exchange.Hours.TimeZone` property.

```
C#

// Get the time zone of the exchange for a specific asset.
var timeZone = Securities[_symbol].Exchange.Hours.TimeZone;
```

Algorithm Time Zone

LEAN supports international trading across multiple time zones and markets, so it needs a reference time zone for the algorithm to set the `Time` . The default time zone is Eastern Time (ET), which is UTC-4 in summer and UTC-5 in winter. To set a different time zone, call the `SetTimeZone` method. This method accepts either a string following the IANA Time Zone database convention or a NodaTime .DateTimeZone object. If you pass a string, the method converts it to a `NodaTime.DateTimeZone` object. The `TimeZones` class provides the following helper attributes to create `NodaTime.DateTimeZone` objects:

```
C#

SetTimeZone("Europe/London");
SetTimeZone(NodaTime.DateTimeZone.Utc);
SetTimeZone(TimeZones.Chicago);
```

To get the time zone of your algorithm, use the `TimeZone` property.

```
C#

// The algorithm timezone property can assist with multi-asset trading.
var timeZone = TimeZone;
```

To get the algorithm time in Coordinated Universal Time (UTC), use the `UtcTime` property.

```
C#

// Access the current UTC time to coordinate multi-timezone events or improve logging.
var utcTime = UtcTime;
```

The `Time` and `UtcTime` objects have no time zone. LEAN maintains their state to be consistent.

Data Time Zone

Datasets can have different time zones because the time zone is up to the data provider, where they are located, and where they collect the data. LEAN tracks the time zone of each dataset so that you receive the correct data at the right point in time in your algorithm. If you have multiple datasets in your algorithm from different time zones, LEAN synchronizes them to your

algorithm time. Furthermore, if you set up time period consolidators , LEAN consolidates the data based on the data time zone.

To get the time zone of a dataset, view the listing page in the Dataset Market or call the `GetDataTimeZone` method.

```C#
// Get the timezone of an asset.
var timeZone = MarketHoursDatabase.GetDataTimeZone(Market.USA, _symbol, SecurityType.Equity);
```

Examples

The following examples demonstrate some common practices for time zone modeling.

Example 1: Futures Time Zone

The following algorithm changes its time zone to be the same as the EMini SP500 Futures exchange, i.e., Chicago time zone. It is comparable in validating data across different sources and has a more convenient time notification without further conversion.

C#

```
public class TimeZoneModelingAlgorithm : QCAlgorithm
{
    private Future _future;
    private OrderTicket _ticket;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request ES future data for trading.
        _future = AddFuture("ES", Resolution.Minute,
            extendedMarketHours: true,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);

        // Set the time zone to be the same as the Future (Chicago).
        // It will make the time in the backtest more comparable and easily analyzed with any other data sources.
        // Performance of the backtest will only be altered by this change if the trading logic depends on the Time
property.
        SetTimeZone(_future.Exchange.TimeZone);
    }

    public override void OnData(Slice slice)
    {
        if (!Portfolio.Invested && _ticket == null)
        {
            var contract = Securities[_future.Mapped];
            // Set a limit price that repsects the brokerage's precision requirements.
            var limitPrice = AdjustLimitPrice(contract, contract.Price * 0.995m);
            _ticket = LimitOrder(contract.Symbol, 1, limitPrice);
        }

        // Cancel unfilled orders if they are not filled within 2 minutes to avoid stale fills.
        // Note that the Time property in the order ticket is in the UTC timezone.
        if (_ticket.Status != OrderStatus.Filled && _ticket.Time.AddMinutes(2) < UtcTime)
        {
            // You can change to a different time zone and compare the log differences.
            _ticket.Cancel($"{Time} :: utc: {UtcTime} :: Order canceled due to placed over 2 minutes");

            _ticket = null;
        }
    }

    private decimal AdjustLimitPrice(Security security, decimal price, bool roundUp = true)
    {
        decimal pip = security.PriceVariationModel.GetMinimumPriceVariation(
            new GetMinimumPriceVariationParameters(security, price)
        );
        return ((int)(price / pip) + (roundUp ? 1 : 0)) * pip;
    }
}
```

Key Concepts

Security Identifiers

Introduction

We implemented `Symbol` objects in the LEAN open-source project as a way to identify or "finger-print" tradable assets so that no further database look-up is required. All QuantConnect and LEAN Algorithm API methods use `Symbol` objects to identify assets.

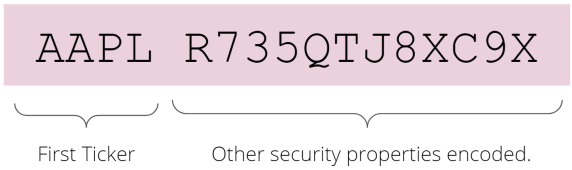
Encoding Symbols

`SecurityIdentifier` objects have several public properties to uniquely identify each asset. The following table describes these properties:

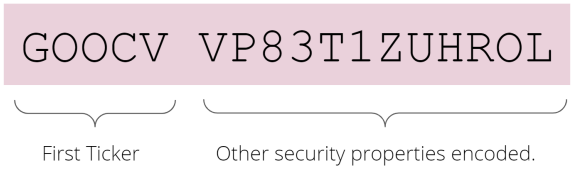
Property	Data Type	Description
`Market`	`string`	The market in which the asset trades
`SecurityType`	`SecurityType`	The asset class
`OptionStyle`	`OptionStyle`	American or European Option style
`OptionRight`	`OptionRight`	Call or put Option type
`StrikePrice`	`decimal`	The Option contract strike price
`Date`	`DateTime`	Earliest listing date for Equities; expiry for Futures and Options; December 30, 1899 for continuous Futures contracts and Indices.
`HasUnderlying`	`bool`	A flag to represent if its a derivative asset with another underlying asset

We encode the preceding properties to create `Symbol` objects. We do our best to hide the details of this process from your algorithm, but you'll occasionally see it come through as an encoded hash like `AAPL R735QTJ8XC9X` . The first half of the encoded string represents the first ticker AAPL was listed under. The other letters at the end of the string represent the serialized form of the preceding `SecurityIdentifier` properties. You may also see an encoded has like `AAPL XL7X5I241SO6|AAPL R735QTJ8XC9X` for a derivative contract. In this case, the part before the `|` is contract hash and the part after the `|` is the underlying hash. This serialization approach lets LEAN assign a short, unique string to octillions of different security objects.

Apple Inc. (same name since listed).



Google Class-C Shares (renamed to GOOG).



LEAN assumes the ticker you pass to the AddEquity method is the current ticker of the Equity asset. To access this ticker, use the `Value` property of the `Symbol` object.

```
C#

// Add equity for "GOOG" and print symbol id value, symbol value and encoded symbol id.
var symbol = AddEquity("GOOG").Symbol;
Debug(symbol.ID.Value);       // Prints "GOOCV"
Debug(symbol.Value);          // Prints "GOOG"
Debug(symbol.ID.ToString());  // Prints "GOOCV VP83T1ZUHROL"
```

If you create the security subscription with a universe selection function, the `Value` property of the `Symbol` object is the point-in-time ticker.

Decoding Symbols

When a `SecurityIdentifier` is serialized to a string, it looks something like `SPY R735QTJ8XC9X` . This two-part string is a base64 encoded set of data. Encoding all of the properties into a short format allows dense communication without requiring a third-party list or look-up. Most of the time, you will not need to work with these encoded strings. However, to deserialize the string into a `Symbol` object, call the `Symbol` method.

```
C#

// Extract the market, security type, and value from the symbol with ID "GOOCV VP83T1ZUHROL".
var symbol = Symbol("GOOCV VP83T1ZUHROL");
symbol.ID.Market;     // => "USA"
symbol.SecurityType;  // => SecurityType.Equity
symbol.Value;         // => "GOOCV"
```

Tickers

Tickers are a string shortcode representation for an asset. Some examples of popular tickers include "AAPL" for Apple Corporation and "IBM" for International Business Machines Corporation. These tickers often change when the company rebrands or they undergo a merger or reverse merger.

The ticker of an asset is not the same as the `Symbol` . `Symbol` objects are permanent and track the underlying entity. When a company rebrands or changes its name, the `Symbol` object remains constant, giving algorithms a way to reliably track assets over time.

Tickers are also often reused by different brokerages. For example Coinbase, a leading US Crypto Brokerage lists the "BTCUSD" ticker for trading. Its competitor, Bitfinex, also lists "BTCUSD". You can trade both tickers with LEAN. `Symbol` objects allow LEAN to identify which market you reference in your algorithms.

To create a `Symbol` object for a point-in-time ticker, call the `GenerateEquity` method to create the security identifier and then

call the `Symbol` constructor. For example, Heliogen, Inc. changed their ticker from ATHN to HLGN on December 31, 2021. To convert the ATHN ticker to the Equity `Symbol` , type:

```
C#
// Generate an Equity security identifier for a ticker and then create a symbol with it.
var ticker = "ATHN";
var securityID = SecurityIdentifier.GenerateEquity(ticker, Market.USA, mappingResolveDate:new DateTime(2021, 12, 1));
var symbol = new Symbol(securityID, ticker);
```

In the preceding code snippet, the `mappingResolveDate` must be a date when the point-in-time ticker was trading.

Symbol Cache

To make using the API easier, we have built the Symbol Cache technology, which accepts strings and tries to guess which `Symbol` object you might mean. With the Symbol Cache, many methods can accept a string such as "IBM" instead of a complete `Symbol` object. We highly recommend you don't rely on this technology and instead save explicit references to your securities when you need them.

```
C#
// Example 1: Relying On Symbol Cache:
AddEquity("IBM");          // Add by IBM string ticker, save reference to Symbol Cache.
MarketOrder("IBM", 100);   // Determine refering to IBM Equity from Symbol Cache.
History("AAPL", 14);       // Guess referring to AAPL Equity.

// Example 2: Correctly Using Symbols:
var ibm = AddEquity("IBM").Symbol;   // Add IBM Equity string ticker, save Symbol.
MarketOrder(ibm, 100);               // Use IBM Symbol in future API calls.

var aapl = Symbol.Create("AAPL", SecurityType.Equity, Market.USA);
History(aapl, 14);
```

Markets

The `Market` property distinguishes between tickers that have the same string value but represent different underlying assets. A prime example of this is the various market makers who have different prices for EURUSD. We store this data separately and as they have different fill prices, we treat the execution venues as different markets.

The following table shows the available markets for each security type:

Security Type	Market(s)
SecurityType.Equity	Market.USA
SecurityType.Option	Market.USA
SecurityType.Crypto	Market.Binance Market.BinanceUS Market.Bitfinex Market.Bybit Market.Coinbase Market.Kraken
SecurityType.CryptoFuture	Market.Binance Market.Bybit Market.dYdX
SecurityType.Forex	Market.Oanda
SecurityType.Future	Market.CBOT Market.CFE Market.CME Market.COMEX Market.EUREX Market.HKFE Market.ICE Market.India Market.NYMEX Market.NYSELIFFE Market.SGX
SecurityType.FutureOption	Market.CBOT Market.COMEX Market.NYSELIFFE
SecurityType.Index	Market.EUREX Market.HKFE Market.OSE Market.USA
SecurityType.IndexOption	Market.USA
SecurityType.Cfd	Market.InteractiveBrokers Market.Oanda

Industry Standard Identifiers

You can convert industry-standard security identifiers like CUSIP, FIGI, ISIN, and SEDOL to `Symbol` objects and you can convert `Symbol` objects to industry-standard security identifiers.

CUSIP

To convert a Committee on Uniform Securities Identification Procedures (CUSIP) number to a `Symbol` or a `Symbol` to a CUSIP number, call the `CUSIP` method.

```C#
// Get the CUSIP for the symbol and vice versa.
var symbol = CUSIP("03783310"); // AAPL Symbol
var cusip = CUSIP(symbol); // AAPL CUSIP (03783310)
```

FIGI

To convert a Financial Instrument Global Identifier (FIGI) to a `Symbol` or a `Symbol` to a FIGI, call the `CompositeFIGI` method.

```
// Get the FIGI for the symbol and vice versa.
var symbol = CompositeFIGI("BBG000B9XRY4"); // AAPL Symbol
var figi = CompositeFIGI(symbol); // AAPL FIGI (BBG000B9XRY4)
```

ISIN

To convert an International Securities Identification Number (ISIN) to a `Symbol` or a `Symbol` to an ISIN, call the `ISIN` method.

```
// Get the ISIN for the symbol and vice versa.
var symbol = ISIN("US0378331005"); // AAPL Symbol
var isin = ISIN(symbol); // AAPL ISIN (US0378331005)
```

SEDOL

To convert a Stock Exchange Daily Official List (SEDOL) number to a `Symbol` or a `Symbol` to a SEDOL number, call the `SEDOL` method.

```
// Get the SEDOL for the symbol and vice versa
var symbol = SEDOL("2046251"); // AAPL Symbol
var sedol = SEDOL(symbol); // AAPL SEDOL (2046251)
```

Examples

The following examples demonstrate some common practices for using the security identifier.

Example 1: Future Contract Expiry

The following example demonstrates the use of the security identifier of a Future contract to access its expiry date for contract selection and schedule a singular non-repeating event to rollover using `future.Symbol.ID.Date` .

C#

```
public class SecurityIdentifierExampleAlgorithm : QCAlgorithm
{
    private Future _future;
    private OrderTicket _ticket;
    private ScheduledEvent _lastScheduledEvent;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price data to allow the mapped contract to fill despite sparse data.
        Settings.SeedInitialPrices = true;
    }

    public override void OnWarmupFinished()
    {
        // Since we do not subscribe to any data source, we can use the OnWarmupFinished event handler instead of
OnData for the initial position.
        var es = QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME);
        OpenFuturePosition(es, Time.AddDays(30), 1);
    }

    private void OpenFuturePosition(Symbol symbol, DateTime minExpiry, decimal quantity)
    {
        // Select the next mapped future contract with the nearest expiry,
        // which should be further than the current contract.
        var selected = FuturesChain(symbol).Where(x => x.ID.Date > minExpiry).First();
        // Subscribe to its data to trade it.
        _future = AddFutureContract(selected, extendedMarketHours: true);

        // Buy back the corresponding number of contracts as the previous mapped contract.
        MarketOrder(_future.Symbol, quantity);

        // Schedule the next rollover to be 1 week before the expiry to avoid excessive volatility.
        // It will only be triggered once 7 days before the expiry and discarded afterward.
        if (_lastScheduledEvent != null) Schedule.Remove(_lastScheduledEvent);
        Schedule.On(
            DateRules.On(new[] { _future.Symbol.ID.Date.AddDays(-7) }),
            TimeRules.At(9, 30),
            RollOver
        );
    }

    private void RollOver()
    {
        // Save the current number of contracts to roll over to the next mapped contract.
        var quantity = _future.Holdings.Quantity;
        // Liquidate the to-be-expired contract to roll over the position.
        Liquidate(_future.Symbol);

        OpenFuturePosition(_future.Symbol.Canonical, _future.Symbol.ID.Date, quantity);
    }
}
```

Key Concepts

Event Handlers

Introduction

Event handlers are called during an algorithm execution to pass information to your strategy. Most of the events are not needed for simple strategies, but can be helpful for debugging issues in more complex algorithms.

Data Events

```C#
// Get data for a specific symbol to analyze its price movements or trading signals.
public override void OnData(Slice slice)
{
    slice.TryGetValue(_symbol, out var myData);
}

// Get split information to adjust holdings and calculations for the asset.
public override void OnSplits(Splits splits)
{
    splits.TryGetValue(_symbol, out var split);
}

// Capture dividend events to account for income or adjust the strategy based on the dividend payout.
public override void OnDividends(Dividends dividends)
{
    dividends.TryGetValue(_symbol, out var dividend);
}

// Track events when a security changes its ticker, allowing the algorithm to adapt to these changes.
public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
{
    symbolChangedEvents.TryGetValue(_symbol, out var symbolChangedEvent);
}

// Handle delisting events to manage the position or adjust the strategy when the symbol is delisted.
public override void OnDelistings(Delistings delistings)
{
    delistings.TryGetValue(_symbol, out var delisting);
}
```

The `OnData` method is the primary event handler for receiving financial data events to your algorithm. It is triggered sequentially at the point in time the data is available; in backtesting and live. For daily data, this means the event is processed at market close. In this method, all data for a given moment of time is grouped in a single event, including custom data types. This data is passed with the Slice object.

When fill-forward is enabled for your asset, the OnData event handler will be called regularly even if there was no new data. This is the default behavior.

In backtesting, if your algorithm takes a long time to process a slice, the following slice objects queue up and the next event triggers when your algorithm finishes processing the current slice. In live trading, if your algorithm takes longer to process the current slice than the time period that the slice spans, the next event triggers when your algorithm finishes processing the current slice, but the slice of the following event is the most recent slice. For example, say your algorithm consumes second resolution Crypto data but it takes your algorithm 3.5 seconds to process each slice. In backtesting, you'll get every slice. In live trading, if you deploy at 12:00:00 AM Coordinated Universal Time (UTC), you'll get the first slice at 12:00:01 AM UTC (spanning 12:00:00 AM UTC to 12:00:01 AM UTC) and you'll get the second slice at 12:00:04.5 AM UTC (roughly spanning 12:00:03 AM UTC to 12:00:04 AM UTC).

The `OnSplits` , `OnDividends` , `OnSymbolChangedEvents` , and `OnDelistings` event handlers provide data for their respective types in an isolated way. However, all of the data for these corporate actions is also available in the `Slice` in `OnData` .

To perform intensive computation before the market opens, use a Scheduled Event or the Train method.

For more information on the `Slice` object and OnData event, see Handling Data .

Securities Changed Event

```
C#
// Log the universe changes.
public override void OnSecuritiesChanged(SecurityChanges changes)
{
    foreach (var security in changes.AddedSecurities)
    {
        Debug($"{Time}: Added {security.Symbol}");
    }
    foreach (var security in changes.RemovedSecurities)
    {
        Debug($"{Time}: Removed {security.Symbol}");

        if (security.Invested)
        {
            Liquidate(security.Symbol, "Removed from Universe");
        }
    }
}
```

The `OnSecuritiesChanged` event notifies the algorithm when assets are added or removed from the universe. This can be due to changes in the Universe constituents , delisting , contract expiration, or an explicit call to the RemoveSecurity method.

The event is triggered immediately when the asset is removed from the universe; however the data feed for the asset may remain active if the algorithm has open orders.

For more information, see how to use Security Changed Events .

Order Events

```
C#
// Track filled orders and get the details of each fill.
public override void OnOrderEvent(OrderEvent orderEvent)
{
    var order = Transactions.GetOrderById(orderEvent.OrderId);
    if (orderEvent.Status == OrderStatus.Filled)
    {
        Debug($"{Time}: {order.Type}: {orderEvent}");
    }
}

// Track Option assignment events to handle assigned Equity holdings.
public override void OnAssignmentOrderEvent(OrderEvent assignmentEvent)
{
    Log(assignmentEvent.ToString());
}
```

The `OnOrderEvent` method notifies the algorithm of new orders, and changes in the order status such as fill events and cancelations. For options assignment events there is a dedicated event handler `OnAssignmentOrderEvent` .

In backtesting order events are triggered synchronously after the main data events. In live trading, order events are asynchronously as they occur. To avoid infinite loops, we recommend not to place orders in the OnOrderEvent.

For more information, see how to use Order Events .

Brokerage Events

```
// Track brokerage messages.
public override void OnBrokerageMessage(BrokerageMessageEvent message)
{
    if (message.Type== BrokerageMessageType.Reconnect)
    {
        Log($"{Time}: {message.Type}: Message: {message.Message}");
    }
}

// Track brokerage disconnections and respond to connectivity interruptions.
public override void OnBrokerageDisconnect()
{
    Log($"Brokerage disconnection detected at {Time}.");
}

// Track brokerage reconnections to resume trading operations.
public override void OnBrokerageReconnect()
{
    Log($"Brokerage reconnected at {Time}.");
}
```

The `OnBrokerageDisconnect` and `OnBrokerageReconnect` event handlers pass information to the algorithm about the brokerage connection status. This can be helpful for considering when to place a trade when a brokerage API is unreliable or under maintenance. The `OnBrokerageMessage` event handler provides information from the brokerages, including the disconnect and reconnect messages. Message content varies with each brokerage.

Brokerage events are triggered asynchronously in live trading, and are not created in backtesting.

Margin Call Events

```
// Track when remaining margin is low.
public override void OnMarginCallWarning()
{
    Log("Margin call warning, 5% margin remaining");
}

// Review and adjust liquidation orders in response to a margin call.
public override void OnMarginCall(List<SubmitOrderRequest> requests)
{
    // Modify order requests to choose what to liquidate.
    foreach (var orderRequest in requests)
    {
    }
}
```

The `OnMarginCallWarning` and `OnMarginCall` event handlers provide information and control over how to reduce algorithm leverage when performance is poor.

The `OnMarginCallWarning` method is called when there is less than 5% margin remaining to give you an opportunity to reduce leverage before an official margin call is performed by the brokerage. The `OnMarginCall` event handler is passed a list of `SubmitOrderRequest` objects which will be executed on exiting the method.

Margin events are called before the data events are processed.

The following demonstration processes suggested orders and modifies the qualities to liquidate more than necessary and prevent a second margin call. For more information, see how to handle Margin Calls .

Warmup Finished Event

```
// This event handler runs when the algorithm is done warming up.
public override void OnWarmupFinished()
{
    // Done warming up.
}
```

The `OnWarmupFinished` event handler runs once initialization and warm up is complete.

Command Events

```
// An event handler for receiving external commands.
public override bool? OnCommand(dynamic data)
{
    Log($"Got command at {Time} with data: {data}");
    return true;
}
```

The `OnCommand` event handler runs when you send external commands to your algorithm.

End Of Algorithm Events

```
// The final step after algorithm execution.
public override void OnEndOfAlgorithm()
{
    Debug("Algorithm done");
}
```

The `OnEndOfAlgorithm` event handler is when the algorithm has finished executing as its final step. This event handler is helpful for performing final analysis, or saving algorithm state.

Event Flow

When you deploy an algorithm, LEAN first calls the Initialize method. In live mode, the engine loads your holdings and open orders from your brokerage account to add data subscriptions and populate the `Securities` , `Portfolio` , and `Transactions` objects. LEAN receives the data from the subscriptions, synchronizes the data to create a timeslice , and then performs the following steps. Your algorithm can spend up to 10 minutes on each timeslice unless you call the Train method.

1. If it's a backtest, check if there are Scheduled Events in the past that didn't fire because there was no data between the previous slice and the current slice. LEAN automatically creates a Scheduled Event to call the `OnEndOfDay` method at the end of each day.

   In live mode, Scheduled Events occur in a separate thread from the algorithm manager, so they run at the correct time.

2. Update the algorithm time.
3. Update the `CurrentSlice` .
4. Pass the `SymbolChangedEvents` to the `OnSymbolChangedEvents` method.
5. Cancel all open orders for securities that changed their ticker .
6. Add a `Security` object to the `Securities` collection for each new security in the universe.
7. Update the `Security` objects with the latest data.
8. Update the `Cash` objects in the CashBook with the latest data.
9. Process fill models for non-market orders.
10. Submit market on open orders to liquidate Equity Option contracts if the underlying Equity has a split warning .

11. Process margin calls .
12. If it's time to settle unsettled cash , perform settlement.
13. Call the OnSecuritiesChanged method with the latest security changes.
14. Apply dividends to the portfolio.
15. For securities that have a split warning, update their portfolio holdings and adjust their open orders to account for the split.
16. Update consolidators with the latest data.
17. Pass custom data to the `OnData` method.
18. Pass the `Dividends` to the `OnDividends` method.
19. Pass the `Splits` to the `OnSplits` method.
20. Pass the `Delistings` to the `OnDelistings` method.
21. Pass the `Slice` to the `OnData` method.
22. Perform universe selection .
23. Pass the `Slice` to the `Update` method of each Alpha model .
24. Pass the `Insight` objects from the Alpha model to the Portfolio Construction model .
25. Pass the `PortfolioTarget` objects from the Portfolio Construction model to each Risk Management model .
26. Pass the risk-adjusted `PortfolioTarget` objects from the Risk Management models to the Execution model .

When your algorithm stops executing, LEAN calls the `OnEndOfAlgorithm` method .

Key Concepts

Python and LEAN

Introduction

The LEAN open-source package powers the core functionality of QuantConnect. Strategies plugin to LEAN to request data, and process trades. LEAN is written in C# and accessed in python with a defined API. Most of these interactions are using native python types, with a few key exceptions. To comfortably use LEAN you should learn to recognize error messages when you hit a non-native API, and how to convert back to a native type.

Enumerable Types

When LEAN returns an enumerable, the object should be converted to a `list()` to be easily read by python classes. Popular API methods which return an enumerable are shown below:

Historical Data

QuantConnect also provides methods to request historical data that return a pandas dataframe, or an enumerable. If loading a large amount of data using an enumerable streams the results reducing RAM usage.

The enumerable types might look like the `MemoizingEnumerable` that is a raw C# type accessible in python.

```
qb = QuantBook()
start = datetime(2023, 2, 1)
end = datetime(2023, 2, 4)
ibm = qb.AddEquity('IBM', Resolution.Minute)
bars = qb.History[TradeBar](ibm.Symbol, start, end, Resolution.Minute)
bars
```

✓ 0.3s Python

```
<QuantConnect.Util.MemoizingEnumerable[TradeBar] object at 0x7fd5313209c0>
```

You can directly enumerate this object with standard python `for` loops, or to convert it to a native type, wrap the object in the `list()`:

```
# Loop over enumerable
import numpy as np
close = []
for bar in bars:
    close.append( bar.Close )
print( np.mean(close) )

# Manipulate as a list
barList =  list(bars)
len(barList)
```

✓ 0.8s Python

```
135.29654786324787

1170
```

Underlying Plugin Architecture

Your strategy code implements the QCAlgorithm class, which can communicate with the LEAN Engine. These method calls are done at the same speed as cython, directly invoking calls at the C layer of python. Your algorithm is imported as syntax checked, interpreted python.

Key Concepts

Duck Typing

Introduction

Duck typing is popular type system in Python. The language documentation defines duck typing as follows:

> A programming style which does not look at an object's type to determine if it has the right interface; instead, the method or attribute is simply called or used ("If it looks like a duck and quacks like a duck, it must be a duck.") By emphasizing interfaces rather than specific types, well-designed code improves its flexibility by allowing polymorphic substitution.
>
> Duck-typing avoids tests using `type()` or `isinstance()` . (Note, however, that duck-typing can be complemented with abstract base classes .) Instead, it typically employs `hasattr()` tests or EAFP programming.

You can't use duck-typing to add members to regular C# types.

```C#
// Duck-typing doesn't work on regular C# types.
class Duck { }
var duck = new Duck();
duck.quacks = "Quack!"   // This yields a compilation error.

dynamic duck = new Duck();
duck.quacks = "Quack!"   // This yields a runtime error.
```

LEAN allows duck-typing in the `Security` type.

Custom Security Properties

You can add properties to the `Security` object. For example, you can add an exponential moving average .

```C#
// Cast the Equity to a dynamic object to add an EMA indicator to it.
dynamic equity = AddEquity("SPY");
equity.ema = EMA(equity.Symbol, 10, Resolution.Daily);
```

This feature is helpful because you can get the `Security` object from the `Securities` object.

```C#
// Get the SPY Equity object from Securities to get the EMA indicator.
var ema = (decimal)(Securities["SPY"] as dynamic).ema.Current.Value;
```

To avoid casting to and from the `dynamic` type, you can use the `Set` method to assign and the `Get<T>` method to access the dynamic member and return the object with its type.

```
var equity = AddEquity("SPY");
// Assign an EMA indicator to the "ema" property
equity.Set("ema", EMA(equity.Symbol, 10, Resolution.Daily));
// Get the SPY Equity object from Securities to get the EMA indicator and its current value
var ema = Securities["SPY"].Get<ExponentialMovingAverage>("ema");   // The type of ema is ExponentialMovingAverage
var emaValue = ema.Current.Value;    // The type of emaValue is decimal
```

If the type or the member name is incorrect, the `Get<T>` method causes a runtime error.

Other Types

You can only add properties to the `Security` type.

Examples

The following examples demonstrate some common practices for duck typing.

Example 1: Store EMA Indicator

The following example implements a trend-following strategy using the EMA indicator for the top 20 liquid equities. It uses duck typing to store the EMA indicator in each Security object , so the indicator is discarded together with the `Security` when it is removed from the universe.

C#

```
public class DuckTypingAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Weekly renewal on the universe to allow time to capitalize on the trend.
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        // Trade on the top 20 liquid equities since they have higher volume and price movements.
        _universe = AddUniverse(Universe.Top(20));
    }

    public override void OnData(Slice slice)
    {
        foreach (var (symbol, security) in _universe.Members)
        {
            // Trade on updated price data.
            if (slice.Bars.TryGetValue(symbol, out var bar))
            {
                var ema = (security as dynamic).ema;
                // Switch to long if the current price is above EMA, suggesting an uptrend.
                if (bar.Close > ema && !Portfolio[symbol].IsLong)
                {
                    SetHoldings(symbol, 0.025m);
                }
                // Switch to short if the current price is below EMA, suggesting a downtrend.
                else if (bar.Close < ema && !Portfolio[symbol].IsShort)
                {
                    SetHoldings(symbol, -0.025m);
                }
            }
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var removed in changes.RemovedSecurities)
        {
            // Liquidate if it is no longer in the top 50 liquidity stocks.
            Liquidate(removed.Symbol);
            // Release resources that update automatic indicators
            DeregisterIndicator(removed.Get<ExponentialMovingAverage>("ema"));
        }

        foreach (var added in changes.AddedSecurities)
        {
            // Use duck typing to create an EMA indicator for trend trading.
            // Discarded together when the security is removed from the universe, you won't need to handle it.
            var security = added as dynamic;
            security.ema = EMA(added.Symbol, 60, Resolution.Daily);
            // Warm up the EMA indicator to ensure its readiness for immediate usage.
            WarmUpIndicator(added.Symbol, (ExponentialMovingAverage)security.ema, Resolution.Daily);
        }
    }
}
```

Key Concepts

Research Guide

Introduction

We aim to teach and inspire our community to create high-performing algorithmic trading strategies. We measure our success by the profits community members create through their live trading. As such, we try to build the best quantitative research techniques possible into the product to encourage a robust research process.

Hypothesis-Driven Research

We recommend you develop an algorithmic trading strategy based on a central hypothesis. You should develop an algorithm hypothesis at the start of your research and spend the remaining time exploring how to test your theory. If you find yourself deviating from your core theory or introducing code that isn't based around that hypothesis, you should stop and go back to thesis development.

Wang et al. (2014) illustrate the danger of creating your hypothesis based on test results. In their research, they examined the earnings yield factor in the technology sector over time. During 1998-1999, before the tech bubble burst, the factor was unprofitable. If you saw the results and then decided to bet against the factor during 2000-2002, you would have lost a lot of money because the factor performed extremely well during that time.

Hypothesis development is somewhat of an art and requires creativity and great observation skills. It is one of the most powerful skills a quant can learn. We recommend that an algorithm hypothesis follow the pattern of cause and effect. Your aim should be to express your strategy in the following sentence:

> *A change in {cause} leads to an {effect}.*

To search for inspiration, consider causes from your own experience, intuition, or the media. Generally, causes of financial market movements fall into the following categories:

- Human psychology
- Real-world events/fundamentals
- Invisible financial actions

Consider the following examples:

Cause	*leads to*	Effect
Share class stocks are the same company, so any price divergence is irrational...		A perfect pairs trade. Since they are the same company, the price will revert.
New stock addition to the S&P500 Index causes fund managers to buy up stock...		An increase in the price of the new asset in the universe from buying pressure.
Increase in sunshine-hours increases the production of oranges...		An increase in the supply of oranges, decreasing the price of Orange Juice Futures.
Allegations of fraud by the CEO causes investor faith in the stock to fall...		A collapse of stock prices for the company as people panic.
FDA approval of a new drug opens up new markets for the pharmaceutical company...		A jump in stock prices for the company.
Increasing federal interest rates restrict lending from banks, raising interest rates...		Restricted REIT leverage and lower REIT ETF returns.

There are millions of potential alpha strategies to explore, each of them a candidate for an algorithm. Once you have chosen a strategy, we recommend exploring it for no more than 8-32 hours, depending on your coding ability.

Data Mining Driven Research

An alternative view is to follow any statistical anomaly without explaining it. In this case, you can use statistical techniques to identify the discontinuities and eliminate them when their edge is gone. Apparently, Renaissance Technologies has data mining models like this.

Overfitting

Overfitting occurs when you fine-tune the parameters of an algorithm to fit the detail and noise of backtesting data to the extent that it negatively impacts the performance of the algorithm on new data. The problem is that the parameters don't necessarily apply to new data and thus negatively impact the algorithm's ability to generalize and trade well in all market conditions. The following table shows ways that overfitting can manifest itself:

Data Practice	Description
Data Dredging	Performing many statistical tests on data and only paying attention to those that come back with significant results.
Hyper-Tuning Parameters	Manually changing algorithm parameters to produce better results without altering the test data.
Overfit Regression Models	Regression, machine learning, or other statistical models with too many variables will likely introduce overfitting to an algorithm.
Stale Testing Data	Not changing the backtesting data set when testing the algorithm. Any improvements might not be able to be generalized to different datasets.

An algorithm that is dynamic and generalizes to new data is more valuable to funds and individual investors. It is more likely to survive across different market conditions and apply to new asset classes and markets.

If you have a collection of factors, you can backtest over a period of time to find the best-performing factors for the time period. If you then narrow the collection of factors to just the best-performing ones and backtest over the same period, the backtest will show great results. However, if you take the same best-performing factors and backtest them on an out-of-sample dataset, the

performance will almost always underperform the in-sample period. To avoid issues with overfitting, follow these guidelines:

- Use walk-forward optimization to train your models on historical data and test them on future data.
- Test your strategy with live paper trading.
- Test your model on different asset classes and markets.

Look-ahead Bias

Look-ahead bias occurs when you use information from the future to inform decisions in the present. An example of look-ahead bias is using financial statement data to make trading decisions at the end of the reporting period instead of when the financial statement data was released. Another example is using updated financial statement data before the updated figures were actually available. Wang et al. (2014) show that using the date of when the period ends instead of when the data is actually available can increase the performance of the earnings yield factor by 60%.

Another culprit of look-ahead bias is adjusted price data. Splits and reverse splits can improve liquidity or attract certain investors, causing the performance of the stock to be different than without the split or reverse split. Wang et al (2014) build a portfolio using the 25 lowest priced stocks in the S&P index based on adjusted and non-adjusted prices. The portfolio based on adjusted prices greatly outperformed the one with raw prices in terms of return and Sharpe ratio . In this case, if you were to analyze the low price factor with adjusted prices, it would lead you to believe the factor is very informative, but it would not perform well out-of-sample with raw data.

Look-ahead bias can also occur if you set the universe to assets that have performed well during the backtest period or initialize indicators with values that have performed well during the backtest period. To avoid issues with look-ahead bias, trade a dynamic universe of assets and use point-in-time data. If point-in-time data is not available for the dataset you use, apply a reporting lag. Since the backtesting environment is event-driven and you can't pass the time frontier, it naturally helps to reduce the risk of look-ahead bias.

Survivorship Bias

Survivorship bias occurs when you test a strategy using only the securities that have survived to the end of the testing period and omit securities that have been delisted. If you use the current constituents of an index and backtest over the past, you'll most likely outperform the index because many of the underperformers have dropped out of the index over time and outperformers have been added to the index. In this case, the current constituent universe would consist of only outperformers. This technique is a form of look-ahead bias because if you were trading the strategy in real-time throughout the backtest period, you would not know the current index constituents until today.

If you analyze a dataset that has survivorship bias, you can discover results that are opposite of the true results. For example, Wang et al. (2014) analyze the low volatility factor using two universes. The first universe was the current S&P 500 constituents and the second universe was the point-in-time constituents. When they used the point-in-time constituents, the low volatility quintile outperformed the high volatility quintile. However, when they used the current constituents, the high volatility quintile significantly outperformed the low volatility quintile.

To avoid issues with survivorship bias, trade a dynamic universe of assets and use the datasets in the Dataset Market . We thoroughly vet the datasets we add to the market to ensure they're free of survivorship bias.

Outliers

Outliers in a dataset can have large impacts on how models train. In some cases, you may leave outliers in a dataset because they can contain useful information. In other cases, you may want to transform the data to handle the outlier data points. There are several common methods to handle outliers.

Winsorization Method

The winsorization method removes outliers at the x% of the extremes. For example, if you winsorize at 1%, it removes the 1% of data points with the lowest value and the 1% of data points with the highest value. This threshold percentage is subjective, so it can result in overfitting.

IQR Method

The interquartile range method removes data points that fall outside of the interval $[Q_1 - k(Q_3 - Q_1),\ Q_3 + k(Q_3 - Q_1)]$ for some constant $k \geq 0$. This method can exclude up to 25% of observations on each side of the extremes. The interquartile range method doesn't work if the data is skewed or non-normal. Therefore, the disadvantage to this method is you need to review the factor distribution properties. If you need to, you can normalize the data with z-scores.

$$Z = \frac{x - \mu}{\sigma}$$

Factor Ranking Method

The factor ranking method ranks the data values instead of taking their raw values. With this method, you don't need to remove any outlier data points. This method transforms the data into a uniform distribution. After converting the data to a uniform distribution, Wang et al. (2014) perform an inverse normal transformation to make the factor values normally distributed. Wang et al. found this ranking technique outperforms the z-score transformation, suggesting that the distance between factor scores doesn't add useful information.

Short Availability

To open a short position, you need to borrow shares from an investor or brokerage that owns them. Wang et al. (2014) show that some factors have a larger edge for long positions and some have a larger edge for short positions. Their research found that the factors that perform better on the short side usually target more securities that are on hard-to-borrow lists than factors that perform better on the long side. Their research also shows that a large part of the returns from these short-biased factors come from securities that are on hard-to-borrow lists. Therefore, if you don't account for short availability, your backtest results can be unrealistic and not reproducible in live trading.

To avoid issues with short availability, add a shortable provider to your algorithm. The shortable provider only lets you open a short trade if there are actually shares available to borrow. By default, LEAN doesn't simulate the cost of borrowing shorts in backtests, but you can enable them by setting a margin interest model.

Examples

The following examples demonstrate some common practices for applying research.

Example 1: Hypothesis-Driven Research

The following example hypothesized that 2 different classes of Google stocks are cointegrated with each other, and we can capitalize spread reversal from occasional, irrational price divergence. To prove it, we make use of the augmented Dickey-Fuller test to verify the cointegration relationship.

C#

```
using Accord.Statistics;
using MathNet.Numerics.LinearRegression;

public class HypothesisDrivenResearchAlgorithm : QCAlgorithm
{
    private Symbol _goog1, _goog2;
    // The threshold that the spread/residual of the cointegrated series triggers a trade.
    private decimal _thresold;
    // Store the coefficient and intercept of the cointegrated series for calculating the spread of a new data point.
    private decimal[] _coefficients = new[] { 0m, 0m };
    // Store the price series of each symbol for cointegration calculation.
    private Dictionary<Symbol, RollingWindow<double>> _windows = new();
```

```
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Subscribe to 2 classes of Google stocks to trade their price divergence.
        _goog1 = AddEquity("GOOGL", Resolution.Minute).Symbol;      // Class A
        _goog2 = AddEquity("GOOG", Resolution.Minute).Symbol;       // Class C

        foreach (var symbol in new[] { _goog1, _goog2 })
        {
            _windows[symbol] = new(252);

            // Add a consolidator to aggregate a daily bar to update the window's daily price series.
            var consolidator = new TradeBarConsolidator(TimeSpan.FromDays(1));
            consolidator.DataConsolidated += (_, bar) => {
                _windows[bar.Symbol].Add((double)bar.Close);
            };
            // Subscribe the consolidator to update automatically.
            SubscriptionManager.AddConsolidator(symbol, consolidator);

            // Warm up the rolling window's daily price series with historical data.
            var history = History<TradeBar>(symbol, 253, Resolution.Daily);
            foreach (var bar in history)
            {
                consolidator.Update(bar);
            }
        }

        // Adjust the cointegration factor between the 2 classes' monthly price series.
        Schedule.On(
            DateRules.MonthStart(),
            TimeRules.At(0, 1),
            CalculateCointegration
        );

        CalculateCointegration();
    }

    public override void OnData(Slice slice)
    {
        if (slice.QuoteBars.TryGetValue(_goog1, out var bar1) && slice.QuoteBars.TryGetValue(_goog2, out var bar2))
        {
            // Calculate the current cointegrated series spread.
            var residual = _coefficients[0] * bar2.Close + _coefficients[1] - bar1.Close;

            // If the residual is lower than the negative threshold, it means class A price is much higher than what
it should be compared to class C.
            // We sell class A and buy class C to bet on their price convergence.
            if (residual < -_thresold && !Portfolio[_goog1].IsShort)
            {
                SetHoldings(_goog1, -0.5m);
                SetHoldings(_goog2, 0.5m * _coefficients[0]);
            }
            // If the residual is higher than the threshold, it means class A price is much lower than what it should
be compared to class C.
            // We buy class A and sell class C to bet on their price convergence.
            else if (residual > _thresold && !Portfolio[_goog1].IsLong)
            {
                SetHoldings(_goog1, 0.5m);
                SetHoldings(_goog2, -0.5m * _coefficients[0]);
            }
            // Close positions of the price are converged.
            else if ((Portfolio[_goog1].IsShort && residual > 0m) || (Portfolio[_goog1].IsLong && residual < 0m))
            {
                Liquidate();
            }
        }
    }

    private void CalculateCointegration()
    {
        // Lag direction is unimportant; it is just a sign flip in the linear regression, so we don't need to flip
the window order.
        var y = _windows[_goog1].ToArray();
        var x = _windows[_goog2].ToArray();

        // Perform Linear Regression on both price series to investigate their relationship.
        var regressionResult = SimpleRegression.Fit(x, y);
        var intercept = regressionResult.Item1;
```

```
        var slope = regressionResult.Item2;

        // Calculate the residuals series to check if it is stationary, meaning if the 2 price series move together.
        var residuals = new double[x.Length];
        for (int i = 0; i < x.Length; i++)
        {
            residuals[i] = y[i] - (intercept + slope * x[i]);
        }

        // Check if the residuals are stationary using the augmented Dickey-Fuller test.
        if (ADFTest(residuals))
        {
            // If cointegrated, update the positional sizing ratio and the spread threshold of the trade trigger.
            _coefficients = new[] { Convert.ToDecimal(slope), Convert.ToDecimal(intercept) };
            _thresold = 2m * Convert.ToDecimal(Measures.StandardDeviation(residuals));
        }
        else
        {
            // If not cointegrated, liquidate and set the size to zeros for no positions.
            Liquidate();
            _coefficients = new[] { 0m, 0m };
            _thresold = 100000000m;             // An arbitrarily large number that the class A price will never
reach.
        }
    }

    private static bool ADFTest(double[] series)
    {
        var n = series.Length;
        var lagged = new double[n - 1];
        var differences = new double[n - 1];

        // Fit linear regression for the residual series on unit root: ΔY_t = α + βY_{t-1} + ε_t.
        for (int i = 1; i < n; i++)
        {
            lagged[i - 1] = series[i - 1];
            differences[i - 1] = series[i] - series[i - 1];
        }

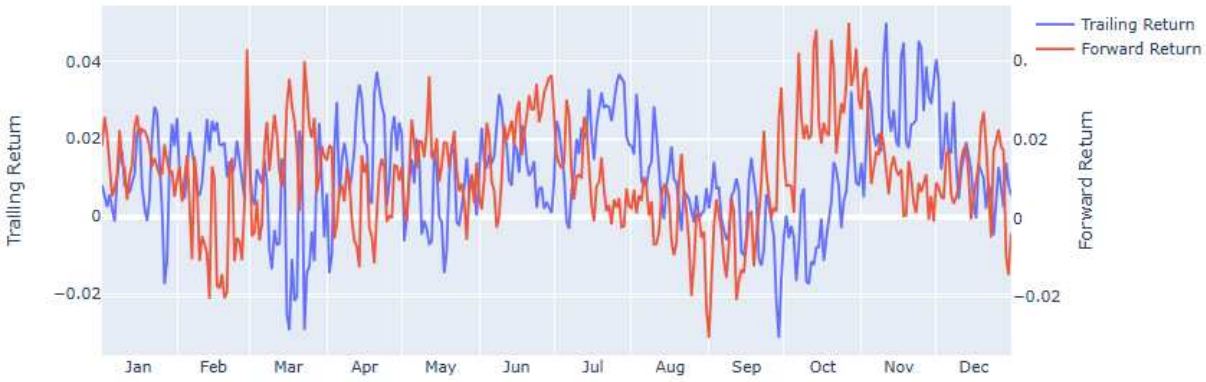
        var regressionResult = SimpleRegression.Fit(lagged, differences);
        var alpha = regressionResult.Item1;  // Intercept
        var beta = regressionResult.Item2;   // Coefficient of lagged term

        // Calculate the ADF statistic and check if the null hypothesis is rejected.
        var adfStatistic = beta / Measures.StandardError(differences);

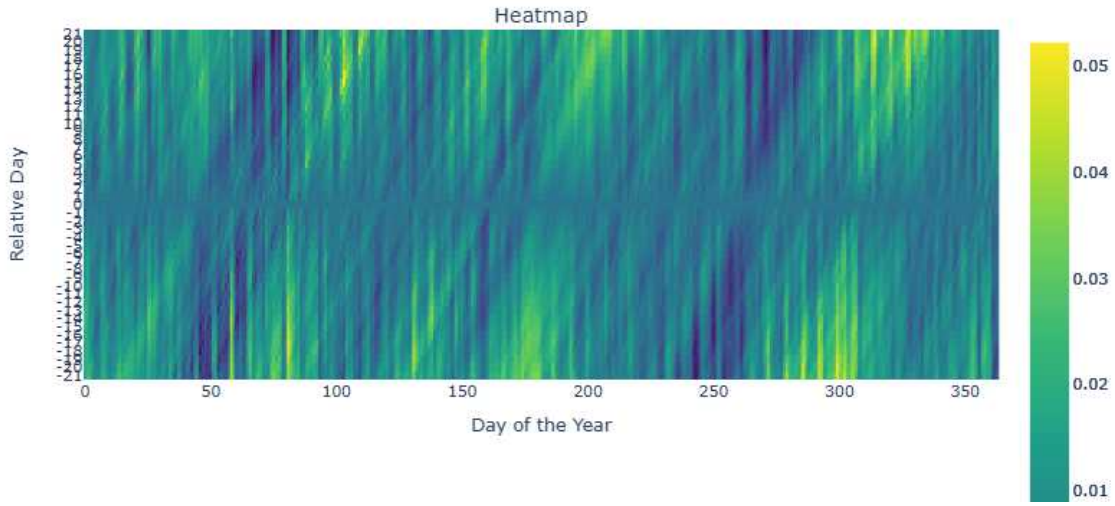
        // Reject the null hypothesis of a unit root is present if test statistic <= -3.45 (approximate α=0.05 for
n=250)
        // Which means no unit root for difference series and the residuals are stationary.
        return adfStatistic <= -3.45d;
    }
}
```

Example 2: Data-Driven Research

By exploring the return pattern of SPY in 2020, we use that information to invest in 2021. Since the macroeconomic environment is similar (low interest rate), we assume the market seasonality would follow through. We can observe from the figures below that an around 50-day cycle, like a sine function, exists, and the next cycle starts around Jan 2021. Hence, we switch long and short every 25 days in 2021.



Return Analysis



C#

```
public class DataDrivenResearchAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ScheduledEvent _lastScheduledEvent;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Request SPY data to trade it.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;
        // Add a warm-up period so SPY has a price before the first trade.
        SetWarmUp(TimeSpan.FromDays(7));
    }

    public override void OnWarmupFinished()
    {
        // According to the data, the first cycle is downgoing.
        SetHoldings(_spy, -1m);
        // Schedule a switch in 25 days later.
        _lastScheduledEvent = Schedule.On(
            DateRules.On(Time.AddDays(25)),
            TimeRules.At(9, 30),
            Switch
        );
    }

    private void Switch()
    {
        // Switch long/short after the cycle change.
        if (Portfolio[_spy].IsLong)
        {
            SetHoldings(_spy, -1m);
        }
        else
        {
            SetHoldings(_spy, 1m);
        }

        // Schedule the next switch in 25 days later.
        Schedule.Remove(_lastScheduledEvent);
        _lastScheduledEvent = Schedule.On(
            DateRules.On(Time.AddDays(25)),
            TimeRules.At(9, 30),
            Switch
        );
    }
}
```

Key Concepts

Globals and Statics

Introduction

It is often convenient to access the QCAlgorithm API in classes outside of the QCAlgorithm class. To achieve this, pass an instance reference or access a global static variable. Whenever possible, we recommend using an instance reference to keep your global namespace clean.

API Access by Algorithm Instance

You can access the QCAlgorithm API by passing the `this` object into a constructor of your target class. The class constructor receives it as a variable you can use to initialize your algorithm. The following algorithm demonstrates this process:

C#

```
public class CustomPartialFillModelAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private SecurityHolding _holdings;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data for trading.
        var equity = AddEquity("SPY", Resolution.Hour);
        _spy = equity.Symbol;
        _holdings = equity.Holdings;

        // Set the fill model with the algorithm instance.
        equity.SetFillModel(new CustomPartialFillModel(this));
    }

    public override void OnData(Slice data)
    {
        // To get all SPY open orders, use the transaction manager.
        var openOrders = Transactions.GetOpenOrders(_spy);
        if (openOrders.Count != 0) return;

        // Hold SPY during 10th-20th in each month.
        if (Time.Day > 10 && _holdings.Quantity <= 0)
        {
            MarketOrder(_spy, 105, true);
        }
        else if (Time.Day > 20 && _holdings.Quantity >= 0)
        {
            MarketOrder(_spy, -100, true);
        }
    }

    internal class CustomPartialFillModel : FillModel
    {
        private readonly QCAlgorithm _algorithm;
        private readonly Dictionary<int, decimal> _absoluteRemainingByOrderId = new();

        public CustomPartialFillModel(QCAlgorithm algorithm)
            : base()
        {
            _algorithm = algorithm;
        }

        public override OrderEvent MarketFill(Security asset, MarketOrder order)
        {
            if (!_absoluteRemainingByOrderId.TryGetValue(order.Id, out var absoluteRemaining))
            {
                absoluteRemaining = order.AbsoluteQuantity;
            }
```

```
            }

            var fill = base.MarketFill(asset, order);

            // Allow at most 10 shares to be filled at once.
            fill.FillQuantity = Math.Sign(order.Quantity) * 10m;

            // If the remaining shares are less than or equal to 10, the order will be fully filled.
            if (Math.Min(Math.Abs(fill.FillQuantity), absoluteRemaining) == absoluteRemaining)
            {
                fill.FillQuantity = Math.Sign(order.Quantity) * absoluteRemaining;
                fill.Status = OrderStatus.Filled;
                _absoluteRemainingByOrderId.Remove(order.Id);
            }
            // Otherwise, the order is only partially filled out, and we need to update the remaining quantity.
            else
            {
                fill.Status = OrderStatus.PartiallyFilled;
                _absoluteRemainingByOrderId[order.Id] = absoluteRemaining - Math.Abs(fill.FillQuantity);
                var price = fill.FillPrice;

                // Use the instance of the algorithm to log the information
                _algorithm.Debug($"{_algorithm.Time} - Partial Fill - Remaining
{_absoluteRemainingByOrderId[order.Id]} Price - {price}");
            }
            return fill;
        }
    }
}
```

API Access by Global Static Variable

Occasionally, passing the QCAlgorithm object to your class constructor is impossible, so you need to use global static variables to access the API for debugging and initialization purposes. The most common case is custom data implementations , where the LEAN Engine is creating the objects, and you're unable to specify a custom constructor.

To create a global static variable, assign the reference to the global variable in the algorithm's `Initialize` method. This assignment sets the active instance of the variable to the global static. Then, in your custom class, you can access the QCAlgorithm API through the global. The following algorithm demonstrates this process:

C#

```
public class MyAlgorithmInstance : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2012, 9, 1);
        SetEndDate(2024, 12, 31);

        // Instantiate a custom type as a global variable in the QCAlgorithm instance.
        // Assign self to Static Cape Variable.
        Cape.ALGORITHM = this;
        // Request data for trading or signal.
        _symbol = AddData<Cape>("CAPE").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (data.TryGet<Cape>(_symbol, out var cape))
            Plot("CAPE", "Value", cape.Value);
    }
}

public class Cape : BaseData
{
    public static QCAlgorithm ALGORITHM;

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        ALGORITHM.Debug("Test Static: GetSource");
        return new
SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/CAPE.csv", SubscriptionTransportMedium.RemoteFile);
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        var data = line.Split(',').ToArray(x => x.Trim());
        if (data.Length < 12 || line.StartsWith("Date"))
            return null;

        try
        {
            // Construct the custom data type with input data entry.
            return new Cape()
            {
                Symbol = config.Symbol,
                Value = data[12].IfNotNullOrEmpty(
                    s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture)),
                Time = DateTime.ParseExact(data[0], "yyyy.M", CultureInfo.InvariantCulture),
            };
        }
        catch (Exception e)
        {
            ALGORITHM.Debug($"Test Static 2: ValueError: {e.Message}, line: {line}");
        }
        return null;
    }
}
```

Key Concepts

Libraries

Introduction

Libraries (or packages) are third-party software that you can use in your projects. You can use many of the available open-source libraries to complement the classes and methods that you create. Libraries reduce your development time because it's faster to use a pre-built, open-source library than to write the functionality. Libraries can be used in backtesting, research, and live trading. The environments support various libraries for machine learning, plotting, and data processing. As members often request new libraries, we frequently add new libraries to the underlying docker image that runs the Lean engine.

This feature is primarily for Python algorithms as not all Python libraries are compatible with each other. We've bundled together different sets of libraries into distinct environments. To use the libraries of an environment, set the environment in your project and add the relevant `using` statement of a library at the top of your file.

Default Environment Libraries

The default environment supports the following libraries:

```C#
Accord                              3.6.0
Accord.Fuzzy                        3.6.0
Accord.MachineLearning              3.6.0
Accord.Math                         3.6.0
Accord.Statistics                   3.6.0
CloneExtensions                     1.3.0
Common.Logging                      3.4.1
Common.Logging.Core                 3.4.1
CsvHelper                           19.0.0
Deedle                              2.1.0
DotNetZip                           1.16.0
DynamicInterop                      0.9.1
fasterflect                         3.0.0
MathNet.Numerics                    5.0.0
McMaster.Extensions.CommandLineUtils 2.6.0
Microsoft.IO.RecyclableMemoryStream  3.0.1
Microsoft.NET.Test.Sdk              16.9.4
Microsoft.TestPlatform.ObjectModel  16.9.4
Moq                                 4.16.1
NetMQ                               4.0.1.6
Newtonsoft.Json                     13.0.2
NodaTime                            3.0.5
NUnit                               4.2.2
NUnit3TestAdapter                   4.6.0
protobuf-net                        3.1.3
QLNet                               1.13.1
QuantConnect.pythonnet              2.0.48
RestSharp                           106.12.0
SharpZipLib                         1.3.3
System.ComponentModel.Composition   6.0.0
```

Legacy Environment Libraries

This environment is only available for Python projects.

Autogluon Environment Libraries

This environment is only available for Python.

Add New Libraries

To request a new library, contact us . We will add the library to the queue for review and deployment. Since the libraries run on our servers, we need to ensure they are secure and won't cause harm. The process of adding new libraries takes 2-4 weeks to complete. View the list of libraries currently under review on the Issues list of the Lean GitHub repository .

Project Libraries

Project libraries are QuantConnect projects you can merge into your project to avoid duplicating code files. If you have tools that you use across several projects, create a library.

The process to create a library depends on if you use the Cloud Platform , Local Platform , or CLI .

Key Concepts

Debugging Tools

Introduction

When your algorithm throws errors or doesn't operate how you expect, use debugging tools to diagnose and resolve the issue. The tools to debug LEAN algorithms include a built-in debugger, logs, charts, and the Object Store.

Debugger

The debugger is a built-in tool to help you debug coding errors while backtesting. The debugger enables you to slow down the code execution, step through the program line-by-line, and inspect the variables to understand the internal state of the program. The learn how to start and operate the backtest debugger in your development environment, see the Debugging page in the Cloud Platform , Local Platform , or CLI documentation.

Logs

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code or recording key decision moments. Backtests can process millions of data points. If you place a log statement in the wrong place, it can generate gigabytes of logs, which can be difficult to sift through. When you add to the log file, ensure they are readable.

```C#
// Logging records messages to a file so you can debug errors and record key decisions.
Log($"Signal triggered. Placing limit order: {limit}");
```

Debug statements are the same as log statements, but `Debug` method statements are orange in the Cloud Terminal to provide more emphasis. Debug statements are streamed to the Cloud Terminal while the backtest is running. This can be helpful for real-time updates or monitoring in live-trading.

```C#
// Debugging streams messages to the Cloud Terminal for real-time analysis.
Debug($"Exposure to the {sectorName} sector is above 50%!");
```

For more information about log statements, see Logging .

Charts

Plotting values over time can help you understand its range, identify outliers in data, and see times when your algorithm generates unusual values. Before you create a plot, develop a theory about what you expect to see before you view it to gain a deeper understanding of your algorithm. For example, a plot of an asset's price standard deviations should be between -4 and +4, with any outliers happening during extreme market conditions like the COVID pandemic in March 2020. LEAN provides a powerful charting API. You can create time series plots with just a single line of code.

```C#
// Create time series plots to understand the asset range and identify outliers.
Plot("Deviations", "aapl", assetDeviation);
```

For more information about creating charts, see Charting .

Object Store

The Object Store is a key-value data store for low-latency information storage and retrieval. During a backtest, you can build large objects you'd like to analyze and write them for later analysis. This workflow can be helpful when the objects are large and plotting is impossible or when you want to perform analysis across many backtests.

```C#
// The Object Store provides a key-value data store optimized for fast access and retrieval of information.
ObjectStore.Save("key", value);
```

For more information about the Object Store, see Object Store . For a specific example of saving indicator values during a backtest into the Object Store and then plotting them in the Research Environment, see Example for Plotting .

Profiling Speed

QuantConnect provides a series of metrics to help you analyze the computational performance of your algorithms. For more information, see Performance Chart .

JIT Compilation

JIT Compilation is only relevant for Python users.

Key Concepts

Glossary

Introduction

This page defines terms in QuantConnect products and documentation.

alpha

The quantity of an algorithm's returns that aren't explained by its underlying benchmark.

annual standard deviation

A staticial measure that describes the dispersion of annual returns relative to the mean annual return. It's the square root of the annual variance.

annual variance

A staticial measure that describes the dispersion of annual returns relative to the mean annual return.

average loss

The average rate of return for unprofitable trades.

average win

The average rate of return for profitable trades.

beta

The scale and direction of an algorithm's returns relative to movements in the underlying benchmark.

capacity

The maximum amount of money an algorithm can trade before its performance degrades from market impact.

compounding annual return

The annual percentage return that would be required to grow a portfolio from its starting value to its ending value.

day trade

Buying and selling the same asset within one trading day.

drawdown

The largest peak to trough decline in an algorithm's equity curve.

equity

The total portfolio value if all of the holdings were sold at current market rates.

expectancy

The expected return per trade.

holdings

The absolute sum of the items in the portfolio.

information ratio

The amount of excess return from the risk-free rate per unit of systematic risk.

intrinsic value

(Call Option) The price of an asset minus the strike price if the price is above the strike price, otherwise zero.

(Put Option) The strike price minus the price of an asset if the price is below the strike price, otherwise zero.

look-ahead bias

The practice of making decisions using information that would not be available until some time in the future.

loss rate

The proportion of trades that were not profitable.

lowest capacity asset

The asset an algorithm traded that has the lowest capacity.

net profit

(Percent) The rate of return across the entire trading period.

(Dollar-value) The dollar-value return across the entire trading period.

out-of-the-money amount

(Call Option) The strike price minus the price of an asset if the price is below the strike price, otherwise zero.

(Put Option) The price of an asset minus the strike price if the price is above the strike price, otherwise zero.

payoff

The profit or loss that an Option buyer or seller makes from a trade.

pattern day trader

A trader who executes four or more day trades in the US Equity market within five business days.

Probabilistic Sharpe ratio

The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark (1).

profit-loss ratio

The ratio of the average win rate to the average loss rate.

return

The rate of return across the entire trading period.

risk-free interest rate

The interest rate an investor can expect to earn on an investment that carries zero risk such as the interest paid on a 10-year highly rated government treasury note

Sharpe ratio

A measure of the risk-adjusted return, developed by William Sharpe.

Sortino ratio

A measure of the risk-adjusted return, developed by Frank Sortino. It only penalizes returns falling below a user-specified target or required rate of return.

total fees

The total quantity of fees paid for all the transactions.

total net profit

The rate of return across the entire trading period.

total trades

The number of orders that were filled or partially filled.

tracking error

A measure of how closely a portfolio follows the index to which it is benchmarked. A tracking error of 0 is a perfect match.

Treynor ratio

A measurement of the returns earned in an algorithm in excess of the risk-free rate per unit of benchmark risk, developed by Jack Treynor.

unrealized

The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread.

volume

The total value of assets traded for all of an algorithm's transactions.

win rate

The proportion of trades that were profitable after transaction fees.

Initialization

Introduction

The `Initialize` method is the entry point of your algorithm where you define a series of settings, including security subscriptions, starting cash balances, and warm-up periods. LEAN only calls the `Initialize` method one time, at the start of your algorithm.

Set Dates

To set the date range of backtests, call the `SetStartDate` and `SetEndDate` methods. The dates you provide are based in the algorithm time zone. By default, the end date is yesterday, one millisecond before midnight. In live trading, LEAN ignores the start and end dates.

```C#
// Set the start and end dates for the algorithm, defining the backtesting period.
SetStartDate(2013, 1, 5);                 // Set the start date to January 5, 2013.
SetEndDate(2015, 1, 5);                   // Set the end date to January 5, 2015.
SetEndDate(DateTime.Now.Date.AddDays(-7)); // Set the end date to last week.
```

Organization managers can enforce all backtests to end a certain number of months before the current date to reduce the chance of overfitting. For more information, see Out-of-Sample Period .

Set Account Currency

The algorithm equity curve, benchmark, and performance statistics are denominated in the account currency. To set the account currency and your starting cash, call the `SetAccountCurrency` method. By default, the account currency is USD and your starting cash is $100,000. If you call the `SetAccountCurrency` method, you must call it before you call the `SetCash` method or add data . If you call the `SetAccountCurrency` method more than once, only the first call takes effect.

```C#
// Set the account currency and your starting cash.
SetAccountCurrency("BTC"); // Set the account currency to Bitcoin and its quantity to 100,000 BTC.
SetAccountCurrency("INR"); // Set the account currency to Indian Rupees and its quantity to 100,000 INR.
SetAccountCurrency("BTC", 10);  // Set the account currency to Bitcoin and its quantity to 10 BTC.
```

Set Cash

To set your starting cash in backtests, call the `SetCash` method. By default, your starting cash is $100,000 USD. In live trading, LEAN ignores the `SetCash` method and uses the cash balances in your brokerage account instead.

```C#
// Set the initial cash balance for the account for supported currencies.
SetCash(100000);       // Set the quantity of the account currency to 100,000.
SetCash("BTC", 10);    // Set the Bitcoin quantity to 10.
SetCash("EUR", 10000); // Set the EUR quantity to 10,000.
```

Set Brokerage and Cash Model

We model your algorithm with margin modeling by default, but you can select a cash account type. Cash accounts don't allow leveraged trading, whereas Margin accounts can support leverage on your account value. To set your brokerage and account type, call the `SetBrokerageModel` method. For more information about each brokerage and the account types they support, see

the brokerage integration documentation. For more information about the reality models that the brokerage models set, see Supported Models .

```
// Set the brokerage model and account type to model fees, supported order types, and available margin.
SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Margin);
```

The `AccountType` enumeration has the following members:

Set Universe Settings

The universe settings of your algorithm configure some properties of the universe constituents. The following table describes the properties of the `UniverseSettings` object:

Property: `Asynchronous` Should the universe selection run asynchronously to boost speed? Data Type: `bool` | Default Value: `false`
Property: `ExtendedMarketHours` Should assets also feed extended market hours? You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours. Data Type: `bool` | Default Value: `false`
Property: `FillForward` Should asset data fill forward? Data Type: `bool` | Default Value: `true`
Property: `MinimumTimeInUniverse` What's the minimum time assets should be in the universe? Data Type: `TimeSpan` | Default Value: `TimeSpan.FromDays(1)`
Property: `Resolution` What resolution should assets use? Data Type: `Resolution` | Default Value: `Resolution.Minute`

Method: `Schedule.On` What days should universe selection run? If it's `null` , it's the data resolution. For example, US Equity fundamentals universes are daily at midnight. Argument Type: `IDateRule` | Default Value: `null`
Property: `ContractDepthOffset` What offset from the current front month should be used for continuous Future contracts ? 0 uses the front month and 1 uses the back month contract. This setting is only available for Future assets. Data Type: `int` | Default Value: `0`
Property: `DataMappingMode` How should continuous Future contracts be mapped? This setting is only available for Future assets. Data Type: `DataMappingMode` | Default Value: `DataMappingMode.OpenInterest`
Property: `DataNormalizationMode data_normalization_mode` How should historical prices be adjusted? This setting is only available for Equity and Futures assets. Data Type: `DataNormalizationMode` | Default Value: `DataNormalizationMode.Adjusted`
Property: `Leverage` What leverage should assets use in the universe? This setting is not available for derivative assets. Data Type: `decimal` | Default Value: `Security.NullLeverage`

To set the `UniverseSettings` , update the preceding properties in the `Initialize` method before you add the universe. These settings are globals, so they apply to all universes you create.

```
C#
// Request second resolution data. This will be slow!
UniverseSettings.Resolution = Resolution.Second;
AddUniverse(Universe.Top(50));
```

For more information about universe settings, see the related documentation for classic and framework algorithms.

Set Security Initializer

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `Initialize` method, call the `SetSecurityInitializer` method and then define the security initializer.

```
// A custom security initializer can override default models such as
// setting new fee and fill models for the security.
SetSecurityInitializer(CustomSecurityInitializer);

private void CustomSecurityInitializer(Security security)
{
    security.SetFeeModel(new ConstantFeeModel(0, "USD"));
}
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```
// Disable the trading fees for each security by passing a functional
// implementation for the SetSecurityInitializer argument.
SetSecurityInitializer(security => security.SetFeeModel(new ConstantFeeModel(0, "USD")));
```

If you call the `SetSecurityInitializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, call `AddSecurityInitializer` before you create the subscriptions.

```
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetFeeModel(new ConstantFeeModel(0, "USD"));
    }
}
```

Add Data

You can subscribe to asset, fundamental, alternative, and custom data. The Dataset Market provides 400TB of data that you can easily import into your algorithms.

Asset Data

To subscribe to asset data, call one of the asset subscription methods like `AddEquity` or `AddForex` . Each asset class has its own method to create subscriptions. For more information about how to create subscriptions for each asset class, see Asset Classes

.

```
AddEquity("AAPL"); // Add Apple 1 minute bars (minute by default)
AddForex("EURUSD", Resolution.Second); // Add EURUSD 1 second bars
```

In live trading, you define the securities you want, but LEAN also gets the securities in your live portfolio and sets their resolution to the lowest resolution of the subscriptions you made. For example, if you create subscriptions in your algorithm for securities with Second, Minute, and Hour resolutions, the assets in your live portfolio are given a resolution of Second.

Alternative Data

To add alternative datasets to your algorithms, call the `AddData` method. For full examples, in the Datasets chapter, select a dataset and see the Requesting Data section.

Custom Data

To add custom data to your algorithms, call the `AddData` method. For more information about custom data, see Importing Data .

Limitations

There is no official limit to how much data you can add to your algorithms, but there are practical resource limitations. Each security subscription requires about 5MB of RAM, so larger machines let you run algorithms with bigger universes. For more information about our cloud nodes, see Resources .

Set Indicators and Consolidators

You can create and warm-up indicators in the `Initialize` method.

```
private Symbol _symbol;
private SimpleMovingAverage _sma;

_symbol = AddEquity("SPY").Symbol;
_sma = SMA(_symbol, 20);
WarmUpIndicator(_symbol, _sma);
```

Set Algorithm Settings

The following table describes the `AlgorithmSettings` properties:

Property: `AutomaticIndicatorWarmUp` A flag that defines if the `WarmUpIndicator` method can warm up indicators. Data Type: `bool` | Default Value: `false`
Property: `SeedInitialPrices` Determines whether to seed initial prices for all selected and manually added securities. Data Type: `bool` | Default Value: `false`

Property: `DailyPreciseEndTime`

A flag that defines if daily bars should have an EndTime that matches the market close time (`true`) or the following midnight (`false`).

Data Type: `bool` | Default Value: `true`

Property: `FreePortfolioValue`

The buying power buffer value.

Data Type: `decimal` | Default Value: `250 m`

Property: `FreePortfolioValuePercentage`

The buying power buffer percentage value.

Data Type: `decimal` | Default Value: `0.0025 m`

Property: `IgnoreUnknownAssetHoldings`

Determines whether to terminate the algorithm when an asset holding is not supported by Lean or the brokerage.

Data Type: `bool` | Default Value: `true`

Property: `LiquidateEnabled`

A flag to enable and disable the `Liquidate` method.

Data Type: `bool` | Default Value: `true`

Property: `MaxAbsolutePortfolioTargetPercentage`

The absolute maximum valid total portfolio value target percentage.

Data Type: `decimal` | Default Value: `1000000000 m`

Property: `MinAbsolutePortfolioTargetPercentage`

The absolute minimum valid total portfolio value target percentage.

Data Type: `decimal` | Default Value: `0.0000000001 m`

Property: `MinimumOrderMarginPortfolioPercentage`

The minimum order margin portfolio percentage to ignore bad orders and orders with small sizes.

Data Type: `decimal` | Default Value: `0.001 m`

Property: `PerformanceSamplePeriod`

Performance tracking sample period to use if any, useful to debug performance issues. See Performance Chart .

Data Type: `TimeSpan` | Default Value: `TimeSpan.Zero`

Property: `RebalancePortfolioOnInsightChanges`

Rebalance the portfolio when you emit new insights or when insights expire.

Data Type: `bool/NoneType` | Default Value: `true`

Property: `RebalancePortfolioOnSecurityChanges`

Rebalance the portfolio when your universe changes.

Data Type: `bool/NoneType` | Default Value: `true`

Property: `StalePriceTimeSpan`

The minimum time span elapsed to consider a market fill price as stale

Data Type: `TimeSpan` | Default Value: `TimeSpan.FromHours(1)`

Property: `TradingDaysPerYear`

Number of trading days per year for this algorithm's portfolio statistics .

Data Type: `integer` | Default Value: `252`

Property: `WarmUpResolution`

The resolution to use during the warm-up period

Data Type: `Resolution/NoneType` | Default Value: `null`

To change the `Settings` , update some of the preceding properties.

```
// Set the algorithm behavior using the Settings property on your algorithm.
Settings.RebalancePortfolioOnSecurityChanges = false;
Settings.TradingDaysPerYear = 365;
```

To successfully update the `FreePortfolioValue` , you must update it after the `Initialize` method.

Set Benchmark

The benchmark performance is input to calculate several statistics on your algorithm, including alpha and beta . To set a benchmark for your algorithm, call the `SetBenchmark` method. You can set the benchmark to a security, a constant value, or a value from a custom data source . If you don't set a brokerage model , the default benchmark is SPY. If you set a brokerage model, the model defines the default benchmark.

```
// Set the benchmark to IBM
SetBenchmark("IBM");

// Set the benchmark to a constant value of 0
SetBenchmark(x => 0);

// Set the benchmark to a value from a custom data source
var symbol = AddData<CustomData>("CustomData", Resolution.Hour).Symbol;
SetBenchmark(symbol);
```

If you pass a ticker to the `SetBenchmark` method, LEAN checks if you have a subscription for it. If you have a subscription for it, LEAN uses the security subscription. If you don't have a subscription for it, LEAN creates a US Equity subscription with the ticker. Since the ticker you pass may not reference a US Equity, we recommend you subscribe to the benchmark security before you call the `SetBenchmark` method.

Set Time Zone

LEAN supports international trading across multiple time zones and markets, so it needs a reference time zone for the algorithm to set the `Time` . The default time zone is Eastern Time (ET), which is UTC-4 in summer and UTC-5 in winter. To set a different time zone, call the `SetTimeZone` method. This method accepts either a string following the IANA Time Zone database convention or a NodaTime .DateTimeZone object. If you pass a string, the method converts it to a `NodaTime.DateTimeZone` object. The `TimeZones` class provides the following helper attributes to create `NodaTime.DateTimeZone` objects:

```
SetTimeZone("Europe/London");
SetTimeZone(NodaTime.DateTimeZone.Utc);
SetTimeZone(TimeZones.Chicago);
```

The algorithm time zone may be different from the data time zone . If the time zones are different, it might appear like there is a lag between the algorithm time and the first bar of a history request, but this is just the difference in time zone. All the data is internally synchronized in Coordinated Universal Time (UTC) and arrives in the same Slice object. A slice is a sliver of time with all the data available for this moment.

To keep trades easy to compare between asset classes, we mark all orders in UTC time.

Set Warm Up Period

You may need some historical data at the start of your algorithm to prime technical indicators or populate historical data arrays. The warm-up period pumps data into your algorithm from before the start date. To set a warm-up period, call the `SetWarmUp` method. The warm-up feature uses the subscriptions you add in `Initialize` to gather the historical data that warms up the

algorithm. If you don't create security subscriptions in the `Initialize` method, the warm-up won't occur.

```
C#

// Wind time back 7 days from the start date
SetWarmUp(TimeSpan.FromDays(7));

// Feed in 100 trading days worth of data before the start date
SetWarmUp(100, Resolution.Daily);

// If you don't provide a resolution argument, it uses the lowest resolution in your subscriptions
SetWarmUp(100);
```

Set Name and Tags

You can categorize your backtest with a name and tags. To set the algorithm `Name` , call the `SetName` method.

```
C#

// Set the name of your backtest to help categorize your results.
SetName("Backtest Name");
```

The `SetName` method overwrites the names of backtests of an optimization , which contains the parameter values. To keep these values, create a name that includes them.

```
C#

// Setting the backtest name to a mix of the parameters can help identify backtests in optimization results.
var fastPeriod = GetParameter("fast_period", 100);
var midPeriod = GetParameter("mid_period", 200);
var slowPeriod = GetParameter("slow_period", 300);
SetName($"Backtest Name ({fastPeriod},{midPeriod},{slowPeriod})");
```

To add tags to you algorithm, call the `AddTag` method.

```
C#

// Add additional information to the algorithm with tags for better organization in the backtest results.
AddTag("Long Only");
AddTag("Momentum");
```

Your algorithm can add 20 tags. The name and each tag can have up to 200 characters or else they are truncated.

Post Initialization

After the `Initialize` method, the `PostInitialize` method performs post-initialization routines, so don't override it. To be notified when the algorithm is ready to begin trading, define an `OnWarmupFinished` method. This method executes even if you don't set a warm-up period.

```
C#

// Notify yourself when the algorithm is ready to begin trading.
public override void OnWarmupFinished()
{
    Log("Algorithm Ready");
}
```

Examples

The following examples demonstrate some common practices for initializing algorithms.

Example 1: Set the Data Seed

Some data feeds might not have data on its first fetch, making the algorithm prone to error. The following algorithm seeds the initial price of each asset to its last known price to avoid issues.

```
C#
// Seed with the last known price of assets to prevent $0 security price errors.
public override void Initialize()
{
    Settings.SeedInitialPrices = true;
}
```

Example 2: Enable Extended Market Hours

Some traders use pre-market data for filtering assets. The following algorithm enables extended market hour data for assets in the universe.

```
C#
// Add a universe of assets with extended market hours data.
public override void Initialize()
{
    UniverseSettings.ExtendedMarketHours = true;
}
```

Example 3: Train Models When the Warm Up Finishes

The following algorithm uses the `OnWarmupFinished` event handler to train a model with data from the warm-up period.

```
C#
// Train machine learning models after the algorithm warm up is done, so your models
// are ready as soon as the algorithm starts trading.
public override void OnWarmupFinished()
{
    Train(MyTrainingMethod);
}
```

Securities

Securities

Key Concepts

Introduction

A security is an individual financial asset that you can trade on an exchange. LEAN models these unique assets with a `Security` object, which the `AddEquity` , `AddCrypto` , and similar methods return. The `Securities` property of the `QCAlgorithm` class is a dictionary where the keys are `Symbol` objects and the values are `Security` objects. The `Securities` dictionary contains all of the securities that have been in the algorithm during its lifetime.

```
C#
// Add the SPY.
private Symbol _symbol;
_symbol = AddEquity("SPY").symbol;
```

Price

To get the current price of a security, index the `Securities` dictionary and then access the `Price` member.

```
C#
// Get the price of the security.
var price = Securities[_symbol].Price;
```

Holdings

The `holdings` property of a `Security` object contains information about the investment state and history of the security.

```
C#
// Use the holdings object to get information on the asset position, such as the quantity and average price.
var holdings = Securities[_symbol].Holdings;
var quantity = holdings.Quantity;
```

Alternatively, you can get the current holdings of a security with the `Portfolio` dictionary.

```
C#
// Get the quantity of a security you hold through the Portfolio dictionary.
var holdings = Portfolio[_symbol];
var quantity = holdings.Quantity;
```

Reality Models

`Security` objects contain references to the security level reality models . To customize the behavior of each security, configure its reality models.

Tradable Status

The `IsTradable` property shows whether you can trade a security. The property value is true when the security is in the universe, even if the data starts at a later day. Indices, canonical Option securities, and continuous Futures contracts are not tradable. In live mode, custom data objects are also not tradable, even if the custom data represents a tradable asset.

```
C#

// Check if the security is tradable.
var tradable = Securities[_symbol].IsTradable;
```

Symbol Properties

The `SymbolProperties` property of a `Security` contains properties for that specific security, such as the lot size and the minimum price variation.

```
C#

// Round orders to a brokerage's lot size and minimum price variation using the symbol_properties.
var symbolProperties = Securities[_symbol].SymbolProperties;
var lotSize = symbolProperties.LotSize;
var minimumPriceVariation = symbolProperties.MinimumPriceVariation;
```

Market Hours

The `Exchange` property of a `Security` contains information about the exchange that lists the security. For example, the `Exchange.Hours` property contains information on the trading days and hours .

```
C#

// Using the exchange object, check if the exchange's regular trading hours are open at the given time.
var exchange = Securities[_symbol].Exchange;
var hours = exchange.Hours;
var isOpenNow = hours.isOpen(Time, extendedMarketHours: false);
var minimumPriceVariation = symbolProperties.MinimumPriceVariation;
```

Custom Security Properties

You can add properties to the `Security` object. For example, you can add an exponential moving average .

```
C#

// Cast the Equity to a dynamic object to add an EMA indicator to it.
dynamic equity = AddEquity("SPY");
equity.ema = EMA(equity.Symbol, 10, Resolution.Daily);
```

This feature is helpful because you can get the `Security` object from the `Securities` object.

```
C#

// Get the SPY Equity object from Securities to get the EMA indicator.
var ema = (decimal)(Securities["SPY"] as dynamic).ema.Current.Value;
```

To avoid casting to and from the `dynamic` type, you can use the `Set` method to assign and the `Get<T>` method to access the dynamic member and return the object with its type.

```
C#

var equity = AddEquity("SPY");
// Assign an EMA indicator to the "ema" property
equity.Set("ema", EMA(equity.Symbol, 10, Resolution.Daily));
// Get the SPY Equity object from Securities to get the EMA indicator and its current value
var ema = Securities["SPY"].Get<ExponentialMovingAverage>("ema");   // The type of ema is ExponentialMovingAverage
var emaValue = ema.Current.Value;    // The type of emaValue is decimal
```

If the type or the member name is incorrect, the `Get<T>` method causes a runtime error.

Properties

The `Security` type has the following properties:

Examples

The following examples demonstrate some common practices for securities.

Example 1: Accessing Properties

The following example shows how to access various propeties of the `Security` object.

```C#
public class SecuritiesUsageAlgorithm : QCAlgorithm
{
    private Equity _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        _spy = AddEquity("SPY");
    }

    public override void OnData(Slice slice)
    {
        // OHLCV data.
        var price = _spy.Close;
        var volume = _spy.Volume;
        // Quote data.
        var quoteSize = _spy.BidSize;
        var quotePrice = _spy.AskPrice;
        // Symbol Properties.
        var lotSize = _spy.SymbolProperties.LotSize;
        // Fundamentals cached data.
        var peRatio = _spy.Fundamentals.ValuationRatios.PERatio;
        // Properties, e.g. is tradeble, is market open, leverage, ...
        var marketOpen = _spy.IsMarketOpen;
        var leverage = _spy.Leverage;
        // Models, e.g. margin model, buying power model, ...
        var marginModel = _spy.MarginModel;
        // Portfolio Holdings reference.
        var holding = _spy.Holdings;
    }
}
```

Securities

Requesting Data

Introduction

When you add a security to your algorithm, your algorithm creates a data subscription and receives data updates for that security or custom data source .

Add Assets

To create an Equity subscription, call the `AddEquity` method and pass the `ticker` argument. The `ticker` argument represents the current ticker.

```
C#
// Add the SPY ETF.
var equity = AddEquity("SPY");
```

The `AddEquity` method creates a subscription for a single Equity asset and adds it to your user-defined universe.

For more information about adding assets, see Asset Classes .

Add Universes

Universe selection is the process of selecting a basket of assets you may trade. When you add a universe to your algorithm, LEAN sends a large dataset into a filter function you define. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```
C#
// Use the FundamentalFilterFunction to add the 100 most liquid stocks to the universe.
public class MyFundamentalUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        AddUniverse(FundamentalFilterFunction);
    }

    // Get the top 100 stocks by dollar volume.
    private IEnumerable<Symbol> FundamentalFilterFunction(IEnumerable<Fundamental> fundamental)
    {
        return (from c in fundamental
            orderby c.DollarVolume descending
            select c.Symbol).Take(100);
    }
}
```

For more information about universes, see Universes .

Resolutions

Resolution is the duration of time that's used to sample a data source. Market data is sampled and saved in disk with five resolutions. The `Resolution` enumeration has the following members:

- `Resolution.Tick` `Resolution.TICK`
- `Resolution.Second` `Resolution.SECOND`

- `Resolution.Minute` `Resolution.MINUTE`
- `Resolution.Hour` `Resolution.HOUR`
- `Resolution.Daily` `Resolution.DAILY`

For more information about the resolutions of each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Requesting Data .
4. Scroll down to the Resolutions section.

You can subscribe to daily resolution for an asset for updating indicator and subscribe to another asset for denser resolution for trading using the indicator.

```C#
public override void Initialize()
{
    AddEquity("VIX", Resolution.Daily);
    AddEquity("SPY", Resolution.Minute);
}
```

To get data with multiple or customizable resolutions for an asset, use consolidators .

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

For more information about how to enable and disable fill forward for each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Requesting Data .
4. Scroll down to the Fill Forward section.

Example: Disable Fill Forward Data

For some illiquid securities or alternative data, using forward filled data might not be an accurate estimation nor usable information. To avoid this, disable fill forward.

```C#
public override void Initialize()
{
    AddData<BrainSentiment7Days>(symbol, fillForward: false);
}
```

Security Changed Events

When you add and remove assets, LEAN notifies your algorithm through the `OnSecuritiesChanged` event handler. The event handler receives a `SecurityChanges` object, which contains references to the added and removed securities. To access the added securities, iterate the `changes.AddedSecurities` property. To get the removed securities, iterate the `changes.RemovedSecurities` property.

```C#
// Use OnSecuritiesChanged to know when an asset is added or removed.
public override void OnSecuritiesChanged(SecurityChanges changes)
{
    // Iterate through the added assets.
    foreach (var security in changes.AddedSecurities)
    {
        Debug($"{Time}: Added {security.Symbol}");
    }

    // Iterate through the removed assets.
    foreach (var security in changes.RemovedSecurities)
    {
        Debug($"{Time}: Removed {security.Symbol}");

        if (security.Invested)
        {
            Liquidate(security.Symbol, "Removed from Universe");
        }
    }
}
```

The preceding example liquidates securities that leave the universe. You can use this event to create indicators when a new security enters the universe.

Remove Subscriptions

To remove a security subscription, call the `RemoveSecurity` method.

```C#
// Remove the security subscription.
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings.

Examples

The following examples demonstrate some common practices on the subject of requesting data.

Example 1: Add Linked Alternative Data for Universe Constituents

Many traders select universe constituents and then allocate positions with two independent sets of logic. Position sizing usually requires additional information, like alternative data factors. To manage alternative data subscriptions for all the universe constituents, subscribe and unsubscribe from the data in the `OnSecuritiesChanged` method. The following example demonstrates adds the KavoutCompositeFactorBundle when assets enter the universe.

```C#
public class RequestSecuritiesDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe of the 25 most liquid US Equities.
        AddUniverse(Universe.Top(25));
    }

    public override void OnData(Slice slice)
    {
        // Invest by the updated Kavout Factor data.
        var factorData = slice.Get<KavoutCompositeFactorBundle>();
        if (factorData.Count > 0)
        {
            // Obtain the top 10 factor sum score symbols.
            // Invest by equal weighting to dissipate capital risks.
            var topFactorTargets = factorData.OrderByDescending(x =>
                    x.Value.Growth + x.Value.ValueFactor + x.Value.Quality + x.Value.Momentum +
x.Value.LowVolatility
                )
                .Where(x => Securities[x.Key.Underlying].Price != 0)
                .Take(10)
                .Select(x => new PortfolioTarget(x.Key.Underlying, 0.1m))
                .ToList();
            SetHoldings(topFactorTargets, true);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Iterate securities that entered the universe.
        foreach (dynamic security in changes.AddedSecurities)
        {
            // Subscribe to the factor data for the new security.
            // Save the alternative data symbol in the security object.
            security.AltDataSymbol = AddData<KavoutCompositeFactorBundle>(security.Symbol, Resolution.Daily).Symbol;
        }

        // Iterate securities that left the universe.
        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Unsubscribe from the altnerative data updates.
            RemoveSecurity(security.AltDataSymbol);
        }
    }
}
```

Example 2: Add Linked Custom Data

QuantConnect Cloud has a lot of data, but not everything. To import some external data into your algorithm, define a custom data source . The following algorithm loads Bitstamp's BTCUSD trading activity from a CSV file and plots it:

```C#
// Define the algorithm.
public class LinkedCustomDataExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add Bitcoin and the custom dataset.
        dynamic btc = AddCrypto("BTCUSD");
        btc.dataSymbol = AddData<Bitstamp>(btc.Symbol.Value, Resolution.Daily).Symbol;
        // Plot the price from the custom dataset.
        PlotIndicator("BTC Price", Identity(btc.dataSymbol));
    }
}

// Define the custom data source.
public class Bitstamp : BaseData
{
```

```
{
    // Declare the properties of the custom dataset.
    public int Timestamp = 0;
    public decimal Open = 0;
    public decimal High = 0;
    public decimal Low = 0;
    public decimal Close = 0;
    public decimal Bid = 0;
    public decimal Ask = 0;
    public decimal WeightedPrice = 0;
    public decimal VolumeBTC = 0;
    public decimal VolumeUSD = 0;

    // Define the GetSource method to load the data from its location.
    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        var source = "https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/bitstampusd.csv";
        // RemoteFile in the next line means the data file in online storage.
        return new SubscriptionDataSource(source, SubscriptionTransportMedium.RemoteFile);
    }

    // Define the Reader method to parse the CSV rows.
    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        // Ignore empty rows.
        if (string.IsNullOrWhiteSpace(line.Trim()))
        {
            return null;
        }

        // Instantiate a new data object.
        var coin = new Bitstamp() {Symbol = config.Symbol};

        // Ignore non-numeric lines.
        if (!char.IsDigit(line[0]))
        {
            return null;
        }

        // Split the CSV data by its commas.
        var data = line.Split(',');
        coin.Value = data[4].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture));
        // Ignore invalid data.
        if (coin.Value == 0)
        {
            return null;
        }

        // Parse the row.
        coin.Time = DateTime.Parse(data[0], CultureInfo.InvariantCulture);
        coin.EndTime = coin.Time.AddDays(1);
        coin.Open = data[1].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture));
        coin.High = data[2].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture));
        coin.Low = data[3].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture));
        coin.VolumeBTC = data[5].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.VolumeUSD = data[6].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.WeightedPrice = data[7].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.Close = coin.Value;
        return coin;
    }
}
```

Securities

Handling Data

Introduction

If you create a data subscription, your algorithm receives data updates for that security or custom data source .

Get Prices

LEAN uses data updates to set the current prices of a security and compute the contribution of securities you hold to the portfolio value. To get the current prices of a security, find the `Security` object in the `Securities` dictionary and access the price attributes.

```
C#
// Use the Securities object as a dictionary to get the current ask and bid price of the SPY.
var security = Securities["SPY"];
var price = security.Price;
var bidPrice = security.BidPrice;
var askPrice = security.AskPrice;
```

Data Events

The `Slice` that LEAN passes to the `OnData` method represents all of the data for your subscriptions at a single point in time. The `Slice` object contains data like `Tick` objects, `TradeBar` objects, `QuoteBar` objects, corporate actions , and chains for Option and Future contracts. You can use the data in the `Slice` to make trading decisions.

To access data in the `Slice` , index it with the security `Symbol` . If you use the security ticker instead of the `Symbol` , LEAN automatically finds the `Symbol` .

```
C#
// Use the OnData method to get the data for a symbol in the current time slice.
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_symbol))
    {
        var myData = slice[_symbol];
    }
}
```

The following table shows the `Slice` property to index based on the data format you want:

Data Format	Slice Property
`TradeBar`	`Bars`
`QuoteBar`	`QuoteBars`
`Tick`	`Ticks`

```C#
// Get the tradebar from the slice.
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_symbol))
    {
        var bar = slice.Bars[_symbol];
    }
}
```

If you just index the `Slice` instead of the preceding properties, it returns the correct object. For instance, if your data subscription provides `QuoteBar` objects and you index the `Slice` with the security `Symbol` , it returns the `QuoteBar` .

For more information about the `Slice` class, see Timeslices .

Cache

To get the most recent data for a security, call the `GetLastData` method on the `Security` object.

```C#
// Get the most recent data for a security.
var data = Securities["SPY"].GetLastData();
```

The `Cache` property of a `Security` object provides additional price information since you can access `TradeBar` , `QuoteBar` , and `Tick` data.

```C#
// Get additional price information for the security.
var cache = Securities["SPY"].Cache;
var tradeBar = cache.GetData<TradeBar>();
var quoteBar = cache.GetData<QuoteBar>();
var ticks = cache.GetAll<Tick>();
```

Market Session

The `session` property of a `Security` object contains the open, high, low, close, volume, and open interest of trading sessions. The `Session` object is a `RollingWindow` object with size of zero by default. To enable market session tracking, set the size of the `Session` object to 2, so the previous session data is at index 1.

```C#
var session = Securities[_symbol].Session;
session.Size = 2;
var todayOpen = session.Open;
var todayHigh = session.High;
var todayLow = session.Low;
var todayCumulativeVolume = session.Volume;
if (session.IsReady)
{
    var yesterdayClose = session[1].Close;
}
```

Increase the size of the `Session` object to store more session data. You can use cached data in the `session` property instead of requesting historical daily data .

```
var equity = AddEquity("SPY");
// Increase the session lookback to 252 from default (0)
equity.Session.Size = 252;
// Get all closing prices in the session history
var closes = session.OrderBy(x => x.EndTime).Select(x => x.Close);
```

For more information about rolling windows, see Rolling Window .

Examples

The following examples demonstrate some common practices for handling data.

Example 1: Get QuoteBar Data

The following algorithm updates an indicator with the mid-price of a quote bar to increase the accuracy of the indicator values for illiquid assets. Then, make use of the SMA indicator to trade the SMA cross strategy.

```
public class HandlingSecuritiesDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    // Initialize a new instance of a SimpleMovingAverage object.
    private SimpleMovingAverage _indicator = new(250);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        _symbol = AddEquity("SPY").Symbol;

        SetWarmUp(TimeSpan.FromDays(350));
    }

    public override void OnData(Slice slice)
    {
        // Check if the QuoteBars contain SPY quote data.
        if (!slice.QuoteBars.ContainsKey(_symbol))
        {
            return;
        }
        var quoteBar = slice.QuoteBars[_symbol];
        // Calculate the mid price by averaging the bid and ask price.
        var midPrice = (quoteBar.Bid.Close + quoteBar.Ask.Close) * 0.5m;
        // Update the SMA indicator with the mid price.
        _indicator.Update(quoteBar.EndTime, midPrice);

        // Wait for the algorithm and indicator to be warmed up.
        if (IsWarmingUp || !_indicator.IsReady)
        {
            return;
        }
        // Trade SMA cross strategy.
        SetHoldings(_symbol, _indicator > midPrice ? -0.5m : 0.5m);
    }
}
```

Example 2: Get Tick Data

The following algorithm calculates the bid and ask sizes of the latest SPY quote ticks and then trades at the top of each hour. During each rebalance, it buys SPY if bid size is greater than ask size since supply is greater than demand in this case. If bid size is smaller than ask size, it sells SPY since demand is greater than supply in this case.

C#

```
public class BidAskSizeTickAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    // Set up variables to save the bid and ask sizes.
    private decimal _bidSize = 0m, _askSize = 0m;
    private int _hour = -1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 10);
        // Seed the price of each asset with its last known price to
        // avoid trading errors.
        Settings.SeedInitialPrices = true;
        _symbol = AddEquity("SPY", Resolution.Tick).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Check if the Ticks object contain SPY tick data.
        if (slice.Ticks.TryGetValue(_symbol, out var ticks))
        {
            // Iterate all the ticks to calculate the bid and ask sizes.
            foreach (var tick in ticks.Where(tick => tick.TickType == TickType.Quote))
            {
                // Update the bid or ask size.
                _bidSize += tick.BidSize;
                _askSize += tick.AskSize;
            }
        }
        // Trade at the top of each hour.
        if (slice.Time.Hour != _hour)
        {
            // Invest based on supply-demand relationship from all ticks.
            // If bid size is above ask size, supply is greater than
            // demand, which drives the price up. Otherwise, supply is
            // lower than demand, which drives the price down.
            SetHoldings(_symbol, _bidSize > _askSize ? 0.5m : -0.5m);
            // Reset the bid and ask size variables.
            _bidSize = 0;
            _askSize = 0;
            _hour = slice.Time.Hour;
        }
    }
}
```

Example 3: Get US Equity Fundamental Data

The following algorithm gets the latest fundamental data of all the US Equities in the algorithm. We invest in the stocks with the highest PE Ratio equally to ride on the popularity.

```C#
public class HandlingSecuritiesDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request data for a selected list of equities for trading.
        foreach (var ticker in new[] { "AAPL", "MSFT", "TSLA", "GOOG", "AMZN" })
        {
            AddEquity(ticker);
        }
    }

    public override void OnData(Slice slice)
    {
        var peRatios = new Dictionary<Symbol, double>();

        // Iterate active security objects.
        foreach (var security in ActiveSecurities.Values)
        {
            // Get the Fundamental cache.
            var fundamental = security.Fundamentals;
            // Get the sector code.
            var sectorCode = fundamental.AssetClassification.MorningstarSectorCode;

            peRatios[security.Symbol] = fundamental.ValuationRatios.PERatio;
        }

        // Sort by PE ratio to get the most popular stocks.
        var sortedByPeRatio = peRatios.OrderByDescending(x => x.Value)
            .ToDictionary(x => x.Key, x => x.Value);
        var targets = sortedByPeRatio
            .Take(3)
            .Select(x => new PortfolioTarget(x.Key, 1m / 3m))
            .ToList();
        targets.AddRange(sortedByPeRatio
            .TakeLast(2)
            .Select(x => new PortfolioTarget(x.Key, 0m))
            .ToList());
        // Invest equally in the highest PE Ratio stocks for evenly dissipate capital risk.
        SetHoldings(targets);
    }
}
```

Example 4: Get Option Greeks

The following algorithm gets SPY Option Greek values. Sell a straddle with the ATM options, selected by Option Delta (closest to 0.5).

```C#
public class HandlingSecuritiesDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add an SPY Option universe.
        var option = AddOption("SPY");
        // Set the Option universe filter.
        option.SetFilter(x => x.IncludeWeeklys().Strikes(-5, 5).Expiration(7, 60));
        // Save a reference of the canonical symbol.
        _symbol = option.Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Try to get the Option contracts within the Option chain.
        if (!Portfolio.Invested && slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            foreach (var contract in chain)
            {
                // Get the implied volatility and greeks of each Option contract.
                var iv = contract.ImpliedVolatility;
                var greeks = contract.Greeks;
                var delta = greeks.Delta;
                var gamma = greeks.Gamma;
                var vega = greeks.Vega;
                var theta = greeks.Theta;
                var rho = greeks.Rho;
            }

            // Invest in a straddle strategy to capitalize the volatility
            // Trade the ATM options with the closest expiry after 7 days.
            var expiry = chain.Min(x => x.Expiry);
            var selected = chain.Where(x => x.Expiry == expiry)
                .MinBy(x => Math.Abs(x.Greeks.Delta - 0.5m));
            var optionStrategy = OptionStrategies.Straddle(selected.Symbol.Canonical, selected.Strike,
selected.Expiry);
            Sell(optionStrategy, 1);
        }
    }
}
```

Example 5: Get Asset Sentiment Values

The following example gets sentiment values from the Brain Sentiment Indicator dataset. It simply buys AAPL when the sentiment is positive and liquidates the position when the sentiment is negative.

```C#
public class HandlingSecuritiesDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _dataset7DaySymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of AAPL with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add the 7-day sentiment data for AAPL.
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _dataset7DaySymbol = AddData<BrainSentimentIndicator7Day>(_symbol).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Check if the current slice contains the 7-day sentiment data.
        if (slice.ContainsKey(_dataset7DaySymbol))
        {
            var dataPoint = slice[_dataset7DaySymbol];
            // Log the sentiment value.
            Log($"{_dataset7DaySymbol} sentiment at {slice.Time}: {dataPoint.Sentiment}");

            // Invest if the sentiment score is above 0, which indicates positive sentiment.
            if (dataPoint.Sentiment > 0m)
            {
                MarketOrder(_symbol, 1);
            }
            // Liquidate otherwise.
            else if (dataPoint.Sentiment < 0m && Portfolio[_symbol].Invested)
            {
                Liquidate(_symbol);
            }
        }
    }
}
```

Example 6: Market Session as History

Using `Session` instead of history requests or rolling window to cache the last 252 OHLCV bars, the following algorithm buys SPY accordingly when the market opens above the 252-day max of closing prices.

C#

```
public class MarketSessionAsDailyHistory : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var equity = AddEquity("SPY");

        // Increase the session lookback to 252 from default (0)
        // since our strategy break out the 252-day max of closing prices
        equity.Session.Size = 252;
        // Warm up with daily data for speed
        SetWarmUp(equity.Session.Size, Resolution.Daily);

        Schedule.On(DateRules.EveryDay("SPY"), TimeRules.AfterMarketOpen("SPY", 1), () =>
        {
            // Break-out strategy. If the market opens above the 252-day max of closing prices,
            // allocate all in SPY. Liquidate if it opens below the mean.

            var session = Securities["SPY"].Session;
            // The session is ready when the number of samples is greater than the size (252)
            if (IsWarmingUp || !session.IsReady)
                return;

            var closes = session.OrderBy(x => x.EndTime).Select(x => x.Close);
            var open = session.Open;
            var max = closes.Max();
            var mean = closes.Average();

            // Invest all in SPY if the open break out the 252-day max and liquidate below the mean
            if (open > max)
                SetHoldings("SPY", 1, tag: $"_open={open:F2}, _max={max:F2}");
            if (open < mean)
                Liquidate(symbol: "SPY", tag:$"_open={open:F2}, _mean={mean:F2}");
        });
    }
}
```

Securities

Market Hours

Introduction

The `Exchange` property of a `Security` object contains information about the exchange that lists the security, including its time zone and the trading days and hours. To get the exchange market hours, use the `Exchange.Hours` property on a `Security` object.

```
C#

// Get properties of the exchange that lists the security.
var securityExchangeHours = Securities["SPY"].Exchange.Hours;
```

Market Status

To check if the exchange is open at a specific time, call the `IsOpen` method.

```
C#

// Check if the exchange is currently open.
var isOpenNow = securityExchangeHours.IsOpen(Time, extendedMarketHours: false);

// Check if the exchange is open at any point in time over a specific interval.
var isOpen = securityExchangeHours.IsOpen(Time, Time.AddDays(1), extendedMarketHours: false);
```

To check if the exchange is open on a specific date, call the `IsDateOpen` method.

```
C#

// Check if the exchange is open at some time today.
var isOpen = securityExchangeHours.IsDateOpen(Time, extendedMarketHours: true);
```

To get the next market open time, call the `GetNextMarketOpen` method.

```
C#

// Get the next market open time.
var marketOpenTime = securityExchangeHours.GetNextMarketOpen(Time, extendedMarketHours: false);
```

To get the next market close time, call the `GetNextMarketClose` method.

```
C#

// Get the next market close time.
var marketCloseTime = securityExchangeHours.GetNextMarketClose(Time, extendedMarketHours: false);
```

To get the previous trading day, call the `GetPreviousTradingDay` method.

```
C#

// Get the previous trading day.
var day = securityExchangeHours.GetPreviousTradingDay(Time);
```

To get the next trading day, call the `GetNextTradingDay` method.

```
// Get the next trading day.
var day = securityExchangeHours.GetNextTradingDay(Time);
```

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
AddEquity("SPY", extendedMarketHours: true);
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

Properties

The `SecurityExchange` object has the following attributes:

Examples

The follow examples demonstrate some common practices for trading with market hours data.

Example 1: Only Within 1 Hour Of Market Open And Close

Buying SPY shortly after market holidays or weekend breaks can be a profitable strategy. Historically, the market has tended to experience positive returns in the trading sessions immediately following extended market closures. This is often attributed to the release of pent-up demand and information during the downtime. By positioning into SPY at the open or within the first few trading hours after a holiday or weekend, investors may be able to capture this post-break bounce in the broader market.

```
public class MarketHourExampleAlgorithm : QCAlgorithm
{
    private Equity _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _spy = AddEquity("SPY", Resolution.Hour);
    }

    public override void OnData(Slice slice)
    {
        // Check if the previous day is holiday
        if (_spy.Exchange.Hours.Holidays.Contains(Time.Date.AddDays(-1)))
        {
            // Buy if it is a holiday a day before
            SetHoldings(_spy.Symbol, 1);
        }
        else if (Portfolio[_spy.Symbol].Invested)
        {
            // Liquidate otherwise if any open position
            Liquidate(_spy.Symbol);
        }
    }
}
```

Example 2: Pre-market Short Limit Order

A pre-market short limit order is a type of order placed before the regular trading session begins. It allows a trader to take a short position at a price higher than the current market price, with the intention of selling the position shortly after the market

opens and profiting from the expected price decline. This strategy is often used by traders who anticipate a decline in the asset's value and want to capitalize on it.

```C#
public class MarketHourExampleAlgorithm : QCAlgorithm
{
    private Equity _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add SPY data with extended market hours.
        _spy = AddEquity("SPY", extendedMarketHours: true);
    }

    public override void OnData(Slice slice)
    {
        if (!slice.QuoteBars.ContainsKey(_spy.Symbol)) return;
        // During pre-market hours, place an unmarketable limit order.
        if (!_spy.Invested &&
            IsBeforeMarketOpenExtendedHours(slice.Time) &&
            Transactions.GetOpenOrderTickets(_spy.Symbol).Count() == 0)
        {
            LimitOrder(_spy.Symbol, -10, _spy.BidPrice * 1.005m);
        }
        // Check if the normal market is opening and any position
        else if (_spy.Invested && _spy.Exchange.Hours.IsOpen(slice.Time, false))
        {
            Liquidate(_spy.Symbol);
        }
    }

    private bool IsBeforeMarketOpenExtendedHours(DateTime time)
    {
        return (
            // It's currently extended market hours.
            _spy.Exchange.Hours.IsOpen(time, true) &&
            // The next market open for regular trading hours is today.
            _spy.Exchange.Hours.GetNextMarketOpen(time, false).Day == time.Day
        );
    }
}
```

However, it is important to note that pre-market trading can be more volatile and riskier than regular trading, and the intended price may not be achieved on this strategy.

Example 3: Last Hour Trades

Establishing a scheduled trading event in the hour before market close can be an effective strategy. This allows the trader to analyze market conditions, identify potential trade opportunities, and prepare orders ahead of the close. By emitting their trading insights and planned actions to the market in this critical final hour, the trader can influence other market participants and potentially gain an edge.

C#

```
public class MarketHourExampleAlgorithm : QCAlgorithm
{
    private Equity _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _spy = AddEquity("SPY");

        // Set up a portfolio construction model to handle insights for trading
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Expiry.EndOfDay));

        // Set up a scheduled event on 1-hour before market close to open position
        Schedule.On(
            DateRules.EveryDay(_spy.Symbol),
            TimeRules.BeforeMarketClose(_spy.Symbol, 60),
            LastHourTrade
        );
    }

    private void LastHourTrade()
    {
        // Get the time of next market close
        var marketCloseTime = _spy.Exchange.Hours.GetNextMarketClose(Time, extendedMarketHours: false);
        // Emit an insight that expires 1 minutye before the next market close
        EmitInsights(Insight.Price(_spy.Symbol, marketCloseTime.AddMinutes(-1), InsightDirection.Up));
    }
}
```

Securities

Filtering Data

Introduction

Unfiltered raw data can be faulty for a number of reasons, including invalid data entry. Moreover, high-frequency traders can deploy bait-and-switch strategies by submitting bait orders to deceive other market participants, making raw data noisy and untradeable. To avoid messing up with our trading logic and model training, you can filter out suspicious raw data with a data filter.

Set Models

To set a data filter for a security, call the `SetDataFilter` property on the `Security` object.

```
C#

// Use the SetDataFilter method to use the SecurityDataFilter on the SPY ETF data.
var spy = AddEquity("SPY");
spy.SetDataFilter(new SecurityDataFilter());
```

You can also set the data filter model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

```
C#

public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetDataFilter(new SecurityDataFilter());
    }
}
```

Default Behavior

The following table shows the default data filter for each security type:

Security Type	Default Filter
`Equity`	EquityDataFilter
`Option`	OptionDataFilter
`Forex`	ForexDataFilter
`Index`	IndexDataFilter
`Cfd`	CfdDataFilter
Others	SecurityDataFilter

None of the preceding filters filter out any data.

Model Structure

Data filtering models should implement the `ISecurityDataFilter` interface. Extensions of the `ISecurityDataFilter` interface must implement the `Filter` method, which receives `Security` and `BaseData` objects and then returns a `boolean` object that represents if the data point should be filtered out.

```C#
// Include or exclude a data point from the algorithm.
public class MyDataFilter : ISecurityDataFilter
{
    public override bool Filter(Security vehicle, BaseData data)
    {
        return true;
    }
}
```

Examples

The following examples demonstrate some common practices for filtering data.

Example 1: Filter Out Outliers

When analyzing high-frequency price data, it's important to filter out potential outliers and anomalies that may skew the analysis. One effective method is to use simple moving average (SMA) and standard deviation indicators to identify ticks that significantly deviate from the short-term trend. By comparing each tick to the indicator values, you can flag any data points that fall outside a threshold (for example, three standard deviations). This filtration process removes suspicious or erroneous price information from entering your algorithm, ensuring a cleaner dataset for trading.

```
C#
public class CustomDataFilterAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 3);
        dynamic equity = AddEquity("AAPL", Resolution.Tick);
        // Create the indicators.
        equity.Sma = SMA(equity.Symbol, 100);
        equity.Std = IndicatorExtensions.Of(new StandardDeviation(100), equity.Sma, true);
        // Set the data filter.
        equity.SetDataFilter(new CustomDataFilter());
    }
}

class CustomDataFilter : SecurityDataFilter
{
    public CustomDataFilter() : base() { }
    public override bool Filter(Security vehicle, BaseData data)
    {
        // Wait until the indicators are ready.
        var security = vehicle as dynamic;
        if (!(security.Sma.IsReady && security.Std.Window.IsReady))
        {
            return true; // Keep the data point.
        }
        // Check if the current value is within 3 standard deviations of the mean.
        // Return true (keep) or false (discard).
        var sma = security.Sma.Current.Value;
        var std = security.Std.Current.Value;
        return sma - 3m*std <= data.Value && data.Value <= sma + 3m*std;
    }
}
```

Example 2: Filter Out Major Exchanges

When you trade illiquid financial instruments, it can be advantageous to focus on the BATS exchange since its quote data may not fully reflect the fair market value. Due to the lower trading volume and visibility of BATS, the quotes there may lag behind the true value of illiquid assets. A carefully designed algorithm can analyze the BATS feed to identify situations where the quotes appears to be undervalued compared to the asset's intrinsic worth. By executing trades to capture this disconnect, rather than arbitraging between exchanges, you may be able to profit from the market inefficiencies present in the less liquid instrument. The following example demonstrates how to only consume data from the BATS exchange:

```
C#
public class BatsDataFilterAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 3);
        dynamic equity = AddEquity("AAPL", Resolution.Tick);
        // Set the data filter.
        equity.SetDataFilter(new BatsDataFilter());
    }
}

class BatsDataFilter : SecurityDataFilter
{
    public BatsDataFilter() : base() { }
    public override bool Filter(Security vehicle, BaseData data)
    {
        // Get the tick object.
        var tick = data as Tick;
        // Return true (keep) or false (discard).
        return tick != null && tick.Exchange == Exchange.BATS;
    }
}
```

US Equity

Requesting Data

Introduction

Request US Equity data in your algorithm to receive a feed of asset prices in the `OnData` method.

Every stock traded in the US Securities Information Processors (SIP) CTA/UTP feed is available. Over-the-Counter (OTC) trades are not included. For more information about the specific dataset we use for backtests, see the US Equities dataset listing .

To trade US Equities live, you can use the QuantConnect data provider or one of the brokerage data providers .

Create Subscriptions

To create an Equity subscription, in the `Initialize` method, call the `AddEquity` method. The `AddEquity` method returns an `Equity` object, which contains a `Symbol` property. Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
_symbol = AddEquity("SPY").Symbol;
```

The `AddEquity` method creates a subscription for a single Equity asset and adds it to your user-defined universe. To create a dynamic universe of Equities, add an Equity universe or an Equity Universe Selection model .

To view the supported assets in the US Equities dataset, see the Data Explorer . It doesn't include Over-the-Counter (OTC) stocks.

Resolutions

The following table shows the available resolutions and data formats for Equity subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓			
`Daily`	✓			

The default resolution for Equity subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddEquity` method.

```
C#
_symbol = AddEquity("SPY", Resolution.Daily).Symbol;
```

To create custom resolution periods, see Consolidating Data .

Asset Primary Exchange

When a stock like Apple is listed, it's listed on Nasdaq. The open auction tick on Nasdaq is the price that's used as the official open of the day. NYSE, BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

Supported Markets

LEAN groups all of the US Equity exchanges under `Market.USA` . In live mode, the brokerage routes the orders to the exchange that provides the best price.

To set the market for a security, pass a `market` argument to the `AddEquity` method.

```
C#
_symbol = AddEquity("SPY", market: Market.USA).Symbol;
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
C#
AddEquity("SPY", fillForward: false);
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. In backtests, the default leverage for margin accounts is 2x leverage and leverage is not available for cash accounts. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `AddEquity` method.

```
C#
_symbol = AddEquity("SPY", leverage: 3).Symbol;
```

In live trading, the brokerage determines how much leverage you may use. For more information about the leverage they provide, see Brokerages .

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
C#
AddEquity("SPY", extendedMarketHours: true);
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode defines how historical data is adjusted for corporate actions . The data normalization mode affects the data that LEAN passes to `OnData` and the data from history requests . By default, LEAN adjusts US Equity data for splits and dividends to produce a smooth price curve, but the following data normalization modes are available for Equity subscriptions:

If you use `Adjusted` , `SplitAdjusted` , or `TotalReturn` , we use the entire split and dividend history to adjust historical prices. This process ensures you get the same adjusted prices, regardless of the backtest end date.

To set the data normalization mode for a security, pass a `dataNormalizationMode` argument to the `AddEquity` method.

```
C#
_symbol = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
```

The `ScaledRaw` data normalization is only for history requests . When you use `ScaledRaw` , we use the split and dividend history before the algorithm's current time to adjust historical prices. The `ScaledRaw` data normalization model enables you to warm up indicators with adjusted data when you subscribe to `Raw` security data.

Properties

The `AddEquity` method returns an `Equity` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting US Equity data.

Example 1: Add Multiple Assets

The following algorithm adds multiple US Equities with extended market hours data. Extended market hours data enables you to monitor price movements during pre-market and after-hours trading sessions.

```
C#
public class IndexDemoAlgorithm : QCAlgorithm
{
    private List<Equity> _equities = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Create a list of tickers you want to add.
        var tickers = new string[] { "AAPL", "TSLA", "GOOG" };
        // Add extended market hours data for each US Equity.
        _equities = tickers.Select(ticker => AddEquity(ticker, extendedMarketHours: true)).ToList();
    }
}
```

Example 2: Import External Trade Signals

Say you source trading signals from outside your algorithm and organize them into a CSV file on Dropbox with the following structure:

```
#ticker,source1,source2,source3,source4,source5
AAPL,1.25,1.10,1.32,1.13,1.21
AMZN,1.15,1.05,1.07,1.11,1.03
GOOG,0.97,0.99,0.98,1.04,0.95
META,1.04,1.03,1.10,1.04,0.98
MSFT,0.92,0.96,0.98,1.01,0.98
```

The following algorithm uses a Scheduled Event to periodically pull the CSV file from Dropbox , parse its signals, and place trades. To determine the target weight for each asset, it takes the mean score from all the sources. If the mean score is greater than 1, it allocates 20% of the portfolio to the asset. Otherwise, it allocates -20% to the asset.

C#

```
public class USEquityDemoAlgorithm : QCAlgorithm
{
    private readonly Dictionary<string, decimal> _signalByTicker = [];

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        Settings.SeedInitialPrices = true;

        // Add the US Equities.
        foreach (var ticker in "AAPL,AMZN,GOOG,META,MSFT".Split(","))
        {
            AddEquity(ticker, Resolution.Daily);
            _signalByTicker.Add(ticker, 1);
        }
        // Set up a Scheduled Event to download the data file and place orders.
        Schedule.On(DateRules.MonthStart(), TimeRules.Midnight, DownloadDataAndPlaceOrders);
    }

    private void DownloadDataAndPlaceOrders()
    {
        // Download the file from DropBox.
        var fileContent = Download("<DropBoxUrl>&dl=1");

        // Convert the file content into trading signals.
        foreach (var line in fileContent.Split(['\n', '\r'], StringSplitOptions.RemoveEmptyEntries).Skip(1))
        {
            var values = line.Split(',');
            _signalByTicker[values[0]] = values.Skip(1).Select(decimal.Parse).ToArray().Average();
        }

        // Place orders according to the signals.
        var targets = _signalByTicker.Select(kvp => new PortfolioTarget(kvp.Key, kvp.Value >= 1m ? 0.2m : -0.2m));
        SetHoldings([.. targets], true);
    }
}
```

US Equity

Handling Data

Introduction

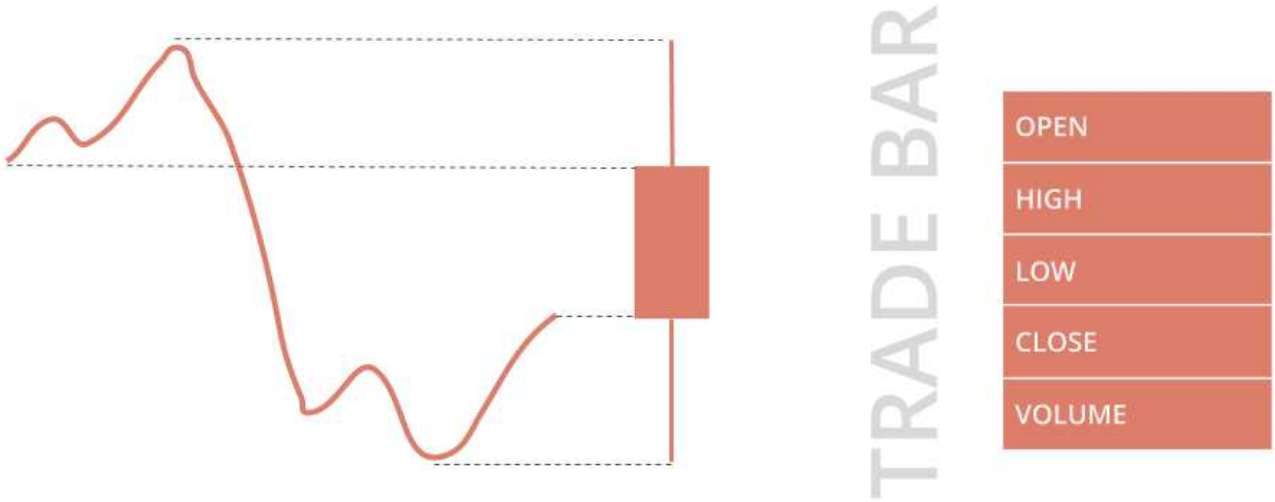
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `TradeBar` argument, it only receives `TradeBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for US Equity data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the security `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in TradeBars object
    if (slice.Bars.ContainsKey(_symbol))
    {
        // Obtain the mapped TradeBar of the symbol
        var tradeBar = slice.Bars[_symbol];
    }
}
```

You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

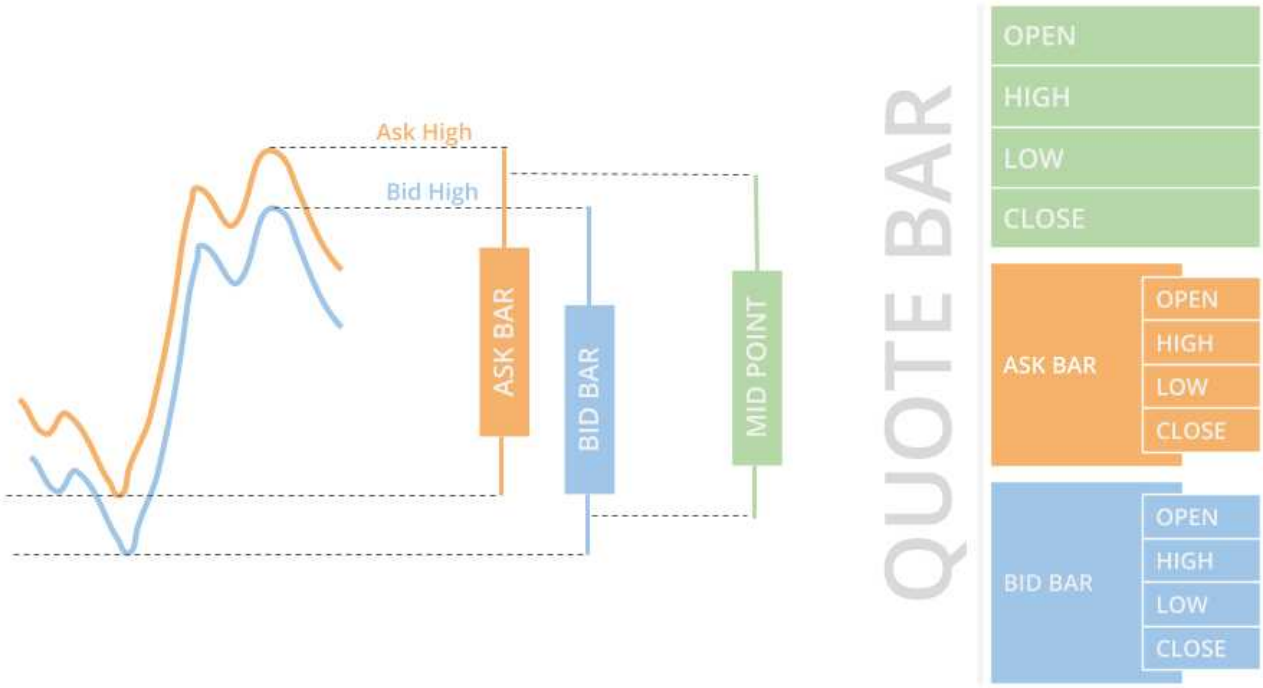
```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-TradeBar key-value pairs
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        var closePrice = tradeBar.Close;
    }
}
```

`TradeBar` objects have the following properties:

We adjust the daily open and close price of bars to reflect the official auction prices .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the QuoteBar objects in the Slice , index the QuoteBars property of the Slice with the security Symbol . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the Slice may not contain data for your Symbol . To avoid issues, check if the Slice contains data for your security before you index the Slice with the security Symbol .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_symbol];
    }
}
```

You can also iterate through the QuoteBars dictionary. The keys of the dictionary are the Symbol objects and the values are the QuoteBar objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

QuoteBar objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

QuoteBar objects have the following properties:

Ticks

Tick objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price.

Trade ticks have a non-zero value for the Quantity and Price properties, but they have a zero value for the BidPrice , BidSize , AskPrice , and AskSize properties. Quote ticks have non-zero values for BidPrice and BidSize properties or have non-zero values for AskPrice and AskSize properties. To check if a tick is a trade or a quote, use the TickType property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the Tick objects in the Slice , index the Ticks property of the Slice with a Symbol . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the Slice may not contain data for your Symbol . To avoid issues, check if the Slice contains data for your security before you index the Slice with the security Symbol .

```C#
public override void OnData(Slice slice)
{
    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `List<Tick>` objects.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

If we detect a tick that may be suspicious , we set its `Suspicious` flag to true.

Other Data Formats

For more information about data formats available for US Equities, see Corporate Actions .

Examples

The following examples demonstrate some common practices for handling US Equity data.

Example 1: Various Data Resolutions and Formats

The following algorithm handles three data resolutions (Daily, Minute, and Tick) and three data formats (TradeBar, QuoteBar, and Tick). The Equity subscriptions provide the ticks and daily TradeBar objects. To create the 5-minute QuoteBar objects, it consolidates the AAPL ticks.

The algorithm enters a long position in AAPL when the following conditions are met:

- The 16-day Fractal Adaptive Moving Average (FRAMA) of QQQ is increasing, which indicates the trend is up.
- The Relative Strength Index (RSI) of AAPL is above 70, which indicates AAPL has been rising from large buying pressure.

The algorithm enters a short position in AAPL when the following conditions are met:

- The 16-day FRAMA of QQQ is rising, which indicates the trend is down.
- The RSI of AAPL is above, which indicates AAPL has been declining from large selling pressure.

The algorithm liquidates the portfolio when the FRAMA changes direction.

C#

```
public class USEquityExampleAlgorithm : QCAlgorithm
{
    private dynamic _qqq, _aapl;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 4);
        SetEndDate(2024, 9, 10);

        // Add QQQ and AAPL data.
        _qqq = AddEquity("QQQ", Resolution.Daily);
        _aapl = AddEquity("AAPL", Resolution.Tick);

        // Create the indicators.
        _qqq.Frama = FRAMA(_qqq.Symbol, 16);
        _aapl.Rsi = new RelativeStrengthIndex(10);

        // Create a 5-minute consolidator to aggregate AAPL tick data into quote bars.
        var consolidator = new TickQuoteBarConsolidator(TimeSpan.FromMinutes(5));
        // Subscribe the consolidator for automatic updates.
        SubscriptionManager.AddConsolidator(_aapl.Symbol, consolidator);
        // Attach an event handler to update the RSI indicator with the consolidated bars.
        consolidator.DataConsolidated += (sender, bar) => _aapl.Rsi.Update(bar.EndTime, bar.Close);

        // Warm up the indicators.
        WarmUpIndicator(_qqq.Symbol, _qqq.Frama);
        var history = History<QuoteBar>(_aapl.Symbol, 10, Resolution.Minute);
        foreach (var bar in history)
        {
            _aapl.Rsi.Update(bar.EndTime, bar.Close);
        }
    }

    public override void OnData(Slice slice)
    {
        // Ensure AAPL ticks are in the current slice.
        if (!slice.Ticks.ContainsKey(_aapl.Symbol))
        {
            return;
        }

        // Get the indicator values.
        var frama = _qqq.Frama.Current.Value;
        var prevFrama = _qqq.Frama.Previous.Value;
        var rsi = _aapl.Rsi.Current.Value;

        // Check if we have an AAPL position.
        if (_aapl.Holdings.Invested)
        {
            // If there is divergence between our position and the Frama direction, exit the position.
            if ((_aapl.Holdings.IsLong && frama < prevFrama) || (_aapl.Holdings.IsShort && frama > prevFrama))
            {
                Liquidate(_aapl.Symbol);
            }
        }
        // Look for a long entry.
        else if (frama > prevFrama && rsi >= 70)
        {
            SetHoldings(_aapl.Symbol, 0.5);
        }
        // Look for a short entry.
        else if (frama < prevFrama && rsi <= 30)
        {
            SetHoldings(_aapl.Symbol, -0.5);
        }
    }
}
```

US Equity

Corporate Actions

Introduction

US Equity subscriptions provide notifications for splits, dividends, symbol changes, and delistings.

Splits

When a company does a stock split, the number of shares each shareholder owns increases and the price of each share decreases. When a company does a reverse stock split, the number of shares each shareholder owns decreases and the price of each share increases. A company may perform a stock split or a reverse stock split to adjust the price of their stock so that more investors trade it and the liquidity increases.

When a stock split or reverse stock split occurs for an Equity in your algorithm, LEAN sends a `Split` object to the `OnData` method. You receive `Split` objects when a split is in the near future and when it occurs. To know if the split occurs in the near future or now, check the `Type` property.

If you backtest without the `Raw` data normalization mode , the splits are factored into the price and volume. If you backtest with the `Raw` data normalization mode or trade live, when a split occurs, LEAN automatically adjusts your positions based on the `SplitFactor` . If the post-split quantity isn't a valid lot size , LEAN credits the remaining value to your cashbook in your account currency. If you have indicators or consolidators in your algorithm, reset and warm-up them up with `ScaledRaw` data when splits occur so that the data in your indicators and consolidators account for the price adjustments that the splits cause. For examples, see Reset Indicators or Reset Consolidators .

To get the `Split` objects, index the `Splits` object with the security `Symbol` . The `Splits` object may not contain data for your `Symbol` . To avoid issues, check if the `Splits` object contains data for your security before you index it with the security `Symbol` .

```C#
public override void OnData(Slice slice)
{
    if (slice.Splits.ContainsKey(_symbol))
    {
        var split = slice.Splits[_symbol];
    }
}

public override void OnSplits(Splits splits)
{
    if (splits.ContainsKey(_symbol))
    {
        var split = splits[_symbol];
    }
}
```

You can also iterate through the `Splits` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Split` objects.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Splits)
    {
        var symbol = kvp.Key;
        var split = kvp.Value;
    }
}

public override void OnSplits(Splits splits)
{
    foreach (var kvp in splits)
    {
        var symbol = kvp.Key;
        var split = kvp.Value;
    }
}
```

To get historical splits, make a history request with the `Split` type.

```C#
var splits = History<Split>(symbol, TimeSpan.FromDays(4*365));
```

LEAN stores the data for stock splits in factor files. To view some example factor files, see the LEAN GitHub repository . In backtests, your algorithm receives `Split` objects at midnight. In live trading, your algorithm receives `Split` objects when the factor files are ready.

If you hold an Option contract for an underlying Equity when a split occurs, LEAN closes your Option contract position.

If a split event occurs before your order is filled, the unfilled portion of the order is adjusted automatically, where its quantity is multiplied by the split factor and the limit/stop/trigger price (if any) is divided by the split factor.

`Split` objects have the following properties:

Dividends

A dividend is a payment that a company gives to shareholders to distribute profits. When a dividend payment occurs for an Equity in your algorithm, LEAN sends a `Dividend` object to the `OnData` method.

If you backtest with the `Adjusted` or `TotalReturn` data normalization mode, the dividends are factored into the price. If you backtest with the other data normalization modes or trade live, when a dividend payment occurs, LEAN automatically adds the payment amount to your cashbook. If you have indicators or consolidators in your algorithm, reset and warm-up them up with `ScaledRaw` data when dividend payments occur so that the data in your indicators and consolidators account for the price adjustments that the dividend causes. For examples, see Reset Indicators or Reset Consolidators .

To get the `Dividend` objects, index the `Dividends` object with the security `Symbol` . The `Dividends` object may not contain data for your `Symbol` . To avoid issues, check if the `Dividends` object contains data for your security before you index it with the security `Symbol` .

```C#
public override void OnData(Slice slice)
{
    if (slice.Dividends.ContainsKey(_symbol))
    {
        var dividend = slice.Dividends[_symbol];
    }
}

public override void OnDividends(Dividends dividends)
{
    if (dividends.ContainsKey(_symbol))
    {
        var dividend = dividends[_symbol];
    }
}
```

You can also iterate through the `Dividends` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Dividend` objects.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Dividends)
    {
        var symbol = kvp.Key;
        var dividend = kvp.Value;
    }
}

public override void OnDividends(Dividends dividends)
{
    foreach (var kvp in dividends)
    {
        var symbol = kvp.Key;
        var dividend = kvp.Value;
    }
}
```

To get historical dividends, make a history request with the `Dividend` type.

```C#
var dividends = History<Dividend>(symbol, TimeSpan.FromDays(4*365));
```

For a full example, see the DividendAlgorithm in the LEAN GitHub repository.

`Dividend` objects have the following properties:

Symbol Changes

The benefit of the `Symbol` class is that it always maps to the same security, regardless of their trading ticker. When a company changes its trading ticker, LEAN sends a `SymbolChangedEvent` to the `OnData` method.

To get the `SymbolChangedEvent` objects, index the `SymbolChangedEvents` object with the security `Symbol` . The `SymbolChangedEvents` object may not contain data for your `Symbol` . To avoid issues, check if the `SymbolChangedEvents` object contains data for your security before you index it with the security `Symbol` .

```C#
public override void OnData(Slice slice)
{
    if (slice.SymbolChangedEvents.ContainsKey(_symbol))
    {
        var symbolChangedEvent = slice.SymbolChangedEvents[_symbol];
    }
}

public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
{
    if (symbolChangedEvents.ContainsKey(_symbol))
    {
        var symbolChangedEvent = symbolChangedEvents[_symbol];
    }
}
```

You can also iterate through the `SymbolChangedEvents` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `SymbolChangedEvent` objects.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.SymbolChangedEvents)
    {
        var symbol = kvp.Key;
        var symbolChangedEvent = kvp.Value;
    }
}

public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
{
    foreach (var kvp in symbolChangedEvents)
    {
        var symbol = kvp.Key;
        var symbolChangedEvent = kvp.Value;
    }
}
```

If you have an open order for a security when they change their ticker, LEAN cancels your order. To keep your order, in the `OnOrderEvent` method, get the quantity and `Symbol` of the cancelled order and submit a new order.

```C#
public override void OnOrderEvent(OrderEvent orderEvent)
{
    if (orderEvent.Status == OrderStatus.Canceled)
    {
        var ticket = Transactions.GetOrderTicket(orderEvent.OrderId);
        if (ticket.Tag.Contains("symbol changed event"))
        {
            Transactions.AddOrder(ticket.SubmitRequest);
        }
    }
}
```

LEAN stores the data for ticker changes in map files. To view some example map files, see the LEAN GitHub repository .

`SymbolChangedEvent` objects have the following properties:

Delistings

When a company is delisting from an exchange, LEAN sends a `Delisting` object to the `OnData` method. You receive `Delisting` objects when a delisting is in the near future and when it occurs. To know if the delisting occurs in the near future or now, check the `Type` property.

To get the `Delisting` objects, index the `Delistings` object with the security `Symbol` . The `Delistings` objects may not contain data for your `Symbol` . To avoid issues, check if the `Delistings` object contains data for your security before you index it with the security `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    if (slice.Delistings.ContainsKey(_symbol))
    {
        var delisting = slice.Delistings[_symbol];
    }
}

public override void OnDelistings(Delistings delistings)
{
    if (delistings.ContainsKey(_symbol))
    {
        var delisting = delistings[_symbol];
    }
}
```

You can also iterate through the `Delistings` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `Delisting` objects.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Delistings)
    {
        var symbol = kvp.Key;
        var delisting = kvp.Value;
    }
}

public override void OnDelistings(Delistings delistings)
{
    foreach (var kvp in delistings)
    {
        var symbol = kvp.Key;
        var delisting = kvp.Value;
    }
}
```

The delist warning occurs on the final trading day of the stock to give you time to gracefully exit out of positions before LEAN automatically liquidates them.

```
C#
if (delisting.Type == DelistingType.Warning)
{
    // Liquidate with MarketOnOpenOrder on delisting warning
    var quantity = Portfolio[symbol].Quantity;
    if (quantity != 0)
    {
        MarketOnOpenOrder(symbol, -quantity);
    }
}
```

The `OnSecuritiesChanged` event notifies the algorithm when delisted assets are removed from the universe.

To improve iteration speed, LEAN removes delisted securities from the `Securities` primary collection. To access all the securities, iterate the `Securities.Total` property.

```
// Access all the securities.
foreach (var security in Securities.Total)
{

}

// Exclude delisted securities.
foreach (var security in Securities.Values)
{

}
```

For a full example, see the DelistingEventsAlgorithm in the LEAN GitHub repository.

`Delisting` objects have the following properties:

Live Trading Considerations

In backtesting, corporate actions occurs at midnight Eastern Time (ET). In live trading, the live data for corporate actions arrives at 6/7 AM ET, so that's when they occur.

Examples

The following examples demonstrate some common practices for US Equity corporate actions.

Example 1: Resetting Indicators on Split Events

The following algorithm adds raw TSLA data and uses it to update an Exponential Moving Average (EMA) indicator. When a split occurs, it resets and warms up the indicator with scaled raw data to ensure the indicator doesn't reflect price discontinuities.

```
public class USEquityCorporateActionExampleAlgorithm : QCAlgorithm
{
    private dynamic _equity;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add raw US Equity data.
        _equity = AddEquity("TSLA", Resolution.Daily, dataNormalizationMode: DataNormalizationMode.Raw);
        // Create an EMA indicator.
        _equity.Ema = EMA(_equity.Symbol, 50);
    }

    public override void OnSplits(Splits splits)
    {
        // Wait until the split has occurred.
        var split = splits[_equity.Symbol];
        if (split.Type != SplitType.SplitOccurred)
        {
            return;
        }
        // Reset the indicator.
        _equity.Ema.Reset();
        // Warm up the indicator with scaled raw data.
        var history = History<TradeBar>(
            _equity.Symbol, _equity.Ema.WarmUpPeriod, dataNormalizationMode: DataNormalizationMode.ScaledRaw
        );
        foreach (var bar in history)
        {
            _equity.Ema.Update(bar.EndTime, bar.Close);
        }
    }
}
```

Example 2: Reinvesting Dividend Payments

The following algorithm adds raw SPY data. It then holds the SPY and re-invests the dividend payments into additional shares.

C#

```
public class USEquityCorporateActionExampleAlgorithm : QCAlgorithm
{
    private Equity _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add raw Equity data.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw);
    }

    public override void OnData(Slice slice)
    {
        // Buy and hold.
        if (!_spy.Holdings.Invested)
        {
            SetHoldings(_spy.Symbol, 0.5);
        }
    }

    public override void OnDividends(Dividends dividends)
    {
        // Get the total dividend payment amount.
        var totalDividendAmount = dividends[_spy.Symbol].Distribution * _spy.Holdings.Quantity;

        // Calculate the number of shares you can buy with the dividend payment.
        var quantity = Math.Floor(totalDividendAmount / _spy.Price);
        if (quantity > 0)
        {
            // Place an order to re-invest the dividends.
            MarketOrder(_spy.Symbol, quantity);
        }
    }
}
```

US Equity

Corporate Fundamentals

Introduction

Corporate fundamental data contains all the information on the underlying company of an Equity asset and the information in their financial statements. Since corporate data contains information not found in price and alternative data, adding corporate data to your trading strategies provides you with more information so you can make more informed trading decisions. Corporate fundamental data is available through the US Fundamental Data from Morningstar .

Direct Access

To get fundamental data for Equities in your algorithm, use the `Fundamentals` property of the `Equity` objects. The fundamental data represent the company's fundamentals for the current algorithm time.

```
C#
var fundamentals = Securities[_symbol].Fundamentals;
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `Fundamentals` method. If you pass one `Symbol` , the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects. The fundamental data represents the corporate fundamentals for the current algorithm time.

```
C#
// Single asset
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);
var ibmFundamental = Fundamentals(ibm);

// Multiple assets
var nb = QuantConnect.Symbol.Create("NB", SecurityType.Equity, Market.USA);
var fundamentals = Fundamentals(new List<Symbol>{ nb, ibm }).ToList();
```

Data Availability

Some assets don't have fundamentals (for example, ETFs) and the Morningstar dataset doesn't provide fundamentals for all US Equities. To check if fundamental data is available for an asset, use the `HasFundamentalData` property.

```
C#
var hasFundamentalData = Securities[_symbol].Fundamentals.HasFundamentalData;
```

Object References

If you save a reference to the `Fundamentals` object or its properties, you can access the fundamental properties as they change over time.

```
C#
_fundamentals = Securities[_symbol].Fundamentals;
var earningRatios = _fundamentals.EarningRatios;
```

Universe Selection

You can access fundamental data in the selection function of your fundamental universe .

```
C#
public class MyUniverseAlgorithm : QCAlgorithm {
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        AddUniverse(FundamentalFilterFunction);
    }

    private IEnumerable<Symbol> FundamentalFilterFunction(IEnumerable<Fundamental> fundamental)
    {
         return (from f in fundamental
                where f.HasFundamentalData
                select f.Symbol);
    }
}
```

Historical Data

To get historical fundamental data, call the `History` method. The return type depends on how you call the method.

```
C#
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);

// Fundamental objects
var fundamentalHistory = History<Fundamental>(ibm, TimeSpan.FromDays(30));

// Fundamentals objects for all US Equities (including delisted companies)
var fundamentalsHistory = History<Fundamentals>(TimeSpan.FromDays(30));

// Collection of Fundamental objects for all US Equities (including delisted companies)
var collectionHistory = History(_universe, 30, Resolution.Daily);
foreach (var fundamental in collectionHistory)
{
    // Cast to Fundamental is required
    var highestMarketCap = fundamental.OfType<Fundamental>().OrderByDescending(x => x.MarketCap).Take(5);
}
```

For more information about historical fundamental data, see Equity Fundamental Data .

Data Updates

The US Fundamental dataset only provides the originally-reported figures. If there was a mistake in reporting a figure, the data value isn't fixed later. In live trading, new fundamental data is available to your algorithms at approximately 6/7 AM Eastern Time (ET) each day. The majority of the corporate data update occurs once per month, but the financial ratios update daily. If there is no new data for a period of time, the previous data is filled forward.

Properties

The US Fundamentals dataset provides Fundamental objects. To filter Fundamental objects, you can use the `MorningstarSectorCode` , `MorningstarIndustryGroupCode` , and `MorningstarIndustryCode` enumeration values.

Fundamentals Attributes

Fundamentals objects have the following attributes:

MorningstarSectorCode Enumeration

Sectors are large super categories of data. To access the sector of an Equity, use the **MorningstarSectorCode** property.

```C#
filtered = fundamental.Where(x => x.AssetClassification.MorningstarSectorCode == MorningstarSectorCode.Technology);
```

The **MorningstarSectorCode** enumeration has the following members:

MorningstarIndustryGroupCode Enumeration

Industry groups are clusters of related industries which tie together. To access the industry group of an Equity, use the **MorningstarIndustryGroupCode** property.

```C#
filtered = fundamental.Where(x => x.AssetClassification.MorningstarIndustryGroupCode ==
MorningstarIndustryGroupCode.ApplicationSoftware);
```

The **MorningstarIndustryGroupCode** enumeration has the following members:

MorningstarIndustryCode Enumeration

Industries are the finest level of classification available and are the individual industries according to the Morningstar classification system. To access the industry group of an Equity, use the **MorningstarIndustryCode** property:

```C#
filtered = fundamental.Where(x => x.AssetClassification.MorningstarIndustryCode ==
MorningstarIndustryCode.SoftwareApplication);
```

The **MorningstarIndustryCode** enumeration has the following members:

Exchange Id Values

Exchange Id is mapped to represent the exchange that lists the Equity. To access the exchange Id of an Equity, use the **PrimaryExchangeID** property.

```C#
filtered = fundamental.Where(x => x.CompanyReference.PrimaryExchangeID == "NAS");
```

The exchanges are represented by the following string values:

String Representation	**Exchange**
NYS	New York Stock Exchange (NYSE)
NAS	NASDAQ
ASE	American Stock Exchange (AMEX)
TSE	Tokyo Stock Exchange
AMS	Amsterdam Internet Exchange
SGO	Santiago Stock Exchange
XMAD	Madrid Stock Exchange

ASX	Australian Securities Exchange
BVMF	B3 (stock exchange)
LON	London Stock Exchange
TKS	Istanbul Stock Exchange Settlement and Custody Bank
SHG	Shanghai Exchange
LIM	Lima Stock Exchange
FRA	Frankfurt Stock Exchange
JSE	Johannesburg Stock Exchange
MIL	Milan Stock Exchange
TAE	Tel Aviv Stock Exchange
STO	Stockholm Stock Exchange
ETR	Deutsche Boerse Xetra Core
PAR	Paris Stock Exchange
BUE	Buenos Aires Stock Exchange
KRX	Korea Exchange
SWX	SIX Swiss Exchange
PINX	Pink Sheets (OTC)
CSE	Canadian Securities Exchange
PHS	Philippine Stock Exchange
MEX	Mexican Stock Exchange
TAI	Taiwan Stock Exchange
IDX	Indonesia Stock Exchange
OSL	Oslo Stock Exchange
BOG	Colombia Stock Exchange
NSE	National Stock Exchange of India
HEL	Nasdaq Helsinki
MISX	Moscow Exchange
HKG	Hong Kong Stock Exchange

IST	Istanbul Stock Exchange
BOM	Bombay Stock Exchange
TSX	Toronto Stock Exchange
BRU	Brussels Stock Exchange
BATS	BATS Global Markets
ARCX	NYSE Arca
GREY	Grey Market (OTC)
DUS	Dusseldorf Stock Exchange
BER	Berlin Stock Exchange
ROCO	Taipei Exchange
CNQ	Canadian Trading and Quotation System Inc.
BSP	Bangko Sentral ng Pilipinas
NEOE	NEO Exchange

Examples

The following examples demonstrate some common practices for US Equity corporate fundamentals.

Example 1: Capturing the Overreaction to Financial Reports

The following algorithm is based on the hypothesis that investors overreact to new financial report releases. It buys TSLA stock on every new 10Q or 8K filing and then liquidates the position after seven days.

```C#
public class USEquityCorporateFundamentalsExampleAlgorithm : QCAlgorithm
{
    private Equity _equity;
    // Add a member to track the last financial statement filing date.
    private DateTime? _lastFilingDate = null;
    private DateTime _exitTime;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        // Add Equity data.
        _equity = AddEquity("TSLA");
    }

    public override void OnData(Slice slice)
    {
        // Get the most recent filing date.
        var lastFilingDate = _equity.Fundamentals.FinancialStatements.FileDate.Value;

        // When new financial statements are released, buy TSLA.
        if (_lastFilingDate.HasValue && lastFilingDate != _lastFilingDate.Value)
        {
            SetHoldings(_equity.Symbol, 1);
            _exitTime = Time.AddDays(7);
        }

        // Liquidate the position after 1 week.
        if (_equity.Holdings.Invested && Time >= _exitTime)
        {
            Liquidate();
        }

        // Update the last filing date to identify future changes.
        _lastFilingDate = lastFilingDate;
    }
}
```

Example 2: Diversifying Across Sectors

The follow algorithm aims to reduce concentration risk in any one sector. It selects the 500 largest Equities at the start of each month and then forms a portfolio that gives equal weight to each sector and equal weight to the assets within each sector.

C#

```
public class USEquityCorporateFundamentalsExampleAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        SetCash(10_000_000);
        // Define the universe settings.
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart("SPY"));
        // Add a universe of the 500 largest Equities.
        _universe = AddUniverse(coarse => coarse
            .OrderByDescending(x => x.MarketCap)
            .Take(500)
            .Select(x => x.Symbol)
        );
        // Create a Scheduled Event to rebalance the portfolio each month.
        Schedule.On(DateRules.MonthStart("SPY", 1), TimeRules.Midnight, Rebalance);
    }

    private void Rebalance()
    {
        // Wait until there are assets in the universe.
        if (_universe.Selected == null)
        {
            return;
        }
        // Group the universe constituents by sector.
        var symbolsBySector = new Dictionary<int, List<Symbol>>();
        foreach (var symbol in _universe.Selected)
        {
            var equity = Securities[symbol];
            if (equity.Price == 0)
            {
                continue;
            }
            var sectorCode = equity.Fundamentals.AssetClassification.MorningstarSectorCode;
            if (!symbolsBySector.ContainsKey(sectorCode))
            {
                symbolsBySector[sectorCode] = new List<Symbol>();
            }
            symbolsBySector[sectorCode].Add(symbol);
        }

        // Create targets to invest equally in each sector and invest equally in the assets within each sector.
        var targets = new List<PortfolioTarget>();
        var sectorCount = symbolsBySector.Count;
        foreach (var symbols in symbolsBySector.Values)
        {
            var weight = 1m / sectorCount / symbols.Count;
            targets.AddRange(symbols.Select(symbol => new PortfolioTarget(symbol, weight)));
        }

        // Place the trades.
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}
```

US Equity

Shorting

Introduction

In a regular long position, you buy shares and then sell them later to close the trade. In a short position, you borrow shares, sell them, and then buy the shares back later to close the trade. Short positions let you profit when a security's price decreases while you have the position open, but there are risks involved. For example, you can get a margin call and you may incur borrowing costs.

Holdings Accounting

If you have an open long position, your portfolio has a positive quantity of shares for that security. In contrast, if you have an open short position, your portfolio has a negative quantity of shares for that security.

Short Availability

To short sell, you need to borrow the shares from another investor or your brokerage. The short availability is the number of shares available for you to borrow. If you don't model the short availability in backtests, you could have a strategy that performs well in backtesting but doesn't trade in live mode because the shares aren't available to borrow. If you assume your short orders are successful in backtests, your backtesting results likely won't represent the true performance of actually trading the strategy during the backtest period. To get the short availability in your algorithms, use the US Equities Short Availability dataset . For more information about this topic, see Short Availability .

Borrowing Costs

In live trading, your brokerage charges an interest fee when you borrow shares to short a security. In backtesting, use the ShortMarginInterestRateModel .

To get valid borrowing rates, use the InteractiveBrokersShortableProvider .

C#

```
public override void Initialize()
{
    var security = AddEquity("SPY");
    // For US Equity, use the ShortMarginInterestRateModel with IB data
    security.SetShortableProvider(new InteractiveBrokersShortableProvider());
    security.MarginInterestRateModel = new ShortMarginInterestRateModel();
}
```

Examples

The following examples demonstrate some common practices for shorting US Equities:

Example 1: Shorting Penny Stock Top Gainers

The following algorithm adds a universe of penny stocks that have experienced the greatest upward momentum over the last two trading days. For each asset in the universe, it monitors an hourly Bollinger Bands indicator. When an asset breaks above the upper band, it shorts the asset. It exits each position when the asset drops 10% from the entry price or when the price reverts back below the middle Bollinger Band.

C#

```
using QuantConnect.Data.Shortable;
public class USEquityShortingExampleAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, RateOfChange> _rocBySymbol = [];

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Enable automatic indicator warm-up.
        Settings.AutomaticIndicatorWarmUp = true;
        // Add a universe of low-cap penny stocks that have high upward momentum.
        AddUniverse(SelectAssets);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> fundamentals)
    {
        // Select all the penny stocks that have a momentum score.
        var pennyStocks = new List<Symbol>();
        foreach (var f in fundamentals)
        {
            // Create a RateOfChange indicator for each asset.
            if (!_rocBySymbol.TryGetValue(f.Symbol, out var roc))
            {
                _rocBySymbol[f.Symbol] = roc = new RateOfChange(1);
            }
            // Update the indicator and ensure it's ready.
            // Filter out assets above $5M market cap or $1 share price.
            if (!roc.Update(f.EndTime, f.Price) || f.MarketCap > 5e6 || f.Price > 1)
            {
                continue;
            }
            pennyStocks.Add(f.Symbol);
        }

        // Select the 20 penny stocks with the greatest momentum.
        return pennyStocks.OrderByDescending(symbol => _rocBySymbol[symbol].Current.Value).Take(20);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Iterate through the assets that entered the universe.
        foreach (var security in changes.AddedSecurities)
        {
            // Set the shortable provider of the asset to ensure realistic short availability.
            security.SetShortableProvider(new InteractiveBrokersShortableProvider());
            // Create a BollingerBand indicator for this asset.
            var bb = BB(security.Symbol, 20, 2, resolution: Resolution.Hour);
            // Attach an event handler to the indicator to track its updates.
            bb.Updated += OnBBUpdated;
            (security as dynamic).Bbands = bb;
        }

        // Liquidate and remove the indicator updates for assets that leave the universe.
        foreach (var security in changes.RemovedSecurities)
        {
            DeregisterIndicator((security as dynamic).Bbands);
            Liquidate(security.Symbol);
        }
    }

    private void OnBBUpdated(object indicator, IndicatorDataPoint _security_by_bb)
    {
        var bb = indicator as BollingerBands;
        // When the indicator updates, ensure it's ready.
        if (!bb.IsReady)
        {
            return;
        }
        var security = Securities[bb.Current.Symbol];
        // Short the asset if the price is above the upper band.
        if (!security.Invested && security.Price > bb.UpperBand.Current.Value)
        {
            // Get the number of shares avaiable for shorting.
            var shortableQuantity = security.ShortableProvider.ShortableQuantity(security.Symbol, Time) ?? 0m;
            // Calculate the target quantity.
            var quantity = Math.Max(CalculateOrderQuantity(security.Symbol, -0.1m), -shortableQuantity);
            if (quantity == 0) return;

            // Short the asset.
            MarketOrder(security.Symbol, quantity);
```

```
            // Place a take-profit order 10% below the current price.
            LimitOrder(security.Symbol, -quantity, 0.9m * security.BidPrice);
        }
        // If the limit order isn't hit before the price drops below the middle band,
        // exit the position and cancel the limit order.
        else if (security.Invested && security.Price < bb.MiddleBand.Current.Value)
        {
            Liquidate(security.Symbol);
        }
    }
}
```

US Equity

Data Preparation

Introduction

The US Equities dataset provides price data for backtests and live trading.

Sourcing

The QuantConnect data provider consolidates US Equity market data across all of the exchanges. Over-the-Counter (OTC) trades are excluded. The data is powered by the Securities Information Processor (SIP), so it has 100% market coverage. In contrast, free platforms that display data feeds like the Better Alternative Trading System (BATS) only have about 6-7% market coverage .

We provide live splits, dividends, and corporate actions for US companies. We deliver them to your algorithm before the trading day starts.

Bar Building

We aggregate ticks to build bars.

The bar-building process can exclude ticks. If a tick is excluded, its volume is aggregated in the bar but its price is not aggregated in the bar. Ticks are excluded if any of the following statements are true:

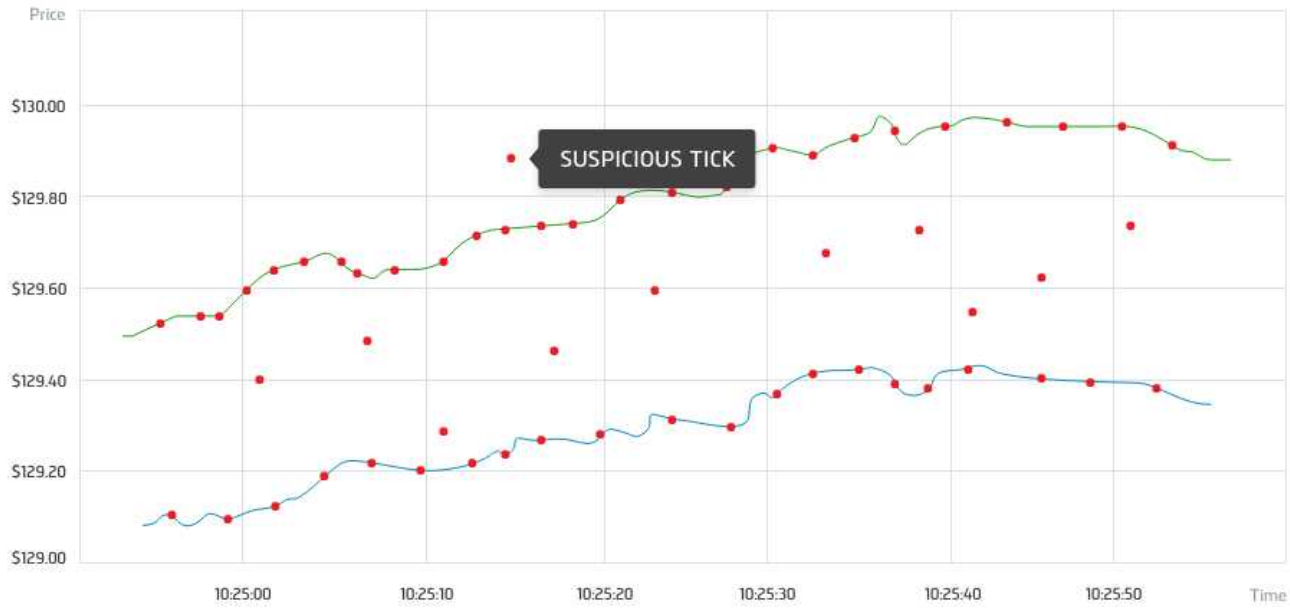
- The tick is suspicious.
- The tick is from the FINRA exchange and meets our price and volume thresholds.
- The trade has none of the following included `TradeConditionFlags` and at least one of the following excluded `TradeConditionFlags` :
  echo file_get_contents(DOCS_RESOURCES."/data-feeds/trade-condition-flags-table.html"); ?>
- The quote has a size of less than 100 shares.
- The quote has none of the following included `QuoteConditionFlags` and at least one of the following excluded `QuoteConditionFlags` :
- The quote has one of the following `QuoteConditionFlags` :
  echo file_get_contents(DOCS_RESOURCES."/data-feeds/quote-condition-flags-table.html"); ?>

In the preceding tables, Participant refers to the entities on page 19 of the Consolidated Tape System Multicast Output Binary Specification .

Suspicious Ticks

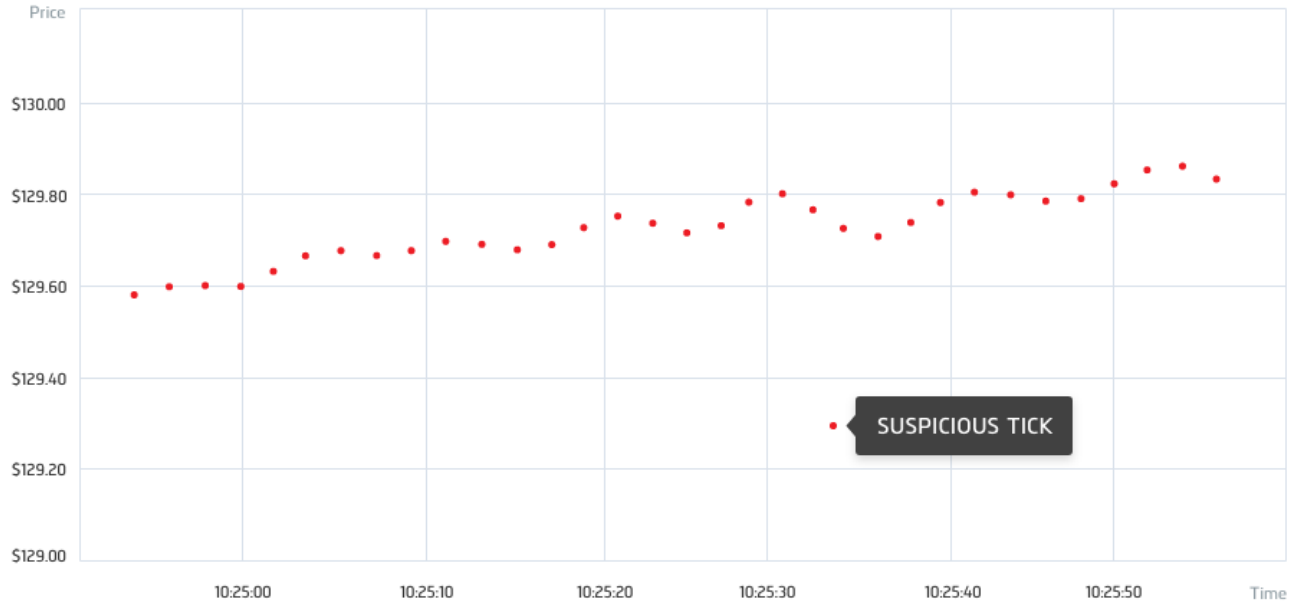
Tick price data is raw and unfiltered, so it can contain a lot of noise. If a tick is not tradable, we flag it as suspicious. This process makes the bars a more realistic representation of what you could execute in live trading. If you use tick data, avoid using suspicious ticks in your algorithms as informative data points. We recommend only using tick data if you understand the risks and are able to perform your own tick filtering. Ticks are flagged as suspicious in the following situations:

- The tick occurs below the best bid or above the best ask



This image shows a tick that occurred above the best ask price of a security. The green line represents the best ask of the security, the blue line represents the best bid of the security, and the red dots represent trade ticks. The ticks between the best bid and ask occur from filling hidden orders. The tick that occurred above the best ask price is flagged as suspicious.

- The tick occurs far from the current market price



This image shows a tick that occurred far from the price of the security. The red dots represent trade ticks. The tick that occurred far from the market price is flagged as suspicious.

- The tick occurs on a dark pool
- The tick is rolled back
- The tick is reported late

Market Auction Prices

The opening and closing price of the day is set by very specific opening and closing auction ticks. When a stock like Apple is listed, it's listed on Nasdaq. The open auction tick on Nasdaq is the price that's used as the official open of the day. NYSE,

BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

We set the opening and closing prices of the first and last bars of the day to the official auction prices. This process is used for second, minute, hour, and daily bars for the 9:30 AM and 4:00 PM Eastern Time (ET) prices. In contrast, other platforms might not be using the correct opening and closing prices.

The official auction prices are usually emitted 2-30 seconds after the market open and close. We do our best to use the official opening and closing prices in the bars we build, but the delay can be so large that there isn't enough time to update the opening and closing price of the bar before it's injected into your algorithms. For example, if you subscribe to second resolution data, we wait until the end of the second for the opening price but most second resolution data won't get the official opening price. If you subscribe to minute resolution data, we wait until the end of the minute for the opening auction price. Most of the time, you'll get the actual opening auction price with minute resolution data, but there are always exceptions. Nasdaq and NYSE can have delays in publishing the opening auction price, but we don't have control over those issues and we have to emit the data on time so that you get the bar you are expecting.

Live and Backtesting Differences

In live trading, bars are built using the exchange timestamps with microsecond accuracy. This microsecond-by-microsecond processing of the ticks can mean that the individual bars between live trading and backtesting can have slightly different ticks. As a result, it's possible for a tick to be counted in different bars between backtesting and live trading, which can lead to bars having slightly different open, high, low, close, and volume values.

Data Availability

In live trading, live data is available in real-time. In backtests, live data is available at the following pre-market trading session.

Examples

The following examples demonstrate some common practices related to our US Equity data preparation process.

Example 1: Trading at the Opening Auction

The following algorithm creates a Scheduled Event that places a Market On Open order , which fill at the official opening auction price.

C#

```
public class USEquityDataPreparationExampleAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add Equity data.
        _spy = AddEquity("SPY", extendedMarketHours: true).Symbol;
        // Create a Scheduled Event that rebalances with market on open orders.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.BeforeMarketOpen(_spy, 30), Rebalance);
    }

    public void Rebalance()
    {
        var quantity = CalculateOrderQuantity(_spy, 0.1m);
        if (quantity != 0)
        {
            MarketOnOpenOrder(_spy, quantity);
        }
    }
}
```

Example 2: Demonstrate Using Tick Flags to Identify Opening Auction Tick

This example demonstrates using the tick flags to identify the official opening price on the security primary exchange. All exchanges have an opening auction to determine the market on open price, but only the primary listed exchange is used as the official open price for the asset. The algorithm subscribes to the raw tick data of QQQ ETF and logs the auction price tick data of the asset.

C#

```
public class USEquityDataPreparationExampleAlgorithm : QCAlgorithm
{
    private Equity _asset;
    uint officialOpen;
    uint openingPrints;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 5);
        SetEndDate(2024, 9, 5);
        // Subscribe to tick data of a security and find the exchange code.
        _asset = AddEquity("QQQ", Resolution.Tick, extendedMarketHours: true, dataNormalizationMode:
DataNormalizationMode.Raw);
        // Define flags to help filter opening auctions in the OnData method.
        officialOpen = (uint) (TradeConditionFlags.Regular | TradeConditionFlags.OfficialOpen);
        openingPrints = (uint) (TradeConditionFlags.Regular | TradeConditionFlags.OpeningPrints);
        // Display exchange code and trade condition flags on the console.
        Debug($"Search Codes: Ex:{_asset.PrimaryExchange.Code} OO: {officialOpen} OP: {openingPrints}");
    }

    public override void OnData(Slice slice)
    {
        // Create a list of opening auction tick data.
        var trades = _asset.Cache.GetAll<Tick>()
            .Where(x =>
                x.TickType == TickType.Trade &&
                x.Price > 0 &&
                !string.IsNullOrWhiteSpace(x.SaleCondition) && (
                    (x.ParsedSaleCondition == officialOpen || x.ParsedSaleCondition == openingPrints)
                )
                );
        // Log the opening auction tick price
        foreach(var tick in trades)
        {
            Log($"{Time},{tick.Price},{tick.Quantity},{tick.ParsedSaleCondition},{tick.ExchangeCode},
{tick.Exchange}");
        }
    }
}
```

US Equity

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the US Equity market.

Pre-market Hours

The following table shows the pre-market hours for the US Equity market:

Weekday	**Time (America/New York)**
Monday	04:00:00 to 09:30:00
Tuesday	04:00:00 to 09:30:00
Wednesday	04:00:00 to 09:30:00
Thursday	04:00:00 to 09:30:00
Friday	04:00:00 to 09:30:00

Regular Trading Hours

The following table shows the regular trading hours for the US Equity market:

Weekday	**Time (America/New York)**
Monday	09:30:00 to 16:00:00
Tuesday	09:30:00 to 16:00:00
Wednesday	09:30:00 to 16:00:00
Thursday	09:30:00 to 16:00:00
Friday	09:30:00 to 16:00:00

Post-market Hours

The following table shows the post-market hours for the US Equity market:

Weekday	Time (America/New York)
Monday	16:00:00 to 20:00:00
Tuesday	16:00:00 to 20:00:00
Wednesday	16:00:00 to 20:00:00
Thursday	16:00:00 to 20:00:00
Friday	16:00:00 to 20:00:00

Holidays

LEAN uses the trading holidays from the NYSE website.

The following table shows the dates of holidays for the US Equity market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25

Late Opens

There are no days with late opens.

Time Zone

The US Equity market trades in the `America/New York` time zone.

Asset Classes

Equity Options

Equity Options are a financial derivative that gives the holder the right (but not the obligation) to buy or sell the underlying Equity, such as Apple, at the stated exercise price.

Introduction to Options
Applied Options

Equity Options

Requesting Data

Request Equity Options data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Equity Options dataset listing . To trade Equity Options live, you can use one of the brokerage data providers . We currently only support American-style Options for US Equity Options.

To request Equity Options data, call one of the following methods:

- `AddOption` to add a basket of contracts for a single underlying Equity
- `AddOptionContract` to add individual contracts for an underlying Equity

Request and Filter Contracts for Option Strategies

Universes

Introduction

The `AddOption` method enables you to select a basket of Option contracts for an underlying Equity. To form your universe of contracts, you can filter them down by their strike price and expiry or you can choose to a subset of the contracts that form popular Option strategies . If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Equity Option contracts, in the `Initialize` method, call the `AddOption` method. This method returns an `Option` object, which has a `SetFilter` method you can call to filter the set of tradable contract down to just the contracts you want.

```
C#
public class BasicOptionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        var option = AddOption("SPY");
        option.SetFilter(Filter);
        _symbol = option.Symbol;
    }

    private OptionFilterUniverse Filter(OptionFilterUniverse universe)
    {
        return universe.IncludeWeeklys().Expiration(0, 7).Delta(0.35m, 0.75m);
    }

    public override void OnData(Slice data)
    {
        if (data.OptionChains.TryGetValue(_symbol, out var chain))
        {
            var contract = chain.OrderBy(x => x.Greeks.Delta).FirstOrDefault();
        }
    }
}
```

For more information about the `AddOption` method, see Create Universes .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Equity with different features.

```C#
// Example 1: Select a Straddle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Straddle(30, 5, 10));

// Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));

// Example 3: Select the 0DTE contracts that form an Strangle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Expiration(0, 0).Strangle(30, 5, -
10));
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`NakedCall(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`NakedPut(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`CallSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`PutSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.
`CallCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.
`PutCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.
`Strangle(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Long Strangle or Short Strangle Option strategies.
`Straddle(int minDaysTillExpiry)` Selects two contracts to form Long Straddle or Short Straddle Option strategies.
`ProtectiveCollar(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Protective Collar Option strategies.

`Conversion(int minDaysTillExpiry, decimal strikeFromAtm)` Selects two contracts to form Conversion or Reverse Conversion Option strategies.
`CallButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.
`PutButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.
`IronButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.
`IronCondor(int minDaysTillExpiry, decimal nearStrikeSpread, decimal farStrikeSpread)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`BoxSpread(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`JellyRoll(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.
`CallLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`PutLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

```C#
// Example 1: Select the contracts with delta between 0.25 and 0.75
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Delta(0.25m, 0.75m));

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below
20%
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below
20% that forms an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0,
30).IronCondor(30, 5, 10));
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`IV(decimal min, decimal max)`
`ImpliedVolatility(decimal min, decimal max)`
 	
Selects a contract with implied volatility within the range you set.

`D(decimal min, decimal max)`
`Delta(decimal min, decimal max)`
 	
Selects a contract with delta within the range you set.

`G(decimal min, decimal max)`
`Gamma(decimal min, decimal max)`
 	
Selects a contract with gamma within the range you set.

`R(decimal min, decimal max)`
`Rho(decimal min, decimal max)`
 	
Selects a contract with rho within the range you set.

`V(decimal min, decimal max)`
`Vega(decimal min, decimal max)`
 	
Selects a contract with vega within the range you set.

`T(decimal min, decimal max)`
`Theta(decimal min, decimal max)`
 	
Selects a contract with theta within the range you set.

`OI(long min, long max)`
`OpenInterest(decimal min, decimal max)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```C#
// Select the put contracts with the lowest strike price.
option.SetFilter(Selector);

private OptionFilterUniverse Selector(OptionFilterUniverse optionFilterUniverse)
{
    return universe
        .Delta(0.5m, 1.5m)
        .Gamma(0.0001m, 0.0006m)
        .Vega(0.01m, 1.5m)
        .Theta(-2.0m, -0.5m)
        .Rho(0.5m, 3.0m)
        .ImpliedVolatility(1.0m, 3.0m)
        .OpenInterest(100, 500);
}
```

Filter by Other Contract Properties

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Option` object.

```C#
// Select contracts that have a strike price within 1 strike level above and below the underlying price
option.SetFilter(minStrike: -1, maxStrike: 1);

// Select contracts that expire within 30 days
option.SetFilter(minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select contracts that have a strike price within 1 strike level and expire within 30 days
option.SetFilter(minStrike: -1, maxStrike: 1, minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly());
```

The following table describes the available filter techniques:

`SetFilter(int minStrike, int maxStrike)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302*andtherearestrikesatevery*5. If you set `minStrike` to -1 and `maxStrike` to 1, LEAN selects the contracts that have a strike of 300*or*305. This filter runs asynchronously by default.
`SetFilter(TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`SetFilter(int minStrike, int maxStrike, TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`SetFilter(Func<OptionFilterUniverse, OptionFilterUniverse> universeFunc)` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.
`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.
`StandardsOnly()` Selects standard contracts.
`IncludeWeeklys()` Selects non-standard weeklys contracts.
`WeeklysOnly()` Selects weekly contracts.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.
`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse`, so you can chain the methods together.

```
// Example 1: Select the front month call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly().FrontMonth());

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse`.

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

Historical Data

To get historical chains for an Equity Option, see Historical Data.

Examples

Example 1: Selecting for 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. To create an universe with 0DTE Options, call the `SetFilter` method with expiration set. In order to trade with the contracts with most liquidity, limit the strike range from 10 strikes above and below the current price level.

```
public class EquityOptionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var option = AddOption("SPY");
        // Filter for 0-DTE contracts within +/-10 strike range.
        // They have the highest volatility but low premium, providing sufficient liquidity and higher profit margin.
        option.SetFilter(u => u.IncludeWeeklys().Expiration(0, 0).Strikes(-10, 10));
    }
}
```

Example 2: Straddle

You can also create an universe that return the option contracts that form an option strategy. In this example, we demonstrate filtering for a long straddle strategy that expires 30 days later.

```C#
public class EquityOptionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var option = AddOption("SPY");
        _symbol = option.Symbol;
        // Using Staddle() method, it will only return the best-matched ATM call and put contracts expiring after 30
days.
        // It provides better accuracy in filtering, and subscribe only to the needed contracts to save computation
resources.
        option.SetFilter(u => u.IncludeWeeklys().Straddle(30));
    }

    public override void OnData(Slice slice)
    {
        // Only wants the option chain of the selected symbol.
        if (!Portfolio.Invested &&
            slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            if (chain.Count == 0)
            {
                return;
            }
            // There should only be 1 expiry and 1 strike from the 2 contracts returned, getting from either contract
is fine.
            var expiry = chain.First().Expiry;
            var strike = chain.First().Strike;

            // Forms a long straddle option strategy using abstraction method ensure accuracy.
            var longStraddle = OptionStrategies.Straddle(_symbol, strike, expiry);
            Buy(longStraddle, 1);
        }
    }
}
```

Example 3: Custom Selector

Using a custom selection function, you can filter the option universe to obtain the contracts that you need without subscribing the redundants. This can ensure the accuracy of the filter, as well as avoiding unnecessary subscriptions that drag the algorithm computational performance. In this example, we try to obtain a put contract that expires 30 days later that is 5*belowthecurrentunderlyingpriceandacallcontractthatexpires*60*dayslaterthatis*10 above the current underlying price.

C#

```
public class EquityOptionAlgorithm : QCAlgorithm
{
    private Equity _underlying;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price with last known price to ensure the underlying price data is available on initial option
contract filtering.
        Settings.SeedInitialPrices = true;
        // Subscribe to underlying data for ATM calculation using the update underlying price.
        // Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw);
        // Subscribe to SPY option data.
        var option = AddOption(_underlying.Symbol);
        option.SetFilter(u => u.IncludeWeeklys().Contracts((contracts) =>
        {
            var selected = new List<Symbol>();

            // Select the best-match put contracts that expires 30 days later that is $5 below the current underlying
price.
            // We should first filter the hard requirement, then sort the reminders for faster computation.
            var puts = contracts.Where(x =>
                    x.ID.OptionRight == OptionRight.Put &&
                    x.ID.Date >= Time.AddDays(30) &&
                    x.ID.StrikePrice <= _underlying.Price - 5m
                ).ToList();
            if (puts.Count > 0)
            {
                var put = puts.OrderBy(x => x.ID.Date)
                    .ThenByDescending(x => x.ID.StrikePrice)
                    .First();
                selected.Add(put);
            }

            // Select the best-match call contract that expires 60 days later that is $10 above the current
underlying price.
            var calls = contracts.Where(x =>
                    x.ID.OptionRight == OptionRight.Call &&
                    x.ID.Date >= Time.AddDays(60) &&
                    x.ID.StrikePrice >= _underlying.Price + 10m
                ).ToList();
            if (calls.Count > 0)
            {
                var call = calls.OrderBy(x => x.ID.Date)
                    .ThenBy(x => x.ID.StrikePrice)
                    .First();
                selected.Add(call);
            }

            return selected;
        }));
    }
}
```

Requesting Data

Individual Contracts

Introduction

The `AddOptionContract` method enables you to add an individual Option contract to your algorithm. To check which contracts are currently available to add to your algorithm, use the `OptionChain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to an Option contract, you must configure the underlying Equity and get the contract `Symbol` .

```
C#
public class BasicOptionAlgorithm : QCAlgorithm
{
    private Symbol _underlying, _contractSymbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
    }

    public override void OnData(Slice data)
    {
        if (_contractSymbol != null)
        {
            return;
        }
        var chain = OptionChain(_underlying);
        var expiry = chain.Select(contract => contract.Expiry).Min();
        _contractSymbol = chain
            .Where(contract =>
                contract.Expiry == expiry &&
                contract.Right == OptionRight.Call &&
                contract.Greeks.Delta > 0.3m &&
                contract.Greeks.Delta < 0.7m
            )
            .OrderByDescending(contract => contract.OpenInterest)
            .First()
            .Symbol;
        AddOptionContract(_contractSymbol);
    }
}
```

Configure the Underlying Equity

If you want to subscribe to the underlying Equity in the `Initialize` method, set the Equity data normalization to `DataNormalizationMode.Raw` .

```
C#
_underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
```

If your algorithm has a dynamic universe of Equities, before you add the Equity universe in the `Initialize` method, set the universe data normalization mode to `DataNormalizationMode.Raw` .

```
UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
```

Get Contract Symbols

To subscribe to an Option contract, you need the contract `Symbol`. The preferred method to getting Option contract `Symbol` objects is to use the `OptionChain` method. This method returns an `OptionChain` object, which represent an entire chain of Option contracts for a single underlying security. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
// Get the contracts available to trade.
var chain = OptionChain(_underlying);

// Select a contract.
var expiry = chain.Select(contract => contract.Expiry).Min();
_contractSymbol = chain
    .Where(contract =>
        // Select call contracts with the closest expiry.
        contract.Expiry == expiry &&
        contract.Right == OptionRight.Call &&
        // Select contracts with a 0.3-0.7 delta.
        contract.Greeks.Delta > 0.3m &&
        contract.Greeks.Delta < 0.7m
    )
    // Select the contract with the largest open interest.
    .OrderByDescending(contract => contract.OpenInterest)
    .First()
    // Get the Symbol of the target contract.
    .Symbol;
```

Alternatively, you can create a Option contract `Symbol` object directly parsing its OSI ticker using the `SymbolRepresentation.ParseOptionTickerOSI` method.

```
// Create the contract Symbol for the SPY Call 564 3 Sept 2024.
_contractSymbol = SymbolRepresentation.ParseOptionTickerOSI("SPY 240903C00564000");
```

Subscribe to Contracts

To create an Equity Option contract subscription, pass the contract `Symbol` to the `AddOptionContract` method. Save a reference to the contract `Symbol` so you can easily access the Option contract in the OptionChain that LEAN passes to the `OnData` method. This method returns an `Option` object. To override the default pricing model of the Option, set a pricing model .

```
var option = AddOptionContract(_contractSymbol);
option.PriceModel = OptionPriceModels.BinomialCoxRossRubinstein();
```

The `AddOptionContract` method creates a subscription for a single Option contract and adds it to your user-defined universe. To create a dynamic universe of Option contracts, add an Equity Options universe or an Options Universe Selection model .

Warm Up Contract Prices

If you subscribe to an Option contract with `AddOptionContract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
Settings.SeedInitialPrices = true;
```

Supported Assets

To view the supported assets in the US Equities dataset, see the Data Explorer .

Resolutions

The following table shows the available resolutions and data formats for Equity Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Option contract subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddOptionContract` method.

```
AddOptionContract(_contractSymbol, Resolution.Minute);
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

LEAN groups all of the US Equity exchanges under `Market.USA` . You don't need to pass a `Market` argument to the `AddOptionContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
AddOptionContract(_contractSymbol, fillForward: false);
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Options are already leveraged products, so you can't change their leverage.

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a

specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
C#
AddOptionContract(_contractSymbol, extendedMarketHours: true);
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . By default, LEAN doesn't adjust Equity Options data for splits and dividends of their underlying. If you change the data normalization mode, it won't change the outcome.

If you hold an Option contract when a corporate action occurs for the underlying Equity, LEAN automatically closes your position.

Remove Subscriptions

To remove a contract subscription that you created with `AddOptionContract` , call the `RemoveOptionContract` method. This method is an alias for `RemoveSecurity` .

```
C#
RemoveOptionContract(_contractSymbol);
```

The `RemoveOptionContract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `AddOptionContract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `Symbol` to access the value in the `Securities` object.

```
C#
var option = Securities[_contractSymbol];
var underlying = Securities[_contractSymbol.Underlying];
var underlyingPrice = underlying.Price;
```

To get the Option payoff , call the `GetPayOff` method.

```
C#
var payOff = option.GetPayOff(underlyingPrice);
```

To get the Option intrinsic value , call the `GetIntrinsicValue` method.

```
C#
var intrinsicValue = option.GetIntrinsicValue(underlyingPrice);
```

To get the Option out-of-the-money amount , call the `OutOfTheMoneyAmount` method.

```
var otmAmount = option.OutOfTheMoneyAmount(underlyingPrice);
```

To check whether the Option can be automatic exercised, call the `IsAutoExercised` method.

```
var isAutoExercised = option.IsAutoExercised(underlyingPrice);
```

Exceptions and Edge Cases

The following sections explain exceptions and edge cases with subscribing to individual Option contracts.

Manually Creating Option Symbol Objects

To subscribe to an Option contract, you need the contract `Symbol` . You can get the contract `Symbol` from the `CreateOption` or `OptionChain` methods. If you use the `CreateOption` method, you need to provide the details of an existing contract.

```
_contractSymbol = QuantConnect.Symbol.CreateOption(_underlying, Market.USA,
    OptionStyle.American, OptionRight.Call, 365, new DateTime(2022, 6, 17));
```

Default Underlying Subscription Settings

If you subscribe to an Equity Option contract but don't have a subscription to the underlying Equity, LEAN automatically subscribes to the underlying Equity with the following settings:

Setting	Value
Fill forward	Same as the Option contract
Leverage	0
Extended Market Hours	Same as the Option contract
Data Normalization	`DataNormalizationMode.Raw`

In this case, you still need the Equity `Symbol` to subscribe to Equity Option contracts. If you don't have access to it, create it.

```
_underlying = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
```

Overriding the Initial Implied Volatility Guess

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Examples

The following examples demonstrate some common practices for requesting individual Equity Option contract data.

Example 1: Covered Call

A cover call consists of a short call and with a lot of the underlying equity. Although it capped the maximum profit if the

underlying skyrocketted, it also provide extra credit received while speculating the underlying will rise.

```C#
public class EquityOptionExampleAlgorithm : QCAlgorithm
{
    private Symbol _aapl;
    private List<Symbol> _options = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the security price to ensure the retrieval of the ATM calls at the initial filtering.
        Settings.SeedInitialPrices = true;
        // Set the data normalization mode as raw for option strike-price comparability.
        _aapl = AddEquity("AAPL", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Filter an updated option list at market open everyday by a scheduled event.
        Schedule.On(
            DateRules.EveryDay(_aapl),
            TimeRules.AfterMarketOpen(_aapl, 0),
            RefreshOptionList
        );
    }

    private void RefreshOptionList()
    {
        // Select the calls expires within 30 days and within $5 strike from ATM as leg of the covered call.
        // $5 buffer is given on selecting the ATM call due to price movement.
        _options = OptionChain(_aapl)
            .Where(x =>
                x.Expiry < Time.AddDays(30) &&
                x.Right == OptionRight.Call &&
                Math.Abs(x.Strike - Securities[_aapl].Price) <= 5
            )
            .Select(symbol => AddOptionContract(symbol).Symbol)
            .ToList();
    }

    public override void OnData(Slice slice)
    {
        if (!Portfolio.Invested && slice.Bars.ContainsKey(_aapl) && _options.Count > 0)
        {
            // To form a covered call, get the contract closest to ATM and expiry.
            var contract = _options.OrderBy(x => x.ID.Date)
                .ThenBy(x => Math.Abs(x.ID.StrikePrice - slice.Bars[_aapl].Price))
                .First();

            // Covered call involves shorting 1 ATM call and ordering 1 lot of underlying.
            MarketOrder(contract, -1);
            MarketOrder(_aapl, Securities[contract].SymbolProperties.ContractMultiplier);
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // Close AAPL position if the short call is not exercised (OTM).
        // If it is exercised, the underlying will be used to settle the contract automatically.
        if (orderEvent.Ticket.OrderType == OrderType.OptionExercise &&
            !orderEvent.IsInTheMoney)
        {
            MarketOrder(_aapl, -Securities[orderEvent.Symbol].SymbolProperties.ContractMultiplier);
        }
    }
}
```

Example 2: 0-DTE Bull Put Spread

0DTE options often trades with high volume and volatility, providing arbitration opportunities and higher profit margin on spread type trading. In this example, we make use of 0-DTE SPY options to trade bull put spread option strategy.

C#

```
public class EquityOptionExampleAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private List<Leg> _legs = [];

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the underlying security price to ensure accurate filtering for puts of $5 above/below current market
price.
        Settings.SeedInitialPrices = true;
        // Set the data normalization mode as raw for option strike-price comparability.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Filter an updated option list at market open everyday by a scheduled event.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.BeforeMarketOpen(_spy, 10), RefreshOptionList);

        // Use a scheduled event to close all positions before market close.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.BeforeMarketClose(_spy, 1), ExitPositions);
    }

    private void RefreshOptionList()
    {
        // Get all tradable option contracts for SPY at the current time for filtering.
        var filteredContracts = OptionChain(_spy)
            // Select the 0-DTE puts by setting expiry within 1 day.
            .Where(x => x.Expiry < Time.AddDays(1) && x.Right == OptionRight.Put)
            .ToList();

        // Ensure at least 2 contracts available to form a put spread.
        if (filteredContracts.Count < 2)
        {
            _legs = [];
            return;
        }
        // To form a put spread, select and subscribe to put contracts $5 above and below from the current underlying
price.
        var underlyingPrice = Securities[_spy].Price;
        var itmPut = filteredContracts.MinBy(x => Math.Abs(x.Strike - underlyingPrice - 5));
        var otmPut = filteredContracts.MinBy(x => Math.Abs(x.Strike - underlyingPrice + 5));
        Leg getLeg(OptionContract contract, int quantity)
        {
            AddOptionContract(contract.Symbol);
            return Leg.Create(contract.Symbol, quantity);
        }
        _legs = [ getLeg(itmPut, -1), getLeg(otmPut, 1) ];
    }

    public override void OnData(Slice slice)
    {
        // To avoid over-trading, limit the position opening to before 3pm.
        // To ensure the put spread formed correctly, make sure at least 2 contracts selected.
        if (!Portfolio.Invested && Time.Hour < 15 && _legs.Count == 2)
        {
            // A bull put spread involves buying a lower-strike put and selling a high-strike put
            _legs.ForEach(leg => MarketOrder(leg.Symbol, leg.Quantity));
        }
    }

    private void ExitPositions()
    {
        // Exit all positions by removing the contract before market close to avoid option assignment and overnight
risk.
        _legs.ForEach(leg => RemoveOptionContract(leg.Symbol, "Exit position"));
        _legs.Clear();
    }
}
```

Example 3: Select Option Contracts by Greeks

The following algorithm creates a weekly Scheduled Event that adds a universe of contracts with a Delta >= 0.99. This universe is useful for creating a hedge replicate portfolio for arbitrage.

C#

```
public class EquityOptionExampleAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private List<Option> _universe = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add the underlying asset with raw data to enable Option strike-price comparability.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
        // Add a Scheduled Event to select the Option contracts to trade each week.
        Schedule.On(
            DateRules.WeekStart(_underlying),
            TimeRules.At(7, 30),
            AddContracts
        );
    }

    private void AddContracts()
    {
        _universe.Clear();
        // Get all the tradable Option contracts for SPY at the current time.
        var chain = OptionChain(_underlying);
        // Add the contracts that have the nearest expiry after 7 days and a delta >= 0.99.
        var expiryThreshold = Time.AddDays(7);
        var contracts = chain.Where(contract => contract.Expiry >= expiryThreshold);
        if (!contracts.IsNullOrEmpty())
        {
            var expiry = contracts.Select(contract => contract.Expiry).Min();
            _universe = contracts
                .Where(contract => contract.Expiry == expiry & contract.Greeks.Delta >= 0.99m)
                .Select(contract => AddOptionContract(contract.Symbol))
                .ToList();
        }
        // Plot the number of contracts in the universe.
        Plot("Universe", "Size", _universe.Count);
    }
}
```

Example 4: Wheel Strategy

The Wheel strategy is a popular trading strategy for Options that enables traders to build a steady flow of income from Equity assets they want to hold for the long term.

C#

```
public class EquityOptionExampleAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Set OTM threshold for wheel strategy profit margin.
    private decimal _otmThreshold = 0.05m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 5);
        SetEndDate(2024, 9, 5);
        SetCash(1000000000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Set the data normalization mode as raw for option strike-price comparability.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // To use the latest underlying price to filter the option contract, ensure the SPY in the bar data.
        // Open short put contract position only when the last wheel is completed.
        if (!Portfolio.Invested && slice.Bars.ContainsKey(_spy))
        {
            // Initiate the wheel by shorting a least-OTM put contract that the strike is below the threshold.
            var symbol = GetTargetContract(OptionRight.Put, slice.Bars[_spy].Price * (1 - _otmThreshold));
            SetHoldings(symbol, -0.2m);
        }
        // Open short call contract position only when the put is assigned (portfolio with the underlying) to close
the wheel and underlying position by the call assignment.
        else if (Portfolio[_spy].Invested && slice.Bars.ContainsKey(_spy))
        {
            // Short the corresponding number of a least-OTM call contract that the strike is above the threshold.
            var symbol = GetTargetContract(OptionRight.Call, slice.Bars[_spy].Price * (1 + _otmThreshold));
            MarketOrder(symbol, -Portfolio[_spy].Quantity / Securities[_spy].SymbolProperties.ContractMultiplier);
        }
    }

    private Symbol GetTargetContract(OptionRight right, decimal targetPrice)
    {
        // Get all tradable option contracts for SPY at the current time for filtering.
        var contractSymbols = OptionChain(_spy).ToList();
        // Filter for the least-OTM contract that is off by the threshold to form the wheel.
        // Expiry is set to be at least 30 days to earn the time decay, which is highest in the last month.
        var expiry = contractSymbols.Where(x => x.ID.Date > Time.AddDays(30))
            .Min(x => x.ID.Date);
        var filtered = contractSymbols.Where(x =>
                x.ID.Date == expiry &&
                x.ID.OptionRight == right &&
                (right == OptionRight.Call ? x.ID.StrikePrice >= targetPrice : x.ID.StrikePrice <= targetPrice)
            )
            .OrderBy(x => x.ID.StrikePrice)
            .ToList();
        var selected = right == OptionRight.Call ? filtered.First() : filtered.Last();
        // Request the selected contract data for trading.
        return AddOptionContract(selected).Symbol;
    }
}
```

For more details, refer to the Wheel Strategy research post .

Example 5: Scan and Update Option Chain Every 5 Minutes

The following example shows how to update the Option chain every five minutes. The `OptionChainManager` class implements the selection logic and manages the contract subscriptions.

C#

```
public class OptionChainFullExample : QCAlgorithm
{
    private Dictionary<Symbol, OptionChainManager> _chainManager = new();
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(100000);
```

```
        UniverseSettings.Asynchronous = true;
        UniverseSettings.MinimumTimeInUniverse = TimeSpan.Zero;
        // Seed the security price to ensure the underlying price data is ready at the initial filtering
        Settings.SeedInitialPrices = true;
        // Set the data normalization mode as raw for option strike-price comparability
        var spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
        // Set up a OptionChainManager to filter the contracts based on latest data by request
        _chainManager[QuantConnect.Symbol.CreateCanonicalOption(spy)] = new(-10, 10, 0, 7);
        // Daily population of the available contracts to ensure the contracts are tradable
        PopulateOptionChain();
        Schedule.On(DateRules.EveryDay(spy), TimeRules.AfterMarketOpen(spy, 1), PopulateOptionChain);
        // Filter for contract in every 5 minutes interval through scheduled event
        Schedule.On(DateRules.EveryDay(spy), TimeRules.Every(TimeSpan.FromMinutes(5)), Filter);
    }

    private void PopulateOptionChain()
    {
        // The contract list is updated daily, so we can get it and apply
        // the expiration filter as soon as the market opens.
        foreach (var (symbol, manager) in _chainManager)
        {
            manager.SetChain(OptionChain(symbol), Time);
        }
        Filter();
    }

    private void Filter()
    {
        foreach (var (symbol, manager) in _chainManager)
        {
            manager.Select(this, symbol);
        }
    }

    public override void OnData(Slice slice)
    {
        // Iterate the saved symbol and chain manager to obtain only the contract wanted
        foreach (var (symbol, manager) in _chainManager)
        {
            if (!slice.OptionChains.TryGetValue(symbol, out var chain))
                continue;
            // Handle option exercise and assignment on unwanted underlying position
            if (Portfolio[symbol.Underlying].Invested)
            {
                Liquidate(symbol.Underlying);
            }

            // Buy the ATM call with nearest expiry to speculate-trade the underlying through low cost, leveraging
position
            var expiry = chain.Min(x => x.Expiry);
            var atmCall = chain
                .Where(x => x.Expiry == expiry && x.Right == OptionRight.Call && Securities[x.Symbol].IsTradable)
                .OrderBy(x => Math.Abs(chain.Underlying.Price - x.Strike))
                .FirstOrDefault();
            if (atmCall != null && !Portfolio[atmCall.Symbol].Invested)
            {
                MarketOrder(atmCall.Symbol, 1);
            }
        }
    }
}

internal class OptionChainManager
{
    private readonly int _minStrike;
    private readonly int _maxStrike;
    private readonly int _minExpiry;
    private readonly int _maxExpiry;
    private List<OptionContract> _chain = new();
    private readonly List<Symbol> _symbols = new();

    public OptionChainManager(int minStrike, int maxStrike, int minExpiry, int maxExpiry)
    {
        _minStrike = minStrike;
        _maxStrike = maxStrike;
        _minExpiry = minExpiry;
        _maxExpiry = maxExpiry;
    }

    public void SetChain(OptionChain chain, DateTime time)
```

```
    {
        // Expiry criteria will not affect intra-day universe filtering, so it is done in a daily basis in higher
level
        _chain = chain.Where(x =>
        {
            var totalDays = (x.Expiry - time).TotalDays;
            return _minExpiry <= totalDays && totalDays <= _maxExpiry;
        }).ToList();
    }

    {
        if (_chain.IsNullOrEmpty())
            return;
        if (underlyingSymbol.IsCanonical())
            underlyingSymbol = underlyingSymbol.Underlying;

        var strikes = _chain.Select(x => x.Strike).OrderBy(x => x).Distinct().ToList();
        var spot = algorithm.Securities[underlyingSymbol].Price;
        var atm = strikes.OrderBy(x => Math.Abs(spot - x)).FirstOrDefault();
        var index = strikes.IndexOf(atm);
        var minStrike = strikes[Math.Max(0, index + _minStrike)];
        var maxStrike = strikes[Math.Min(strikes.Count - 1, index + _maxStrike)];
        var symbols = _chain
            .Where(x => minStrike <= x.Strike && x.Strike <= maxStrike)
            .Select(x => x.Symbol).ToList();

        // Also remove data subscription on the contracts being filtered out to release computation resources
            foreach (var symbol in _symbols.Except(symbols).ToList())
        {
            if (algorithm.RemoveOptionContract(symbol))
                _symbols.Remove(symbol);
        }
        foreach (var symbol in symbols.Except(_symbols).ToList())
        {
            _symbols.Add(symbol);
            algorithm.AddOptionContract(symbol);
        }
    }
}
```

Equity Options

Handling Data

Introduction

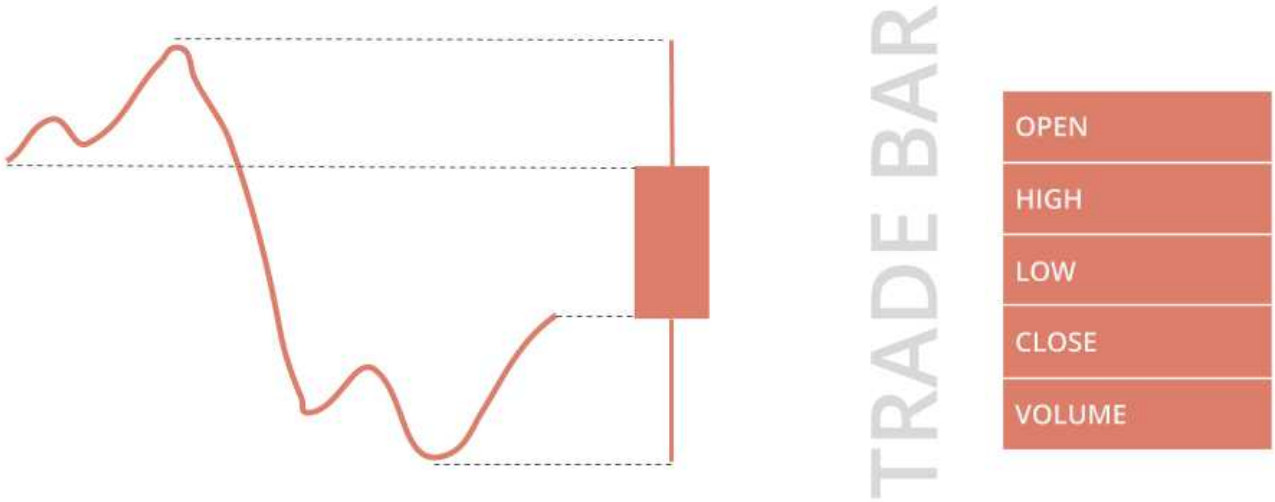
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `TradeBar` argument, it only receives `TradeBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Equity Options data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in TradeBars object
    if (slice.Bars.ContainsKey(_contractSymbol))
    {
        // Obtain the mapped TradeBar of the symbol
        var tradeBar = slice.Bars[_contractSymbol];
    }
}
```

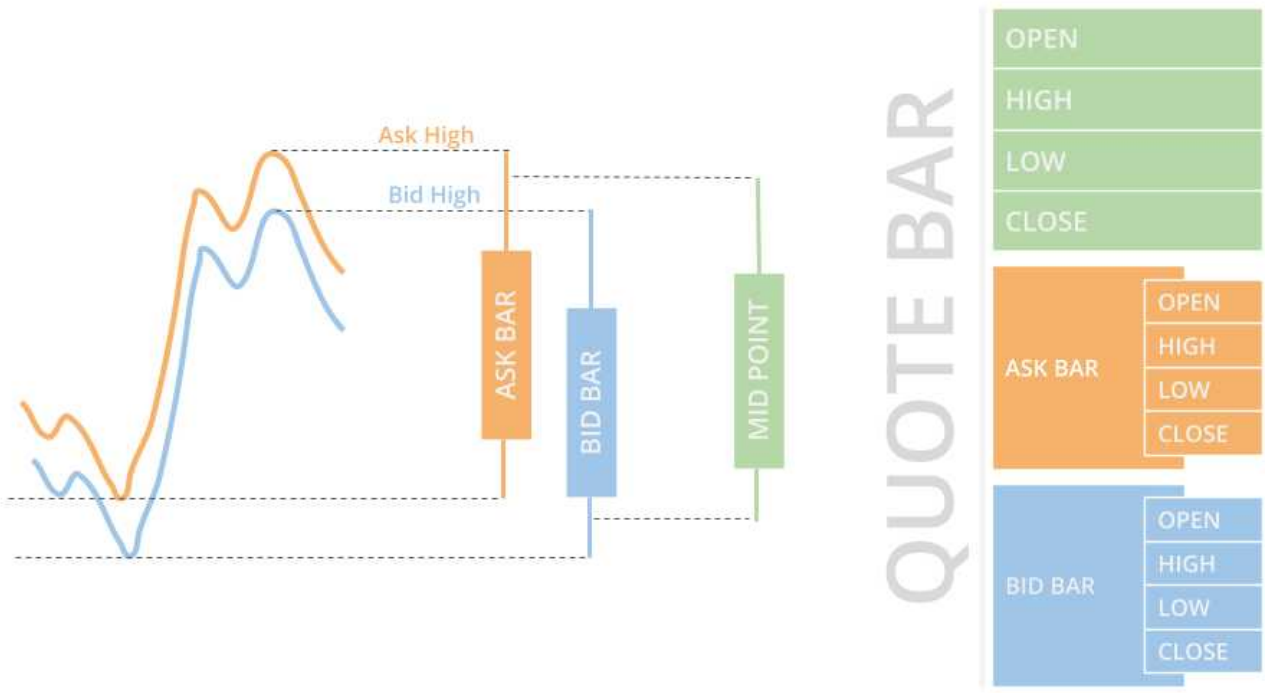
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-TradeBar key-value pairs
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        var closePrice = tradeBar.Close;
    }
}
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not

contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_contractSymbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_contractSymbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get all contracts if the OptionChain contains any member
        var contracts = chain.Contracts;
    }
}
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-OptionChain key-value pairs
    foreach (var kvp in slice.OptionChains)
    {
        var canonicalSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}
```

`OptionChain` objects have the following properties:

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. To get the Option contracts in the `Slice` , use the `Contracts` property of the `OptionChain` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            var price = contract.Price;
        }
    }
}
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `Greeks` and `implied_volatility` members.

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get greeks data of the selected contract
            var delta = contract.Greeks.Delta;
            var iv = contract.ImpliedVolatility;
        }
    }
}
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `Greeks` property, the Greeks aren't calculated. However, if you invoke the `Greeks.Delta` , LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Option` or `OptionContract` .

```C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChains using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get the open interest of the selected contracts
            var openInterest = contract.OpenInterest;
        }
    }
}

public void OnData(OptionChains optionChains)
{
    // Try to get the OptionChains using the canonical symbol
    if (optionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get the open interest of the selected contracts
            var openInterest = contract.OpenInterest;
        }
    }
}
```

Properties

`OptionContract` objects have the following properties:

Examples

Example 1: Get Mid Price For Individual Contracts

This example shows how to handle `QuoteBar` data for shortlisted Equity Option contracts to calculate mid price using bid close and ask close data, while filter individual option contracts and request data using `OptionChain` method for the contracts that expires within the current week. Using mid price, we can examine the market fair value of the Option and compare with model theoretical price.

C#

```
public class EquityOptionHandlingDataAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private List<Symbol> _contracts = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);

        // Seed the price with last known price to ensure the underlying price data is available on initial option
contract filtering.
        Settings.SeedInitialPrices = true;
        // Subscribe to underlying data for ATM calculation using the update underlying price.
        // Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Update the tradable contracts daily before market open since the option contract list provider populate
them daily.
        Schedule.On(
            DateRules.EveryDay(_spy),
            TimeRules.At(9, 0),
            UpdateContracts
        );
    }

    private void UpdateContracts()
    {
        // Get all contracts that expiring this week to trade with, subscribe to data for trading need.
        _contracts = OptionChain(_spy)
            .Where(x => x.ID.Date <= Expiry.EndOfWeek(Time))
            .Select(x => AddOptionContract(x).Symbol)
            .ToList();
    }

    public override void OnData(Slice slice)
    {
        // Only focus on filtered list of option contracts to trade.
        foreach (var contract in _contracts)
        {
            // Mid price can only be calculated when quote bar data is available.
            if (slice.QuoteBars.TryGetValue(contract, out var quote))
            {
                if (quote.Bid != null && quote.Ask != null)
                {
                    // Mid price = average of bid close price and ask close price.
                    var midPrice = (quote.Bid.Close + quote.Ask.Close) * 0.5m;
                }
            }
        }
    }
}
```

Example 2: Get Mid Price For Universe

This example shows how to handle `QuoteBar` data for shortlisted Equity Option contracts to calculate mid price using bid close and ask close data, while request data through universe selection function using `SetFilter` method for the contracts that expires within the current week. Using mid price, we can examine the market fair value of the Option and compare with model theoretical price.

```C#
public class EquityOptionHandlingDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);

        // Seed the price with last known price to ensure the underlying price data is available on initial option
contract filtering.
        Settings.SeedInitialPrices = true;
        // Subscribe to underlying data for ATM calculation using the update underlying price.
        // Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        var spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
        // Subscribe to SPY option data.
        var option = AddOption(spy);
        _symbol = option.Symbol;
        // We wish to only trade the contracts expiring within the same week since they have the highest volume.
        option.SetFilter((u) => u.IncludeWeeklys().Contracts((x) => x.Where(s => s.ID.Date <=
Expiry.EndOfWeek(Time))));
    }

    public override void OnData(Slice slice)
    {
        // Only want to obtain the option chain of the selected symbol.
        if (slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            foreach (var contract in chain)
            {
                // Mid price = average of bid close price and ask close price.
                var midPrice = (contract.BidPrice + contract.AskPrice) * 0.5m;
            }
        }
    }
}
```

Example 3: Get Instant Delta

The option greeks change rapidly, so we need to obtain the instant greeks to accurately calculate the hedge size for arbitration or replication portfolio. You can call the `Greeks` property from the `OptionChain` data to access various greeks. In this example, we will demonstrate how to obtain the contract with delta closest to 0.4 among all call contracts expiring the same week.

C#

```
public class EquityOptionHandlingDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 5);
        SetEndDate(2024, 9, 5);

        // Seed the price with last known price to ensure the underlying price data is available on initial option
contract filtering.
        Settings.SeedInitialPrices = true;
        // Subscribe to underlying data for ATM calculation using the update underlying price.
        // Set data normalization mode to raw is required to ensure strike price and underlying price is comparable.
        var spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
        // Subscribe to SPY option data.
        var option = AddOption(spy);
        _symbol = option.Symbol;
        // We wish to only trade the contracts expiring within the same week since they have the highest volume.
        // 0.4 Delta will only appear in call contracts.
        option.SetFilter((u) => u.IncludeWeeklys().Delta(0.2m, 0.6m).Contracts((x) => x.Where(s => s.ID.Date <=
Expiry.EndOfWeek(Time))));
    }

    public override void OnData(Slice slice)
    {
        // Only want to obtain the option chain of the selected symbol.
        if (slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            // Get the contract with Delta closest to 0.4 to trade.
            // The arbitary delta criterion might be set due to hedging need or risk adjustment.
            var selected = chain.OrderBy(x => Math.Abs(x.Greeks.Delta - 0.4m)).First();
        }
    }
}
```

Equity Options

Greeks and Implied Volatility

The Greeks are measures that describe the sensitivity of an Option's price to various factors like underlying price changes (Delta), time decay (Theta), volatility (Vega), and interest rates (Rho), while Implied Volatility (IV) represents the market's expectation of the underlying asset's volatility over the life of the Option.

Greeks and Implied Volatility

Key Concepts

Introduction

LEAN provides multiple ways for you to get the Greeks and implied volatility (IV) of Option contracts. There is a daily, pre-calculated dataset based on the end of the previous trading day. There is also a stream of values that are calculated on-the-fly as your algorithm runs.

Greeks on Universes

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```C#
public override void Initialize()
{
    var option = AddOption("SPY");
    option.SetFilter(universe => universe.IncludeWeeklys().Delta(0.3m, 0.7m).Expiration(0, 7));
}
```

To calculate the values, we use our implementation of the forward tree pricing model, which accounts for the interest rate and dividend payments.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greek History

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day.

```C#
public class OptionHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var option = AddOption("SPY");
        var history = History<OptionUniverse>(option.Symbol, 5);
        foreach (var chain in history)
        {
            var endTime = chain.EndTime;
            var filteredContracts = chain.Data
                .Select(contract => contract as OptionUniverse)
                .Where(contract => contract.Greeks.Delta > 0.3m);
            foreach (var contract in filteredContracts)
            {
                var price = contract.Price;
                var iv = contract.ImpliedVolatility;
            }
        }
    }
}
```

You can't customize the Greeks and IV values that you get from a history request. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greeks on Data Events

The Greeks and IV values that you get from the current Slice are from the price model calculations. These values aren't the same as the values you get in the universe filter function.

```
C#
public class OptionDataEventsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var option = AddOption("GOOG");
        option.PriceModel = OptionPriceModels.CrankNicolsonFD();
    }

    public override void OnData(Slice data)
    {
        foreach (var chain in data.OptionChains.Values)
        {
            foreach (var contract in chain)
            {
                var iv = contract.ImpliedVolatility;
                var delta = contract.Greeks.Delta;
            }
        }
    }
}
```

To view all the models LEAN supports, see Supported Models .

Greek Indicators

The Greeks and IV values that you get from the indicators are calculated in the same way as the values you get in the filter function, but they can reflect intraday prices instead of just the daily closing prices.

For Equity Options, the `IndicatorHistory` uses the `ScaledRaw` data normalization mode when requesting historical prices.

Examples

For detailed examples on using Option Greeks and Implied Volatility indicators in algorithm, you may refer to the Greeks Indicators page examples.

Greeks and Implied Volatility

Indicators

Introduction

Option indicators enable you to calculate daily and intraday values for the Greeks and implied volatility of Option contracts. This page explains the most popular Option indicators and how to use them with LEAN.

Parameters

The following table describes the arguments that the automatic Option indicators methods accept:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The contract to use when calculating the indicator values.	
`mirrorOption`	`Symbol`	The mirror contract to use in parity type calculations.	`null`
`riskFreeRate`	`decimal`	The risk-free interest rate. If you don't provide a value, the default value is the US primary credit rate from the Interest Rate Provider Model .	`null`
`dividendYield`	`decimal`	The dividend yield rate. If you don't provide a value, the default value comes from the Dividend Yield Provider Model .	`null`
`optionModel`	`OptionPricingModelType`	The Option pricing model that's used to calculate the Greeks. If you don't provide a value, the default value is `OptionPricingModelType.BinomialCoxRossRubinstein` for Equity Options.	`null`
`resolution`	`Resolution`	The resolution of the indicator data. If you don't provide a value, the default value is the resolution of the subscription you have for the Option contract(s).	`null`

To perform implied volatility (IV) smoothing with a put-call pair, pass one of the contracts as the `symbol` argument and pass the other contract in the pair as the `mirrorOption` argument. The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, call the `SetSmoothingFunction` method of the `ImpliedVolatility` class/property.

Several different Option pricing models are supported to calculate the IV and Greeks. The following table describes the

`OptionPricingModelType` enumeration members:

Implied Volatility

Implied volatility, σ , is the market's expectation for the future volatility of an asset and is implied by the price of the assets's Options contracts. You can't observe it in the market but you can derive it from the price of an Option. For more information about implied volatility, see Implied Volatility .

Automatic Indicators

To create an automatic indicator for implied volatility, call the `QCAlgorithm.IV` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticImpliedVolatilityIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]) as dynamic;
                var contract2 = AddOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic ImpliedVolatility indicators.
                contract1.IV = IV(contracts[0], contracts[1]);
                contract2.IV = IV(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }
```

```
    public override void OnData(Slice slice)
    {
        // Get the ImpliedVolatility indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.IV;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `IV` method, see Parameters and Using IV Indicator .

Manual Indicators

To create a manual indicator for implied volatility, call the `ImpliedVolatility` constructor.

C#

```
public class ManualImpliedVolatilityIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
```

```
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]);
                var contract2 = AddOptionContract(contracts[1]);

                // Create and save the manual ImpliedVolatility indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.ImpliedVolatility = new ImpliedVolatility(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).ImpliedVolatility;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                );

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the ImpliedVolatility indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
```

```
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `ImpliedVolatility` constructor, see Using IV Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the `IV` method or `ImpliedVolatility` constructor and then call the `SetSmoothingFunction` method of the resulting `ImpliedVolatility` object. The follow table describes the arguments of the custom function:

Argument	Data Type	Description
`iv`	`decimal`	The IV of the Option contract.
`mirrorIv`	`decimal`	The IV of the mirror Option contract.

The method must return a `decimal` as the smoothened IV.

C#

```
private ImpliedVolatility _iv;

public override void Initialize()
{
    var option = QuantConnect.Symbol.CreateOption("AAPL", Market.USA, OptionStyle.American, OptionRight.Put, 505m,
new DateTime(2014, 6, 27));
    AddOptionContract(option);

    var mirrorOption = QuantConnect.Symbol.CreateOption("AAPL", Market.USA, OptionStyle.American, OptionRight.Call,
505m, new DateTime(2014, 6, 27));
    AddOptionContract(mirrorOption);

    _iv = IV(option, mirrorOption);
    // example: take average of the call-put pair
    _iv.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
}
```

Delta

Delta, Δ , is the rate of change of the Option price with respect to the price of the underlying asset. It measures the first-order sensitivity of the price to a movement in underlying price. For example, an Option delta of 0.4 means that if the underlying asset moves by 1%, then the value of the Option moves by $0.4 \times 1\% = 0.4\%$. For more information about delta, see Delta .

Automatic Indicators

To create an automatic indicator for delta, call the `QCAlgorithm.D` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticDeltaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset
```

```
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]) as dynamic;
                var contract2 = AddOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Delta indicators.
                contract1.D = D(contracts[0], contracts[1]);
                contract2.D = D(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Delta indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.D;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `D` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
ivModel	OptionPricingModelType	The Option pricing model to use to estimate the IV when calculating Delta. If you don't provide a value, the default value is to match the optionModel parameter.	null

For more information about the D method, see Using D Indicator .

Manual Indicators

To create a manual indicator for delta, call the Delta constructor.

C#

```
public class ManualDeltaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
```

```
                var contract1 = AddOptionContract(contracts[0]);
                var contract2 = AddOptionContract(contracts[1]);

                // Create and save the manual Delta indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Delta = new Delta(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Delta;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                );

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Delta indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Delta` constructor, see Using D Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the

`SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

```
// Example: Average IV of the call-put pair.
deltaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Gamma

Gamma, Γ, is the rate of change of the portfolio's delta with respect to the underlying asset's price. It represents the second-order sensitivity of the Option to a movement in the underlying asset's price. For more information about Gamma, see Gamma .

Automatic Indicators

To create an automatic indicator for gamma, call the `QCAlgorithm.G` method with the Option contract `Symbol` object(s).

```
public class AutomaticGammaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]) as dynamic;
                var contract2 = AddOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Gamma indicators.
                contract1.G = G(contracts[0], contracts[1]);
                contract2.G = G(contracts[1], contracts[0]);
```

```
                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Gamma indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.G;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `G` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Gamma. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `G` method, see Using G Indicator .

Manual Indicators

To create a manual indicator for gamma, call the `Gamma` constructor.

C#

```
public class ManualGammaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open
```

```
        // Set up a scheduled event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]);
                var contract2 = AddOptionContract(contracts[1]);

                // Create and save the manual Gamma indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Gamma = new Gamma(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Gamma;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                );

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
```

```
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Gamma indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Gamma` constructor, see Using G Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

C#

```
// Example: Average IV of the call-put pair.
gammaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Vega

Vega, ν , is the rate of change in the value of the Option with respect to the volatility of the underlying asset. For more information about vega, see Vega .

Automatic Indicators

To create an automatic indicator for vega, call the `QCAlgorithm.V` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticVegaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }
```

```
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]) as dynamic;
                var contract2 = AddOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Vega indicators.
                contract1.V = V(contracts[0], contracts[1]);
                contract2.V = V(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Vega indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.V;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `V` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
ivModel	OptionPricingModelType	The Option pricing model to use to estimate the IV when calculating Vega. If you don't provide a value, the default value is to match the optionModel parameter.	null

For more information about the V method, see Using V Indicator .

Manual Indicators

To create a manual indicator for vega, call the Vega constructor.

C#

```
public class ManualVegaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
```

```
                var contract1 = AddOptionContract(contracts[0]);
                var contract2 = AddOptionContract(contracts[1]);

                // Create and save the manual Vega indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Vega = new Vega(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Vega;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                );

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Vega indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Vega` constructor, see Using V Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the

`SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

```
// Example: Average IV of the call-put pair.
vegaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Theta

Theta, Θ, is the rate of change of the value of the Option with respect to the passage of time. It is also known to as the time decay of an Option. For more information about theta, see Theta .

Automatic Indicators

To create an automatic indicator for theta, call the `QCAlgorithm.T` method with the Option contract `Symbol` object(s).

```
public class AutomaticThetaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]) as dynamic;
                var contract2 = AddOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Theta indicators.
                contract1.T = T(contracts[0], contracts[1]);
                contract2.T = T(contracts[1], contracts[0]);
```

```
                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Theta indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.T;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `T` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating theta. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `T` method, see Using T Indicator .

Manual Indicators

To create a manual indicator for theta, call the `Theta` constructor.

C#

```
public class ManualThetaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open
```

```
        // Set up a scheduled event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]);
                var contract2 = AddOptionContract(contracts[1]);

                // Create and save the manual Theta indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Theta = new Theta(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Theta;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                );

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
```

```
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Theta indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Theta` constructor, see Using T Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

C#

```
// Example: Average IV of the call-put pair.
thetaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Rho

Rho, ρ , is the rate of change of the value of a derivative with respect to the interest rate . It is usually small and not a big issue in practice unless the Option is deep in-the-money and has a long horizon. In this case, the interest rate matters because you need to discount a larger cash flow over a longer horizon. For more information about rho, see Rho .

Automatic Indicators

To create an automatic indicator for rho, call the `QCAlgorithm.R` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticRhoIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);

        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `R` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
ivModel	OptionPricingModelType	The Option pricing model to use to estimate the IV when calculating rho If you don't provide a value, the default value is to match the optionModel parameter.	null

For more information about the R method, see Using R Indicator .

Manual Indicators

To create a manual indicator for rho, call the Rho constructor.

C#

```
public class ManualRhoIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddOptionContract(contracts[0]);
```

```
                var contract2 = AddOptionContract(contracts[1]);

                // Create and save the manual Rho indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Rho = new Rho(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Rho;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                );

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Rho indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Rho` constructor, see Using R Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the

`SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

```C#
// Example: Average IV of the call-put pair.
rhoIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Equity Options

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the Equity Option market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the Equity Option market:

Weekday	**Time (America/New York)**
Monday	09:30:00 to 16:00:00
Tuesday	09:30:00 to 16:00:00
Wednesday	09:30:00 to 16:00:00
Thursday	09:30:00 to 16:00:00
Friday	09:30:00 to 16:00:00

Post-market Hours

Post-market trading is not available.

Holidays

LEAN uses the trading holidays from the NYSE website.

The following table shows the dates of holidays for the Equity Option market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25

Crypto

Requesting Data

Introduction

Request Crypto data in your algorithm to receive a feed of asset prices in the `OnData` method. For more information about the specific datasets we use for backtests, see the CoinAPI datasets . To trade Crypto live, you can use the QuantConnect data provider .

Create Subscriptions

To create a Crypto subscription, in the `Initialize` method, call the `AddCrypto` method. The `AddCrypto` method returns a `Crypto` object, which contains a `Symbol` property. Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
_symbol = AddCrypto("BTCUSD").Symbol;
```

The `AddCrypto` method creates a subscription for a single Crypto asset and adds it to your user-defined universe. To create a dynamic universe of Crypto assets, add a Crypto universe .

To view the supported assets, see the CoinAPI datasets .

Fungible Assets

Fungible assets are assets that are interchangeable with each other. For example, every Bitcoin is effectively identical to every other Bitcoin. In contrast, non-fungible tokens (NFTs) are non-fungible because each one is unique. An example of an NFT is the Bored Ape Yacht Club collection. LEAN doesn't currently support trading NFTs.

Resolutions

The following table shows the available resolutions and data formats for Crypto subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Crypto subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddCrypto` method.

```
_symbol = AddCrypto("BTCUSD", Resolution.Daily).Symbol;
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Crypto:

To set the market for a security, pass a `market` argument to the `AddCrypto` method.

```
_symbol = AddCrypto("BTCUSD", market: Market.Coinbase).Symbol;
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
_symbol = AddCrypto("BTCUSD", fillForward: false).Symbol;
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The amount of leverage available to you depends on the brokerage you use. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `AddCrypto` method.

```
_symbol = AddCrypto("BTCUSD", leverage: 3).Symbol;
```

For more information about the leverage each brokerage provides, see Brokerages .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `AddCrypto` method returns a `Crypto` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Crypto data.

Example 1: Initialize Binance Algorithms

The following algorithm requests data for the BTC/USDT and ETH/USDT Crypto pairs on Binance. The Binance brokerage model provides realistic fee and fill modeling for the backtest. Since the quote currency of both pairs is USDT, set the account

currency to USDT instead of USD. Otherwise, some order will fail since the brokerage doesn't automatically convert USD to USDT for you.

```C#
public class CryptoExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the brokerage and account type for accurate fee and margin behavior.
        SetBrokerageModel(BrokerageName.Binance, AccountType.Cash);

        // In some Crypto brokerages, USD is not a valid currency to trade.
        // Therefore, set the account currency to USDT and add the starting cash.
        SetAccountCurrency("USDT", 100000);

        // Subscribe to the Crypto pairs.
        // You don't need to specify the market because the Binance brokerage model already does that.
        AddCrypto("BTCUSDT");
        AddCrypto("ETHUSDT");
    }
}
```

Crypto

Handling Data

Introduction

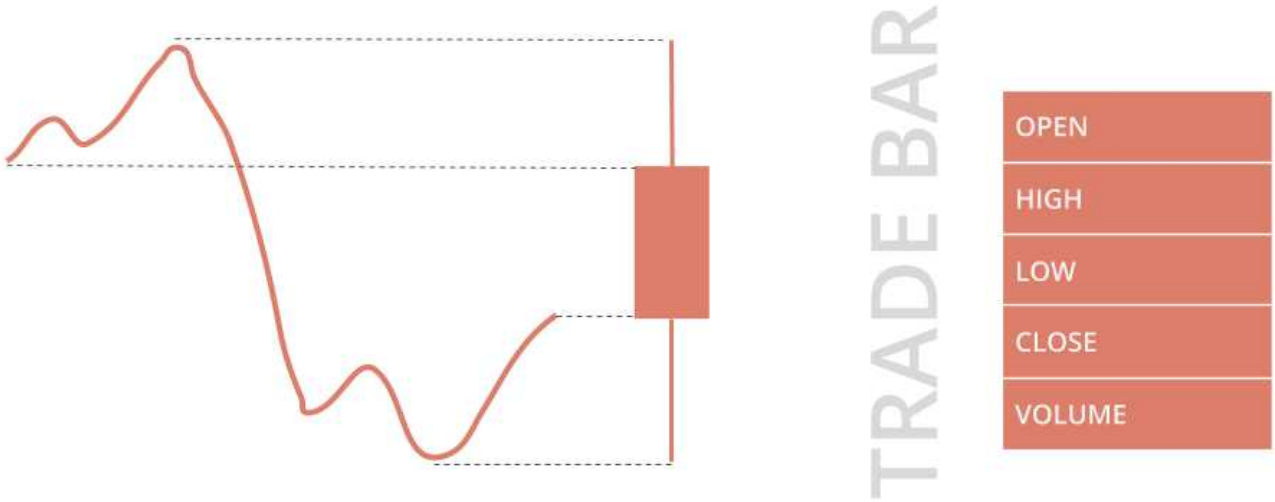
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `TradeBar` argument, it only receives `TradeBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Crypto data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the security `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in TradeBars object
    if (slice.Bars.ContainsKey(_symbol))
    {
        // Obtain the mapped TradeBar of the symbol
        var tradeBar = slice.Bars[_symbol];
    }
}
```

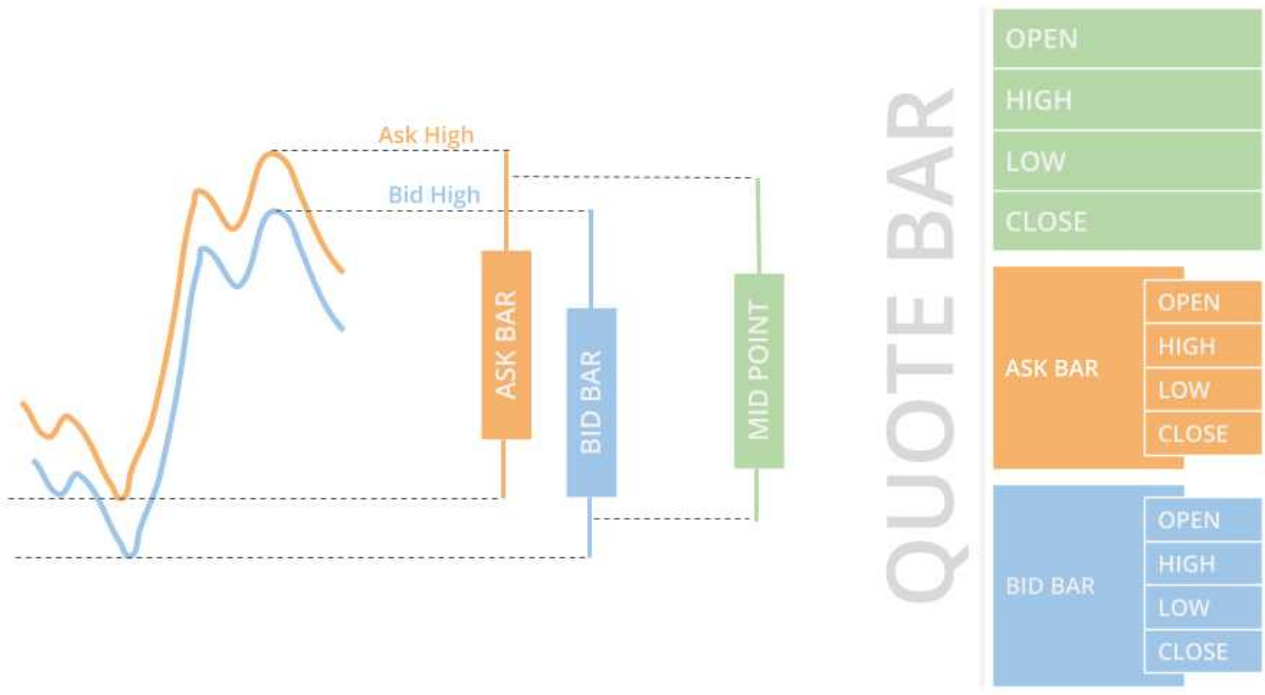
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-TradeBar key-value pairs
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        var closePrice = tradeBar.Close;
    }
}
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `Symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not

contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_symbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price.

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the

`List<Tick>` objects.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Crypto data.

Example 1: Dollar Cost Average BTC

Dollar cost averaging (DCA) is where you consistently invest a fixed dollar amount into an asset on a regular basis (for example, monthly), regardless of the asset's price. It can reduce the volatility in your PnL due to slowly increasing the position size over time. The following algorithm demonstrates a DCA investment into BTC. It buys $3,000 USD worth of BTC every midnight for 30 consecutive days.

```C#
public class CryptoExampleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    // Set a day count variable for counting the days of the DCA trade.
    private int _dayCount = 0;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the brokerage and account type to match your brokerage environment for accurate fee and margin
behavior.
        SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Cash);
        // For daily DCA purchases, subscribe to daily asset data.
        _symbol = AddCrypto("BTCUSD", Resolution.Daily).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // If you haven't invested for 30 consecutive days yet, continue buying.
        if (slice.Bars.ContainsKey(_symbol) && _dayCount++ < 30)
        {
            // Calculate the order size for $3,000 USD using the current price.
            var quantity = 3000m / slice.Bars[_symbol].Close;
            // Round down to observe the lot size.
            var lotSize = Securities[_symbol].SymbolProperties.LotSize;
            quantity = (long)(quantity / lotSize) * lotSize;
            if (quantity != 0)
            {
                MarketOrder(_symbol, quantity);
            }
        }
    }
}
```

Example 2: Inter-Market Spread

There is always a small discrepancy in the price of the same Crypto pair trading on different exchanges. Although you can't currently live trade on algorithm with multiple brokerages, you can study the cointegration pattern and implement 2 live nodes to capture the arbitrage opportunity. The following algorithm demonstrates how to obtain the spread between the BTCUSD pair on Kraken and on Coinbase:

```C#
public class CryptoExampleAlgorithm : QCAlgorithm
{
    private Symbol _krakenBtc;
    private Symbol _coinbaseBtc;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Subscribe to BTC/USD on 2 different exchanges.
        _krakenBtc = AddCrypto("BTCUSD", market: Market.Kraken).Symbol;
        _coinbaseBtc = AddCrypto("BTCUSD", market: Market.Coinbase).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Only calculate the spread if the prices on both exchanges are in the current Slice.
        if (slice.Bars.ContainsKey(_krakenBtc) && slice.Bars.ContainsKey(_coinbaseBtc))
        {
            // Calculate the spread between the 2 exchanges, making sure the comparison is always in the same
direction.
            var spread = slice.Bars[_krakenBtc].Close - slice.Bars[_coinbaseBtc].Close;
        }
    }
}
```

Crypto

Holdings

Introduction

Crypto holdings require special consideration because not all brokerages track your positions in each currency pair.

Cash vs Margin Brokerage Accounts

Some of the Crypto brokerages integrated into QuantConnect support cash and margin accounts while some only support cash accounts. If you want to short Crypto assets or use leverage, you need a margin account. Follow these steps to view which account types each brokerage supports:

1. Open the brokerage guides .
2. Click a Crypto brokerage.
3. Scroll down to the Account Types section.

Virtual Pairs

All fiat and Crypto currencies are individual assets. When you buy a pair like BTCUSD, you trade USD for BTC. In this case, LEAN removes some USD from your portfolio cashbook and adds some BTC. The virtual pair BTCUSD represents your position in that trade, but the virtual pair doesn't actually exist. It simply represents an open trade. If you call the Liquidate method with the `Symbol` of a virtual pair, the method only liquidates the quantity in your virtual pair. For more information about liquidating Crypto postitions, see Crypto Trades .

Access Cypto Holdings

The `CashBook` stores the quantity of your Crypto holdings. To access your Crypto holdings, index the `CashBook` with the currency ticker. The values of the `CashBook` dictionary are `Cash` objects, which have the following properties:

```
C#
var btcQuantity = Portfolio.CashBook["BTC"].Amount;
var btcValue = Portfolio.CashBook["BTC"].ValueInAccountCurrency;
```

To access the virtual pair of your Crypto trades, index the `Portfolio` object with the pair `Symbol` .

```
C#
var securityHolding = Portfolio[_btcUsdSymbol];
```

Stateful Redeployments

When you make a trade inside of a running algorithm, LEAN tracks the virtual position state for you, but it won't survive between deployments. Some brokerages save your virtual pairs, so you can load them into your algorithm when you stop and redeploy it. Depending on the brokerage you select, you may be able to manually add virtual pairs when you deploy live algorithms with the LEAN CLI or cloud deployment wizard .

Examples

The following examples demonstrate some common practices for crypto holdings.

Example 1: ETH-BTC Proxy Trading

The following algorithm trades trend-following of the ETHBTC crypto pair using a 20-day EMA indicator. To reduce friction (e.g. slippage), we trade the more liquid and popular BTCUSDT and ETHUSDT pair instead. For example, if ETHBTC is above EMA (uptrend), we sell all BTCUSDT holdings and buy ETHUSDT with the same USDT value, going flat on BTC while holding ETH.

C#

```
public class CryptoHoldingsAlgorithm : QCAlgorithm
{
    private Symbol _btcusdt, _ethusdt, _ethbtc;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetAccountCurrency("USDT", 1000000m);

        // We would like to trade the EMA cross between 2 popular cryptos: BTC & ETH,
        // so request ETHBTC data to find trading opportunities.
        _ethbtc = AddCrypto("ETHBTC", Resolution.Daily, market: Market.Coinbase).Symbol;
        // Trade through BTCUSDT & ETHUSDT, though, since stable coin trades have lower friction costs and higher
liquidity.
        var btcusdt = AddCrypto("BTCUSDT", Resolution.Daily, market: Market.Coinbase);
        var ethusdt = AddCrypto("ETHUSDT", Resolution.Daily, market: Market.Coinbase);
        _btcusdt = btcusdt.Symbol;
        _ethusdt = ethusdt.Symbol;

        // Simulate an account with various crypto cash through holdings.
        btcusdt.Holdings.SetHoldings(btcusdt.Price, 5m);
        btcusdt.BaseCurrency.AddAmount(5m);
        ethusdt.Holdings.SetHoldings(ethusdt.Price, 22.5m);
        ethusdt.BaseCurrency.AddAmount(22.5m);

        // Add automatic updating of the EMA indicator for trend trade signal emission.
        _ema = EMA(_ethbtc, 20, Resolution.Daily);
        // Warm up the indicator for its readiness usage immediately.
        WarmUpIndicator(_ethbtc, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_ethbtc, out var bar) && _ema.IsReady &&
            slice.Bars.TryGetValue(_btcusdt, out var btc) && slice.Bars.TryGetValue(_ethusdt, out var eth))
        {
            var ema = _ema.Current.Value;
            var btcHoldings = Portfolio.CashBook["BTC"].Amount;
            var ethHoldings = Portfolio.CashBook["ETH"].Amount;

            // ETHBTC's current price is higher than EMA, suggesting an uptrend.
            if (bar.Close > ema && !Portfolio[_btcusdt].IsShort)
            {
                // To follow the up trend of ETHBTC, sell ALL BTCUSDT and buy ETHUSDT with the same value.
                if (btcHoldings > 0)
                {
                    var btcValue = btcHoldings * btc.Close;
                    MarketOrder(_btcusdt, -btcHoldings);
                    var ethSize = btcValue / eth.Close;
                    MarketOrder(_ethusdt, ethSize);
                }
            }
            // ETHBTC's current price is below the EMA, suggesting a downtrend.
            else if (bar.Close < ema && !Portfolio[_btcusdt].IsLong)
            {
                // To follow the downtrend of ETHBTC, sell ALL ETHUSDT and buy BTCUSDT with the same value.
                if (ethHoldings > 0)
                {
                    var ethValue = ethHoldings * eth.Close;
                    MarketOrder(_ethusdt, -ethHoldings);
                    var btcSize = ethValue / btc.Close;
                    MarketOrder(_btcusdt, btcSize);
                }
            }
        }
    }
}
```

Crypto

Market Hours

Introduction

The Crypto markets are open 24/7. There are no pre-market hours, post-market hours, holidays, late opens, or early closes.

Asset Classes

Crypto Futures

Crypto Perpetual Futures are derivative financial contracts that obligate parties to buy or sell an asset at an unspecified future date.

Crypto Futures

Requesting Data

Introduction

Request Crypto Futures data in your algorithm to receive a feed of asset prices in the `OnData` method. For more information about the specific datasets we use for backtests, see the Binance Crypto Future Price Data dataset listing . To trade Crypto Futures live, you can use the QuantConnect data provider .

Create Subscriptions

To create a Crypto Futures subscription, in the `Initialize` method, call the `AddCryptoFuture` method. The `AddCryptoFuture` method returns a `CryptoFuture` object, which contains a `Symbol` property. Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
_symbol = AddCryptoFuture("BTCUSD").Symbol;
```

The `AddCryptoFuture` method creates a subscription for a single Crypto Futures asset and adds it to your user-defined universe.

To view the supported assets in the Crypto Futures dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Crypto Futures contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Crypto Futures subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddCryptoFuture` method.

```
C#
_symbol = AddCryptoFuture("BTCUSD", Resolution.Daily).Symbol;
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Cryptofuture:

```
_symbol = AddCryptoFuture("BTCUSD", market: Market.Binance).Symbol;
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
_symbol = AddCryptoFuture("BTCUSD", fillForward: false).Symbol;
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The amount of leverage available to you depends on the brokerage you use. To change the amount of leverage you can use for a security, pass a `leverage` argument to the `AddCryptoFuture` method.

```
_symbol = AddCryptoFuture("BTCUSD", leverage: 3).Symbol;
```

For more information about the leverage each brokerage provides, see Brokerages .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `AddCryptoFuture` method returns a `CryptoFuture` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Crypto Futures data.

Example 1: Respect Lot Sizes

Like Futures, Crypto Futures contracts have a fixed discrete lot size to trade instead of fractional like spot Crypto pairs. The following algorithm demonstrates how to place orders that respect the lot size to avoid rounding errors.

C#

```
public class CryptoFutureAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set brokerage and account type to match your brokerage environment for accurate fee and margin behavior.
        SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);
        // In the Binance brokerage, you can't trade with USD.
        // Set the account currency as USDT and add the starting cash.
        SetAccountCurrency("USDT", 100000);
        // Subscribe to the BTCUSDT perpetual Future contract.
        _symbol = AddCryptoFuture("BTCUSDT").Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Only place orders when market is open since market on open orders aren't supported.
        if (!Portfolio.Invested && IsMarketOpen(_symbol))
        {
            // Get the lot size from the symbol properties. Placing an order that respects the lot size
            // ensures the order is valid and allows accurate profit and risk calculations for the whole portfolio.
            var lotSize = Securities[_symbol].SymbolProperties.LotSize;
            // This example demonstrates an initial desired order size of 2.5 contracts, which will be rounded
            // to 2 contracts since the lot size is 1.
            var quantity = Convert.ToDecimal(Math.Floor(2.5 / (double)lotSize)) * lotSize;
            MarketOrder(_symbol, quantity);
        }
    }
}
```

Crypto Futures

Handling Data

Introduction

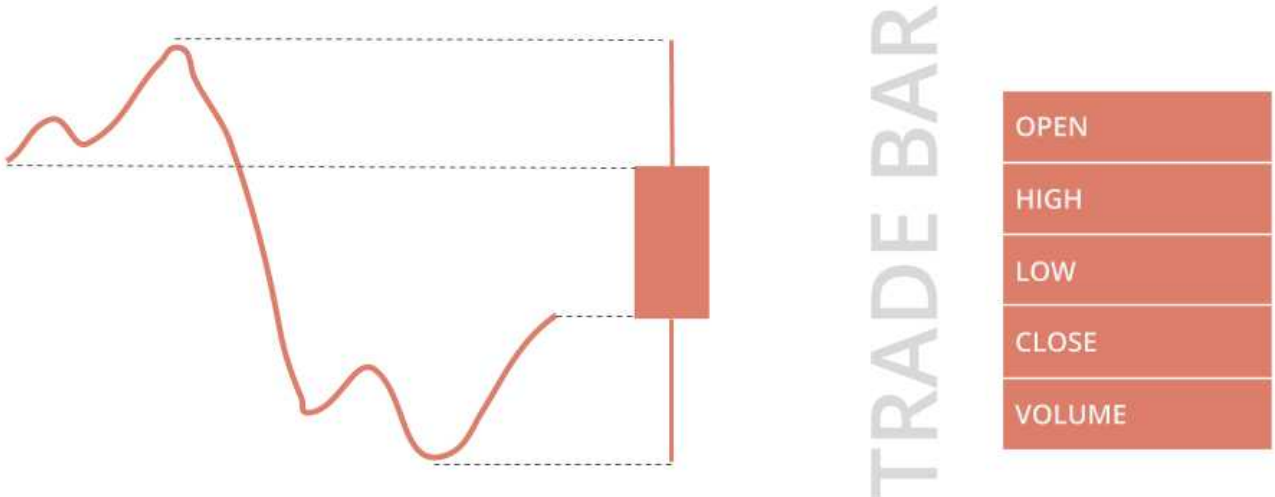
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `TradeBar` argument, it only receives `TradeBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the security ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Crypto Futures data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the security `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in TradeBars object
    if (slice.Bars.ContainsKey(_symbol))
    {
        // Obtain the mapped TradeBar of the symbol
        var tradeBar = slice.Bars[_symbol];
    }
}
```

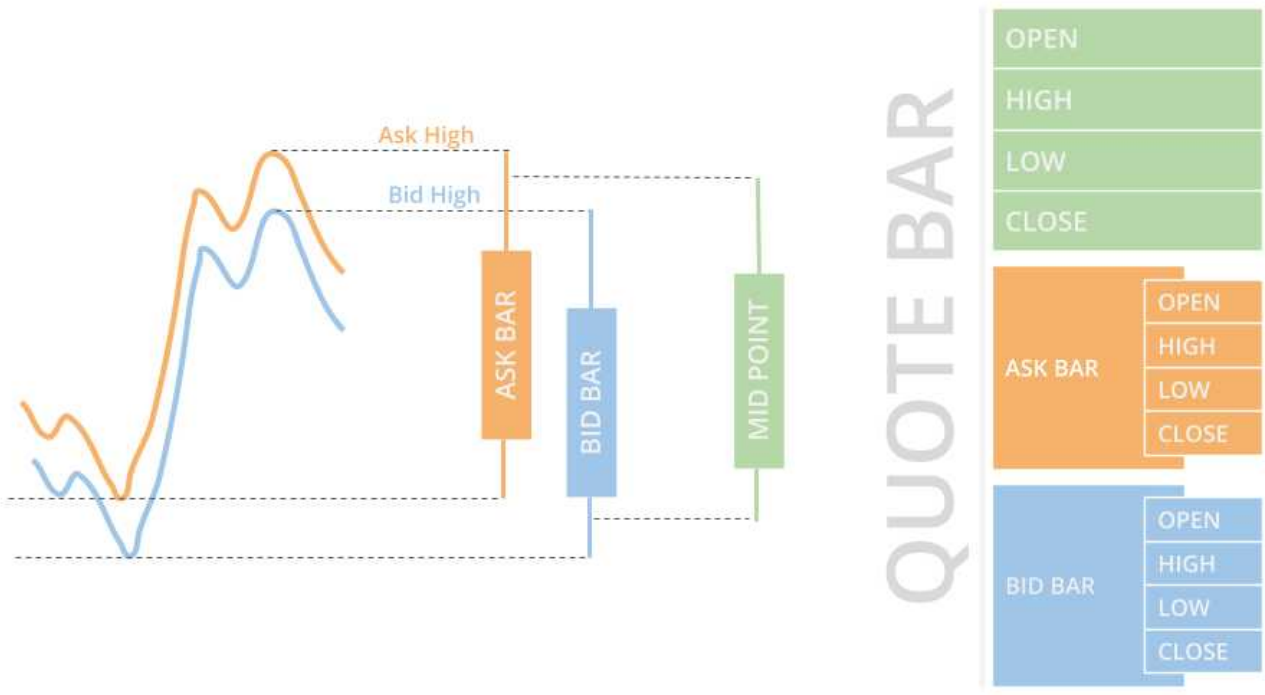
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-TradeBar key-value pairs
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        var closePrice = tradeBar.Close;
    }
}
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the security `Symbol` . If the security doesn't actively get quotes or you are in the same time step as when you added the security subscription, the `Slice` may not

contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_symbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the security. A quote tick is an offer to buy or sell the security at a specific price.

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the security doesn't actively trade or you are in the same time step as when you added the security subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your security before you index the `Slice` with the security `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the

`List<Tick>` objects.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Margin Interest Rates

`MarginInterestRate` objects contain the margin interest rate, which is a cost associated with trading on margin. To get the `MarginInterestRate` objects in the `Slice` , index the `MarginInterestRates` property of the `Slice` with the Crypto Future `Symbol` . The `MarginInterestRates` property of the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the property contains data for your Crypto Future before you index it with the Crypto Future `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    if (slice.MarginInterestRates.TryGetValue(_symbol, out var marginInterestRate))
    {
        var interestRate = marginInterestRate.InterestRate;
    }
}
```

You can also iterate through the `MarginInterestRates` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `MarginInterestRate` objects.

```
C#
public override void OnData(Slice slice)
{
    foreach (var (symbol, marginInterestRate) in slice.MarginInterestRates)
    {
        var interestRate = marginInterestRate.InterestRate;
    }
}
```

`MarginInterestRate` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Crypto Futures data.

Example 1: Adjust Holdings on Margin Payments

Perpetual futures have a mechanism called funding , where if you're holding a position at certain times (the funding timestamp), you might have to pay or receive funding based on the difference between the perpetual contract price and the spot price. This

example demonstrates how to adjust your position in Crypto Future based on the funding rate. The funding is settled in the quote currency, which is USDT in this case. When you receive USDT, the algorithm increases its position size in BTCUSDT. When you pay USDT, the algorithm decreases its position size.

```C#
public class CryptoFutureAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private decimal _lotSize;
    private int _day = -1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set brokerage and account type to match your brokerage environment for accurate fee and margin behavior.
        SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);
        // In the Binance brokerage, you can't trade with USD.
        // Set the account currency as USDT and add the starting cash.
        SetAccountCurrency("USDT", 1000000);
        // Subscribe to the BTCUSDT perpetual Future contract.
        var btcusdt = AddCryptoFuture("BTCUSDT");
        _symbol = btcusdt.Symbol;
        // Save the lot size to avoid order errors.
        _lotSize = btcusdt.SymbolProperties.LotSize;
        // Set the starting BTC balance to 10.
        btcusdt.BaseCurrency.SetAmount(10);
    }

    public override void OnData(Slice slice)
    {
        // Only place orders when the market is open since market on open orders aren't supported.
        if (!Portfolio.Invested && IsMarketOpen(_symbol))
        {
            // Open a long position in the perpetual Crypto Future.
            MarketOrder(_symbol, 10);
        }
        // Only run the following logic once per day.
        if (_day == Time.Day)
        {
            return;
        }
        // Get the current margin interest rate.
        MarginInterestRate interestRate;
        if (!slice.MarginInterestRates.TryGetValue(_symbol, out interestRate))
        {
            return;
        }
        // Calculate the funding payment.
        var holding = Portfolio[_symbol];
        var positionValue = holding.GetQuantityValue(holding.Quantity).Amount;
        var funding = interestRate.InterestRate * positionValue / holding.Price;
        // Increase/decrease the position size based on the funding payment.
        var quantity = -(int)(funding / _lotSize) * _lotSize;
        if (quantity != 0)
        {
            MarketOrder(_symbol, quantity);
            // Plot the portfolio state.
            Plot("CashBook", "USDT", Portfolio.CashBook["USDT"].Amount);
            Plot("CashBook", "BTC", Portfolio.CashBook["BTC"].Amount);
            Plot("Quantity", "BTCUSDT", Portfolio[_symbol].Quantity);
        }
        _day = Time.Day;
    }
}
```

Example 2: Future-Spot Arbitrage

Long-short arbitrage involves simultaneously trading BTCUSDT in the spot market and BTCUSDT Futures with the same size but in the opposite direction. The following algorithm monitors the spread between these markets. If the spot price exceeds the Future price by a threshold, it shorts the spot market and buys the Future contract (and vice vera for the other way around), assuming their discrepancies will be wiped out within a short period due to market efficiency. It closes the positions after the

spread inverts.

C#

```
public class CryptoFutureArbitrageAlgorithm : QCAlgorithm
{
    private Crypto _spot;
    private CryptoFuture _future;
    private decimal _multiplier;
    private decimal _threshold = 1.005m;  // 0.5%

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set brokerage and account type to match your brokerage
        // environment for accurate fee and margin behavior.
        SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);
        // In the Binance brokerage, you can't trade with USD.
        // Set the account currency to USDT and add the starting cash.
        SetAccountCurrency("USDT", 50000000);
        // Add the BTCUSDT spot and Futures markets.
        _spot = AddCrypto("BTCUSDT", fillForward: false, market: Market.Binance);
        _future = AddCryptoFuture("BTCUSDT", fillForward: false, market: Market.Binance);
        _multiplier = _future.SymbolProperties.ContractMultiplier;
    }

    public override void OnData(Slice slice)
    {
        // Wait for there to be a TradeBar for each asset, so we know
        // the prices are up-to-date.
        foreach (var security in new List<Security>() {_spot, _future})
            if (!slice.Bars.ContainsKey(security.Symbol)) return;
        var spot = _spot.Price;
        var future = _future.Price;
        // Buy low sell high: If one's price is above another by the
        // set threshold, sell it and buy the other security. The
        // threshold ensures there is enough profit potential to overcome
        // the fees and slippage. Make sure to equalize the actual order
        // size with the contract multiplier.
        if (!_spot.Invested)
        {
            if (spot >= future * _threshold)
            {
                Enter(-1, 1);
            }
            else if (future >= spot * _threshold)
            {
                Enter(1, -1);
            }
            return;
        }
        // When the mispricing converges, close both positions to earn
        // the spread.
        if ((_spot.Holdings.IsShort && spot < future) ||
            (_spot.Holdings.IsLong && spot > future))
        {
            // Liquidate the spot position.
            var quantity = Math.Min(_spot.Holdings.Quantity, _spot.BaseCurrency.Amount);
            if (quantity < 0m)
            {
                quantity /= (1 - 0.001m);  // To cover the taker fees.
            }
            var lotSize = _spot.SymbolProperties.LotSize;
            quantity = -Math.Round(quantity / lotSize) * lotSize;
            MarketOrder(_spot.Symbol, quantity, tag: "Liquidate Spot");
            // Liquidate the Future position.
            Liquidate(_future.Symbol, tag: "Liquidate Future");
        }
    }

    private void Enter(int spotSign, int futureSign)
    {
        var quantity = CalculateOrderQuantity(_future.Symbol, 0.5d);
        if (quantity == 0) return;
        // Enter the spot position.
        MarketOrder(_spot.Symbol, spotSign * quantity * _multiplier, tag: "Spot");
        // Enter the Future position.
        MarketOrder(_future.Symbol, futureSign * quantity, tag: "Future");
    }
}
```

Crypto Futures

Market Hours

Introduction

The Crypto Futures markets are open 24/7. There are no pre-market hours, post-market hours, holidays, late opens, or early closes.

Asset Classes

Forex

Forex markets are for trading foreign currencies.

Forex

Requesting Data

Introduction

Request Forex data in your algorithm to receive a feed of exchange rates in the `OnData` method. For more information about the specific dataset we use for backtests, see the FOREX dataset listing . To trade Forex live, you can use the QuantConnect data provider .

Create Subscriptions

To create a Forex pair subscription, in the `Initialize` method, call the `AddForex` method. The `AddForex` method returns a `Forex` object, which contains a `Symbol` property. Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
_symbol = AddForex("EURUSD").Symbol;
```

To view the supported Forex pairs, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Forex subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				✓
`Second`		✓		
`Minute`		✓		
`Hour`		✓		
`Daily`		✓		

The default resolution for Forex subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddForex` method.

```
C#
_symbol = AddForex("EURUSD", Resolution.Daily).Symbol;
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Forex pairs is `Market.Oanda` , so you don't need to pass a `market` argument to the `AddForex` method.

```
_symbol = AddForex("EURUSD", market: Market.Oanda).Symbol;
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
_symbol = AddForex("EURUSD", fillForward: false).Symbol;
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The OANDA brokerage let's you use up to 50x leverage on margin accounts. To change the amount of leverage you can use for a Forex pair, pass a `leverage` argument to the `AddForex` method.

```
_symbol = AddForex("EURUSD", leverage: 35).Symbol;
```

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `AddForex` method returns a `Forex` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Forex data.

Example 1: Add All Forex Pairs

The following algorithm adds all the Forex pairs that trade on the OANDA exchange . To get all of the pairs from the Symbol Properties Database , call the `SymbolPropertiesDatabase.GetSymbolPropertiesList` method. Adding all of the pairs is particularly useful for spotting arbitrage opportunities among the pairs.

C#

```
public class ForexExampleAlgorithm : QCAlgorithm
{
    private List<Forex> _forexPairs;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Get all of the OANDA Forex pairs from the Symbol Properties Database.
        _forexPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(Market.Oanda, SecurityType.Forex)
            // Add all of the pairs. You don't need to specify the market because the Symbol object already does.
            .Select(x => AddForex(x.Key.Symbol, Resolution.Daily))
            .ToList();
    }
}
```

Forex

Handling Data

Introduction

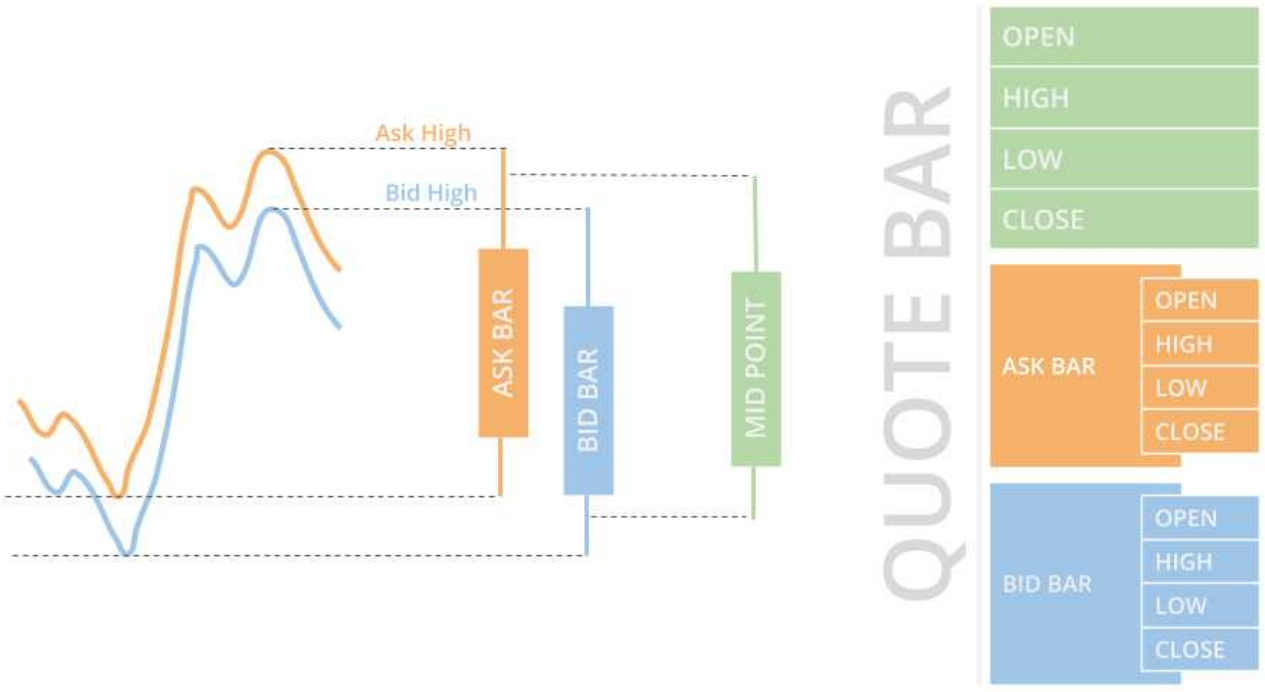
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `QuoteBar` argument, it only receives `QuoteBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `QuoteBars DataDictionary` is made up of `QuoteBar` objects. To access individual data points in the dictionary, you can index the dictionary with the Forex pair ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Forex data, see Resolutions .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the Forex pair `Symbol` . If the Forex pair doesn't actively get quotes or you are in the same time step as when you added the Forex pair subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your Forex pair before you index the

`Slice` with the Forex pair `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_symbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the Forex pair. A quote tick is an offer to buy or sell the Forex pair at a specific price.

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the Forex pair doesn't actively trade or you are in the same time step as when you added the Forex pair subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your Forex pair before you index the `Slice` with the Forex pair `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the

`List<Tick>` objects.

```
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Forex data.

Example 1: Trade the USDJPY Spread

USDJPY is a Forex pair where the reserve banks of the base currency and quote currency act at different time, which results in a 12-hour period of seasonal peak volume. To reduce slippage costs, place orders when bid-ask spread is relatively low. The following algorithm demonstrates how to utilize the Minimum indicator to check for a narrow spread.

```C#
public class ForexExampleAlgorithm : QCAlgorithm
{
    private dynamic _forex;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add the USDJPY trading pair.
        _forex = AddForex("USDJPY");
        // Create a Minimum indicator to track the lowest bid-ask spread for the past 12 hours.
        _forex.SpreadLow = new Minimum(12*60);
        // Warm up the indicator so it's immediately ready to use.
        WarmUpIndicator<IndicatorDataPoint>(_forex.Symbol, _forex.SpreadLow);
    }

    public override void OnData(Slice slice)
    {
        // Ensure we have quote data for USDJPY in the current slice.
        if (!slice.QuoteBars.ContainsKey(_forex.Symbol))
        {
            return;
        }
        var quoteBar = slice.QuoteBars[_forex.Symbol];
        // Bid-ask spread = Ask price - Bid price
        var bidAskSpread = quoteBar.Ask.Close - quoteBar.Bid.Close;
        // Update the spread minimum indicator to calculate the lowest bid-ask spread over the last 12 hours.
        _forex.SpreadLow.Update(quoteBar.EndTime, bidAskSpread);

        // Trade if the current spread is the lowest bid-ask spread, since it is the most efficient,
        // liquid price with lowest slippage.
        if (!Portfolio.Invested && bidAskSpread == _forex.SpreadLow.Current.Value)
        {
            MarketOrder(_forex.Symbol, 1000);
        }

        // Plot the bid-ask spread to validate the minimum bid-ask spread calculation.
        Plot("Bid-Ask Spread", "spread", bidAskSpread);
    }
}
```

Example 2: 5-Minute EURUSD Trend Reversal

The following algorithm applies a mean reveral strategy to EURUSD. To smooth out the noise of minute resolution data, it consolidates the data into 5-minute bars and then calculates their 200-bar Exponential Moving Average (EMA). After every time the indicator updates, the algorithm checks for a trading opportuniity. When the current EURUSD price is below the EMA, it takes a long position. Otherwise, it takes a short position.

C#

```
public class ForexExampleAlgorithm : QCAlgorithm
{
    private dynamic _forex;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add EURUSD minute data.
        _forex = AddForex("EURUSD");
        // Create an EMA indicator to estimate the trend of EURUSD.
        _forex.ema = new ExponentialMovingAverage(200);
        // Attach an event handler to the indicator to track its updates.
        (_forex.ema as ExponentialMovingAverage).Updated += OnUpdated;
        // Create a consolidator that produces 5-minute quote bars to reduce reduce noise.
        var consolidator = new QuoteBarConsolidator(TimeSpan.FromMinutes(5));
        // Define the consolidator handler so it updates the EMA with the consoildated bars.
        consolidator.DataConsolidated += (_, bar) => _forex.ema.Update(bar.EndTime, bar.Close);
        // Warm up the indicator with historical data.
        foreach (var bar in History<QuoteBar>(_forex.Symbol, 1000))
        {
            consolidator.Update(bar);
        }
        // Subscribe the consolidator for automatic updates.
        SubscriptionManager.AddConsolidator(_forex.Symbol, consolidator);
    }

    private void OnUpdated(object sender, IndicatorDataPoint point)
    {
        // Wait until the indicator is ready and the Forex pair has a price.
        if (!_forex.ema.IsReady || _forex.Price == 0)
        {
            return;
        }
        // Rebalance the portfolio. If the current price is below the EMA, long. Otherwise, short.
        SetHoldings(_forex.Symbol, _forex.Price <= point.Value ? 0.5m : -0.5m);
    }
}
```

Example 3: New York Time Alignment

The following algorithm creates daily Forex bars that close at 4:30 PM Eastern Time (ET). This technique is helpful when you want to align the daily bars with the close of the New York.

C#

```
public class ForexExampleAlgorithm : QCAlgorithm
{
    private Symbol _forex;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);;
        // Add EURUSD minute data.
        _forex = AddForex("EURUSD", Resolution.Minute, Market.Oanda).Symbol;
        // Create a daily bar consolidator with a custom period (4:30 PM-4:30 PM Eastern Time).
        var consolidator = new QuoteBarConsolidator(ConsolidationPeriod);
        // Attach a consolidation handler to plot the consolidated bars.
        consolidator.DataConsolidated += (_, bar) => Plot("Consolidated Bar", "Close", bar.Close);
        // Subscribe the consolidator for automatic updates.
        SubscriptionManager.AddConsolidator(_forex, consolidator);
    }

    private CalendarInfo ConsolidationPeriod(DateTime dt)
    {
        // Set the start time to be 4:30 PM of the previous day.
        var start = dt.Date.AddHours(16).AddMinutes(30);
        var period = TimeSpan.FromDays(1);
        if (dt.Hour < 17)
        {
            start = start - period;
        }
        // Set the period to 1 day to make daily bars.
        return new CalendarInfo(start, period);
    }
}
```

Forex

Market Hours

Introduction

This page shows the trading hours, holidays, and time zone of the Forex market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the Forex market:

Weekday	**Time (America/New York)**
Sunday	17:03:00 to 24:00:00
Monday	00:00:00 to 16:58:00, 17:03:00 to 24:00:00
Tuesday	00:00:00 to 16:58:00, 17:03:00 to 24:00:00
Wednesday	00:00:00 to 16:58:00, 17:03:00 to 24:00:00
Thursday	00:00:00 to 16:58:00, 17:03:00 to 24:00:00
Friday	00:00:00 to 16:58:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the Forex market:

Date (*yyyy-mm-dd*)				
2005-01-01	2010-01-01	2010-12-25	2011-01-01	2012-12-25
2013-01-01	2015-12-25	2016-01-01	2016-12-25	2017-01-01
2020-12-25	2021-01-01	2022-12-25	2022-12-26	2023-01-01
2023-01-02	2023-12-24	2023-12-31		

Early Closes

The following table shows the early closes for the Forex market:

Date (*yyyy-mm-dd*)	Time Of Market Close (America/New York)
2005-12-29	17:00:00
2005-12-30	17:00:00
2007-12-31	17:00:00
2008-12-31	17:00:00

2024-12-25	17:05:00
2025-01-01	17:05:00
2025-12-25	17:05:00
2026-01-01	17:05:00

Time Zone

The Forex market trades in the `America/New York` time zone.

Assets With Other Hours

The following list shows the pairs that have different trading periods than the overall Forex market:

- EURNZD
- GBPNZD
- NZDCAD
- NZDCHF
- NZDHKD
- NZDJPY
- NZDSGD
- NZDUSD

Market Hours

EURNZD

Introduction

This page shows the trading hours, holidays, and time zone of the EUR/NZD pair in the Forex market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the EUR/NZD pair in the Forex market:

Weekday	**Time (America/New York)**
Sunday	17:03:00 to 24:00:00
Monday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Tuesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Wednesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Thursday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Friday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the Forex market:

Date (*yyyy-mm-dd*)				
2005-01-01	2010-01-01	2010-12-25	2011-01-01	2012-12-25
2013-01-01	2015-12-25	2016-01-01	2016-12-25	2017-01-01
2020-12-25	2021-01-01	2022-12-25	2022-12-26	2023-01-01
2023-01-02	2023-12-24	2023-12-31		

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The EUR/NZD pair in the Forex market trades in the `America/New York` time zone.

Market Hours

GBPNZD

Introduction

This page shows the trading hours, holidays, and time zone of the GBP/NZD pair in the Forex market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the GBP/NZD pair in the Forex market:

Weekday	**Time (America/New York)**
Sunday	17:03:00 to 24:00:00
Monday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Tuesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Wednesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Thursday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Friday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the Forex market:

Date (*yyyy-mm-dd*)				
2005-01-01	2010-01-01	2010-12-25	2011-01-01	2012-12-25

Market Hours

NZDSGD

Introduction

This page shows the trading hours, holidays, and time zone of the NZD/SGD pair in the Forex market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the NZD/SGD pair in the Forex market:

Weekday	**Time (America/New York)**
Sunday	17:03:00 to 24:00:00
Monday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Tuesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Wednesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Thursday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Friday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the Forex market:

Date (*yyyy-mm-dd*)				
2005-01-01	2010-01-01	2010-12-25	2011-01-01	2012-12-25
2013-01-01	2015-12-25	2016-01-01	2016-12-25	2017-01-01
2020-12-25	2021-01-01	2022-12-25	2022-12-26	2023-01-01
2023-01-02	2023-12-24	2023-12-31		

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The NZD/SGD pair in the Forex market trades in the `America/New York` time zone.

Market Hours

NZDUSD

Introduction

This page shows the trading hours, holidays, and time zone of the NZD/USD pair in the Forex market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the NZD/USD pair in the Forex market:

Weekday	**Time (America/New York)**
Sunday	17:03:00 to 24:00:00
Monday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Tuesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Wednesday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Thursday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00, 17:03:00 to 24:00:00
Friday	00:00:00 to 12:58:00, 13:03:00 to 16:58:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the Forex market:

Date (*yyyy-mm-dd*)				
2005-01-01	2010-01-01	2010-12-25	2011-01-01	2012-12-25
2013-01-01	2015-12-25	2016-01-01	2016-12-25	2017-01-01
2020-12-25	2021-01-01	2022-12-25	2022-12-26	2023-01-01
2023-01-02	2023-12-24	2023-12-31		

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The NZD/USD pair in the Forex market trades in the `America/New York` time zone.

Asset Classes

Futures

A Futures contract is an agreement to buy or sell a particular commodity, asset, or security at a predetermined price at a specified time in the future.

Futures

Requesting Data

Request Futures data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Futures dataset listing . To trade Futures live, you can use the QuantConnect data provider or one of the brokerage data providers .

To request Futures data, call one of the following methods:

- `AddFuture` to add a basket of contracts for a single Future
- `AddFutureContract` to add individual contracts for an underlying Future

Request Continuous Contracts

`AddFuture`

Request and Filter All Contracts

`AddFuture`

Select Individual Contracts

`AddFutureContract`

Requesting Data

Universes

Introduction

The `AddFuture` method enables you to select a basket of Future contracts for an underlying Future. To form your universe of contracts, you can filter them down by their expiry. If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Future contracts, in the `Initialize` method, call the `AddFuture` method. This method returns an `Future` object, which has a `SetFilter` method you can call to filter the set of tradable contract down to just the contracts you want.

```C#
public class BasicFutureAlgorithm : QCAlgorithm
{
    private Future _future;
    public override void Initialize()
    {
        _future = AddFuture(
            Futures.Indices.SP500EMini,
            Resolution.Daily,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0
        );
        _future.SetFilter(0, 182);
    }

    public override void OnData(Slice data)
    {
        foreach (var (continuousSymbol, chain) in data.FuturesChains)
        {
            foreach (var (symbol, contract) in chain.Contracts)
            {
                var expiry = contract.Expiry;
            }
        }
    }
}
```

For more information about the `AddFuture` method, see Create Universes .

Continous Contracts

By default, LEAN only subscribes to the continuous Future contract. A continuous Future contract represents a series of separate contracts stitched together to form a continuous price. If you need a lot of historical data to warm up an indicator, apply the indicator to the continuous contract price series. The `Future` object has a `Symbol` property and a `Mapped` property. The price of the `Symbol` property is the adjusted price of the continuous contract. The price of the `Mapped` property is the raw price of the currently selected contract in the continuous contract series.

```
// Get the adjusted price of the continuous contract.
var adjustedPrice = Securities[_future.Symbol].Price;

// Get the raw price of the currently selected contract in the continuous contract series.
var rawPrice = Securities[_future.Mapped].Price;
```

The continuous Futures contract isn't a tradable security . You must place orders for a specific Futures contract. To access the currently selected contract in the continuous contract series, use the `Mapped` property of the `Future` object.

```
// Place a market order for the currently selected contract in the continuous contract series.
MarkerOrder(_future.Mapped, 1);
```

For more information, see Continous Contracts .

Filter by Contract Properties

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Future` object. The following table describes the available filter techniques:

`SetFilter(int minExpiry, int maxExpiry)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`SetFilter(Func<FutureFilterUniverse, FutureFilterUniverse> universeFunc)` Selects the contracts that a function selects.

```
// Select the contracts that expire within 182 days.
_future.SetFilter(0, 182);

// Select the front month contract.
_future.SetFilter(futureFilterUniverse => futureFilterUniverse.FrontMonth());
```

The following table describes the filter methods of the `FutureFilterUniverse` class:

`StandardsOnly()` Selects standard contracts
`FrontMonth()` Selects the front month contract
`BackMonths()` Selects the non-front month contracts
`BackMonth()` Selects the back month contracts
`Expiration(TimeSpan minExpiry, TimeSpan maxExpiry)` Selects contracts that expire within a range of dates relative to the current day
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects

The preceding methods return an `FutureFilterUniverse` , so you can chain the methods together.

```
// Select the front month standard contracts
_future.SetFilter(futureFilterUniverse => futureFilterUniverse.StandardsOnly().FrontMonth());
```

You can also define an isolated filter method.

```
// In Initialize
_future.SetFilter(Selector);

private FutureFilterUniverse Selector(FutureFilterUniverse futureFilterUniverse)
{
    return futureFilterUniverse.StandardsOnly().FrontMonth();
}
```

Default Filter

By default, LEAN doesn't add any contracts to the FuturesChain it passes to the `OnData` method.

Historical Data

To get historical data for a Futures universe, see Historical Data .

Examples

The following examples demonstrate some common practices for requesting Futures universe data.

Example 1: Rollover

Future contracts expire monthly or quarterly in most cases. Hence, if we hold Future position in month or quarter end, we must consider rolling over to the mapped contract. The following algorithm shows how to buy and roll over to the next front month Future contract. We make use of the universe selection filter to select the front month contract and order the next mapped contract during the previous one expires.

```
C#
public class FutureExampleAlgorithm : QCAlgorithm
{
    private Symbol _future;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price with last known price to ensure the contract price data is available for the limit order.
        Settings.SeedInitialPrices = true;
        var future = AddFuture(Futures.Indices.SP500EMini, extendedMarketHours: true);
        _future = future.Symbol;
        // We only want to hold position of the front month contract.
        future.SetFilter(u => u.FrontMonth());
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Liquidate if expired (or not being the front month contract anymore) and exit universe.
        foreach (var removed in changes.RemovedSecurities)
        {
            Liquidate(removed.Symbol);
        }

        foreach (var added in changes.AddedSecurities)
        {
            // Make sure the newly added contract is an actual mapped tradable contract.
            if (!added.Symbol.IsCanonical())
            {
                // Roll over by ordering the same quantity.
                // Use limit order since market on open order is not supported on Future and avoid extreme quote
filling.
                LimitOrder(added.Symbol, 1m, added.Price);
            }
        }
    }
}
```

Example 2: Continuous Future Indicator

One of the major applications of Continuous Futures is to obtain a smooth price series to feed into indicators. This technique ensures the indicator gets the price data that is comparable to the current contract in the continuous contract series. This example demonstrates a Exponential Moving Average crossover strategy based on the continuous ES contract data.

C#

```
public class FutureEMACrossAlgorithm : QCAlgorithm
{
    private Future _future;
    private decimal _threshold = 0.01m;  // 1% above/below the EMA.

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        // Seed the price of each asset with its last known price to
        // avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Use backward ratio normalization for the continuous contract
        // so the indicator receives a smooth price series.
        _future = AddFuture(
            Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio
        );
        // Only add the front-month contract.
        _future.SetFilter(u => u.FrontMonth());
        // Create a 252-day EMA indicator as a trend estimator.
        ((dynamic)_future).ema = EMA(_future.Symbol, 252, Resolution.Daily);
        // Warm up the EMA indicator to so we can trade right away.
        WarmUpIndicator(_future.Symbol, _future.Get<ExponentialMovingAverage>("ema"));
    }

    public override void OnData(Slice slice)
    {
        // Ensure the TradeBar data is available for the Future before
        // placing trades.
        if (!slice.Bars.TryGetValue(_future.Symbol, out var bar))
        {
            return;
        }
        // Buy the mapped contract if the trend is estimated to go up
        // (price above the EMA).
        var ema = _future.Get<ExponentialMovingAverage>("ema");
        if (bar.Close >= ema * (1 + _threshold))
        {
            SetHoldings(_future.Mapped, 0.1m);
        }
        // Short the mapped contract if the trend is estimated to go down
        // (price below the EMA).
        else if (bar.Close <= ema * (1 - _threshold))
        {
            SetHoldings(_future.Mapped, -0.1m);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Liquidate the contract when it is no longer the front-month
        // contract (expired).
        foreach (var contract in changes.RemovedSecurities)
        {
            Liquidate(contract.Symbol);
        }
    }
}
```

Example 3: Contango

In Future trading, contango refers to the far-to-expiry Future contract price is higher than the spot price due to various reasons, such as storage fee and insurance of the commodities. The following example shows a contango trading by shorting the far contract that the price is above a threshold compared to the front month contract price and buying the front month contract to earn the premium in between.

C#

```
public class FutureExampleAlgorithm : QCAlgorithm
{
    private Symbol _future;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add Gold Futures.
        var future = AddFuture(Futures.Metals.Gold);
        _future = future.Symbol;
        // Limit the expiration to within 6 months, as the longer the expiration, the higher the price uncertainty.
        future.SetFilter((u) => u.Expiration(0, 183));
    }

    public override void OnData(Slice slice)
    {
        // Get Future chain only for the selected Future contract.
        if (!Portfolio.Invested && slice.FutureChains.TryGetValue(_future, out var chain))
        {
            // It takes 2 contracts with different expiries to form a horizontal spread arbitration to earn price
difference in contango.
            if (chain.Count() < 2) return;
            var farContract = chain.MaxBy(x => x.Expiry);
            var nearContract = chain.MinBy(x => x.Expiry);

            // Check if the far contract price is 1% higher than the near one.
            // If so, short the far contract and buy the near one to earn the horizontal spread premium.
            if (farContract.BidPrice >= nearContract.AskPrice * 1.01m)
            {
                MarketOrder(farContract.Symbol, -1);
                MarketOrder(nearContract.Symbol, 1);
            }
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Liquidate if expired (or not being the front month contract anymore) and exit universe.
        foreach (var removed in changes.RemovedSecurities)
        {
            Liquidate();
        }
    }
}
```

Requesting Data

Individual Contracts

Introduction

The `AddFutureContract` method enables you to add an individual Future contract to your algorithm. To check which contracts are currently available to add to your algorithm, call the `FuturesChain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to a Future contract, you must have the underlying Future `Symbol` to get the contract `Symbol` .

```
C#
public class BasicFutureAlgorithm : QCAlgorithm
{
    private Symbol _continuous, _contractSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _continuous = AddFuture(Futures.Indices.SP500EMini).Symbol;
    }

    public override void OnData(Slice data)
    {
        if (_contractSymbol == null)
        {
            _contractSymbol = FuturesChain(_continuous).First().Symbol;
            AddFutureContract(_contractSymbol);
        }
    }
}
```

Get Contract Symbols

To subscribe to a Future contract, you need the contract `Symbol` . The preferred method to getting Future contract `Symbol` objects is to use the `FuturesChain` method. This method returns a `FuturesChain` object, which represent an entire chain of Option contracts for a single underlying security. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
C#
// Select the first contract in the chain, which is the front-month contract.
_contractSymbol = FuturesChain(_continuous).First().Symbol;
```

Alternatively, you can create a Future contract `Symbol` object directly parsing its ticker using the `SymbolRepresentation.ParseFutureSymbol` method.

```
C#
// Create the contract Symbol for the December 2025 E-mini S&P 500 Future.
_contractSymbol = SymbolRepresentation.ParseFutureSymbol("ESZ25");
// Create the contract Symbol using the 1-digit year format.
_contractSymbol = SymbolRepresentation.ParseFutureSymbol("ESZ5");
// To avoid ambiguity, specify the 4-digit year.
_contractSymbol = SymbolRepresentation.ParseFutureSymbol("ESZ5", 2015);
```

Subscribe to Contracts

To create an Future contract subscription, pass the contract `Symbol` to the `AddFutureContract` method. Save a reference to the contract `Symbol` so you can easily access the Future contract in the FutureChain that LEAN passes to the `OnData` method. This method returns an `Future` object.

```
C#
AddFutureContract(_contractSymbol);
```

The `AddFutureContract` method creates a subscription for a single Future contract and adds it to your user-defined universe. To create a dynamic universe of Futures contracts, add an Future universe or an Future Universe Selection model .

Warm Up Contract Prices

If you subscribe to an Future contract with `AddFutureContract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
C#
Settings.SeedInitialPrices = true;
```

Supported Assets

To view the supported assets in the Futures dataset, see the Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Futures subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`			✓	✓
`Second`	✓	✓		
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Futures contract subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddFutureContract` method.

```
C#
AddFutureContract(_contractSymbol, Resolution.Daily);
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Futures:

Historical data for backtesting is unavailable for `ICE` , `INDIA` , `SGX` and `NYSELIFFE` . In live trading, LEAN sources this data from

your brokerage or a third-party data provider .

You don't need to pass a `market` argument to the `AddFutureContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
C#
AddFutureContract(_contractSymbol, fillForward: false);
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Futures are already leveraged products, so you can't change their leverage with the default margin model .

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
C#
AddFutureContract(_contractSymbol, extendedMarketHours: true);
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

In general, we model most Futures market hours with the following segments:

Market Segment	**Time**
Pre-market	00:00:00 to 09:30:00
Market	09:30:00 to 17:00:00
Post-market	18:00:00 to 00:00:00

We model it this way because some Futures, like VIX, have pre- and post-market hours, so we standardized it. With this segmentation, if you set a Scheduled Events for the market open, it's set for 9:30 AM instead of midnight.

Continuous Contracts

A continuous Futures contract represents a single contract that maps to other contracts over time as the rollover rules are met. For more information about continuous Futures contracts, see Continuous Contracts .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request for Futures contracts. If you change the data normalization mode, it won't change the outcome.

The following data normalization modes are available for continuous Futures contracts :

Properties

The `AddFutureContract` method returns a `Future` object, which have the following properties:

Examples

The following examples demonstrate common practices for requesting individual Future contract data.

Example 1: Add the Front-Month Contract

The following algorithm adds the front-month contract, with a two-day buffer, for the E-Mini S&P 500 Future and plots the daily closing price of the contract three days before month end. Then, trade an EMA cross strategy.

C#

```
public class FutureExampleAlgorithm : QCAlgorithm
{
    private Symbol _future, _contractSymbol;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request the future underlying data for ATM strike selection.
        _future = AddFuture(
            Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio
        ).Symbol;

        // Create an EMA indicator for trade signal generation.
        _ema = EMA(_future, 20, Resolution.Daily);
        // Warm up the indicator for immediate readiness to trade with.
        WarmUpIndicator(_future, _ema, Resolution.Daily);

        // Set a scheduled event to select the option contract periodically.
        Schedule.On(
            // 3 days offset to select in prior.
            DateRules.MonthEnd(3),
            TimeRules.At(0, 1),
            SelectContract
        );
        SelectContract();
    }

    private void SelectContract()
    {
        // Get all the contracts that are currently tradable.
        var chain = FuturesChain(_future);
        // Select the front-month contract due to liquidity, with a 2-day buffer to avoid volatility.
        var contracts = chain.Where(contract => contract.Expiry >= Time.AddDays(2));
        if (contracts.Count() == 0)
        {
            return;
        }
        var contract = contracts.First().Symbol;
        // Request the Futures contract for trading.
        _contractSymbol = AddFutureContract(contract).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Trade based on updated data.
        if (slice.Bars.TryGetValue(_contractSymbol, out var bar) && IsMarketOpen(_contractSymbol))
        {
            // Trade trend-following strategy with EMA cross.
            if (bar.Close > _ema && !Portfolio[_future].IsLong)
            {
                SetHoldings(_contractSymbol, 0.5m);
            }
            else if (bar.Close < _ema && !Portfolio[_future].IsShort)
            {
                SetHoldings(_contractSymbol, -0.5m);
            }
        }
    }
}
```

Futures

Handling Data

Introduction

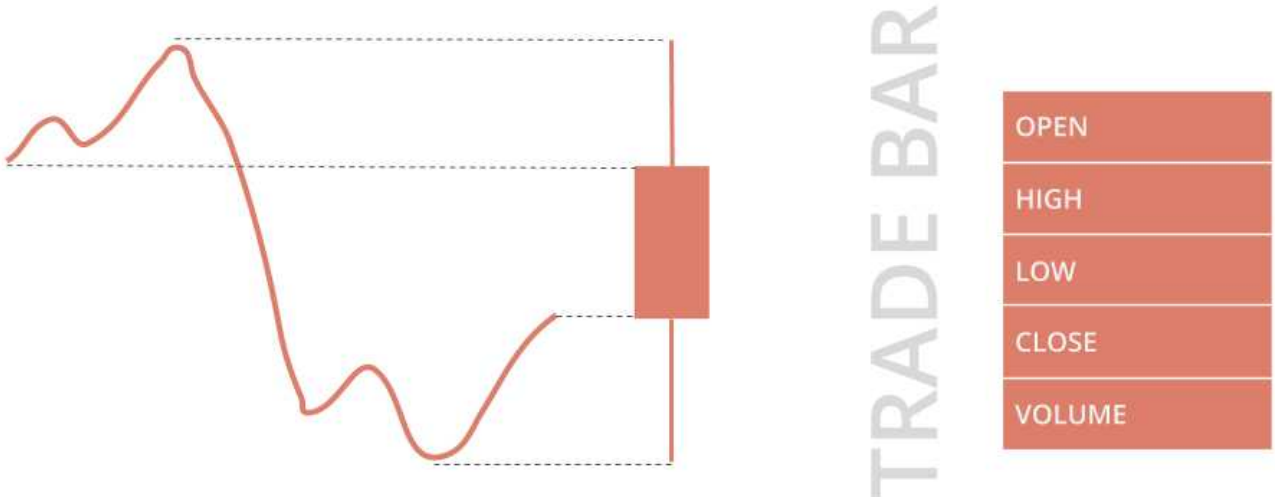
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `TradeBar` argument, it only receives `TradeBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Futures data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in TradeBars object
    if (slice.Bars.ContainsKey(_contractSymbol))
    {
        // Obtain the mapped TradeBar of the symbol
        var tradeBar = slice.Bars[_contractSymbol];
    }
}
```

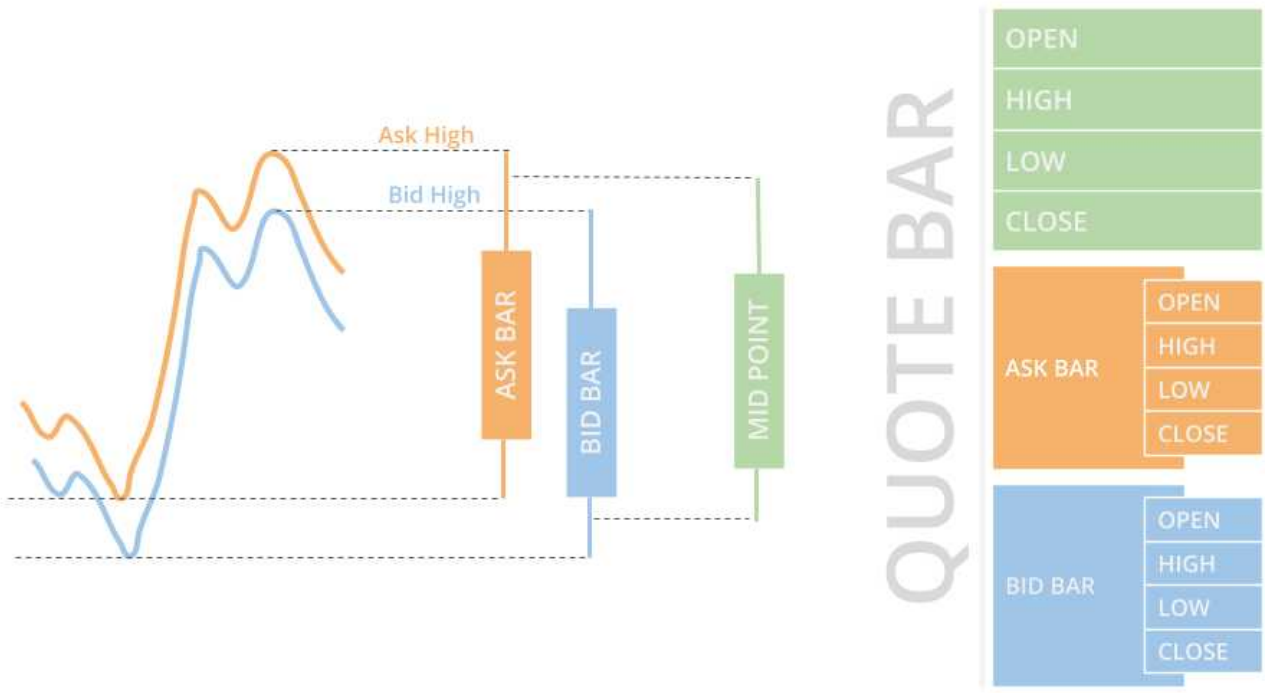
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-TradeBar key-value pairs
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        var closePrice = tradeBar.Close;
    }
}
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not

contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_contractSymbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_contractSymbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the contract. A quote tick is an offer to buy or sell the contract at a specific price.

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    if (slice.Ticks.ContainsKey(_contractSymbol))
    {
        var ticks = slice.Ticks[_contractSymbol];
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the

`List<Tick>` objects.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. To get the `FuturesChain` , index the `FuturesChains` property of the `Slice` with the continuous contract `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the FutureChain using the canonical symbol
    if (slice.FuturesChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get all contracts if the FutureChain contains any member
        var contracts = chain.Contracts;
    }
}
```

You can also loop through the `FuturesChains` property to get each `FuturesChain` .

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-FutureChain key-value pairs
    foreach (var kvp in slice.FuturesChains)
    {
        var continuousContractSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}

// Using this overload will only handle any FutureChains object received
public void OnData(FuturesChains futuresChains)
{
    // Iterate all received Canonical Symbol-FutureChain key-value pairs
    foreach (var kvp in futuresChains)
    {
        var continuousContractSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}
```

`FuturesChain` objects have the following properties:

Futures Contracts

`FuturesContract` objects represent the data of a single Futures contract in the market. To get the Futures contracts in the `Slice` , use the `Contracts` property of the `FuturesChain` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the FutureChain using the canonical symbol
    if (slice.FuturesChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            var price = contract.LastPrice;
        }
    }
}

// // Using this overload will only handle any FutureChains object received
public void OnData(FuturesChains futuresChains)
{
    // Try to get the FutureChain using the canonical symbol
    if (futuresChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            var price = contract.LastPrice;
        }
    }
}
```

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Future` or `FutureContract` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the FuturesChains using the canonical symbol
    if (slice.FuturesChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get the open interest of the selected contracts
            var openInterest = contract.OpenInterest;
        }
    }
}
```

`FuturesContract` objects have the following properties:

Symbol Changes

When the continuous contract rolls over, LEAN passes a `SymbolChangedEvent` to your `OnData` method, which contains the old contract `Symbol` and the new contract `Symbol` . To get the `SymbolChangedEvent` , use the `SymbolChangedEvents` property of the `Slice` . You can use the `SymbolChangedEvent` to roll over contracts.

```C#
public override void OnData(Slice slice)
{
    foreach (var (symbol, changedEvent) in slice.SymbolChangedEvents)
    {
        var oldSymbol = changedEvent.OldSymbol;
        var newSymbol = changedEvent.NewSymbol;
        var tag = $"Rollover - Symbol changed at {Time}: {oldSymbol} -> {newSymbol}";
        var quantity = Portfolio[oldSymbol].Quantity;
        // Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
        Liquidate(symbol: oldSymbol, tag: tag);
        if (quantity != 0) MarketOrder(newSymbol, quantity, tag: tag);
        Log(tag);
    }
}
```

LEAN passes a `SymbolChangedEvent` to your `OnSymbolChangedEvents` method as well. LEAN only invokes this method when the continuous contract rolls over.

```C#
public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
{
    foreach (var (symbol, changedEvent) in symbolChangedEvents)
    {
        var oldSymbol = changedEvent.OldSymbol;
        var newSymbol = changedEvent.NewSymbol;
        var tag = $"Rollover - Symbol changed at {Time}: {oldSymbol} -> {newSymbol}";
        var quantity = Portfolio[oldSymbol].Quantity;
        // Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
        Liquidate(symbol: oldSymbol, tag: tag);
        if (quantity != 0) MarketOrder(newSymbol, quantity, tag: tag);
        Log(tag);
    }
}
```

In backtesting, the `SymbolChangedEvent` occurs at midnight Eastern Time (ET). In live trading, the live data for continuous contract mapping arrives at 6/7 AM ET, so that's when it occurs.

`SymbolChangedEvent` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Futures data.

Example 1: Rollovers

Spot Future is referred to as the continuous Future contract, which is usually mapped by the front month contract or the contract with the most open interest. When a contract expires or is very close to expiring, traders usually rollover from the current contract to the next contract to avoid price settlement and remain invested. The following algorithm demonstrates rolling over with limit orders .

C#

```
public class FutureExampleAlgorithm : QCAlgorithm
{
    private Future _future;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add the E-mini Futures and set the continuous contract mapping criteria for the rollovers.
        _future = AddFuture(
            Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0
        );
        _future.SetFilter(0, 182);
    }

    public override void OnData(Slice slice)
    {
        // Place the initial order so you can start rolling over contracts later.
        if (!Portfolio.Invested && Transactions.GetOpenOrders().Count == 0)
        {
            // Buy the contract that's currently selected in the continous contract series.
            MarketOrder(_future.Mapped, 1m);
        }
    }

    // Track rollover events.
    public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
    {
        foreach (var (symbol, changedEvent) in symbolChangedEvents)
        {
            var oldSymbol = changedEvent.OldSymbol;
            var newSymbol = changedEvent.NewSymbol;
            // The quantity to roll over should be consistent.
            var quantity = Portfolio[oldSymbol].Quantity;
            // Rolling over: Liquidate the old mapped contract and switch to the newly mapped contract.
            var tag = $"Rollover: {oldSymbol} -> {newSymbol}";
            Liquidate(oldSymbol, tag: tag);
            if (quantity != 0)
            {
                // Place a limit order to avoid extreme quote filling.
                var newContract = Securities[newSymbol];
                LimitOrder(
                    newSymbol, quantity,
                    // To avoid warnings, round the target limit price to a price that respects
                    // the minimum price variation for the Future.
                    GetLimitPrice(newContract, newContract.Price),
                    tag: tag
                );
            }
        }
    }

    private decimal GetLimitPrice(Security security, decimal targetLimitPrice, bool roundUp = true)
    {
        var parameters = new GetMinimumPriceVariationParameters(security, targetLimitPrice);
        var pip = security.PriceVariationModel.GetMinimumPriceVariation(parameters);
        return ((int)(targetLimitPrice / pip) + (roundUp ? 1 : 0)) * pip;
    }
}
```

Example 2: Micro Gold vs Gold

The following example demonstrates how to use the `SymbolPropertiesDatabase` to obtain the contract multipliers of both Micro Gold and Gold Future contracts. The algorithm uses it to invest $500k of nominal value into each contract.

C#

```
public class FutureNominalBuysAlgorithm : QCAlgorithm
{
    private List<Future> _futures = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1_000_000);
        // Set the continuous contract mapping criteria for both Futures
        // since we want to trade the most liquid contracts.
        foreach (var ticker in new[] { Futures.Metals.Gold, Futures.Metals.MicroGold })
        {
            var future = AddFuture(
                ticker,
                extendedMarketHours: true,
                dataMappingMode: DataMappingMode.OpenInterest,
                dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
                contractDepthOffset: 0
            );
            future.SetFilter(0, 180);
            _futures.Add(future);
        }
    }

    public override void OnData(Slice slice)
    {
        // Wait until we aren't invested and we have bars for all Futures.
        if (!Portfolio.Invested && _futures.All(f => slice.Bars.ContainsKey(f.Symbol)))
        {
            foreach (var future in _futures)
            {
                // Calculate the order size for $500k. Get the quotient
                // after dividing by the contract multiplier  since the
                // order size must be whole number.
                var quantity = (int)Math.Floor(
                    500_000m / (future.Price * future.SymbolProperties.ContractMultiplier)
                );
                if (quantity == 0) {
                    continue;
                }
                MarketOrder(future.Mapped, quantity);
            }
        }
    }
}
```

Introduction

This page shows the trading hours, holidays, and time zone of the CBOT Future market.

Pre-market Hours

The following table shows the pre-market hours for the CBOT Future market:

Weekday	**Time (America/Chicago)**
Sunday	18:00:00 to 24:00:00
Monday	00:00:00 to 08:30:00
Tuesday	00:00:00 to 08:30:00
Wednesday	00:00:00 to 08:30:00
Thursday	00:00:00 to 08:30:00
Friday	00:00:00 to 08:30:00

Regular Trading Hours

The following table shows the regular trading hours for the CBOT Future market:

Weekday	**Time (America/Chicago)**
Monday	08:30:00 to 16:00:00
Tuesday	08:30:00 to 16:00:00
Wednesday	08:30:00 to 16:00:00
Thursday	08:30:00 to 16:00:00
Friday	08:30:00 to 16:00:00

Post-market Hours

The following table shows the post-market hours for the CBOT Future market:

Weekday	Time (America/Chicago)
Monday	17:00:00 to 24:00:00
Tuesday	17:00:00 to 24:00:00
Wednesday	17:00:00 to 24:00:00
Thursday	17:00:00 to 24:00:00

Holidays

The following table shows the dates of holidays for the CBOT Future market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25
1998-07-03	1998-09-07	1998-11-26	1998-12-25	1999-01-01

Time Zone

The Australian Dollar/New Zealand Dollar Futures contract in the CME Future market trades in the `America/Chicago` time zone.

CME

BIO

Introduction

This page shows the trading hours, holidays, and time zone of the E-mini Nasdaq-100 Biotechnology Index Futures contract in the CME Future market.

Pre-market Hours

The following table shows the pre-market hours for the E-mini Nasdaq-100 Biotechnology Index Futures contract in the CME Future market:

Weekday	**Time (America/Chicago)**
Sunday	17:00:00 to 24:00:00
Monday	00:00:00 to 08:30:00
Tuesday	00:00:00 to 08:30:00
Wednesday	00:00:00 to 08:30:00
Thursday	00:00:00 to 08:30:00
Friday	00:00:00 to 08:30:00

Regular Trading Hours

The following table shows the regular trading hours for the E-mini Nasdaq-100 Biotechnology Index Futures contract in the CME Future market:

Weekday	**Time (America/Chicago)**
Monday	08:30:00 to 16:00:00
Tuesday	08:30:00 to 16:00:00
Wednesday	08:30:00 to 16:00:00
Thursday	08:30:00 to 16:00:00
Friday	08:30:00 to 16:00:00

Post-market Hours

The following table shows the post-market hours for the E-mini Nasdaq-100 Biotechnology Index Futures contract in the CME Future market:

Weekday	Time (America/Chicago)
Monday	17:00:00 to 24:00:00
Tuesday	17:00:00 to 24:00:00
Wednesday	17:00:00 to 24:00:00
Thursday	17:00:00 to 24:00:00

Holidays

The following table shows the dates of holidays for the E-mini Nasdaq-100 Biotechnology Index Futures contract in the CME Future market:

Date (*yyyy-mm-dd*)	
2026-12-25	2027-01-01

Early Closes

The following table shows the early closes for the E-mini Nasdaq-100 Biotechnology Index Futures contract in the CME Future market:

Date (*yyyy-mm-dd*)	Time Of Market Close (America/Chicago)

Future Options

Requesting Data

Request Future Options data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Future Options dataset listing . To trade Future Options live, you can use one of the brokerage data providers . We currently only support European-style Options for US Future Options.

To request Future Options data, call one of the following methods:

- `AddFutureOption` to add a basket of contracts for a single underlying Future
- `AddFutureOptionContract` to add individual contracts for an underlying Future

Request and Filter Contracts for Option Strategies

Universes

Introduction

The `AddFutureOption` method enables you to select a basket of Option contracts for an underlying Future. To form your universe of contracts, you can filter them down by their strike price and expiry or you can choose a subset of the contracts that form popular Option strategies . If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Future Option contracts, in the `Initialize` method, call the `AddFutureOption` method. Pass the `optionFilter` argument to filter the set of tradable contract down to just the contracts you want.

```C#
public class BasicFutureOptionAlgorithm : QCAlgorithm
{
    private Future _future;
    public override void Initialize()
    {
        _future = AddFuture(Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.Strikes(-1, 1));
    }

    public override void OnData(Slice data)
    {
        // Iterate all Option chains to find the desired future and future options contracts
        foreach (var (canonicalSymbol, chain) in data.OptionChains)
        {
            var futureContract = canonicalSymbol.Underlying;
            foreach (var (symbol, contract) in chain.Contracts)
            {
                var strike = contract.Strike;
            }
        }

        // Get the Option chain for the mapped contract
        if (data.OptionChains.TryGetValue(QuantConnect.Symbol.CreateCanonicalOption(_future.Mapped), out var
mappedChain))
        {
            foreach (var (symbol, contract) in mappedChain.Contracts)
            {
                var strike = contract.Strike;
            }
        }
    }
}
```

For more information about the `AddFutureOption` method, see Create Universes .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Future with different features. The following table describes the filter methods of the `OptionFilterUniverse` class that select

contract for Option strategies.

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`NakedCall(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`NakedPut(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`CallSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`PutSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.
`CallCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.
`PutCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.
`Strangle(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Long Strangle or Short Strangle Option strategies.
`Straddle(int minDaysTillExpiry)` Selects two contracts to form Long Straddle or Short Straddle Option strategies.
`ProtectiveCollar(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Protective Collar Option strategies.
`Conversion(int minDaysTillExpiry, decimal strikeFromAtm)` Selects two contracts to form Conversion or Reverse Conversion Option strategies.
`CallButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.

`PutButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.
`IronButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.
`IronCondor(int minDaysTillExpiry, decimal nearStrikeSpread, decimal farStrikeSpread)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`BoxSpread(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`JellyRoll(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.
`CallLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`PutLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```C#
// Example 1: Select a Straddle
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.Straddle(30, 5, 10));

// Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));

// Example 3: Select the front month contracts that form an Strangle
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.FrontMonth().Strangle(30, 5, -10));
```

Filter by Other Contract Properties

To set a contract filter, in the `Initialize` method, call the `AddFutureOption` method and pass the `optionFilter` argument.

```
C#
// Select contracts that have a strike price within 1 strike level above and below the underlying price
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.Strikes(-1,1));

// Select contracts that expire within 30 days
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.Expiration(0, 30));

// Select contracts that have a strike price within 1 strike level and expire within 30 days
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.Strikes(-1,1).Expiration(0, 30));

// Select call contracts
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.CallsOnly());
```

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.
`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.
`StandardsOnly()` Selects standard contracts.
`IncludeWeeklys()` Selects non-standard weeklys contracts. This filter doesn't currently work. To add this functionality to our roadmap , react to this GitHub Issue with a thumbs up emoji.
`WeeklysOnly()` Selects weekly contracts. This filter doesn't currently work. To add this functionality to our roadmap , react to this GitHub Issue with a thumbs up emoji.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.

`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse`, so you can chain the methods together.

The preceding methods return an `OptionFilterUniverse`, so you can chain the methods together.

```C#
// Example 1: Select the front month call contracts
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.CallsOnly().FrontMonth());

// Example 2: Select the contracts that expire in the next 90 days
AddFutureOption(_future.Symbol, optionFilterUniverse => optionFilterUniverse.Strikes(-20, 20).Expiration(0, 90));
```

To perform thorough filtering on the `OptionFilterUniverse`, define an isolated filter method.

```C#
public class BasicFutureOptionAlgorithm : QCAlgorithm
{
    private Future _future;
    public override void Initialize()
    {
        AddFutureOption(_future.Symbol, Selector);
    }

    private OptionFilterUniverse Selector(OptionFilterUniverse optionFilterUniverse)
    {
        var symbols = optionFilterUniverse.PutsOnly();
        var strike = symbols.Select(symbol => symbol.ID.StrikePrice).Min();
        symbols = symbols.Where(symbol => symbol.ID.StrikePrice == strike);
        return optionFilterUniverse.Contracts(symbols);
    }
}
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse`.

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

Historical Data

To get historical data for a Future Options universe, see Historical Data .

Examples

The following examples demonstrate some common practices for requesting Future Option data through universe filtering.

Example 1: Call Spread

The following example demonstrates how to implement a bull call spread option strategy using universe filtering. We have to first subscribe to the underlying Future (with filtering), then call `AddFutureOption` with the underlying `Symbol` and the filtering function. We use `CallSpread` method in the `OptionFilterUniverse` object to return only the 2 best match call contracts that forms a bull call spread.

C#

```
public class FutureOptionAlgorithm : QCAlgorithm
{
    private Future _underlying;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Filter the underlying continuous Futures to narrow the FOP spectrum.
        _underlying = AddFuture(Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        _underlying.SetFilter(0, 182);
        // Use CallSpread filter to obtain the 2 best-matched contracts that forms a call spread.
        // It simplifies from further filtering and reduce computation on redundant subscription.
        AddFutureOption(_underlying.Symbol, (u) => u.CallSpread(5, 5, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested)
            return;

        // Create canonical symbol for the mapped future contract, since we need that to access the option chain.
        var symbol = QuantConnect.Symbol.CreateCanonicalOption(_underlying.Mapped);

        // Get option chain data for the mapped future only.
        // It requires 2 contracts with different strikes to form a call spread, so we make sure at least 2 contracts
are present.
        if (!slice.OptionChains.TryGetValue(symbol, out var chain) || chain.Count() < 2)
            return;

        // Separate the contracts by strike, as we need to access their strike.
        var expiry = chain.Min(x => x.Expiry);
        var itmStrike = chain.Min(x => x.Strike);
        var otmStrike = chain.Max(x => x.Strike);

        // Use abstraction method to order a bull call spread to avoid manual error.
        var optionStrategy = OptionStrategies.BullCallSpread(symbol, itmStrike, otmStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Note that since both the underlying Future and the Future Option are expiring on the same day and are cash-settling in most cases, Lean can exercise the Future Option into account cash automatically at expiry and we do not need to handle the option exercise/assignment event.

Requesting Data

Individual Contracts

Introduction

The `AddFutureOptionContract` method enables you to add an individual Option contract to your algorithm. To check which contracts are currently available to add to your algorithm, use the `OptionChain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to an Option contract, you must configure the underlying Future and get the contract `Symbol` .

C#

```
public class BasicFutureOptionAlgorithm : QCAlgorithm
{
    private Future _future;
    private Symbol _contractSymbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _future = AddFuture(Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);
    }

    public override void OnData(Slice data)
    {
        if (_contractSymbol == null)
        {
            // Method 1: Add the desired option chain for the mapped contract
            _contractSymbol = SelectOptionContract(_future.Mapped);
            AddFutureOptionContract(_contractSymbol);

            // Method 2: Get all future contracts from the Future chain provider
            var futureContractSymbol = FuturesChain(_future.Symbol).First().Symbol;
            var symbol = SelectOptionContract(futureContractSymbol);
            AddFutureOptionContract(symbol);

            // Method 3: Iterate all Future chains to find the desired future options contracts
            foreach (var (_, chain) in data.FutureChains)
            {
                var expiry = chain.Min(contract => contract.Expiry);
                var futureContract = chain.Where(contract => contract.Expiry == expiry).FirstOrDefault();
                symbol = SelectOptionContract(futureContract.Symbol);
                AddFutureOptionContract(symbol);
            }
        }
    }

    private Symbol SelectOptionContract(Symbol futureContractSymbol)
    {
        var chain = OptionChain(futureContractSymbol)
            .Where(contract => contract.Right == OptionRight.Call).ToList();
        var expiry = chain.Min(contract => contract.Expiry);
        return chain
            .Where(contract => contract.Expiry == expiry)
            .OrderBy(contract => contract.Strike)
            .Select(contract => contract.Symbol).FirstOrDefault();
    }
}
```

Configure the Underlying Futures Contracts

In most cases, you should subscribe to the underlying Futures contract before you subscribe to a Futures Option contract.

```
C#

_future = AddFuture(Futures.Indices.SP500EMini,
    extendedMarketHours: true,
    dataMappingMode: DataMappingMode.OpenInterest,
    dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
    contractDepthOffset: 0);
```

To get a `Symbol` of a specific Futures contract, use the `Mapped` property of the `Future` object or the `Symbol` property of the `FutureContract` objects in the `Slice.FutureChains` collection.

Get Contract Symbols

To subscribe to a Future Option contract, you need the contract `Symbol` . The preferred method to getting Option contract `Symbol` objects is to use the `OptionChain` method. This method returns an `OptionChain` object, which represent an entire chain of Option contracts for a single underlying security. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
C#

// Get the contracts available to trade.
var chain = OptionChain(futureContractSymbol)
    .Where(contract => contract.Right == OptionRight.Call).ToList();

// Select a contract.
var expiry = chain.Min(contract => contract.Expiry);
_contractSymbol = chain
    // Select call contracts with the closest expiry.
    .Where(contract => contract.Expiry == expiry)
    // Select the contract with the lowest strike price.
    .OrderBy(contract => contract.Strike)
    .Select(contract => contract.Symbol).FirstOrDefault();
```

Alternatively, you can create a Future Option contract `Symbol` object directly parsing its OSI ticker using the `SymbolRepresentation.ParseOptionTickerOSI` method.

```
C#

// Create the contract Symbol for the Sept 2024 E-mini S&P 500 Call 7900 20 Sept 2024.
_contractSymbol = SymbolRepresentation.ParseOptionTickerOSI("ESU24 240920C07900000", SecurityType.FutureOption,
OptionStyle.American, Market.CME);
// Create the contract Symbol using the 1-digit year format.
_contractSymbol = SymbolRepresentation.ParseOptionTickerOSI("ESU4 240920C07900000", SecurityType.FutureOption,
OptionStyle.American, Market.CME);
```

Subscribe to Contracts

To create a Future Option contract subscription, pass the contract `Symbol` to the `AddFutureOptionContract` method. Save a reference to the contract `Symbol` so you can easily access the Option contract in the OptionChain that LEAN passes to the `OnData` method. This method returns an `Option` object. To override the default pricing model of the Option, set a pricing model .

```
C#

var option = AddFutureOptionContract(_contractSymbol);
option.PriceModel = OptionPriceModels.BinomialCoxRossRubinstein();
```

Warm Up Contract Prices

If you subscribe to a Future Option contract with `AddFutureOptionContract` , you'll need to wait until the next `Slice` to receive

data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
C#
Settings.SeedInitialPrices = true;
```

Supported Assets

To view the supported assets in the US Future Options dataset, see the Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Future Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

There is only one resolution option, so you don't need to pass a `resolution` argument to the `AddFutureOptionContract` method.

```
C#
AddFutureOptionContract(_optionContractSymbol, Resolution.Minute);
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for Future Options:

You don't need to pass a `Market` argument to the `AddFutureOptionContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
C#
AddFutureOptionContract(_optionContractSymbol, fillForward: false);
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Future Options are already leveraged products, so you can't change their leverage.

Extended Market Hours

By default, your security subscriptions only cover regular trading hours. To subscribe to pre and post-market trading hours for a specific asset, enable the `extendedMarketHours` argument when you create the security subscription.

```
C#
AddFutureOptionContract(_optionContractSymbol, extendedMarketHours: true);
```

You only receive extended market hours data if you create the subscription with minute, second, or tick resolution. If you create the subscription with daily or hourly resolution, the bars only reflect the regular trading hours.

To view the schedule of regular and extended market hours, see Market Hours .

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Remove Subscriptions

To remove a contract subscription that you created with `AddFutureOptionContract` , call the `RemoveOptionContract` method. This method is an alias for `RemoveSecurity` .

```
C#
RemoveOptionContract(_optionContractSymbol);
```

The `RemoveOptionContract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `AddFutureOptionContract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `Symbol` to access the value in the `Securities` object.

```
C#
var option = Securities[_optionContractSymbol];
var underlying = Securities[_optionContractSymbol.Underlying];
var underlyingPrice = underlying.Price;
```

To get the Option payoff , call the `GetPayOff` method.

```
C#
var payOff = option.GetPayOff(underlyingPrice);
```

To get the Option intrinsic value , call the `GetIntrinsicValue` method.

```
C#
var intrinsicValue = option.GetIntrinsicValue(underlyingPrice);
```

To get the Option out-of-the-money amount , call the `OutOfTheMoneyAmount` method.

```C#
var otmAmount = option.OutOfTheMoneyAmount(underlyingPrice);
```

To check whether the Option can be automatic exercised, call the `IsAutoExercised` method.

```C#
var isAutoExercised = option.IsAutoExercised(underlyingPrice);
```

Future Options

Handling Data

Introduction

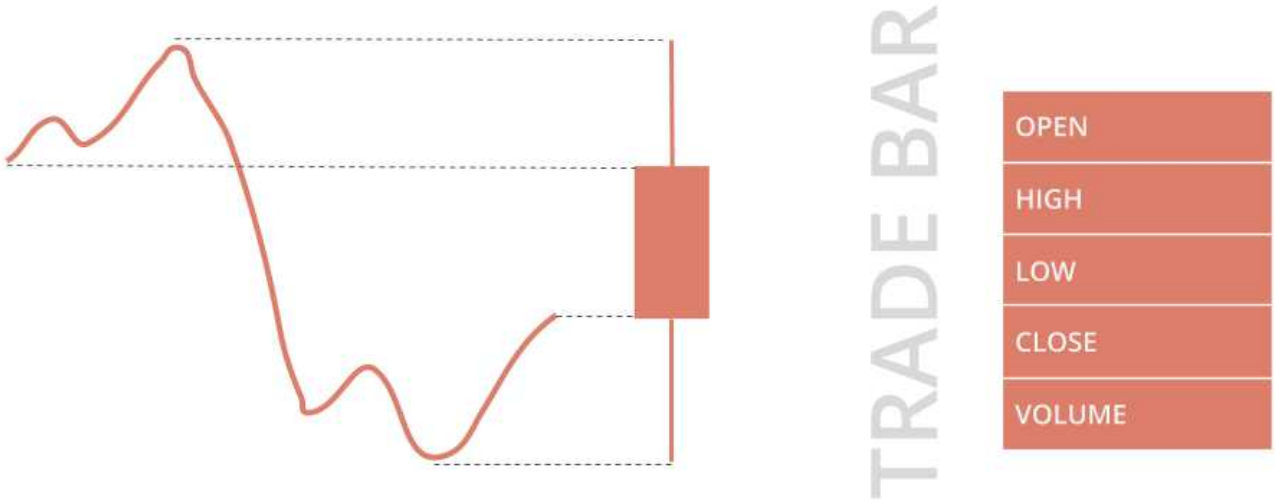
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `TradeBar` argument, it only receives `TradeBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the Futures Option contract ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Future Options data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the Option contract `Symbol` . If the Option contract doesn't actively trade or you are in the same time step as when you added the Option contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your Option contract before you index the `Slice` with the Option contract `Symbol` .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in TradeBars object
    if (slice.Bars.ContainsKey(_optionContractSymbol))
    {
        // Obtain the mapped TradeBar of the symbol
        var tradeBar = slice.Bars[_optionContractSymbol];
    }
}
```

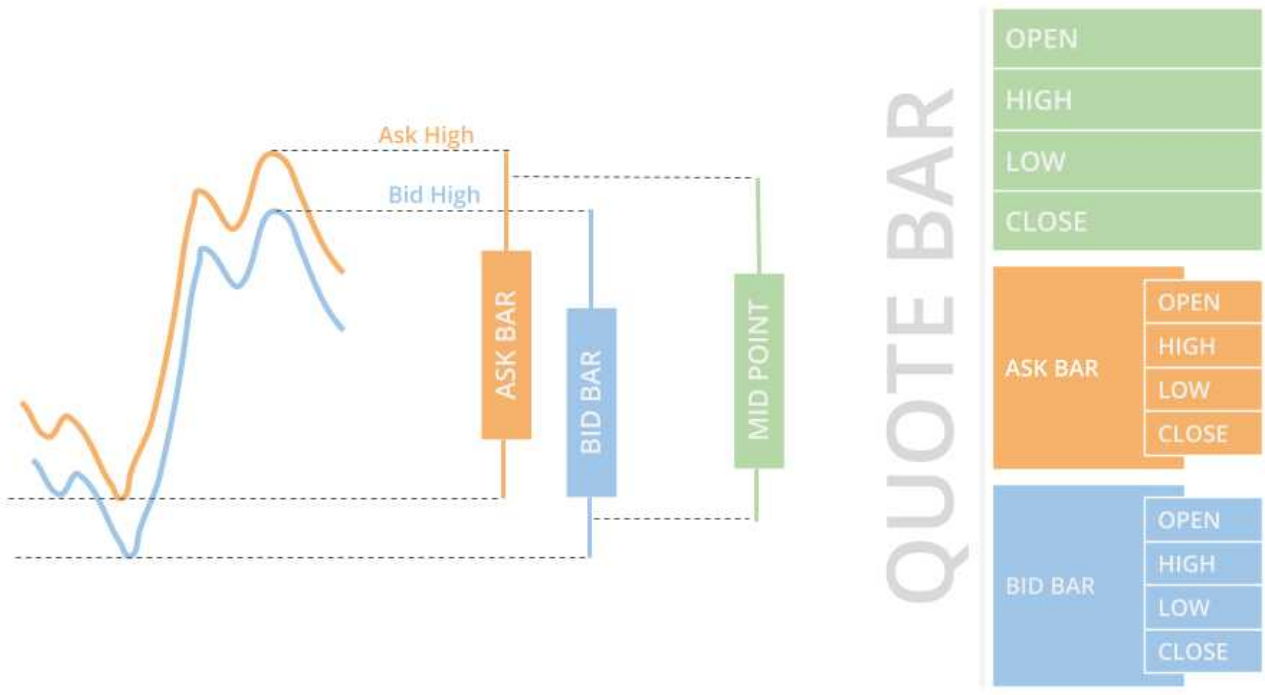
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-TradeBar key-value pairs
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        var closePrice = tradeBar.Close;
    }
}
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the Option contract `Symbol` . If the Option contract doesn't actively get quotes or you are in the same time step as when you added the Option contract

subscription, the `Slice` may not contain data for your `Symbol`. To avoid issues, check if the `Slice` contains data for your Option contract before you index the `Slice` with the Option contract `Symbol`.

```
C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_optionContractSymbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_optionContractSymbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. To get the `FuturesChain`, index the `FuturesChains` property of the `Slice` with the continuous contract `Symbol`.

```
C#
public override void OnData(Slice slice)
{
    // Try to get the FutureChain using the canonical symbol
    if (slice.FuturesChains.TryGetValue(_futureContractSymbol.Canonical, out var chain))
    {
        // Get all contracts if the FutureChain contains any member
        var contracts = chain.Contracts;
    }
}
```

You can also loop through the `FuturesChains` property to get each `FuturesChain`.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-FutureChain key-value pairs
    foreach (var kvp in slice.FuturesChains)
    {
        var continuousContractSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}

// Using this overload will only handle any FutureChains object received
public void OnData(FuturesChains futuresChains)
{
    // Iterate all received Canonical Symbol-FutureChain key-value pairs
    foreach (var kvp in futuresChains)
    {
        var continuousContractSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}
```

`FuturesChain` objects have the following properties:

Futures Contracts

`FuturesContract` objects represent the data of a single Futures contract in the market. To get the Futures contracts in the `Slice`, use the `Contracts` property of the `FuturesChain`.

```C#
public override void OnData(Slice slice)
{
    // Try to get the FutureChain using the canonical symbol
    if (slice.FuturesChains.TryGetValue(_futureContractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_futureContractSymbol, out var contract))
        {
            var price = contract.LastPrice;
        }
    }
}

// // Using this overload will only handle any FutureChains object received
public void OnData(FuturesChains futuresChains)
{
    // Try to get the FutureChain using the canonical symbol
    if (futuresChains.TryGetValue(_futureContractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_futureContractSymbol, out var contract))
        {
            var price = contract.LastPrice;
        }
    }
}
```

`FuturesContract` objects have the following properties:

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain`, index the `OptionChains` property of the `Slice` with the canonical `Symbol`.

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_optionContractSymbol.Canonical, out var chain))
    {
        // Get all contracts if the OptionChain contains any member
        var contracts = chain.Contracts;
    }
}
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-OptionChain key-value pairs
    foreach (var kvp in slice.OptionChains)
    {
        var canonicalFOPSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}
```

`OptionChain` objects have the following properties:

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. To get the Option contracts in the `Slice` , use the `Contracts` property of the `OptionChain` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_optionContractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_optionContractSymbol, out var contract))
        {
            var price = contract.Price;
        }
    }
}
```

You can also iterate through the `FuturesChains` first.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-FuturesChain key-value pairs
    foreach (var kvp in slice.FuturesChains)
    {
        var continuousContractSymbol = kvp.Key;
        var futuresChain = kvp.Value;

        // Select a Future Contract and create its canonical FOP Symbol
        var futuresContract = futuresChain.First();
        var canonicalFOPSymbol = QuantConnect.Symbol.CreateCanonicalOption(futuresContract.Symbol);
        // Try to get the OptionChain using the canonical FOP symbol
        if (slice.OptionChains.TryGetValue(canonicalFOPSymbol, out var optionChain))
        {
            // Get individual contract data
            if (optionChain.Contracts.TryGetValue(_optionContractSymbol, out var optionContract))
            {
                var price = optionContract.Price;
            }
        }
    }
}
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `Greeks` and `implied_volatility` members.

```C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_optionContractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_optionContractSymbol, out var contract))
        {
            // Get greeks data of the selected contract
            var delta = contract.Greeks.Delta;
            var iv = contract.ImpliedVolatility;
        }
    }
}
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `Greeks` property, the Greeks aren't calculated. However, if you invoke the `Greeks.Delta` , LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Option` or `OptionContract` .

```C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChains using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get the open interest of the selected contracts
            var openInterest = contract.OpenInterest;
        }
    }
}

public void OnData(OptionChains optionChains)
{
    // Try to get the OptionChains using the canonical symbol
    if (optionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get the open interest of the selected contracts
            var openInterest = contract.OpenInterest;
        }
    }
}
```

Properties

`OptionContract` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Future Option data.

Example 1: Monthly Protective Put

The following algorithm shows how to perform monthly selection on individual ES Future Option contract to implement a protective put option strategy to hedge speculation on S&P500 Future. It is a useful tool to hedge the excessive risk on leverage using Futures to trade.

C#

```
public class FutureOptionExampleAlgorithm : QCAlgorithm
{
    private Future _underlying;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000000);

        // Seed the security price to ensure the underlying price is available at the initial filtering.
        Settings.SeedInitialPrices = true;
        // Set data normalization mode to raw for fair strike price comparison.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        // Subscribe the underlying since the updated price is needed for filtering.
        _underlying = AddFuture(Futures.Indices.SP500EMini,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.Raw,
            contractDepthOffset: 0);
        // Filter the underlying continuous Futures to narrow the FOP spectrum.
        _underlying.SetFilter(0, 31);

        // Schedule a monthly event on selection of future-future option pair, since the portfolio rebalance on a
monthly basis.
        Schedule.On(
            DateRules.MonthStart(_underlying.Symbol),
            TimeRules.AfterMarketOpen(_underlying.Symbol, 0),
            SelectionAndRebalance
        );
    }

    private void SelectionAndRebalance()
    {
        // Get all available put FOP contract for the mapped underlying contract, since the trade liquidity and
volatility is the highest.
        var contractSymbols = OptionChain(_underlying.Mapped)
            .Where(symbol => symbol.ID.OptionRight == OptionRight.Put)
            .ToList();
        // Select the ATM put expires the same date as the underlying. The max expiry of the FOP will expire the same
time as the front month future.
        var expiry = contractSymbols.Max(symbol => symbol.ID.Date);
        var selected = contractSymbols.Where(symbol => symbol.ID.Date == expiry)
            .OrderBy(symbol => Math.Abs(symbol.ID.StrikePrice - Securities[_underlying.Mapped].Price))
            .First();
        // Request the FOP contract data for trading.
        var contract = AddFutureOptionContract(selected);

        // A Protective Put consists of long a lot of the underlying, and long a put contract.
        MarketOrder(_underlying.Mapped, contract.SymbolProperties.ContractMultiplier);
        MarketOrder(contract.Symbol, 1);
    }
}
```

Example 2: Weekly Covered Call

The below example demonstrates a weekly-renewing covered call strategy to collect credit of selling the option. It filters the ATM call contract that expires within the current week at week start using `SetFilter` filtering function.

C#

```
public class FutureOptionExampleAlgorithm : QCAlgorithm
{
    private Future _underlying;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000000);
        // Set data normalization mode to raw for fair strike price comparison.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;

        // Subscribe the underlying since the updated price is needed for filtering.
        _underlying = AddFuture(Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.Raw,
            contractDepthOffset: 0);
        // Filter the underlying continuous Futures to narrow the FOP spectrum.
        _underlying.SetFilter(0, 182);
        // Filter for the current-week-expiring calls to formulate a covered call that expires at the end of week.
        AddFutureOption(_underlying.Symbol, (u) => u.IncludeWeeklys().CallsOnly().Expiration(0, 5));
    }

    public override void OnData(Slice slice)
    {
        // Create canonical symbol for the mapped future contract, since option chains are mapped by canonical
symbol.
        var symbol = QuantConnect.Symbol.CreateCanonicalOption(_underlying.Mapped);

        // Get option chain data for the mapped future, as both the underlying and FOP have the highest liquidity
among all other contracts.
        if (!Portfolio.Invested &&
            slice.OptionChains.TryGetValue(symbol, out var chain))
        {
            // Obtain the ATM call that expires at the end of week, such that both underlying and the FOP expires the
same time.
            var expiry = chain.Max(x => x.Expiry);
            var atmCall = chain.Where(x => x.Expiry == expiry)
                .OrderBy(x => Math.Abs(x.Strike - x.UnderlyingLastPrice))
                .First();

            // Use abstraction method to order a covered call to avoid manual error.
            var optionStrategy = OptionStrategies.CoveredCall(symbol, atmCall.Strike, expiry);
            Buy(optionStrategy, 1);
        }
    }
}
```

Note that since both the underlying Future and the Future Option are expiring on the same day and are cash-settling in most cases, Lean can exercise the Future Option into account cash automatically at expiry and we do not need to handle the option exercise/assignment event.

Future Options

Greeks and Implied Volatility

The Greeks are measures that describe the sensitivity of an Option's price to various factors like underlying price changes (Delta), time decay (Theta), volatility (Vega), and interest rates (Rho), while Implied Volatility (IV) represents the market's expectation of the underlying asset's volatility over the life of the Option.

Greeks and Implied Volatility

Key Concepts

Introduction

LEAN provides multiple ways for you to get the Greeks and implied volatility (IV) of Option contracts. There is a daily, pre-calculated dataset based on the end of the previous trading day. There is also a stream of values that are calculated on-the-fly as your algorithm runs.

Greeks on Universes

This feature is coming soon for Future Options.

Greek History

This feature is coming soon for Future Options.

Greeks on Data Events

The Greeks and IV values that you get from the current Slice are from the price model calculations. These values aren't the same as the values you get in the universe filter function.

C#

```
public class FutureOptionDataEventsAlgorithm : QCAlgorithm
{
    private Future _future;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =>
        {
            if (security.Type == SecurityType.FutureOption)
            {
                (security as Option).PriceModel = OptionPriceModels.CrankNicolsonFD();
            }
        });
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);
        AddFutureOption(_future.Symbol, universe => universe.Strikes(-5, 5));
    }

    public override void OnData(Slice data)
    {
        foreach (var chain in data.OptionChains.Values)
        {
            foreach (var contract in chain)
            {
                var iv = contract.ImpliedVolatility;
                var delta = contract.Greeks.Delta;
            }
        }
    }
}
```

To view all the models LEAN supports, see Supported Models .

Greek Indicators

Option indicators provide daily and intraday values for the Greeks and implied volatility of Future Option contracts.

Examples

For detailed examples on using Option Greeks and Implied Volatility indicators in algorithm, you may refer to the Greeks Indicators page examples.

Greeks and Implied Volatility

Indicators

Introduction

Option indicators enable you to calculate daily and intraday values for the Greeks and implied volatility of Option contracts. This page explains the most popular Option indicators and how to use them with LEAN.

Parameters

The following table describes the arguments that the automatic Option indicators methods accept:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The contract to use when calculating the indicator values.	
`mirrorOption`	`Symbol`	The mirror contract to use in parity type calculations.	`null`
`riskFreeRate`	`decimal`	The risk-free interest rate. If you don't provide a value, the default value is the US primary credit rate from the Interest Rate Provider Model .	`null`
`dividendYield`	`decimal`	The dividend yield rate. If you don't provide a value, the default value comes from the Dividend Yield Provider Model .	`null`
`optionModel`	`OptionPricingModelType`	The Option pricing model that's used to calculate the Greeks. If you don't provide a value, the default value is `OptionPricingModelType.BlackScholes` for European-style Options.	`null`
`resolution`	`Resolution`	The resolution of the indicator data. If you don't provide a value, the default value is the resolution of the subscription you have for the Option contract(s).	`null`

To perform implied volatility (IV) smoothing with a put-call pair, pass one of the contracts as the `symbol` argument and pass the other contract in the pair as the `mirrorOption` argument. The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, call the `SetSmoothingFunction` method of the `ImpliedVolatility` class/property.

Several different Option pricing models are supported to calculate the IV and Greeks. The following table describes the

`OptionPricingModelType` enumeration members:

Implied Volatility

Implied volatility, σ , is the market's expectation for the future volatility of an asset and is implied by the price of the assets's Options contracts. You can't observe it in the market but you can derive it from the price of an Option. For more information about implied volatility, see Implied Volatility .

Automatic Indicators

To create an automatic indicator for implied volatility, call the `QCAlgorithm.IV` method with the Option contract `Symbol` object(s).

```
C#
public class AutomaticImpliedVolatilityIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]) as dynamic;
                var contract2 = AddFutureOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic ImpliedVolatility indicators.
                contract1.IV = IV(contracts[0], contracts[1]);
                contract2.IV = IV(contracts[1], contracts[0]);
```

```
                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the ImpliedVolatility indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.IV;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

For more information about the `IV` method, see Parameters and Using IV Indicator .

Manual Indicators

To create a manual indicator for implied volatility, call the `ImpliedVolatility` constructor.

C#

```
public class ManualImpliedVolatilityIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private ConstantDividendYieldModel _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new ConstantDividendYieldModel(0m);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
```

```
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]);
                var contract2 = AddFutureOptionContract(contracts[1]);

                // Create and save the manual ImpliedVolatility indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.ImpliedVolatility = new ImpliedVolatility(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).ImpliedVolatility;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the ImpliedVolatility indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
```

```
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

For more information about the `ImpliedVolatility` constructor, see Using IV Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the `IV` method or `ImpliedVolatility` constructor and then call the `SetSmoothingFunction` method of the resulting `ImpliedVolatility` object. The follow table describes the arguments of the custom function:

Argument	Data Type	Description
`iv`	`decimal`	The IV of the Option contract.
`mirrorIv`	`decimal`	The IV of the mirror Option contract.

The method must return a `decimal` as the smoothened IV.

C#

```
private ImpliedVolatility _iv;

public override void Initialize()
{
    var option = QuantConnect.Symbol.CreateOption("AAPL", Market.USA, OptionStyle.American, OptionRight.Put, 505m,
new DateTime(2014, 6, 27));
    AddOptionContract(option);

    var mirrorOption = QuantConnect.Symbol.CreateOption("AAPL", Market.USA, OptionStyle.American, OptionRight.Call,
505m, new DateTime(2014, 6, 27));
    AddOptionContract(mirrorOption);

    _iv = IV(option, mirrorOption);
    // example: take average of the call-put pair
    _iv.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
}
```

Delta

Delta, Δ , is the rate of change of the Option price with respect to the price of the underlying asset. It measures the first-order sensitivity of the price to a movement in underlying price. For example, an Option delta of 0.4 means that if the underlying asset moves by 1%, then the value of the Option moves by $0.4 \times 1\% = 0.4\%$. For more information about delta, see Delta .

Automatic Indicators

To create an automatic indicator for delta, call the `QCAlgorithm.D` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticDeltaIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private (Symbol option1, Symbol option2) _options;
```

```
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]) as dynamic;
                var contract2 = AddFutureOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Delta indicators.
                contract1.D = D(contracts[0], contracts[1]);
                contract2.D = D(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Delta indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.D;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
```

```
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

The follow table describes the arguments that the `D` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Delta. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `D` method, see Using D Indicator .

Manual Indicators

To create a manual indicator for delta, call the `Delta` constructor.

C#

```
public class ManualDeltaIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private ConstantDividendYieldModel _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new ConstantDividendYieldModel(0m);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
```

```
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]);
                var contract2 = AddFutureOptionContract(contracts[1]);

                // Create and save the manual Delta indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Delta = new Delta(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Delta;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Delta indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
```

```
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

For more information about the `Delta` constructor, see Using D Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

C#

```
// Example: Average IV of the call-put pair.
deltaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Gamma

Gamma, Γ , is the rate of change of the portfolio's delta with respect to the underlying asset's price. It represents the second-order sensitivity of the Option to a movement in the underlying asset's price. For more information about Gamma, see Gamma .

Automatic Indicators

To create an automatic indicator for gamma, call the `QCAlgorithm.G` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticGammaIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
```

```
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]) as dynamic;
                var contract2 = AddFutureOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Gamma indicators.
                contract1.G = G(contracts[0], contracts[1]);
                contract2.G = G(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Gamma indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.G;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

The follow table describes the arguments that the `G` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Gamma. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `G` method, see Using G Indicator .

Manual Indicators

To create a manual indicator for gamma, call the `Gamma` constructor.

```
C#

public class ManualGammaIndicatorAlgorithm : QCAlgorithm
```

```
{
    private Future _future;
    private ConstantDividendYieldModel _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new ConstantDividendYieldModel(0m);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]);
                var contract2 = AddFutureOptionContract(contracts[1]);

                // Create and save the manual Gamma indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Gamma = new Gamma(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
```

```
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Gamma;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Gamma indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

For more information about the `Gamma` constructor, see Using G Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

```
// Example: Average IV of the call-put pair.
gammaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Vega

Vega, ν , is the rate of change in the value of the Option with respect to the volatility of the underlying asset. For more information about vega, see Vega .

Automatic Indicators

To create an automatic indicator for vega, call the `QCAlgorithm.V` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticVegaIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]) as dynamic;
                var contract2 = AddFutureOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Vega indicators.
                contract1.V = V(contracts[0], contracts[1]);
                contract2.V = V(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Vega indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.V;
```

```
                var indicator = option.V;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

The follow table describes the arguments that the `V` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Vega. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `V` method, see Using V Indicator .

Manual Indicators

To create a manual indicator for vega, call the `Vega` constructor.

C#

```
public class ManualVegaIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private ConstantDividendYieldModel _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new ConstantDividendYieldModel(0m);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
```

```
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]);
                var contract2 = AddFutureOptionContract(contracts[1]);

                // Create and save the manual Vega indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Vega = new Vega(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Vega;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Vega indicator.
                    var value = indicator.Current.Value;
                }
            }
        }
```

```
        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

For more information about the `Vega` constructor, see Using V Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

C#

```
// Example: Average IV of the call-put pair.
vegaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Theta

Theta, Θ , is the rate of change of the value of the Option with respect to the passage of time. It is also known to as the time decay of an Option. For more information about theta, see Theta .

Automatic Indicators

To create an automatic indicator for theta, call the `QCAlgorithm.T` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticThetaIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
```

```
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]) as dynamic;
                var contract2 = AddFutureOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Theta indicators.
                contract1.T = T(contracts[0], contracts[1]);
                contract2.T = T(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Theta indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.T;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

The follow table describes the arguments that the `T` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating theta. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the T method, see Using T Indicator .

Manual Indicators

To create a manual indicator for theta, call the Theta constructor.

C#

```
public class ManualThetaIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private ConstantDividendYieldModel _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Theta indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

For more information about the `Theta` constructor, see Using T Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

```
C#
// Example: Average IV of the call-put pair.
thetaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Rho

Rho, ρ, is the rate of change of the value of a derivative with respect to the interest rate. It is usually small and not a big issue in practice unless the Option is deep in-the-money and has a long horizon. In this case, the interest rate matters because you need to discount a larger cash flow over a longer horizon. For more information about rho, see Rho.

Automatic Indicators

To create an automatic indicator for rho, call the `QCAlgorithm.R` method with the Option contract `Symbol` object(s).

```
C#
public class AutomaticRhoIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]) as dynamic;
                var contract2 = AddFutureOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Rho indicators.
                contract1.R = R(contracts[0], contracts[1]);
                contract2.R = R(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
```

```
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Rho indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.R;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

The follow table describes the arguments that the `R` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating rho If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `R` method, see Using R Indicator .

Manual Indicators

To create a manual indicator for rho, call the `Rho` constructor.

C#

```
public class ManualRhoIndicatorAlgorithm : QCAlgorithm
{
    private Future _future;
    private ConstantDividendYieldModel _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _future = AddFuture(Futures.Indices.SP500EMini,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0);
        _future.SetFilter(0, 182);

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new ConstantDividendYieldModel(0m);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
```

```
        Schedule.On(
            DateRules.EveryDay(_future.Symbol),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_future.Mapped == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_future.Mapped);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddFutureOptionContract(contracts[0]);
                var contract2 = AddFutureOptionContract(contracts[1]);

                // Create and save the manual Rho indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Rho = new Rho(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Rho;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
```

```
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Rho indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_future.Mapped].Invested)
        {
            Liquidate(_future.Mapped);
        }
    }
}
```

For more information about the `Rho` constructor, see Using R Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

C#

```
// Example: Average IV of the call-put pair.
rhoIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Future Options

Market Hours

Introduction

The Future Option markets have the same hours as the Futures market. For more information, see the supported contracts and the market hours of Future markets .

Asset Classes

Index

There are cash Indices and volatility Indices. The former is a hypothetical portfolio that represents a segment of the financial market and the latter shows the expected level of price fluctuation in an Index Option.

Index

Requesting Data

Introduction

Request Index data in your algorithm to receive a feed of Index prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Cash Indices dataset listing . To trade live with Index data, you can use one of the brokerage data providers .

Create Subscriptions

To create an Index subscription, in the `Initialize` method, call the `AddIndex` method. The `AddIndex` method returns an `Index` object, which contains a `Symbol` property. Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
_symbol = AddIndex("VIX").Symbol;
```

To view the supported assets in the US Cash Indices dataset, see the Supported Indices .

Resolutions

The following table shows the available resolutions and data formats for Index subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓			
`Hour`	✓			
`Daily`	✓			

The default resolution for Index subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddIndex` method.

```
C#
_symbol = AddIndex("VIX", Resolution.Daily).Symbol;
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Indices is `Market.USA` , so you don't need to pass a `market` argument to the `AddIndex` method.

```
_symbol = AddIndex("VIX", market: Market.USA).Symbol;
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
_symbol = AddIndex("VIX", fillForward: false).Symbol;
```

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Properties

The `AddIndex` method returns an `Index` object, which have the following properties:

Examples

The following examples demonstrate some common practices for requesting Index data.

Example 1: VIX EMA Cross

The following algorithm adds daily VIX Index data and uses the Exponential Moving Average (EMA) indicator to create trading signals. The algorithm uses a 30-day slow EMA and a 15-day fast EMA. It enters a long SPY position when the fast EMA crosses above the slow EMA and liquidates the position when the fast EMA crosses below the slow EMA.

C#

```
public class IndexDemoAlgorithm : QCAlgorithm
{
    private ExponentialMovingAverage _emaFast, _emaSlow;
    private Symbol _vix, _spy;
    private decimal _tolerance;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add the daily VIX and SPY data.
        _vix = AddIndex("VIX", Resolution.Daily).Symbol;
        _spy = AddEquity("SPY", Resolution.Daily).Symbol;
        // Create fast and slow EMA indicators.
        _emaFast = EMA(_vix, 15);
        _emaSlow = EMA(_vix, 30);
        // Define a small tolerance to reduce trading churn.
        _tolerance = 0.00015m;
    }

    public override void OnData(Slice data)
    {
        // Check if the indicators is ready.
        if (!(_emaSlow.IsReady))
        {
            return;
        }
        // When the fast VIX EMA crosses above the slow EMA, buy SPY.
        if (!Portfolio.Invested && (_emaFast.Current.Value > _emaSlow.Current.Value  * (1 + _tolerance)))
        {
            SetHoldings(_spy, 0.8m);
        }
        // When the fast VIX EMA crosses below the slow EMA, liquidate the position.
        else if (Portfolio.Invested && (_emaFast.Current.Value < _emaSlow.Current.Value  * (1 - _tolerance)))
        {
            Liquidate(_spy);
        }
    }
}

Handling Data

Introduction

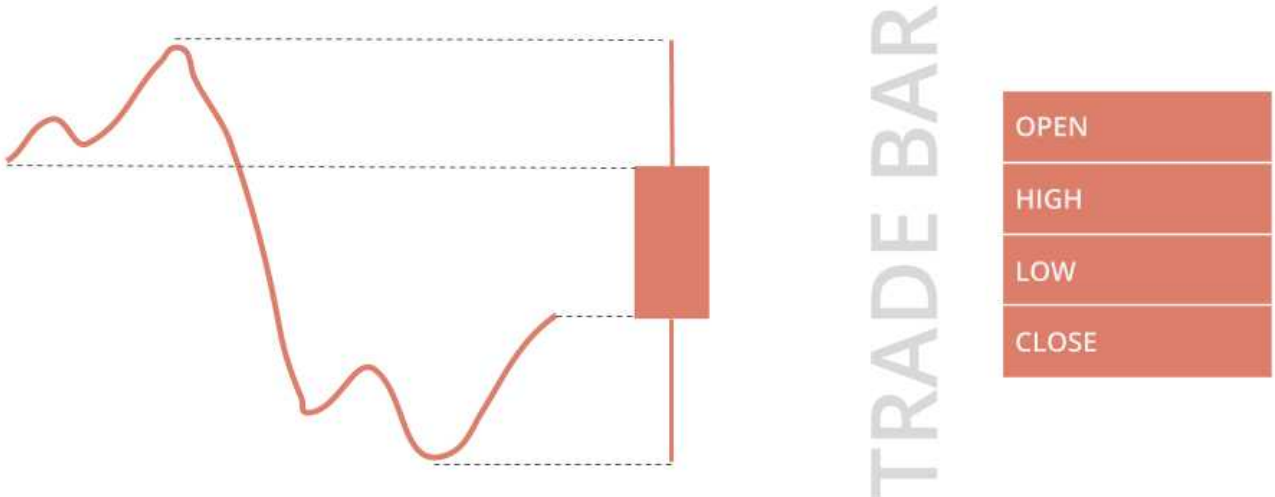
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `Tick` argument, it only receives `Tick` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `Ticks DataDictionary` is made up of `Tick` objects. To access individual data points in the dictionary, you can index the dictionary with the Index ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Index data, see Resolutions .

Bars

You can't trade Indices, but `TradeBar` objects are bars that represent the open, high, low, and close of an Index price over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the Index `Symbol` . The `Slice` may not contain data for your `Symbol` at every time step. To avoid issues, check if the `Slice` contains data for your Index before you index the `Slice` with the Index `Symbol` .

```C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        var value = tradeBar.Value;
    }
}
```

`TradeBar` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Index data.

Example 1: Trading ES Futures Based on the SPX Index RSI

The following algorithm adds daily data for the SPX Index and uses the Relative Strength Index (RSI) indicator to generate trading signals for the E-Mini S&P 500 Future. When the RSI crosses below 30, it buys the front-month ES contract. When the RSI crosses above 70, it liquidates the portfolio.

```C#
public class IndexDemoAlgorithm : QCAlgorithm
{
    private dynamic _spx;
    private Future _es;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add daily SPX Index data.
        _spx = AddIndex("SPX", Resolution.Daily);
        // Create an RSI indicator for the SPX index.
        _spx.Rsi = RSI(_spx.Symbol, 15);
        // Add the ES front-month Futures contract.
        _es = AddFuture(Futures.Indices.SP500EMini, dataMappingMode: DataMappingMode.OpenInterest);
        _es.SetFilter(futureFilterUniverse => futureFilterUniverse.StandardsOnly().FrontMonth());
    }

    public override void OnData(Slice slice)
    {
        // Check if the indicator is ready and we have the front-month contract data.
        if (!_spx.Rsi.IsReady || !slice.Bars.ContainsKey(_es.Mapped))
        {
            return;
        }

        // If the SPX RSI is <30, buy the ES.
        if (!Portfolio.Invested && _spx.Rsi.Current.Value < 30)
        {
            SetHoldings(_es.Mapped, 0.5);
        }

        // If the SPX RSI is >70, liquidate the portfolio.
        else if (Portfolio.Invested && _spx.Rsi.Current.Value > 70)
        {
            Liquidate();
        }
    }
}
```

Market Hours

USA

Introduction

This page shows the trading hours, holidays, and time zone of the US Indices market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the US Indices market:

Weekday	**Time (America/Chicago)**
Monday	08:30:00 to 15:20:00
Tuesday	08:30:00 to 15:20:00
Wednesday	08:30:00 to 15:20:00
Thursday	08:30:00 to 15:20:00
Friday	08:30:00 to 15:20:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the US Indices market:

Date (*yyyy-mm-dd*)
