The N225 market trades in the `Asia/Tokyo` time zone.

Asset Classes

Index Options

Index Options are a financial derivative that gives the holder the right (but not the obligation) to buy or sell the value of an underlying Index, such as the S&P 500 index, at the stated exercise price. No actual assets are bought or sold.

Index Options

Requesting Data

Request Index Options data in your algorithm to receive a feed of contract prices in the `OnData` method. For more information about the specific dataset we use for backtests, see the US Index Options dataset listing . To trade Index Options live, you can use one of the brokerage data providers . Index Options are exclusively European-style Options.

To request Index Options data, call one of the following methods:

- `AddIndexOption` to add a basket of contracts for a single underlying Index
- `AddIndexOptionContract` to add individual contracts for an underlying Index

Universes

Introduction

The `AddIndexOption` method enables you to select a basket of Option contracts for an underlying Index. To form your universe of contracts, you can filter them down by their strike price and expiry or you can choose to a subset of the contracts that form popular Option strategies . If you want to subscribe to individual contracts one-by-one instead of a set of contracts, see Individual Contracts .

Create Universes

To add a universe of Index Option contracts, in the `Initialize` method, call the `AddIndexOption` method. This method returns an `Option` object, which has a `SetFilter` method you can call to filter the set of tradable contract down to just the contracts you want.

```C#
public class BasicIndexOptionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        var option = AddIndexOption("SPX", "SPXW");
        option.SetFilter(Filter);
        _symbol = option.Symbol;
    }

    private OptionFilterUniverse Filter(OptionFilterUniverse universe)
    {
        return universe.IncludeWeeklys().Expiration(0, 7).Delta(0.35m, 0.75m);
    }

    public override void OnData(Slice data)
    {
        if (data.OptionChains.TryGetValue(_symbol, out var chain))
        {
            var contract = chain.OrderBy(x => x.Expiry).ThenBy(x => x.Greeks.Delta).FirstOrDefault();
        }
    }
}
```

For more information about the `AddIndexOption` method, see Create Universes .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Index with different features. The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for Option strategies.

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`NakedCall(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.

`NakedPut(int minDaysTillExpiry, decimal strikeFromAtm)`

Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.

`CallSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)`

Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.

`PutSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)`

Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.

`CallCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)`

Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.

`PutCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)`

Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.

`Strangle(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)`

Selects two contracts to form Long Strangle or Short Strangle Option strategies.

`Straddle(int minDaysTillExpiry)`

Selects two contracts to form Long Straddle or Short Straddle Option strategies.

`ProtectiveCollar(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)`

Selects two contracts to form Protective Collar Option strategies.

`Conversion(int minDaysTillExpiry, decimal strikeFromAtm)`

Selects two contracts to form Conversion or Reverse Conversion Option strategies.

`CallButterfly(int minDaysTillExpiry, decimal strikeSpread)`

Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.

`PutButterfly(int minDaysTillExpiry, decimal strikeSpread)`

Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.

`IronButterfly(int minDaysTillExpiry, decimal strikeSpread)`

Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.

`IronCondor(int minDaysTillExpiry, decimal nearStrikeSpread, decimal farStrikeSpread)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`BoxSpread(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`JellyRoll(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.
`CallLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`PutLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse`, so you can chain the methods together.

```C#
// Example 1: Select a Straddle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Straddle(30, 5, 10));

// Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0, 30).IronCondor(30, 5, 10));

// Example 3: Select the 0DTE contracts that form an Strangle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Expiration(0, 0).Strangle(30, 5, -10));
```

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio. The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest.

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`IV(decimal min, decimal max)`
`ImpliedVolatility(decimal min, decimal max)`
 	
Selects a contract with implied volatility within the range you set.

`D(decimal min, decimal max)`
`Delta(decimal min, decimal max)`
 	
Selects a contract with delta within the range you set.

`G(decimal min, decimal max)`
`Gamma(decimal min, decimal max)`
 	
Selects a contract with gamma within the range you set.

`R(decimal min, decimal max)`
`Rho(decimal min, decimal max)`
 	
Selects a contract with rho within the range you set.

`V(decimal min, decimal max)`
`Vega(decimal min, decimal max)`
 	
Selects a contract with vega within the range you set.

`T(decimal min, decimal max)`
`Theta(decimal min, decimal max)`
 	
Selects a contract with theta within the range you set.

`OI(long min, long max)`
`OpenInterest(decimal min, decimal max)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
C#
```

```
// Example 1: Select the contracts with delta between 0.25 and 0.75
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Delta(0.25m, 0.75m));

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below
20%
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below
20% that forms an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0,
30).IronCondor(30, 5, 10));
```

Filter by Other Contract Properties

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Option` object.

```C#
// Select contracts that have a strike price within 1 strike level above and below the underlying price
option.SetFilter(minStrike: -1, maxStrike: 1);

// Select contracts that expire within 30 days
option.SetFilter(minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select contracts that have a strike price within 1 strike level and expire within 30 days
option.SetFilter(minStrike: -1, maxStrike: 1, minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly());
```

The following table describes the available filter techniques:

`SetFilter(int minStrike, int maxStrike)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302*andthereare*strikes*at*every5. If you set `minStrike` to -1 and `maxStrike` to 1, LEAN selects the contracts that have a strike of 300*or*305. This filter runs asynchronously by default.
`SetFilter(TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`SetFilter(int minStrike, int maxStrike, TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`SetFilter(Func<OptionFilterUniverse, OptionFilterUniverse> universeFunc)` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.
`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.
`StandardsOnly()` Selects standard contracts.
`IncludeWeeklys()` Selects non-standard weeklys contracts.
`WeeklysOnly()` Selects weekly contracts.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.
`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```C#
// Example 1: Select the front month call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly().FrontMonth());

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

Historical Data

To get historical chains for an Index Option, see Historical Data .

Examples

The following examples demonstrate some common practices for requesting Index Options universe data.

Example 1: Selecting for 0DTE Contracts

0DTE Options are option contracts that expire on the same day they are traded. To create a universe with 0DTE options, call the `SetFilter` or method. In this example, we will select 0DTE contracts within 1 strike price level and a Delta between 0.25 and 0.75. Then, we will go long on the highest strike price call contract of the SPX index and hold until expiry.

C#

```
public class BasicIndexOptionAlgorithm : QCAlgorithm
{
    private Option _option;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Subscribe to the option chain.
        _option = AddIndexOption("SPX", "SPXW");
        // Filter the option universe to only select 0DTE options.
        _option.SetFilter(u => u.IncludeWeeklys().Expiration(0, 0).Strikes(-1, 1));
        // Filter the option universe by Delta. The last SetFilter call prevails.
        // _option.SetFilter(optionFilterUniverse => optionFilterUniverse.Delta(0.25m, 0.75m));
    }

    public override void OnData(Slice slice)
    {
        // Get the option chain data.
        if (Portfolio.Invested || !slice.OptionChains.TryGetValue(_option.Symbol, out var chain))
        {
            return;
        }
        // Sorted the call Option contracts according to their strike prices.
        var call = chain.Where(contract => contract.Right == OptionRight.Call).OrderBy(x =>
x.Strike).FirstOrDefault();
        if (call == null) return;

        // Buy 1 0DTE call option contract for the SPX index.
        Buy(call.Symbol, 1);
    }
}
```

Requesting Data

Individual Contracts

Introduction

The `AddOptionContract` method enables you to add an individual Option contract to your algorithm. To check which contracts are currently available to add to your algorithm, use the `OptionChain` method. If you want to subscribe to a set of contracts instead of individual contracts one-by-one, see Universes .

Create Subscriptions

Before you can subscribe to an Index Option contract, you must configure the underlying Index and get the contract `Symbol` .

```
C#
public class BasicIndexOptionAlgorithm : QCAlgorithm
{
    private Symbol _underlying, _contractSymbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _underlying = AddIndex("SPX").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (_contractSymbol != null)
        {
            return;
        }
        var chain = OptionChain(_underlying);
        var expiry = chain.Select(contract => contract.Expiry).Min();
        _contractSymbol = chain
            .Where(contract =>
                contract.Expiry == expiry &&
                contract.Right == OptionRight.Call &&
                contract.Greeks.Delta > 0.3m &&
                contract.Greeks.Delta < 0.7m
            )
            .OrderByDescending(contract => contract.OpenInterest)
            .First()
            .Symbol;
        AddOptionContract(_contractSymbol);
    }
}
```

Configure the Underlying Index

In most cases, you should subscribe to the underlying Index before you subscribe to an Index Option contract.

```
C#
_underlying = AddIndex("SPX").Symbol;
```

Get Contract Symbols

To subscribe to an Option contract, you need the contract `Symbol` . The preferred method to getting Option contract `Symbol` objects is to use the `OptionChain` method. This method returns an `OptionChain` object, which represent an entire chain of Option contracts for a single underlying security. With the chain, sort and filter the data to find the specific contract(s) you want to trade.

```
// Get the contracts available to trade.
//   Option A: Standard contracts.
var chain = OptionChain(
    QuantConnect.Symbol.CreateCanonicalOption(_underlying, Market.USA, "?SPX")
);

//   Option B: Weekly contracts.
//var chain = OptionChain(
//    QuantConnect.Symbol.CreateCanonicalOption(_underlying, "SPXW", Market.USA, "?SPXW")
//);

// Select a contract.
var expiry = chain.Select(contract => contract.Expiry).Min();
_contractSymbol = chain
    .Where(contract =>
        // Select call contracts with the closest expiry.
        contract.Expiry == expiry &&
        contract.Right == OptionRight.Call &&
        // Select contracts with a 0.3-0.7 delta.
        contract.Greeks.Delta > 0.3m &&
        contract.Greeks.Delta < 0.7m
    )
    // Select the contract with the largest open interest.
    .OrderByDescending(contract => contract.OpenInterest)
    .First()
    // Get the Symbol of the target contract.
    .Symbol;
```

Alternatively, you can create a Index Option contract `Symbol` object directly parsing its OSI ticker using the `SymbolRepresentation.ParseOptionTickerOSI` method.

```
// Create the contract Symbol for the SPX Call 5650 3 Sept 2024.
_contractSymbol = SymbolRepresentation.ParseOptionTickerOSI("SPXW 240903C05650000", SecurityType.IndexOption,
OptionStyle.European, Market.USA);
```

Subscribe to Contracts

To create an Index Option contract subscription, pass the contract `Symbol` to the `AddIndexOptionContract` method. Save a reference to the contract `Symbol` so you can easily access the contract in the OptionChain that LEAN passes to the `OnData` method. To override the default pricing model of the Option, set a pricing model .

```
var option = AddIndexOptionContract(_contractSymbol);
option.PriceModel = OptionPriceModels.BlackScholes();
```

The `AddIndexOptionContract` method creates a subscription for a single Index Option contract and adds it to your user-defined universe. To create a dynamic universe of Index Option contracts, add an Index Option universe .

Warm Up Contract Prices

If you subscribe to an Index Option contract with `AddIndexOptionContract` , you'll need to wait until the next `Slice` to receive data and trade the contract. To trade the contract in the same time step you subscribe to the contract, set the current price of the contract in a security initializer .

```
Settings.SeedInitialPrices = true;
```

Supported Assets

To view the supported assets in the US Index Options dataset, see Supported Assets .

Resolutions

The following table shows the available resolutions and data formats for Index Option contract subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				
`Second`				
`Minute`	✓	✓		
`Hour`	✓	✓		
`Daily`	✓	✓		

The default resolution for Index Option subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddIndexOptionContract` method.

```
AddIndexOptionContract(_contractSymbol, Resolution.Hour);
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The only market available for Index Options is `Market.USA` . You don't need to pass a `Market` argument to the `AddIndexOptionContract` method because the contract `Symbol` already contains the market.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
AddIndexOptionContract(_contractSymbol, fillForward: false);
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. Options are already leveraged products, so you can't change their leverage.

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Remove Subscriptions

To remove a contract subscription that you created with `AddIndexOptionContract` , call the `RemoveOptionContract` method. This method is an alias for `RemoveSecurity` .

```
RemoveOptionContract(_contractSymbol);
```

The `RemoveOptionContract` method cancels your open orders for the contract and liquidates your holdings.

Properties

The `AddIndexOptionContract` method returns an `Option` object, which have the following properties:

Helper Methods

The `Option` object provides methods you can use for basic calculations. These methods require the underlying price. To get the `Option` object and the `Security` object for its underlying in any function, use the Option `Symbol` to access the value in the `Securities` object.

```
var option = Securities[_contractSymbol];
var underlying = Securities[_contractSymbol.Underlying];
var underlyingPrice = underlying.Price;
```

To get the Option payoff , call the `GetPayOff` method.

```
var payOff = option.GetPayOff(underlyingPrice);
```

To get the Option intrinsic value , call the `GetIntrinsicValue` method.

```
var intrinsicValue = option.GetIntrinsicValue(underlyingPrice);
```

To get the Option out-of-the-money amount , call the `OutOfTheMoneyAmount` method.

```
var otmAmount = option.OutOfTheMoneyAmount(underlyingPrice);
```

To check whether the Option can be automatic exercised, call the `IsAutoExercised` method.

```
var isAutoExercised = option.IsAutoExercised(underlyingPrice);
```

Exceptions and Edge Cases

The following sections explain exceptions and edge cases with subscribing to individual Option contracts.

Manually Creating Option Symbol Objects

To subscribe to an Option contract, you need the contract `Symbol` . To get Index Option contract `Symbol` objects, call the `CreateOption` or `OptionChain` methods. If you use the `CreateOption` method, you need to know the specific contract details.

```
// Standard contracts
_contractSymbol = QuantConnect.Symbol.CreateOption(_underlying, Market.USA,
    OptionStyle.European, OptionRight.Call, 3650, new DateTime(2022, 6, 17));

// Weekly contracts
_weeklyContractSymbol = QuantConnect.Symbol.CreateOption(_underlying, "SPXW", Market.USA,
    OptionStyle.European, OptionRight.Call, 3650, new DateTime(2022, 6, 17));
```

Default Underlying Subscription Settings

If you subscribe to an Index Option contract but don't have a subscription to the underlying Index, LEAN automatically subscribes to the underlying Index and sets its fill forward property to match that of the Index Option contract. In this case, you still need the Index `Symbol` to subscribe to Index Option contracts. If you don't have access to it, create it.

```
_underlying = QuantConnect.Symbol.Create("SPX", SecurityType.Index, Market.USA);
```

Overriding the Initial Implied Volatility Guess

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Examples

The following examples demonstrate common practices for requesting individual index option contract data.

Example 1: 5-Minute Option Chain

The following example shows how to update the Option chain every five minutes. The custom `OptionChainManager` class implements the selection logic and manages the contract subscriptions.

```
public class OptionChainFullExample : QCAlgorithm
{
    private Dictionary<Symbol, OptionChainManager> _chainManager = new();
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 10, 31);
        SetCash(500000);
        UniverseSettings.Asynchronous = true;
        UniverseSettings.MinimumTimeInUniverse = TimeSpan.Zero;

        // Seed the last price to ensure filtering using the underlying price is available immediately.
        Settings.SeedInitialPrices = true;

        // Request the index underlying data for filtering.
        var spx = AddIndex("SPX").Symbol;
        // Create the 5-minute option chain manager on the SPXW weekly index option.
        _chainManager[QuantConnect.Symbol.CreateCanonicalOption(spx, "SPXW", Market.USA, "?SPXW")] = new(-10, 10, 0,
1);
        // Populate the updated option chain immediately to trade with.
        PopulateOptionChain();

        // Set a schedule event to populate the option chain when the market opens since the option contracts are
updated daily.
        Schedule.On(DateRules.EveryDay(spx), TimeRules.AfterMarketOpen(spx, 1), PopulateOptionChain);
        // Set a scheduled event to filter the closed ATM calls every 5 minutes.
        Schedule.On(DateRules.EveryDay(spx), TimeRules.Every(TimeSpan.FromMinutes(5)), Filter);
    }

    private void PopulateOptionChain()
    {
        // The contract list is updated daily, so we can get it and apply
        // the expiration filter as soon as the market opens.
        foreach (var (symbol, manager) in _chainManager)
        {
            manager.SetChain(OptionChain(symbol), Time);
```

```
        }
        Filter();
    }

    private void Filter()
    {
        foreach (var (symbol, manager) in _chainManager)
        {
            manager.Select(this, symbol);
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (symbol, manager) in _chainManager)
        {
            // Only trade on updated data.
            if (!slice.OptionChains.TryGetValue(symbol, out var chain))
                continue;

            // Filter the closest ATM call contract and trade.
            var expiry = chain.Min(x => x.Expiry);
            var atmCall = chain
                .Where(x => x.Expiry == expiry && x.Right == OptionRight.Call && Securities[x.Symbol].IsTradable)
                .OrderBy(x => Math.Abs(chain.Underlying.Price - x.Strike))
                .FirstOrDefault();

            if (atmCall != null && !Portfolio[atmCall.Symbol].Invested)
                MarketOrder(atmCall.Symbol, 1);
        }
    }
}

internal class OptionChainManager
{
    private readonly int _minStrike;
    private readonly int _maxStrike;
    private readonly int _minExpiry;
    private readonly int _maxExpiry;
    private List<OptionContract> _chain = new();
    private readonly List<Symbol> _symbols = new();

    public OptionChainManager(int minStrike, int maxStrike, int minExpiry, int maxExpiry)
    {
        _minStrike = minStrike;
        _maxStrike = maxStrike;
        _minExpiry = minExpiry;
        _maxExpiry = maxExpiry;
    }

    public void SetChain(OptionChain chain, DateTime time)
    {
        // Filter the expiry daily only since the contract list is updated daily.
        _chain = chain.Where(x =>
        {
            var totalDays = (x.Expiry - time).TotalDays;
            return _minExpiry <= totalDays && totalDays <= _maxExpiry;
        }).ToList();
    }

    public void Select(QCAlgorithm algorithm, Symbol underlyingSymbol)
    {
        if (_chain.IsNullOrEmpty())
            return;
        if (underlyingSymbol.IsCanonical())
            underlyingSymbol = underlyingSymbol.Underlying;

        // Filter the contracts with strike range spread between the preset level.
        var strikes = _chain.Select(x => x.Strike).OrderBy(x => x).Distinct().ToList();
        var spot = algorithm.Securities[underlyingSymbol].Price;
        var atm = strikes.OrderBy(x => Math.Abs(spot - x)).FirstOrDefault();
        var index = strikes.IndexOf(atm);
        var minStrike = strikes[Math.Max(0, index + _minStrike)];
        var maxStrike = strikes[Math.Min(strikes.Count - 1, index + _maxStrike)];
        var symbols = _chain
            .Where(x => minStrike <= x.Strike && x.Strike <= maxStrike)
            .Select(x => x.Symbol).ToList();

        // Remove subscriptions if the contracts are no longer ATMs.
        foreach (var symbol in _symbols.Except(symbols).ToList())
        {
```

```
            if (algorithm.RemoveOptionContract(symbol))
                _symbols.Remove(symbol);
        }
        // Request data of the newly identified ATM contracts.
        foreach (var symbol in symbols.Except(_symbols).ToList())
        {
            _symbols.Add(symbol);
            algorithm.AddOptionContract(symbol);
        }
    }
}
```

Index Options

Handling Data

Introduction

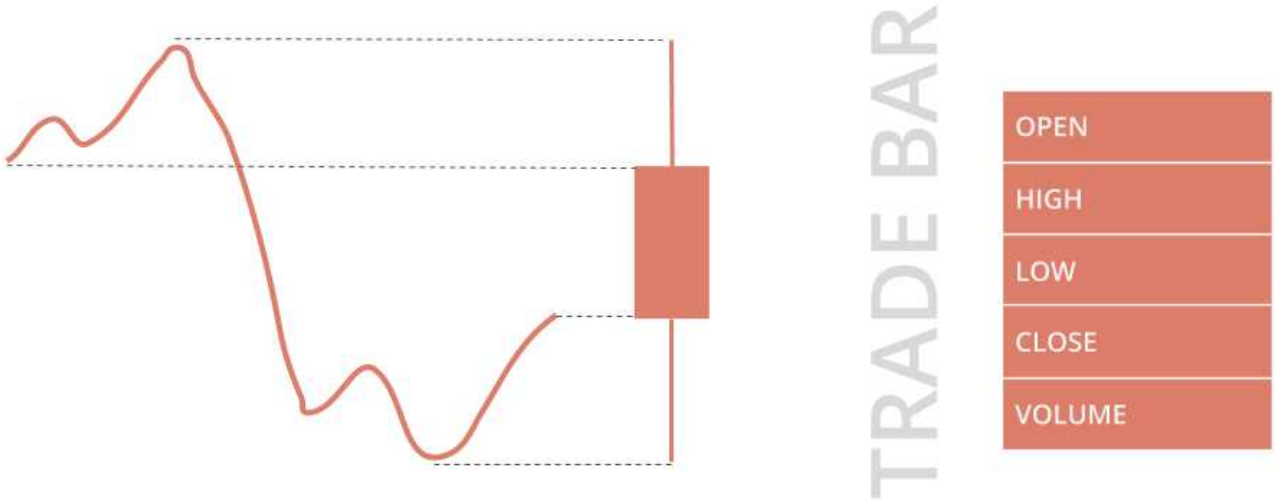
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `TradeBar` argument, it only receives `TradeBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `TradeBars` `DataDictionary` is made up of `TradeBar` objects. To access individual data points in the dictionary, you can index the dictionary with the contract ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for Index Options data, see Resolutions .

Trades

`TradeBar` objects are price bars that consolidate individual trades from the exchanges. They contain the open, high, low, close, and volume of trading activity over a period of time.



To get the `TradeBar` objects in the `Slice` , index the `Slice` or index the `Bars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively trade or you are in the same time step as when you added the contract subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in TradeBars object
    if (slice.Bars.ContainsKey(_contractSymbol))
    {
        // Obtain the mapped TradeBar of the symbol
        var tradeBar = slice.Bars[_contractSymbol];
    }
}
```

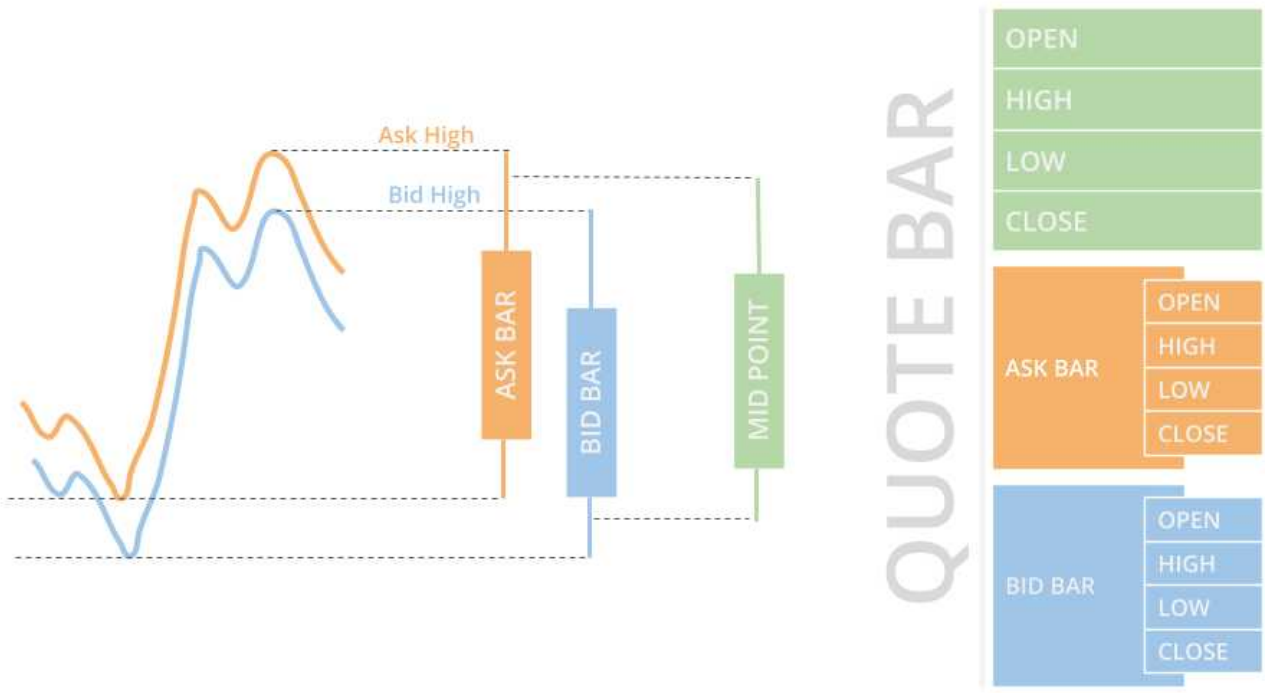
You can also iterate through the `TradeBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `TradeBar` objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-TradeBar key-value pairs
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        var closePrice = tradeBar.Close;
    }
}
```

`TradeBar` objects have the following properties:

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the contract `Symbol` . If the contract doesn't actively get quotes or you are in the same time step as when you added the contract subscription, the `Slice` may not

contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your contract before you index the `Slice` with the contract `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_contractSymbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_contractSymbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get all contracts if the OptionChain contains any member
        var contracts = chain.Contracts;
    }
}
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-OptionChain key-value pairs
    foreach (var kvp in slice.OptionChains)
    {
        var canonicalSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}
```

`OptionChain` objects have the following properties:

Option Contracts

`OptionContract` objects represent the data of a single Option contract in the market. To get the Option contracts in the `Slice` , use the `Contracts` property of the `OptionChain` .

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            var price = contract.Price;
        }
    }
}
```

Greeks and Implied Volatility

To get the Greeks and implied volatility of an Option contract, use the `Greeks` and `implied_volatility` members.

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get greeks data of the selected contract
            var delta = contract.Greeks.Delta;
            var iv = contract.ImpliedVolatility;
        }
    }
}
```

LEAN only calculates Greeks and implied volatility when you request them because they are expensive operations. If you invoke the `Greeks` property, the Greeks aren't calculated. However, if you invoke the `Greeks.Delta` , LEAN calculates the delta. To avoid unecessary computation in your algorithm, only request the Greeks and implied volatility when you need them. For more information about the Greeks and implied volatility, see Options Pricing .

Open Interest

Open interest is the number of outstanding contracts that haven't been settled. It provides a measure of investor interest and the market liquidity, so it's a popular metric to use for contract selection. Open interest is calculated once per day. To get the latest open interest value, use the `OpenInterest` property of the `Option` or `OptionContract` .

```C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChains using the canonical symbol
    if (slice.OptionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get the open interest of the selected contracts
            var openInterest = contract.OpenInterest;
        }
    }
}

public void OnData(OptionChains optionChains)
{
    // Try to get the OptionChains using the canonical symbol
    if (optionChains.TryGetValue(_contractSymbol.Canonical, out var chain))
    {
        // Get individual contract data
        if (chain.Contracts.TryGetValue(_contractSymbol, out var contract))
        {
            // Get the open interest of the selected contracts
            var openInterest = contract.OpenInterest;
        }
    }
}
```

Properties

`OptionContract` objects have the following properties:

Examples

The following examples demonstrate some common practices for handling Index Options.

Example 1: Supply-Demand Pressure Of Individual Contract

This example shows how to handle `QuoteBar` data for the SPXW Index Option contracts to trade based on the supply-demand pressure, while filter individual option contracts and request data using `OptionChain` method for the contracts that expire that day.

C#

```
public class IndexOptionHandlingDataAlgorithm : QCAlgorithm
{
    private Option _spxw;
    private List<Symbol> _contracts = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000000);

        // Subscribe to underlying data for ATM calculation using the updated underlying price.
        // Set data normalization mode to raw is required to ensure the strike price and underlying price are
comparable.
        _spxw = AddIndexOption("SPX", "SPXW");
        _spxw.SetFilter((x) => x.IncludeWeeklys().Expiration(0, 3).Strikes(-5, 5));

        // Update the tradable contracts daily before the market opens since the option contract list provider
populates them daily.
        Schedule.On(
            DateRules.EveryDay(_spxw.Symbol),
            TimeRules.At(9, 0),
            UpdateContracts
        );
    }

    private void UpdateContracts()
    {
        // Get all contracts that expire today, and subscribe to data for trading needs.
        // We do not need to liquidate or handle settlement since all contracts are cash-settled after market close.
        // We only get the strike contracts within $10 of the underlying for higher liquidity and less slippage.
        _contracts = OptionChain(_spxw.Symbol)
            .Where(x => x.Expiry <= Time.AddDays(1) && Math.Abs(x.UnderlyingLastPrice - x.Strike) < 10)
            .Select(x => x.Symbol)
            .ToList();
    }

    public override void OnData(Slice slice)
    {
        // Only focus on a filtered list of option contracts to trade and select the ATM call.
        var contract = _contracts.Where(x => x.ID.OptionRight == OptionRight.Call)
            .MinBy(x => Math.Abs(Securities[x.Underlying].Price - x.ID.StrikePrice));
        if (contract == null)
        {
            return;
        }

        // Trade based on the updated data.
        if (slice.QuoteBars.TryGetValue(contract, out var quote) && !Portfolio.Invested)
        {
            if (quote.Bid != null && quote.Ask != null)
            {
                // If the last trading price is close to the asking price, the selling pressure is higher, so we are
short.
                var diff = quote.Ask.Close - 2 * quote.Close + quote.Bid.Close;
                if (diff < 0)
                {
                    SetHoldings(contract, -0.05m);
                }
                else
                {
                    SetHoldings(contract, 0.05m);
                }
            }
        }
    }
}
```

Example 2: Supply-Demand Pressure Of Universe

This example shows how to handle `QuoteBar` data for shortlisted Index Option contracts to calculate mid-price using bid close and ask close data, while request data through universe selection function using `SetFilter` method for the contracts that expire within the current week. Using mid-price, we can examine the market fair value of the Option and compare it with the model theoretical price.

C#

```
public class IndexOptionHandlingDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 15);
        SetCash(100000000);

        // Subscribe to SPXW option data.
        var option = AddIndexOption("SPX", "SPXW");
        _symbol = option.Symbol;
        // We wish only to trade the contracts expiring within the same week since they have the highest volume.
        option.SetFilter(u => u.IncludeWeeklys().Contracts(x => x.Where(s => s.ID.Date <= Expiry.EndOfWeek(Time))));
    }

    public override void OnData(Slice slice)
    {
        // Only want to obtain the option chain of the selected symbol.
        if (slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            // Select the ATM call to trade.
            var contract = chain.Where(x => x.Right == OptionRight.Call)
                .MinBy(x => Math.Abs(x.UnderlyingLastPrice - x.Strike));

            // If the last trading price is close to the asking price, the selling pressure is higher, so we are
short.
            var diff = contract.AskPrice - 2m * contract.LastPrice + contract.BidPrice;
            if (diff < 0)
            {
                SetHoldings(contract, 0.05m);
            }
            else
            {
                SetHoldings(contract, -0.05m);
            }
        }
    }
}
```

Example 3: Get Instant Delta

The option Greeks change rapidly, so we need to obtain the instant Greeks to calculate the hedge size for arbitration or replication portfolio accurately. You can call the `Greeks` property from the `OptionChain` data to access various Greeks. In this example, we will demonstrate how to obtain a contract with a Delta closest to 0.4 among all call contracts expiring the same week.

C#

```
public class IndexOptionHandlingDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Subscribe to SPXW option data.
        var option = AddIndexOption("SPX", "SPXW");
        _symbol = option.Symbol;
        // We wish only to trade the contracts expiring within the same week since they have the highest volume.
        // 0.4 Delta will only appear in call contracts.
        option.SetFilter(u => u.IncludeWeeklys().Delta(0.2m, 0.6m).Contracts((x) => x.Where(s => s.ID.Date <=
Expiry.EndOfWeek(Time))));
    }

    public override void OnData(Slice slice)
    {
        // Only want to obtain the option chain of the selected symbol.
        if (slice.OptionChains.TryGetValue(_symbol, out var chain) && !Portfolio.Invested)
        {
            // Get the contract with Delta closest to 0.4 to trade.
            // The arbitrary delta criterion might be set due to hedging need or risk adjustment.
            var selected = chain.OrderBy(x => Math.Abs(x.Greeks.Delta - 0.4m)).First();

            // Hold a naked call on the selected contract to speculate an uprise of the SPX index with leverage.
            MarketOrder(selected.Symbol, 1);
        }
    }
}
```

Greeks and Implied Volatility

The Greeks are measures that describe the sensitivity of an Option's price to various factors like underlying price changes (Delta), time decay (Theta), volatility (Vega), and interest rates (Rho), while Implied Volatility (IV) represents the market's expectation of the underlying asset's volatility over the life of the Option.

Greeks and Implied Volatility

Key Concepts

Introduction

LEAN provides multiple ways for you to get the Greeks and implied volatility (IV) of Option contracts. There is a daily, pre-calculated dataset based on the end of the previous trading day. There is also a stream of values that are calculated on-the-fly as your algorithm runs.

Greeks on Universes

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```C#
public override void Initialize()
{
    var option = AddIndexOption("SPX");
    option.SetFilter(universe => universe.IncludeWeeklys().Delta(0.3m, 0.7m).Expiration(0, 7));
}
```

To calculate the values, we use our implementation of the Black-Scholes pricing model, which accounts for the interest rate and dividend payments when applicable. For example, VIX doesn't have dividends. We use SPY for SPX and QQQ for NDX.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greek History

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day.

```C#
public class OptionHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var option = AddIndexOption("SPX");
        var history = History<OptionUniverse>(option.Symbol, 5);
        foreach (var chain in history)
        {
            var endTime = chain.EndTime;
            var filteredContracts = chain.Data
                .Select(contract => contract as OptionUniverse)
                .Where(contract => contract.Greeks.Delta > 0.3m);
            foreach (var contract in filteredContracts)
            {
                var price = contract.Price;
                var iv = contract.ImpliedVolatility;
            }
        }
    }
}
```

You can't customize the Greeks and IV values that you get from a history request. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

Greeks on Data Events

The Greeks and IV values that you get from the current Slice are from the price model calculations. These values aren't the same as the values you get in the universe filter function.

```
C#
public class OptionDataEventsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var option = AddIndexOption("VIX", "VIXW");
        option.PriceModel = OptionPriceModels.CrankNicolsonFD();
    }

    public override void OnData(Slice data)
    {
        foreach (var chain in data.OptionChains.Values)
        {
            foreach (var contract in chain)
            {
                var iv = contract.ImpliedVolatility;
                var delta = contract.Greeks.Delta;
            }
        }
    }
}
```

To view all the models LEAN supports, see Supported Models .

Greek Indicators

The Greeks and IV values that you get from the indicators are calculated in the same way as the values you get in the filter function, but they can reflect intraday prices instead of just the daily closing prices.

Examples

For detailed examples on using Option Greeks and Implied Volatility indicators in algorithm, you may refer to the Greeks Indicators page examples.

Greeks and Implied Volatility

Indicators

Introduction

Option indicators enable you to calculate daily and intraday values for the Greeks and implied volatility of Option contracts. This page explains the most popular Option indicators and how to use them with LEAN.

Parameters

The following table describes the arguments that the automatic Option indicators methods accept:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The contract to use when calculating the indicator values.	
`mirrorOption`	`Symbol`	The mirror contract to use in parity type calculations.	`null`
`riskFreeRate`	`decimal`	The risk-free interest rate. If you don't provide a value, the default value is the US primary credit rate from the Interest Rate Provider Model .	`null`
`dividendYield`	`decimal`	The dividend yield rate. If you don't provide a value, the default value comes from the Dividend Yield Provider Model .	`null`
`optionModel`	`OptionPricingModelType`	The Option pricing model that's used to calculate the Greeks. If you don't provide a value, the default value is `OptionPricingModelType.BlackScholes` for Index Options.	`null`
`resolution`	`Resolution`	The resolution of the indicator data. If you don't provide a value, the default value is the resolution of the subscription you have for the Option contract(s).	`null`

To perform implied volatility (IV) smoothing with a put-call pair, pass one of the contracts as the `symbol` argument and pass the other contract in the pair as the `mirrorOption` argument. The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, call the `SetSmoothingFunction` method of the `ImpliedVolatility` class/property.

Several different Option pricing models are supported to calculate the IV and Greeks. The following table describes the

`OptionPricingModelType` enumeration members:

Implied Volatility

Implied volatility, σ , is the market's expectation for the future volatility of an asset and is implied by the price of the assets's Options contracts. You can't observe it in the market but you can derive it from the price of an Option. For more information about implied volatility, see Implied Volatility .

Automatic Indicators

To create an automatic indicator for implied volatility, call the `QCAlgorithm.IV` method with the Option contract `Symbol` object(s).

```
C#
public class AutomaticImpliedVolatilityIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]) as dynamic;
                var contract2 = AddIndexOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic ImpliedVolatility indicators.
                contract1.IV = IV(contracts[0], contracts[1]);
                contract2.IV = IV(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }
```

```
    public override void OnData(Slice slice)
    {
        // Get the ImpliedVolatility indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.IV;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `IV` method, see Parameters and Using IV Indicator .

Manual Indicators

To create a manual indicator for implied volatility, call the `ImpliedVolatility` constructor.

C#

```
public class ManualImpliedVolatilityIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
```

```
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]);
                var contract2 = AddIndexOptionContract(contracts[1]);

                // Create and save the manual ImpliedVolatility indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.ImpliedVolatility = new ImpliedVolatility(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).ImpliedVolatility;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the ImpliedVolatility indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
```

```
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `ImpliedVolatility` constructor, see Using IV Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the `IV` method or `ImpliedVolatility` constructor and then call the `SetSmoothingFunction` method of the resulting `ImpliedVolatility` object. The follow table describes the arguments of the custom function:

Argument	Data Type	Description
`iv`	`decimal`	The IV of the Option contract.
`mirrorIv`	`decimal`	The IV of the mirror Option contract.

The method must return a `decimal` as the smoothened IV.

C#

```
private ImpliedVolatility _iv;

public override void Initialize()
{
    var option = QuantConnect.Symbol.CreateOption("AAPL", Market.USA, OptionStyle.American, OptionRight.Put, 505m,
new DateTime(2014, 6, 27));
    AddOptionContract(option);

    var mirrorOption = QuantConnect.Symbol.CreateOption("AAPL", Market.USA, OptionStyle.American, OptionRight.Call,
505m, new DateTime(2014, 6, 27));
    AddOptionContract(mirrorOption);

    _iv = IV(option, mirrorOption);
    // example: take average of the call-put pair
    _iv.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
}
```

Delta

Delta, Δ , is the rate of change of the Option price with respect to the price of the underlying asset. It measures the first-order sensitivity of the price to a movement in underlying price. For example, an Option delta of 0.4 means that if the underlying asset moves by 1%, then the value of the Option moves by $0.4 \times 1\% = 0.4\%$. For more information about delta, see Delta .

Automatic Indicators

To create an automatic indicator for delta, call the `QCAlgorithm.D` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticDeltaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset
```

```
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]) as dynamic;
                var contract2 = AddIndexOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Delta indicators.
                contract1.D = D(contracts[0], contracts[1]);
                contract2.D = D(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Delta indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.D;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `D` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Delta. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `D` method, see Using D Indicator .

Manual Indicators

To create a manual indicator for delta, call the `Delta` constructor.

```
C#
public class ManualDeltaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));

        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Delta;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Delta indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Delta` constructor, see Using D Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the

SetSmoothingFunction method of the ImpliedVolatility property of the indicator.

```
// Example: Average IV of the call-put pair.
deltaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Gamma

Gamma, Γ, is the rate of change of the portfolio's delta with respect to the underlying asset's price. It represents the second-order sensitivity of the Option to a movement in the underlying asset's price. For more information about Gamma, see Gamma .

Automatic Indicators

To create an automatic indicator for gamma, call the QCAlgorithm.G method with the Option contract Symbol object(s).

```
public class AutomaticGammaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]) as dynamic;
                var contract2 = AddIndexOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Gamma indicators.
                contract1.G = G(contracts[0], contracts[1]);
                contract2.G = G(contracts[1], contracts[0]);
```

```
                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Gamma indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.G;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `G` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating Gamma. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `G` method, see Using G Indicator .

Manual Indicators

To create a manual indicator for gamma, call the `Gamma` constructor.

C#

```
public class ManualGammaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open
```

```
        // Set up a scheduled event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]);
                var contract2 = AddIndexOptionContract(contracts[1]);

                // Create and save the manual Gamma indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Gamma = new Gamma(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Gamma;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
```

```
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Gamma indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Gamma` constructor, see Using G Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

C#

```
// Example: Average IV of the call-put pair.
gammaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Vega

Vega, ν , is the rate of change in the value of the Option with respect to the volatility of the underlying asset. For more information about vega, see Vega .

Automatic Indicators

To create an automatic indicator for vega, call the `QCAlgorithm.V` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticVegaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }
```

```
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]) as dynamic;
                var contract2 = AddIndexOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Vega indicators.
                contract1.V = V(contracts[0], contracts[1]);
                contract2.V = V(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Vega indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.V;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `V` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
ivModel	OptionPricingModelType	The Option pricing model to use to estimate the IV when calculating Vega. If you don't provide a value, the default value is to match the optionModel parameter.	null

For more information about the V method, see Using V Indicator .

Manual Indicators

To create a manual indicator for vega, call the Vega constructor.

```C#
public class ManualVegaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
```

```
                var contract1 = AddIndexOptionContract(contracts[0]);
                var contract2 = AddIndexOptionContract(contracts[1]);

                // Create and save the manual Vega indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Vega = new Vega(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Vega;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Vega indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Vega` constructor, see Using V Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the

`SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

```
// Example: Average IV of the call-put pair.
vegaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Theta

Theta, Θ , is the rate of change of the value of the Option with respect to the passage of time. It is also known to as the time decay of an Option. For more information about theta, see Theta .

Automatic Indicators

To create an automatic indicator for theta, call the `QCAlgorithm.T` method with the Option contract `Symbol` object(s).

```
public class AutomaticThetaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]) as dynamic;
                var contract2 = AddIndexOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Theta indicators.
                contract1.T = T(contracts[0], contracts[1]);
                contract2.T = T(contracts[1], contracts[0]);
```

```
                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Theta indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.T;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the `T` method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
`ivModel`	`OptionPricingModelType`	The Option pricing model to use to estimate the IV when calculating theta. If you don't provide a value, the default value is to match the `optionModel` parameter.	`null`

For more information about the `T` method, see Using T Indicator .

Manual Indicators

To create a manual indicator for theta, call the `Theta` constructor.

C#

```
public class ManualThetaIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open
```

```
        // Set up a scheduled event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]);
                var contract2 = AddIndexOptionContract(contracts[1]);

                // Create and save the manual Theta indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Theta = new Theta(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Theta;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
```

```
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Theta indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Theta` constructor, see Using T Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the `SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

C#

```
// Example: Average IV of the call-put pair.
thetaIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Rho

Rho, ρ , is the rate of change of the value of a derivative with respect to the interest rate . It is usually small and not a big issue in practice unless the Option is deep in-the-money and has a long horizon. In this case, the interest rate matters because you need to discount a larger cash flow over a longer horizon. For more information about rho, see Rho .

Automatic Indicators

To create an automatic indicator for rho, call the `QCAlgorithm.R` method with the Option contract `Symbol` object(s).

C#

```
public class AutomaticRhoIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up a Scheduled Event to select contracts and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
```

```
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count() > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]) as dynamic;
                var contract2 = AddIndexOptionContract(contracts[1]) as dynamic;

                // Create and save the automatic Rho indicators.
                contract1.R = R(contracts[0], contracts[1]);
                contract2.R = R(contracts[1], contracts[0]);

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        // Get the Rho indicator of each contract.
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var symbol in chain)
            {
                var option = Securities[symbol] as dynamic;
                var indicator = option.R;
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

The follow table describes the arguments that the R method accepts in addition to the standard parameters :

Argument	Data Type	Description	Default Value
ivModel	OptionPricingModelType	The Option pricing model to use to estimate the IV when calculating rho If you don't provide a value, the default value is to match the optionModel parameter.	null

For more information about the R method, see Using R Indicator .

Manual Indicators

To create a manual indicator for rho, call the Rho constructor.

C#

```
public class ManualRhoIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _underlying;
    private DividendYieldProvider _dividendYieldProvider;
    // Define the Option pricing model.
    private readonly OptionPricingModelType _optionPricingModel = OptionPricingModelType.ForwardTree;
    private (Symbol option1, Symbol option2) _options;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(500000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Subscribe to the underlying asset.
        _underlying = AddIndex("SPX").Symbol;

        // Set up dividend yield provider for the underlying
        _dividendYieldProvider = new(_underlying);

        // Set up a Scheduled Event to select contract and create the indicators every day before market open.
        Schedule.On(
            DateRules.EveryDay(_underlying),
            TimeRules.At(9, 0),
            UpdateContractsAndGreeks
        );
    }

    private void UpdateContractsAndGreeks()
    {
        if (_underlying == null)
        {
            return;
        }
        // Get all the tradable Option contracts.
        var chain = OptionChain(_underlying);

        // Filter the contracts down. For example, ATM contracts with atleast 1 month until expiry.
        var filteredChain = chain.Where(contract => contract.Expiry > Time.AddDays(30));
        if (filteredChain.Count() == 0)
        {
            return;
        }
        var expiry = filteredChain.Min(contract => contract.Expiry);
        filteredChain = filteredChain.Where(contract => contract.Expiry == expiry);

        var minStrikeDelta = filteredChain.Min(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice));
        filteredChain = filteredChain.Where(contract => Math.Abs(contract.Strike - contract.UnderlyingLastPrice) ==
minStrikeDelta);

        // Group the contracts into call/put pairs.
        foreach (var group in filteredChain.GroupBy(contract => contract.Strike))
        {
            var contracts = group.ToList();
            if (contracts.Count > 1)
            {
                // Subscribe to both contracts.
                var contract1 = AddIndexOptionContract(contracts[0]);
```

```
                var contract2 = AddIndexOptionContract(contracts[1]);

                // Create and save the manual Rho indicators.
                foreach (var (contractA, contractB) in new[] { (contract1, contract2), (contract2, contract1) })
                {
                    var option = contractA as dynamic;
                    option.Rho = new Rho(
                            contractA.Symbol, RiskFreeInterestRateModel, _dividendYieldProvider,
                            contractB.Symbol, _optionPricingModel
                        );
                }

                _options = (contracts[0], contracts[1]);
            }
        }
    }

    public override void OnData(Slice slice)
    {
        foreach (var (canonical, chain) in slice.OptionChains)
        {
            foreach (var option in chain)
            {
                var indicator = (Securities[option] as dynamic).Rho;
                var underlying = option.Symbol.Underlying;
                var mirror = QuantConnect.Symbol.CreateOption(
                    underlying.Value, option.ID.Market, option.ID.OptionStyle,
                    option.ID.OptionRight == OptionRight.Call ? OptionRight.Put : OptionRight.Call,
                    option.ID.StrikePrice, option.ID.Date
                ).Value;

                // Check if price data is available for both contracts and the underlying asset.
                var q = slice.QuoteBars;
                var b = slice.Bars;
                if (q.ContainsKey(option) && q.ContainsKey(mirror) && b.ContainsKey(underlying))
                {
                    var dataPoints = new List<IndicatorDataPoint>
                    {
                        new IndicatorDataPoint(option, q[option].EndTime, q[option].Close),
                        new IndicatorDataPoint(mirror, q[mirror].EndTime, q[mirror].Close),
                        new IndicatorDataPoint(
                            underlying, b[underlying].EndTime, b[underlying].Close
                        )
                    };
                    foreach (var dataPoint in dataPoints)
                    {
                        indicator.Update(dataPoint);
                    }

                    // Get the current value of the Rho indicator.
                    var value = indicator.Current.Value;
                }
            }
        }

        // Sell straddle as an example to trade.
        if (!Portfolio.Invested && _options != default)
        {
            Sell(_options.option1, 1);
            Sell(_options.option2, 1);
        }
        // Liquidate any assigned positions.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
    }
}
```

For more information about the `Rho` constructor, see Using R Indicator .

Volatility Smoothing

The default IV smoothing method uses the one contract in the pair that's at-the-money or out-of-money to calculate the IV. To change the smoothing function, pass a `mirrorOption` argument to the indicator method or constructor and then call the

`SetSmoothingFunction` method of the `ImpliedVolatility` property of the indicator.

```C#
// Example: Average IV of the call-put pair.
rhoIndicator.ImpliedVolatility.SetSmoothingFunction((iv, mirrorIv) => (iv + mirrorIv) * 0.5m);
```

Market Hours

USA

Introduction

This page shows the trading hours, holidays, and time zone of the US Index Option market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the US Index Option market:

Weekday	Time (America/Chicago)
Monday	08:30:00 to 15:20:00
Tuesday	08:30:00 to 15:20:00
Wednesday	08:30:00 to 15:20:00
Thursday	08:30:00 to 15:20:00
Friday	08:30:00 to 15:20:00

Post-market Hours

Post-market trading is not available.

Holidays

Early Closes

There are no days with early closes.

Late Opens

There are no days with late opens.

Time Zone

The US Index Option market trades in the following time zones:

- `America/Chicago`
- `America/New York`

Assets With Other Hours

The following table shows the contracts that have different trading periods than the overall US Index Option market:

Symbol	Name
NDX	Nasdaq 100 Index
RUT	Russell 2000 Index
SPX	S&P 500 Index
VIX	CBOE Volatility Index

Late Opens

There are no days with late opens.

Time Zone

The CBOE Volatility Index Option contracts market trades in the `America/Chicago` time zone.

Asset Classes

CFD

A contract for difference (CFD) is a contract between a buyer and a seller that stipulates that the buyer must pay the seller the difference between the current value of an asset and its value at contract time.

CFD

Requesting Data

Introduction

Request Contract for Difference (CFD) data in your algorithm to receive a feed of contract prices in the `OnData` method. QuantConnect supports CFD trading with OANDA and Interactive Brokers .

OANDA Subscriptions

To create a CFD subscription, in the `Initialize` method, call the `AddCfd` method. The `AddCfd` method returns a `Cfd` Security object, which contains a `Symbol` property. Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
_symbol = AddCfd("XAUUSD").Symbol;
```

To view the supported CFD contracts, see Supported Assets . For more information about the specific dataset we use for backtests, see the OANDA CFD dataset listing . To trade OANDA CFDs live, use our QuantConnect data provider .

Interactive Brokers Subscriptions

To create a CFD subscription for Interactive Brokers (IB) , in the `Initialize` method, call the `AddCfd` method and set the `market` parameter to `Market.InteractiveBrokers` . The `AddCfd` method returns a `Cfd` Security object, which contains a `Symbol` property. Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
_symbol = AddCfd("SPY", market: Market.InteractiveBrokers).Symbol;
```

Historical data for backtesting IB CFDs is unavailable.

In live trading, include the Interactive Brokers data provider when you deploy the algorithm to access IB CFD data. You can use this data provider for paper or real-money accounts. IB provides data for Indexes, Metals, Forex, and Global Stock CFDs. To view the Index and Forex CFD products that IB supports in live trading, see the Interactive Brokers Supported Contracts . To view the Equity CFD products, see the Products Search page on the IB website.

If you live in the EU and can't trade US ETFs due to regulation, you can trade their CFD equivalents in live mode.

```
C#
var securityType = LiveMode ? SecurityType.Cfd : SecurityType.Equity;
var market = LiveMode ? Market.InteractiveBrokers : Market.USA;
_symbol = QuantConnect.Symbol.Create("SPY", securityType, Market.InteractiveBrokers);
AddSecurity(_symbol);
```

Market hours for IB CFDs are not modeled. You cannot use them for scheduled events or to get market open/close times . To create a scheduled event, use a ticker of any US Equity that you haven't added as a IB CFD or create a US Equity `Symbol` .

```C#
public override void Initialize()
{
    var usEquitySymbol = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
    // Call the BeforeMarketOpen method 10 minutes before open every day US Equity stocks are trading.
    Schedule.On(
        DateRules.EveryDay(usEquitySymbol),
        TimeRules.BeforeMarketOpen(usEquitySymbol, 10),
        BeforeMarketOpen
    );
}
```

Resolutions

The following table shows the available resolutions and data formats for CFD subscriptions:

Resolution	TradeBar	QuoteBar	Trade Tick	Quote Tick
`Tick`				✓
`Second`		✓		
`Minute`		✓		
`Hour`		✓		
`Daily`		✓		

The default resolution for CFD subscriptions is `Resolution.Minute` . To change the resolution, pass a `resolution` argument to the `AddCfd` method.

```C#
_symbol = AddCfd("XAUUSD", Resolution.Daily).Symbol;
```

To create custom resolution periods, see Consolidating Data .

Supported Markets

The following `Market` enumeration members are available for CFDs:

To set the market for a security, pass a `market` argument to the `AddCfd` method.

```C#
_symbol = AddCfd("XAUUSD", market: Market.Oanda).Symbol;
```

The brokerage models have a default market for each asset class. If you set a brokerage model, you may not need to specify the market to use. In backtesting, set the market for CFDs to OANDA.

Fill Forward

Fill forward means if there is no data point for the current slice , LEAN uses the previous data point. Fill forward is the default data setting. If you disable fill forward, you may get stale fills or you may see trade volume as zero.

To disable fill forward for a security, set the `fillForward` argument to false when you create the security subscription.

```
_symbol = AddCfd("XAUUSD", fillForward: false).Symbol;
```

Margin and Leverage

LEAN models buying power and margin calls to ensure your algorithm stays within the margin requirements. The specific margin available depends on your brokerage destination. To change the amount of leverage you can use for a CFD contract, pass a `leverage` argument to the `AddCfd` method.

```
_symbol = AddCfd("XAUUSD", leverage: 35).Symbol;
```

Data Normalization

The data normalization mode doesn't affect the data that LEAN passes to `OnData` or the data from history request . If you change the data normalization mode, it won't change the outcome.

Interactive Brokers Stock CFDs apply corporate actions to the price of the asset, including paying dividends in cash to your account. This behavior is not modeled today and splits in live trading will result in price discontinuities. You should monitor the underlying Equity for events and use the underlying Equity for indicators.

Properties

The `AddCfd` method returns a `Cfd` object, which have the following properties:

Interactive Brokers Supported Contracts

The following table shows the CFD contracts that IB supports:

Contract Available (107)					
AUDCAD	AUDCHF	AUDCNH	AUDHKD	AUDJPY	AUDNZD

Examples

The following examples demonstrate some common practices for requesting CFD data.

Example 1: SMA Crossing

The following strategy purchases ETFs when their fast-moving average crosses over the slow-moving average. In live mode, the strategy purchases their CFD equivalents.

C#

```
public class EtfCfdSwapMovingAverageCrossAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Request the data to feed into indicators and trade.
        // In live mode, request CFD data for trading.
        // CFD is more useful in non-trading hours to reduce slippage when market prices jump at market opening.
        var tickers = new[] {"SPY", "BND", "GLD", "QQQ"};
        var securityType = LiveMode ? SecurityType.Cfd : SecurityType.Equity;
        foreach (var ticker in tickers)
        {
            // Create fast and slow-moving average indicators to trade SAM cross trend-following strategy.
            var equity = AddEquity(ticker, Resolution.Daily);
            equity["smaFast"] = SMA(equity.Symbol, 50);
            equity["smaSlow"] = SMA(equity.Symbol, 200);
            equity["targetVehicle"] = LiveMode ? AddCfd(ticker, Resolution.Daily, market:
Market.InteractiveBrokers).Symbol : equity.Symbol;

            // Create an schduled event to plot the prices.
            // We need to create a symbol representing the US Equity market
            // because market hours for IB CFDs are not modeled
            var market = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
            Schedule.On(DateRules.EveryDay(market), TimeRules.Midnight, ()=>
            {
                foreach (var security in Securities.Values)
                {
                    Plot(security.Symbol.Value, "EOD", security.Price);
                }
            });
        }
    }

    public override void OnData(Slice data)
    {
        foreach (var security in Securities.Values)
        {
            var targetVehicle = security["targetVehicle"] as Symbol;
            // Trade the SMA cross on the updated SMA indicator signals.
            // If fast MA is above slow MA, the price is in an uptrend, and we buy.
            if ((SimpleMovingAverage)security["smaFast"]  > (SimpleMovingAverage)security["smaSlow"])
            {
                SetHoldings(targetVehicle, 0.25m);
            }
            // Else, the price is in a downtrend, and we are short.
            else
            {
                SetHoldings(targetVehicle, 0m);
            }
        }
    }
}
```

CFD

Handling Data

Introduction

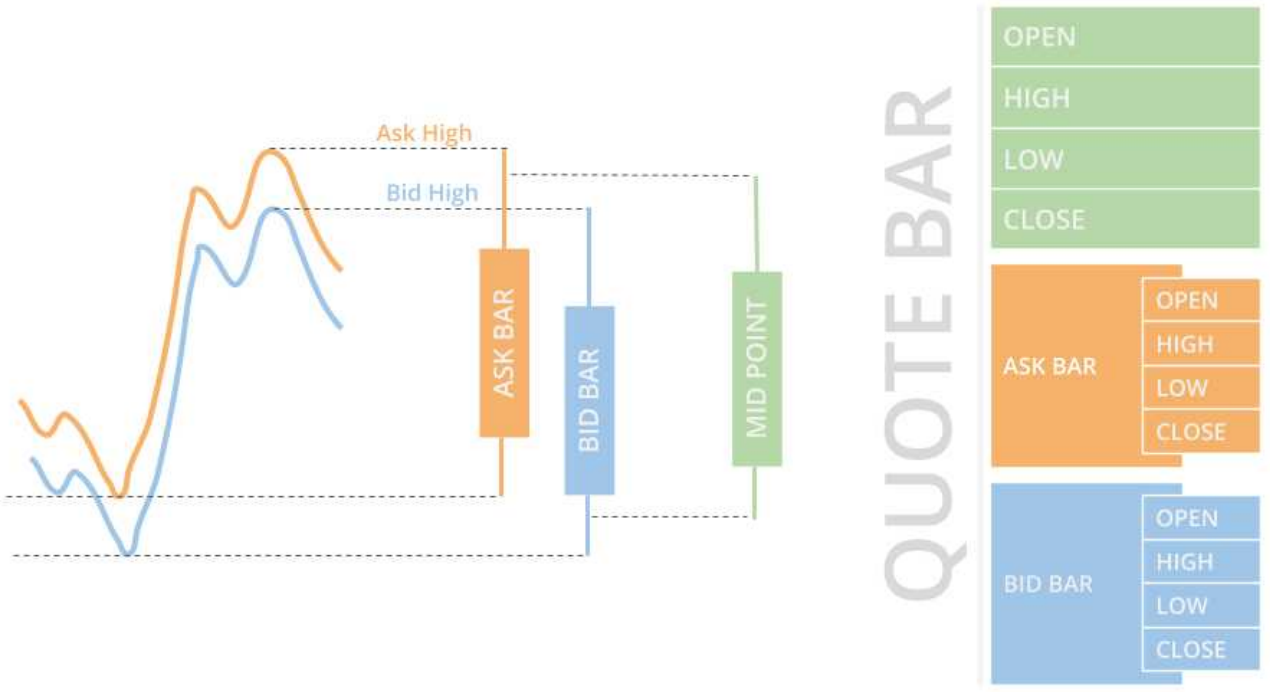
LEAN passes the data you request to the `OnData` method so you can make trading decisions. The default `OnData` method accepts a `Slice` object, but you can define additional `OnData` methods that accept different data types. For example, if you define an `OnData` method that accepts a `QuoteBar` argument, it only receives `QuoteBar` objects. The `Slice` object that the `OnData` method receives groups all the data together at a single moment in time. To access the `Slice` outside of the `OnData` method, use the `CurrentSlice` property of your algorithm.

All the data formats use `DataDictionary` objects to group data by `Symbol` and provide easy access to information. The plural of the type denotes the collection of objects. For instance, the `QuoteBars` `DataDictionary` is made up of `QuoteBar` objects. To access individual data points in the dictionary, you can index the dictionary with the CFD ticker or `Symbol` , but we recommend you use the `Symbol` .

To view the resolutions that are available for CFD data, see Resolutions .

Quotes

`QuoteBar` objects are bars that consolidate NBBO quotes from the exchanges. They contain the open, high, low, and close prices of the bid and ask. The `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` object are the mean of the respective bid and ask prices. If the bid or ask portion of the `QuoteBar` has no data, the `Open` , `High` , `Low` , and `Close` properties of the `QuoteBar` copy the values of either the `Bid` or `Ask` instead of taking their mean.



To get the `QuoteBar` objects in the `Slice` , index the `QuoteBars` property of the `Slice` with the CFD `Symbol` . If the CFD doesn't actively get quotes or you are in the same time step as when you added the CFD subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your CFD before you index the `Slice` with the CFD `Symbol`

.

```C#
public override void OnData(Slice slice)
{
    // Check if the symbol is contained in QuoteBars object
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        // Obtain the mapped QuoteBar of the symbol
        var quoteBar = slice.QuoteBars[_symbol];
    }
}
```

You can also iterate through the `QuoteBars` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `QuoteBar` objects.

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Symbol-QuoteBar key-value pairs
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        var askPrice = quoteBar.Ask.Close;
    }
}
```

`QuoteBar` objects let LEAN incorporate spread costs into your simulated trade fills to make backtest results more realistic.

`QuoteBar` objects have the following properties:

Ticks

`Tick` objects represent a single trade or quote at a moment in time. A trade tick is a record of a transaction for the CFD. A quote tick is an offer to buy or sell the CFD at a specific price.

Trade ticks have a non-zero value for the `Quantity` and `Price` properties, but they have a zero value for the `BidPrice` , `BidSize` , `AskPrice` , and `AskSize` properties. Quote ticks have non-zero values for `BidPrice` and `BidSize` properties or have non-zero values for `AskPrice` and `AskSize` properties. To check if a tick is a trade or a quote, use the `TickType` property.

In backtests, LEAN groups ticks into one millisecond buckets. In live trading, LEAN groups ticks into ~70-millisecond buckets. To get the `Tick` objects in the `Slice` , index the `Ticks` property of the `Slice` with a `Symbol` . If the CFD doesn't actively trade or you are in the same time step as when you added the CFD subscription, the `Slice` may not contain data for your `Symbol` . To avoid issues, check if the `Slice` contains data for your CFD before you index the `Slice` with the CFD `Symbol` .

```C#
public override void OnData(Slice slice)
{
    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

You can also iterate through the `Ticks` dictionary. The keys of the dictionary are the `Symbol` objects and the values are the `List<Tick>` objects.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            var price = tick.Price;
        }
    }
}
```

Tick data is raw and unfiltered, so it can contain bad ticks that skew your trade results. For example, some ticks come from dark pools, which aren't tradable. We recommend you only use tick data if you understand the risks and are able to perform your own online tick filtering.

`Tick` objects have the following properties:

Examples

The following examples demonstrate common practices for handling CFD data.

Example 1: Buy And Hold

The following algorithm is a buy-and-hold strategy on the DE30EUR CFD contract. We only place orders when quote data is available to avoid stale fills. Also, we set the algorithm time zone to Berlin and the account currency to Euros for a more convenient comparison.

```C#
public class CfdExampleAlgorithm : QCAlgorithm
{
    private Symbol _dax, _sgx;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the timezone as Berlin to conveniently compare the data.
        SetTimeZone(TimeZones.Berlin);
        // Set the account currency to EUR to trade the DAX CFD.
        SetAccountCurrency("EUR", 10000);
        // Request the CFD data to trade.
        _dax = AddCfd("DE30EUR").Symbol;
        _sgx = AddCfd("SG30SGD").Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Trade based on updated data; CFDs only have quote data.
        if (slice.QuoteBars.TryGetValue(_dax, out var _))
        {
            // Buy and hold DAX CFD.
            if (!Portfolio[_dax].IsLong)
            {
                SetHoldings(_dax, 0.5m);
            }
        }
    }
}
```

Example 2: Global Indices

The following algorithm buys and holds various Index CFDs that trade in different market hours and currencies during their opening hours.

C#

```
public class CfdExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of each asset with its last known price to
        // avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Let's select CFD contracts that trade in different market
        // hours so the algorithm is always invested.
        foreach (var ticker in new[] { "DE30EUR", "SG30SGD", "US30USD" })
        {
            // Add the CFD.
            var symbol = AddCfd(ticker).Symbol;
            // Set scheduled events to hold each CFD contract during
            // their regular trading hours.
            // Buy after market open.
            Schedule.On(
                DateRules.EveryDay(symbol),
                TimeRules.AfterMarketOpen(symbol, 1),
                () => SetHoldings(symbol, 0.3m)
            );
            // Liquidate before market close.
            Schedule.On(
                DateRules.EveryDay(symbol),
                TimeRules.BeforeMarketClose(symbol, 1),
                () => Liquidate(symbol)
            );
        }
    }
}
```

Introduction

This page shows the trading hours, holidays, and time zone of the CFD market.

Pre-market Hours

Pre-market trading is not available.

Regular Trading Hours

The following table shows the regular trading hours for the CFD market:

Weekday	**Time (America/New York)**
Monday	09:30:00 to 16:00:00
Tuesday	09:30:00 to 16:00:00
Wednesday	09:30:00 to 16:00:00
Thursday	09:30:00 to 16:00:00
Friday	09:30:00 to 16:00:00

Post-market Hours

Post-market trading is not available.

Holidays

The following table shows the dates of holidays for the CFD market:

Date (*yyyy-mm-dd*)				
1998-01-01	1998-01-19	1998-02-16	1998-04-10	1998-05-25

Portfolio

Portfolio

Key Concepts

Introduction

The `Portfolio` object provides information about the investment state and history of all of the securities that have been in the algorithm during its lifetime.

The `Portfolio` property of the `QCAlgorithm` class is a dictionary where the keys are `Symbol` objects and the values are `SecurityHolding` objects. The `SecurityHolding` object provides information about the investment state and history of a security.

Investment Status

To get the investment status of your strategy, access the `Invested` property of a `Portfolio` object.

```
C#

// Get the investment status and return True if the portfolio is invested.
var invested = Portfolio.Invested;
```

Holdings Status

You can identify a position as long- or short-biased based on the sign of the holding quantity. Long positions have a positive quantity and short positions have a negative quantity. The `SecurityHolding` object has the following properties to describe the holding status.

```
C#

var holdings = Portfolio[_symbol];
var quantity = holdings.Quantity;
var invested = holdings.Invested;
var isLong = holdings.IsLong;
var isShort = holdings.IsShort;
```

The quantity can be lower than the minimum order size. If the quantity is less than the lot size of the asset, the `Invested` property is `false` .

Buying Power

To get the maximum buying power in your account currency you can use for a given `Symbol` and order direction, call the `GetBuyingPower` method.

```
C#

// Check the total amount of buying power available. Margin available varies by order direction and current holdings.
var availableBuyingPower = Portfolio.GetBuyingPower(_symbol, OrderDirection.Buy);
```

For more information about buying power, see Buying Power .

Cost Averaging Accounting

LEAN uses the cost averaging accounting method, which determines the cost of your holdings by taking a weighted average of all your purchase prices. For example, say you place the following buy orders:

1. Buy 10 ABC @ $10
2. Buy 5 ABC @ $11
3. Buy 20 ABC @ $14
4. Buy 3 ABC @ $9

In the preceding example, the average cost of your ABC position is (10*10 + 5*11 + 20*14 + 3*9) / (10 + 5 + 20 + 3) = 12.1579/share. In contrast, if you use the first-in, first-out (FIFO) accounting method, the cost of the first 10 shares is 10/share, not 12.1579/share.

To get the cost of your security holdings, use the `HoldingsCost` property of the SecurityHolding object . If you fill buy and sell orders, the holdings cost is the product of the holding quantity and the average price. For example, the following table shows how the average price and holdings cost changes with each buy and sell order order in a long position:

Order Quantity	Fill Price ($)	Holding Quantity	Average Price ($)	Holdings Cost ($)
2	10	2	(2 * 10) / 2 = 10	2 * 10 = 20
-1	11	1	(1 * 10) / 1 = 10	1 * 10 = 10
1	12	2	(1 * 10 + 1 * 12) / 2 = 11	2 * 11 = 22
-2	13	0	0	0 * 0 = 0

The following table shows how the average price and holdings cost changes with each buy and sell order order in a short position:

Order Quantity	Fill Price ($)	Holding Quantity	Average Price ($)	Holdings Cost ($)
-2	10	-2	(-2 * 10) / -2 = 10	-2 * 10 = -20
1	11	-1	(-1 * 10) / -1 = 10	-1 * 10 = -10
-1	12	-2	(-1 * 10 + (-1) * 12) / -2 = 11	-2 * 11 = -22
2	13	0	0	0 * 0 = 0

Note that when you decrease the position size without closing the trade, the average price doesn't change because the denominator and the coefficients in the numerator of its formula are scaled by the quotient of the current holding quantity and the previous holding quantity. For instance, if the last row in the preceding table had an order quantity 1, the holding quantity would be -1 and the average price would be

$$\frac{(-1 * q) * 10 + (-1 * q) * 12}{-2 * q}$$

$$= \frac{(-1 * \frac{-1}{-2}) * 10 + (-1 * \frac{-1}{-2}) * 12}{-2 * \frac{-1}{-2}}$$

$$= \frac{\frac{-1}{2} * 10 + \frac{-1}{2} * 12}{-1}$$

$$= \frac{-5 - 6}{-1} = 11$$

Performance Statistics

The `Portfolio` object has a collection of properties that provide the combined state of holdings and the cashbook .

```C#
// Access key statistics of the portfolio using the properties of the portfolio object.
var value = Portfolio.TotalPortfolioValue;
var totalMarginUsed = Portfolio.TotalMarginUsed;
var marginRemaining = Portfolio.MarginRemaining;
var totalNetProfit = Portfolio.TotalNetProfit;
var totalUnrealisedProfit = Portfolio.TotalUnrealisedProfit;
var totalFees = Portfolio.TotalFees;
var cash = Portfolio.Cash;
```

Properties

The `Portfolio` object has the following properties:

Examples

The following examples demonstrate common practices for handling the portfolio.

Example 1: Martingale

The following algorithm trades a Martingale strategy on AAPL. The trend indicated by an EMA indicator follows the trend with a 1*pershare**stop* – *loss**and*2 take-profit level. Yet, if the last trade is lost, it will double the next trading size to recover the last loss.

C#

```
public class PortfolioExampleAlgorithm : QCAlgorithm
{
    private Symbol _aapl;
    private ExponentialMovingAverage _ema;
    private int _nextQuantity = 1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request AAPL's data to trade.
        _aapl = AddEquity("AAPL").Symbol;

        // Create an EMA indicator to generate trading data.
        _ema = EMA(_aapl, 20, Resolution.Daily);
        // Warm up the indicator to provide an immediate trade signal.
        WarmUpIndicator(_aapl, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        // Ride on the AAPL trend indicated by the EMA indicator.
        if (!Portfolio.Invested)
        {
            if (Securities[_aapl].Price >= _ema)
            {
                MarketOrder(_aapl, _nextQuantity);
            }
            else
            {
                MarketOrder(_aapl, -_nextQuantity);
            }
        }
        else
        {
            var holding = Portfolio[_aapl];
            // Stop loss at $1 per share.
            if (holding.UnrealizedProfit <= -1 * _nextQuantity)
            {
                Liquidate(_aapl);
                // Double the next quantity to recover this loss.
                _nextQuantity *= 2;
            }
            // Take profit at $2 per share.
            else if (holding.UnrealizedProfit >= 2)
            {
                Liquidate(_aapl);
                _nextQuantity = 1;
            }
        }
    }
}
```

Portfolio

Holdings

Introduction

The `Portfolio` is a dictionary where the key is a `Symbol` and the value is a `SecurityHolding` .

```
C#
// Create shortcut helper to the SPY SecurityHolding object from the Portfolio collection.
var securityHolding = Portfolio["SPY"];
```

Properties

`SecurityHolding` objects have the following properties:

```
C#
// Save shortcut to SecurityHolding object, and fetch quantity and invested status.
var securityHolding = Portfolio["SPY"];
var quantity = securityHolding.Quantity;
var invested = securityHolding.Invested;
```

`FutureHolding` objects also have `SettledProfit` and `UnsettledProfit` properties.

Get Total Close Profit

To get the profit of a position holding if you closed the position, call the `TotalCloseProfit` method. The value this method returns is denominated in your account currency and accounts for order fees.

```
C#
var profit = Portfolio["SPY"].TotalCloseProfit();
```

The `TotalCloseProfit` method accepts the following optional arguments:

Argument	Data Type	Description	Default Value
`includeFees`	`bool`	Whether to reduce the profit based on the estimated fee from the fee model .	`true`
`exitPrice`	`decimal?`	A hypothetical exit price to use for the profit calculation. If you don't provide a value, it uses the bid price for sell orders or the ask price for buy orders.	`null`
`entryPrice`	`decimal?`	A hypothetical exit price to use for the profit calculation. If you don't provide a value, it uses the average price of the `SecurityHolding` .	`null`
`quantity`	`decimal?`	The quantity to liquidate. If you don't provide a value, it uses the quantity of the `SecurityHolding` .	`null`

LEAN uses this method to define the `UnrealizedProfit` property.

Get Quantity Value

To get the value of a security at any quantity, call the `GetQuantityValue` method. The value this method returns is denominated in your account currency.

```
C#

// Get the quantity value at the current price
var valueAtCurrentPrice = Portfolio["SPY"].GetQuantityValue(100);

// Get the quantity value at a specific price
var valueAtSpecificPrice = Portfolio["SPY"].GetQuantityValue(100, price: 30);
```

Set Initial Holdings

When you deploy a backtest or a new paper trading algorithm, the default initial portfolio state contains $100,000 USD. However, in the Initialize method, you can define the initial portfolio state to something else. To set the initial cash balances , call `SetCash` with the currency ticker and quantity. To set multiple currencies, call the method multiple times.

```
C#

SetCash(100000);       // Set the quantity of the account currency to 100,000
SetCash("BTC", 10);    // Set the Bitcoin quantity to 10
SetCash("EUR", 10000); // Set the EUR quantity to 10,000
```

To set the initial security holdings, subscribe to the security so that it enters your portfolio , then call the `SecurityHolding.SetHoldings` method with the average purchase price and quantity.

```
C#
if (!LiveMode)
{
    Portfolio["SPY"].SetHoldings(averagePrice: 500, quantity: 100);
}
```

Examples

The following examples demonstrate common practices for setting the portfolio holdings.

Example 1: Initial Holdings

The following algorithm simulates an account with multiple initial positions and cash. Note that these initial holdings will affect the algorithm's performance.

```
C#
public class PortfolioExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Simulate initial cash in multiple currencies.
        // Note that all currencies other than the account currency will affect the performance.
        SetAccountCurrency("USD", 10000);
        SetCash("EUR", 1000);
        SetCash("JPY", 1000000);
        SetCash("HKD", 10000);

        // Add a security initializer that seeds the price of each asset with its
        // last known price. This ensures the holdings we add below will initialize
        // with a non-zero value.
        Settings.SeedInitialPrices = true;

        // Request data for some securities in the account already.
        var spy = AddEquity("SPY").Symbol;
        var aapl = AddEquity("AAPL").Symbol;
        var btcusd = AddCrypto("BTCUSD").Symbol;
        var xauusd = AddCfd("XAUUSD").Symbol;

        // Simulate that the account holds some assets initially.
        // Note that all initial holdings will affect the performance.
        Portfolio[spy].SetHoldings(averagePrice: 420m, quantity: 102m);
        Portfolio[aapl].SetHoldings(averagePrice: 102m, quantity: 25m);
        Portfolio[btcusd].SetHoldings(averagePrice: 45000m, quantity: 0.125m);
        Portfolio[xauusd].SetHoldings(averagePrice: 1000m, quantity: 100m);
    }
}
```

Portfolio

Cashbook

Introduction

The `CashBook` is a dictionary where the keys are currency tickers and the values are `Cash` objects. The `Cash` objects track the amount of each currency in the portfolio. As you buy and sell securities, LEAN credits and debits the `Cash` objects to reflect your cash holdings.

Account Currency

The default account currency is USD, but you can change it. All of the properties of the Portfolio object that return a currency value denominate the currency value in your account currency. Depending on your account currency and security subscriptions, LEAN may add internal security subscriptions to calculate the `ValueInAccountCurrency` . For example, if you only add BTCETH to your algorithm and set the account currency to USDT, LEAN adds BTCUSDT and ETHUSDT as internal feeds.

To get your account currency, use the `AccountCurrency` property.

```
C#
var accountCurrency = AccountCurrency;
```

To set your account currency, in the `Initialize` method, call the `SetAccountCurrency` method. You can only set the account currency once. LEAN ignores each additional call to `SetAccountCurrency` .

```
C#
SetAccountCurrency("EUR");
```

Settled vs Unsettled Cash

The `Portfolio` has two independent cashbooks. The `CashBook` tracks settled cash and the `UnsettledCashBook` tracks unsettled cash, which you can't spend. If you trade with a margin account, trades settle immediately so LEAN credits and debits the `CashBook` at the time of the trade. In some cases, transactions can take time to settle. For example, Equity trades in a cash account settle in T+3. Therefore, if you sell shares of stock on Monday, the transaction settles on Thursday. In contrast, Option trades settle in T+1.

```
C#
var settledCashBook = Portfolio.CashBook;
var unsettledCashBook = Portfolio.UnsettledCashBook;
```

Track Cash Balances

To get the balance of a currency in the cash book, use the `Amount` property.

```
C#
var usd = Portfolio.CashBook["USD"].Amount;
var btc = Portfolio.CashBook["BTC"].Amount;
```

To get the value of a currency in the cash book, denominated in your account currency, use the `ValueInAccountCurrency`

property.

```C#
// Return the cash book value of Ethereum in account currency (US Dollar, Euro, etc.) amount.
var ethValue = Portfolio.CashBook["ETH"].ValueInAccountCurrency;
```

Deposits and Withdrawals

In backtests, you can add and remove cash from the cash book. To add or remove cash, call the `AddAmount` method.

```C#
// Adjust the backtesting cashbook balances to add 100 USD and subtract 1.5 BTC.
var newUSDBalance = Portfolio.CashBook["USD"].AddAmount(100);
var newBTCBalance = Portfolio.CashBook["BTC"].AddAmount(-1.5m);
```

In live trading, add and withdraw cash through your brokerage account. If you adjust the cash balances in your algorithm with the `AddAmount` method, the cash balance in your algorithm will be out of sync with the cash balance in your brokerage account.

Currency Symbols

A currency symbol is a graphic that represents the currency name. For example, $ is for dollars, € for euros, and ฿ for Bitcoin. To get the symbol of a currency in the cash book, use `CurrencySymbol` property.

```C#
var usdSymbol = Portfolio.CashBook["USD"].CurrencySymbol;
```

Conversion Rates

To get the conversion rate for a currency in the cashbook to your account currency, use the `ConversionRate` property.

```C#
var eurConversionRate = Portfolio.CashBook["EUR"].ConversionRate;
```

Examples

The following examples demonstrate common practices for controlling the portfolio cashbook.

Example 1: Dollar Cost Averaging

The following algorithm deposits USD 1000 on every month's start and buys SPY with the deposited cash. It results in a dollar cost averaging investment strategy on the overall market.

```C#
public class PortfolioCashbookAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private decimal _deposit = 1000m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000);

        // Request SPY data to trade the overall market representative.
        _spy = AddEquity("SPY").Symbol;

        // Deposit each month start and invest in SPY by dollar cost averaging.
        Schedule.On(
            DateRules.MonthStart(_spy),
            TimeRules.AfterMarketOpen(_spy, 0),
            DepositAndRebalance
        );

        // To warm up the price data of SPY to calculate the quantity to be brought.
        SetWarmUp(1);
    }

    private void DepositAndRebalance()
    {
        // Deposit the account currency's preset level ($1000) at the start of the month.
        // Simulate the monthly salary deposit for dollar cost-averaging investment in the market.
        Portfolio.CashBook[AccountCurrency].AddAmount(_deposit);

        // Calculate the number of shares that can be invested using the deposited amount.
        var quantity = Math.Floor(_deposit / Securities[_spy].Price);
        MarketOrder(_spy, quantity);
    }
}
```

Example 2: Crypto Cashbook

This example trades an EMA cross strategy on the ETH-BTC crypto pair in a cash account. To obtain the maximum tradable order size, we need to use the cash book and check the amount of BTC in long ETHBTC trades and in short ETHBTC trades to avoid insufficient initial margin.

C#

```
public class PortfolioCashbookAlgorithm : QCAlgorithm
{
    private Symbol _ethbtc;
    private ExponentialMovingAverage _ema;
    // Set a buffer to avoid insufficient margin due to the price fluctuation.
    private decimal _buffer = 0.01m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the account currency as USDT and the starting cash in a cash account.
        SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);
        SetAccountCurrency("USDT", 100);
        SetCash("BTC", 100);
        SetCash("ETH", 2000);

        // We would like to trade the EMA cross between 2 popular cryptos, BTC & ETH,
        // so request ETHBTC data to find trading opportunities.
        _ethbtc = AddCrypto("ETHBTC", Resolution.Minute, market: Market.Coinbase).Symbol;

        // Add automatic-updating EMA indicator for trend trade signal emission.
        _ema = EMA(_ethbtc, 50, Resolution.Daily);
        // Warm up the indicator for its readiness usage immediately.
        WarmUpIndicator(_ethbtc, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (!(slice.Bars.TryGetValue(_ethbtc, out var bar) && _ema.IsReady))
        {
            return;
        }
        decimal quantity;
        // ETHBTC's current price is higher than EMA, suggesting an uptrend.
        if (bar.Close > _ema && !Portfolio[_ethbtc].IsLong)
        {
            // Convert to the corresponding quantity of the quote currency.
            quantity = Portfolio.CashBook["BTC"].Amount * (1m - _buffer) / bar.Close;
        }
        // ETHBTC's current price is below the EMA, suggesting a downtrend.
        else if (bar.Close < _ema && !Portfolio[_ethbtc].IsShort)
        {
            quantity = -Portfolio.CashBook["ETH"].Amount;
        }
        else {
            return;
        }
        // Round down to observe the lot size.
        var lotSize = Securities[_ethbtc].SymbolProperties.LotSize;
        quantity = (long)(quantity / lotSize) * lotSize;
        if (quantity != 0)
        {
            MarketOrder(_ethbtc, quantity);
        }
    }
}
```

Universes

Universes

Key Concepts

Introduction

Universe selection is the process of selecting a basket of assets you may trade. Dynamic universe selection increase diversification and decrease selection bias in your algorithm.

How Universe Selection Works

When you add a universe to your algorithm, LEAN sends a large dataset into a filter function you define. Your filter function needs to return a list of `Symbol` objects. LEAN automatically subscribes to these new symbols and adds them to your algorithm. Your algorithm can do almost anything inside your filter functions, but the goal should be to narrow down the set of securities to the securities that are most applicable for your algorithm.

Selection Functions

The following example filter function selects the 100 most liquid US Equities:

```C#
// Use a fundamental filter function to select the 100 most liquid Equities.
public class MyFundamentalUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        AddUniverse(FundamentalFilterFunction);
    }

    private IEnumerable<Symbol> FundamentalFilterFunction(IEnumerable<Fundamental> fundamental)
    {
        return (from c in fundamental
            orderby c.DollarVolume descending
            select c.Symbol).Take(100);
    }
}
```

To learn how to define filter functions for other asset classes, custom data universes , or alternative data universes , see the following pages in this Universes chapter.

Security Changed Events

When your universe adds and removes assets, LEAN notifies your algorithm through the `OnSecuritiesChanged` event handler. The event handler receives a `SecurityChanges` object, which contains references to the added and removed securities. To access the added securities, check the `changes.AddedSecurities` method property. To access the removed securities, check the `changes.RemovedSecurities` method property.

```C#
// Use the OnSecuritiesChanged method to know when an asset is added or removed.
public override void OnSecuritiesChanged(SecurityChanges changes)
{
    // Iterate through the added securities.
    foreach (var security in changes.AddedSecurities)
    {
        Debug($"{Time}: Added {security.Symbol}");
    }
    // Iterate through the removed securities.
    foreach (var security in changes.RemovedSecurities)
    {
        Debug($"{Time}: Removed {security.Symbol}");

        if (security.Invested)
        {
            Liquidate(security.Symbol, tag: "Removed from Universe");
        }
    }
}
```

The preceding example liquidates securities that leave the universe. In this case, LEAN creates a market on open order and frees up buying power when the market opens.

Custom Security Properties

If you need to save data or create objects for each security in the universe, cast the `Security` objects to `dynamic` objects and then save custom members to them . This technique is useful if you want to track stop loss levels or add indicators for each asset in the universe.

```C#
// Cast the security to a dynamic object to add custom properties to it.
public override void OnSecuritiesChanged(SecurityChanges changes)
{
    foreach (var security in changes.AddedSecurities)
    {
        var dynamicSecurity = security as dynamic;

        // Create an SMA indicator with 10 periods for the asset.
        dynamicSecurity.Indicator = SMA(security.Symbol, 10);

        // Warm up the indicator with historical data.
        WarmUpIndicator(security.Symbol, dynamicSecurity.Indicator);
    }
    // Remove the automatic indicator updates when the security leaves the universe.
    foreach (var security in changes.RemovedSecurities)
    {
        DeregisterIndicator((security as dynamic).Indicator);
    }
}
```

Select Current Constituents

If you don't want to make any changes to the current universe, return `Universe.Unchanged` from your filter functions.

```C#
public class MyUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        AddUniverse(MyFundamentalFilterFunction);
    }
    // Use Universe.Unchanged to leave the universe unchanged.
    IEnumerable<Symbol> MyFundamentalFilterFunction(IEnumerable<Fundamental> fundamental)
    {
        return Universe.Unchanged;
    }
}
```

Universe Manager

The universe manager tracks all the universes in your algorithm. If you add multiple universe, you can access the constituents of each individual universe. To access the constituents of a universe in a multi-universe algorithm, save references to each universe when you add them.

```C#
private Universe _universe;

// In the Initialize method, add a new universe.
UniverseSettings.Asynchronous = true;
_universe = AddUniverse(MyFundamentalFilterFunction);

// Use the UniverseManager to get information about the assets in each universe.
var universeMembers = UniverseManager[_universe.Configuration.Symbol].Members;
foreach (var kvp in universeMembers)
{
    var symbol = kvp.Key; // The symbol of the asset.
    var security = kvp.Value; // The security in the universe.
}
```

When you remove an asset from a universe, LEAN usually removes the security from the `Members` collection and removes the security subscription. However, it won't remove the security in any of the following situations:

- You own the security.
- You have an open order for the security.
- The security wasn't in the universe long enough to meet the `MinimumTimeInUniverse` setting.

To get only the assets that are currently in the universe, see Selected Securities .

Active Securities

The `QCAlgorithm.ActiveSecurities` is a collection of `Universe.Members` of all universes. The `ActiveSecurities` property of the algorithm class contains all of the assets currently in your algorithm. It is a dictionary where the key is a `Symbol` and the value is a `Security` . When you remove an asset from a universe, LEAN usually removes the security from the `ActiveSecurities` collection and removes the security subscription. However, it won't remove the security in any of the following situations:

- You own the security.
- You have an open order for the security.
- The security wasn't in the universe long enough to meet the `MinimumTimeInUniverse` setting.

When LEAN removes the security, the `Security` object remains in the `Securities` collection for record-keeping purposes, like tracking fees and trading volume.

To improve iteration speed, LEAN removes delisted securities from the `Securities` primary collection. To access all the securities, iterate the `Securities.Total` property.

```
C#

// Access all the securities.
foreach (var security in Securities.Total)
{

}

// Exclude delisted securities.
foreach (var security in Securities.Values)
{

}
```

To get only the assets that are currently in the universe, see Selected Securities .

Selected Securities

The `Selected` property of your `Universe` contains references to all the assets that are currently in the universe. The `Universe.Selected` property differs from the `Universe.Members` property because the `Universe.Members` property can contain more assets than `Universe.Selected` when they have assets with open positions, open order orders, or assets that haven't met the minimum time requirement. To access the `Universe` object, save a reference to the result of the `AddUniverse` method. The following algorithm demonstrates how to use the `Universe.Selected` property to create simple rebalancing strategies:

```
C#

// Rebalance after market open to hold the 5 most liquid Equities.
public class SimpleRebalancingAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var symbol = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        // Schedule the universe selection to run at the start of each week.
        var dateRule = DateRules.WeekStart(symbol);
        UniverseSettings.Schedule.On(dateRule);
        // Add a universe of the top 5 most liquid Equities.
        var universe = AddUniverse(Universe.Top(5));
        // 30 minutes after market open, rebalance the portfolio.
        Schedule.On(
            dateRule,
            TimeRules.AfterMarketOpen(symbol, 30),
            () => SetHoldings(
                universe.Selected.Select(symbol => new PortfolioTarget(symbol,
1.0m/universe.Selected.Count)).ToList(),
                liquidateExistingHoldings: true
            )
        );
    }
}
```

Derivative Universes

In a regular universe, you select a basket of assets from the entire universe of securities. In a derivative universe, you select a basket of contracts for an underlying asset. The following derivative universes are available:

- Equity Options
- Futures
- Future Options
- Index Options

Historical Asset Prices

LEAN supports over 100 indicators you can use to generate your trading signals. However, in some cases, it's more efficient to maintain a matrix of historical prices for all the assets in your universe instead of using indicators. For example, say you want to calculate the correlation coefficients between all *n* asset in your universe using a 1-year lookback period. If you were to use the Correlation indicator, when a new asset enters the universe, you would usually need to make a 1-year history request for *n* assets to warm-up the *n* new correlation indicators. These large and frequent history requests can make your algorithm very slow.

The following algorithm demonstrates an alternative, more efficient approach. It defines a `Dictionary` when constructing the algorithm class . When a new asset enters the universe, it adds a new key-value pair to the dictionary. Then, each day, it adds yesterday's open price to each RollingWindow in the dictionary, which covers all the assets in the universe. This approach reduces the size and frequency of history requests you need to make to get the data.

C#

```
using Accord.Statistics;

public class MaintainHistoricalDailyUniversePriceDataAlgorithm : QCAlgorithm
{
    // Create Rolling Window collection to store the historical data.
    private Dictionary<Symbol, RollingWindow<decimal>> _history = new();
    // Define the lookback period.
    private int _lookback = 252;
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Add a universe of daily data.
        UniverseSettings.Resolution = Resolution.Daily;
        // Filter for any coporate announced a material buyback plan, since they have confidence in their
        // future prospect and the reduction in supply can drive their price up.
        _universe = AddUniverse((fundamentals) => {
            return (from Fundamental f in fundamentals
                   orderby f.MarketCap descending
                   select f.Symbol).Take(10);
        });

        // Create a Scheduled Event to record new daily prices and rebelance the portfolio.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(
            DateRules.EveryDay(spy),
            TimeRules.At(0, 1),      // One minute after `OnSecuritiesChanged` runs (in backtests)
            Rebalance
        );
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Remove the historical prices of assets that leave the universe.
        foreach (var removed in changes.RemovedSecurities)
        {
            _history.Remove(removed.Symbol);
        }

        // Warm-up the historical data of assets that enter the universe.
        var symbols = changes.AddedSecurities.Select(x => x.Symbol).ToList();
        var history = History<TradeBar>(symbols, _lookback+1, Resolution.Daily);
        foreach (var bars in history.SkipLast(1))
        {
            foreach (var (symbol, bar) in bars)
            {
                if (!_history.TryGetValue(symbol, out var symbolHistory))
                {
                    _history[symbol] = symbolHistory = new(_lookback);
                }

                // If you trade at market open, it might make more sense to generate signals based on daily
                // opening prices.
                symbolHistory.Add(bar.Open);
            }
        }
```

```
        }

        private void Rebalance()
        {
            // Add yesterday's open price to the Dictionary of historical prices.
            var history = History<TradeBar>(_history.Keys, 1, Resolution.Daily).First();
            foreach (var (symbol, bar) in history)
            {
                _history[symbol].Add(bar.Open);
            }

            // To avoid trading errors, select the assets that have a price.
            var symbols = _history.Keys.Where(symbol => Securities[symbol].Price > 0).ToArray();

            // Calculate asset signals for this rebalance.
            // For example, set the signal to give greater weight to uncorrelated assets.
            var priceMatrix = new double[_lookback, symbols.Count()];
            for (int i = 0; i < _lookback; i++)
            {
                for (int j = 0; j < symbols.Count(); j++)
                {
                    priceMatrix[i, j] = (double)_history[symbols[j]][i];
                }
            }
            var correlation = Measures.Correlation(priceMatrix);
            var signals = NormalizedRowAbsoluteSums(correlation);

            // Rebalance the portfolio based on the signals.
            SetHoldings(
                Enumerable
                    .Range(0, signals.Length)
                    .Select(i => new PortfolioTarget(symbols[i], Convert.ToDecimal(signals[i])))
                    .ToList(),
                liquidateExistingHoldings: true
            );
        }

        private double[] NormalizedRowAbsoluteSums(double[,] array)
        {
            var rows = array.GetLength(0);
            var rowAbsSums = new double[rows];

            for (int i = 0; i < rows; i++)
            {
                var rowAbsSum = 0d;
                for (int j = 0; j < array.GetLength(1); j++)
                {
                    rowAbsSum += Math.Abs(array[i, j]);
                }
                rowAbsSums[i] = rowAbsSum;
            }

            var inverseRowSums = rowAbsSums.Select(sum => 1.0d/sum);
            var allSum = inverseRowSums.Sum();
            return inverseRowSums.Select(x => x / allSum).ToArray();
        }
    }
```

Examples

You may refer to the following table for examples of various asset classes:

Asset Class	Universe Type	Example

Any	Custom Universes	Example
Any	Dataless Scheduled Universes	Example

Universes

Settings

Introduction

Universe settings and security initializers enable you to configure some properties of the securities in a universe.

Resolution

The `Resolution` setting defines the time period of the asset data. The `Resolution` enumeration has the following members:

To view which resolutions are available for the asset class of your universe, follow these steps:

1. Open the Asset Classes documentation page.
2. Click an asset class.
3. Click Requesting Data .
4. On the Requesting Data page, in the table of contents, click Resolutions .

The default value is `Resolution.Minute` . To change the resolution, in the Initialize method, pass a `resolution` argument to the universe creation method.

```
C#
// Add daily Equity Option data for the SPY.
AddOption("SPY", resolution: Resolution.Daily);
```

Leverage

The `Leverage` setting is a `decimal` that defines the maximum amount of leverage you can use for a single asset in a non-derivative universe. The default value is `Security.NullLeverage` (0). To change the leverage, in the Initialize method, adjust the algorithm's `UniverseSettings` before you add the universe.

```
C#
// Assign 2x leverage for all securities in the universe.
UniverseSettings.Leverage = 2.0m;
// Add a universe of the 50 most liquid US Equities.
AddUniverse(Universe.Top(50));
```

Fill Forward

The `FillForward` setting is a `bool` that defines whether or not too fill forward data. The default value is `true` . To disable fill forward in non-derivative universes, in the Initialize method, adjust the algorithm's `UniverseSettings` before you add the universe.

```
C#
// Disable fill-forward data before creating the universe (it's enabled by default).
UniverseSettings.FillForward = false;
// Add the 50 Equities to the universe that have the most dollar trading volume.
AddUniverse(Universe.Top(50));
```

To disable fill forward in derivative universes, pass a `fillForward` argument to the universe creation method.

```
// Disable fill-forward in the VIX Index Option universe.
AddIndexOption("VIX", fillForward: false);
```

Extended Market Hours

The `ExtendedMarketHours` setting is a `bool` that defines the trading schedule. If it's `true` , your algorithm receives price data for all trading hours. If it's `false` , your algorithm receives price data only for regular trading hours. The default value is `false` .

You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours.

To view the trading schedule of an asset, open Asset Classes , click an asset class, then click Market Hours .

To enable extended market hours in non-derivative universes, in the Initialize method, adjust the algorithm's `UniverseSettings` before you add the universe.

```
// Enable pre- and post-market hours data for assets in the universe.
UniverseSettings.ExtendedMarketHours = true;
// Add the 50 Equities to the universe that have the most dollar trading volume.
AddUniverse(Universe.Top(50));
```

To enable extended market hours in derivative universes, pass an `extendedMarketHours` argument to the universe creation method.

```
// Request pre- and post-market hours data for a Futures universe.
AddFuture(Futures.Currencies.BTC, extendedMarketHours: true);
```

Minimum Time in Universe

The `MinimumTimeInUniverse` setting is a `TimeSpan` object that defines the minimum amount of time an asset must be in the universe before the universe can remove it. The default value is `TimeSpan.FromDays(1)` . To change the minimum time, in the Initialize method, adjust the algorithm's `UniverseSettings` before you add the universe.

```
// Keep each security in the universe for a minimum of 7 days.
UniverseSettings.MinimumTimeInUniverse = TimeSpan.FromDays(7);
// Add the top 50 most liquid Equities to the universe.
AddUniverse(Universe.Top(50));
```

Data Normalization Mode

The `DataNormalizationMode` setting is an enumeration that defines how historical data is adjusted. This setting is only applicable for US Equities and Futures.

US Equities

In the case of US Equities, the data normalization mode affects how historical data is adjusted for corporate actions . To view all the available options, see Data Normalization . The default value is `DataNormalizationMode.Adjusted` . To change the data normalization mode, in the Initialize method, adjust the algorithm's `UniverseSettings` before you add the universe.

```
// Pipe raw price data (unadjusted for splits and dividends) into the algorithm.
// Equity Options require raw data and it improves the accuracy of modeling historical periods.
UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
// Add a universe of the 50 most liquid US Equities.
AddUniverse(Universe.Top(50));
```

Futures

In the case of Futures, the data normalization mode affects how historical data of two contracts is stitched together to form the continuous contract . To view all the available options, see Data Normalization . The default value is `DataNormalizationMode.Adjusted` . To change the data normalization mode, in the Initialize method, pass a `dataNormalizationMode` argument to the `AddFuture` method.

```
// Set a specific data normalization mode for the continuous contract
// with the dataNormalizationMode parameter of the AddFuture method.
AddFuture(Futures.Currencies.BTC, dataNormalizationMode: DataNormalizationMode.BackwardsRatio);
```

Contract Depth Offset

The `ContractDepthOffset` setting is an `int` that defines which contract to use for the continuous Futures contract. 0 is the front month contract, 1 is the following back month contract, and 3 is the second back month contract. The default value is 0. To change the contract depth offset, in the Initialize method, pass a `contractDepthOffset` argument to the `AddFuture` method.

```
// To adjust the contract depth offset to the second back month contract,
// pass the value 3 to the contractDepthOffset argument in the AddFuture method.
AddFuture(Futures.Currencies.BTC, contractDepthOffset: 3);
```

Asynchronous Selection

The `Asynchronous` setting is a `bool` that defines whether or not LEAN can run universe selection asynchronously, utilizing concurrent execution to increase the speed of your algorithm. The default value for this setting is `false` . If you enable this setting, abide by the following rules:

- Don't make any history requests in your filter function . History requests can only provide data up to the algorithm time , but if your filter function runs asynchronously, the algorithm time may not be what you expect.
- Don't use the portfolio, security, or orders state. The `Portfolio` , `Securities` , and `Transactions` objects are also functions of the algorithm time.
- If your filter function updates a class variable, don't update the class variable anywhere else in your algorithm.

To enable asynchronous universe selection, in the Initialize method, adjust the algorithm's `UniverseSettings` before you add the universe.

```
// To speed up algorithm performance, enable asynchronous universe selection.
// Only use this when the code is self-contained and stateless.
UniverseSettings.Asynchronous = true;
AddUniverse(Universe.Top(50));
```

Schedule

The `Schedule` setting defines the selection schedule of the universe. Most universes run on a daily schedule. To change the

selection schedule, call the `UniverseSettings.Schedule.On` method with an `IDateRule` object before you add the universe.

```
C#
// Run universe selection on a monthly basis.
UniverseSettings.Schedule.On(DateRules.MonthStart());
AddUniverse(Universe.Top(50));
```

The following table describes the supported `DateRules` :

Member	Description
`DateRules.SetDefaultTimeZone(DateTimeZone timeZone);`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`DateRules.On(int year, int month, int day)`	Trigger an event on a specific date.
`DateRules.On(params DateTime[] dates)`	Trigger an event on specific dates.
`DateRules.EveryDay()`	Trigger an event all seven days of the week.
`DateRules.EveryDay(Symbol symbol, bool extendedMarketHours = false)`	Trigger an event every day a specific symbol is trading.
`DateRules.Every(params DayOfWeek[] days)`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`DateRules.MonthStart(int daysOffset = 0)`	Trigger an event on the first day of each month plus an offset.
`DateRules.MonthStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`DateRules.MonthEnd(int daysOffset = 0)`	Trigger an event on the last day of each month minus an offset.
`DateRules.MonthEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`DateRules.WeekStart(int daysOffset = 0)`	Trigger an event on the first day of each week plus an offset.
`DateRules.WeekStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`DateRules.WeekEnd(int daysOffset = 0)`	Trigger an event on the last day of each week minus an offset.
`DateRules.WeekEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`DateRules.YearStart(int daysOffset = 0)`	Trigger an event on the first day of each year plus an offset.
`DateRules.YearStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.

`DateRules.YearEnd(int daysOffset = 0)`	Trigger an event on the last day of each year minus an offset.
`DateRules.YearEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`DateRules.Today`	Trigger an event once today.
`DateRules.Tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `string` and a `getDatesFunction` argument of type `Func<DateTime, DateTime, IEnumerable<DateTime>>` . The `getDatesFunction` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```
C#

// Create a date rule that specifies the 10th day of each month.
var dateRule = new FuncDateRule(
    name: "10th_day_of_the_month",
    getDatesFunction: (start, end) => Enumerable.Range(start.Year, end.Year - start.Year + 1)
        .SelectMany(year => Enumerable.Range(1, 12).Select(month => new DateTime(year, month, 10)))
);
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `DateRules.EveryDay("ES")` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```
C#

var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

In live trading, scheduled universes run at roughly 8 AM Eastern Time to ensure there is enough time for the data to process.

Configure Universe Securities

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `Initialize` method, call the `SetSecurityInitializer` method and then define the security initializer.

```
C#

// A custom security initializer can override default models such as
// setting new fee and fill models for the security.
SetSecurityInitializer(CustomSecurityInitializer);

private void CustomSecurityInitializer(Security security)
{
    security.SetFeeModel(new ConstantFeeModel(0, "USD"));
}
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```
// Disable the trading fees for each security by passing a functional
// implementation for the SetSecurityInitializer argument.
SetSecurityInitializer(security => security.SetFeeModel(new ConstantFeeModel(0, "USD")));
```

If you call the `SetSecurityInitializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee
- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, call `AddSecurityInitializer` before you create the subscriptions.

```
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetFeeModel(new ConstantFeeModel(0, "USD"));
    }
}
```

Examples

The following examples demonstrate some common practices for universe settings.

Example 1: Weekly-Updating Liquid Universe

The following algorithm demonstrates daily EMA cross, trading on the most liquid stocks. The universe is set to be updated weekly. Various universe settings have been set to simulate the brokerage environment best and for trading needs.

C#

```
public class UniverseSettingsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // To avoid over-updating the universe, which causes insufficient time to earn the trend, update the universe
weekly.
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        UniverseSettings.MinimumTimeInUniverse = TimeSpan.FromDays(7);
        // Rebalancing frequency is daily, so we only need to subscribe to daily resolution.
        UniverseSettings.Resolution = Resolution.Daily;
        // To best simulate IB's margin requirement set the leverage to 50%.
        UniverseSettings.Leverage = 2;
        // Since we trade by market order, we cannot use extended market hours data to fill.
        UniverseSettings.ExtendedMarketHours = false;
        // We want to trade the EMA with raw price but not altered by splits.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.SplitAdjusted;

                // Only trade on the top 10 most traded stocks since they have the most popularity to drive trends.
        AddUniverse(Universe.Top(10));
            }

    public override void OnData(Slice slice)
    {
        foreach (var (symbol, bar) in slice.Bars)
        {
            // Trade the trend by EMA crossing.
            var ema = (Securities[symbol] as dynamic).ema;
            if (bar.Close > ema)
            {
                SetHoldings(symbol, 0.05m);
            }
            else
            {
                SetHoldings(symbol, -0.05m);
            }
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var removed in changes.RemovedSecurities)
        {
            // Liquidate the ones leaving the universe since we will not trade their EMA anymore.
            Liquidate(removed.Symbol);
            // Deregister the EMA indicator to free resources
            DeregisterIndicator((removed as dynamic).ema as ExponentialMovingAverage);
        }

        foreach (var added in changes.AddedSecurities)
        {
            var security = added as dynamic;
            // Create EMA indicator for trend trading signals.
            security.ema = EMA(added.Symbol, 50, Resolution.Daily);
            // Warm up the EMA indicator to ensure its readiness for immediate use.
            WarmUpIndicator(added.Symbol, (ExponentialMovingAverage)security.ema, Resolution.Daily);
        }
    }
}
```

Universes

Equity

You can create any of the following dynamic universes of equity. Click one to learn more.

Equity

Liquidity Universes

Introduction

A liquidity universe lets you select a set of stocks with the greatest dollar volume in the market.

Create Universes

To add a dollar volume universe, call the `Universe.DollarVolume.Top` helper method and pass the result to the `AddUniverse` method.

```
C#
// Add the 50 stocks with the highest dollar volume.
UniverseSettings.Asynchronous = true;
AddUniverse(Universe.Top(50));
```

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Examples

The following examples demonstrate some common liquidity universes for US Equities.

Example 1: Minute-Resolution Universe

The following algorithm asynchronously selects the 10 most liquid US Equities as the universe. It uses minute resolution data to provide the most realistic results.

```
C#
public class MinuteLiquidUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Use asynchronous universe selection to speed up your algorithm.
        UniverseSettings.Asynchronous = true;
        // Use minute resolution data so orders fill at realistic prices.
        UniverseSettings.Resolution = Resolution.Minute;
        // Add a universe of the 10 most liquid US Equities.
        AddUniverse(Universe.Top(10));
    }
}
```

Example 2: Trade Liquid Assets off Bollinger Bands

The following algorithm asynchronously selects the 500 most liquid US Equities as the universe. Each day, it forms a portfolio of the assets in the universe that are below their lower Bollinger Band .

C#

```
public class AsynchronousLiquidUniverseAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.AutomaticIndicatorWarmUp = true;
        // When a new asset enters the universe, seed its current price so you can trade it right away.
        Settings.SeedInitialPrices = true;
        // Use asynchronous universe selection to speed up the algorithm.
        UniverseSettings.Asynchronous = true;
        // Use daily data. It doesn't affect accuracy since the trades fill at the daily market open.
        UniverseSettings.Resolution = Resolution.Daily;
        // Add a universe of the 500 most liquid Equities.
        _universe = AddUniverse(Universe.Top(500));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Create Bollinger Band indicators for the universe constituents.
        foreach (var security in changes.AddedSecurities)
        {
            (security as dynamic).BB = BB(security.Symbol, 60, 2);
        }
        // Deregister the indicators when assets leave the universe.
        foreach (var security in changes.RemovedSecurities)
        {
            DeregisterIndicator((security as dynamic).BB);
        }
    }

    public override void OnData(Slice slice)
    {
        // Ensure there are TradeBar objects in the current slice.
        if (slice.Bars.Count == 0)
        {
            return;
        }
        // Select the Equities that are below their lower Bollinger Band.
        var selected = _universe.Selected
            .Select(symbol => (Securities[symbol] as dynamic))
            .Where(security => security.BB.IsReady && security.Price != 0 && security.Price <
security.BB.LowerBand.Current.Value);
        // Form an equal-weighted portfolio with the selected assets.
        var weight = 1m / selected.Count();
        SetHoldings(selected.Select(security => new PortfolioTarget(security.Symbol, weight)).ToList(),
liquidateExistingHoldings: true);
    }
}
```

Equity

Fundamental Universes

Introduction

A fundamental universe lets you select stocks based on corporate fundamental data. This data is powered by Morningstar® and includes approximately 8,100 tickers (including delisted companies and excluding ETFs, ADRs, and OTC) with 900 properties each.

Create Universes

To add a fundamental universe, in the `Initialize` method, pass a filter function to the `AddUniverse` method. The filter function receives a list of `Fundamental` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. Don't call `AddEquity` in the filter function.

```
C#
public class MyUniverseAlgorithm : QCAlgorithm {
    private Universe _universe;
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        // Add a fundamental universe with a custom filter function.
        _universe = AddUniverse(FundamentalFilterFunction);
    }

    private IEnumerable<Symbol> FundamentalFilterFunction(IEnumerable<Fundamental> fundamental)
    {
         // Select US Equities that have fundamental data.
         return (from f in fundamental
                where f.HasFundamentalData
                select f.Symbol);
    }
}
```

`Fundamental` objects have the following attributes:

Example

The simplest example of accessing the fundamental object would be harnessing the iconic PE ratio for a stock. This is a ratio of the price it commands to the earnings of a stock. The lower the PE ratio for a stock, the more affordable it appears.

```
C#
// Select the top 50 most liquid US Equities and then select the 10 with
// lowest PE ratios.
UniverseSettings.Asynchronous = true;
_universe = AddUniverse(
    fundamental => (from f in fundamental
        where f.Price > 10 && f.HasFundamentalData && !Double.IsNaN(f.ValuationRatios.PERatio)
        orderby f.DollarVolume descending
        select f).Take(100)
        .OrderBy(f => f.ValuationRatios.PERatio).Take(10)
        .Select(f => f.Symbol));
```

Asset Categories

In addition to valuation ratios, the US Fundamental Data from Morningstar has many other data point attributes, including over

200 different categorization fields for each US stock. Morningstar groups these fields into sectors, industry groups, and industries.

Sectors are large super categories of data. To get the sector of a stock, use the `MorningstarSectorCode` property.

```
C#

// Select the US Equities in the technology sector.
var tech = fundamental.Where(x => x.AssetClassification.MorningstarSectorCode == MorningstarSectorCode.Technology);
```

Industry groups are clusters of related industries that tie together. To get the industry group of a stock, use the `MorningstarIndustryGroupCode` property.

```
C#

// Select the US Equities in the agricluture industry group.
var ag = fundamental.Where(x => x.AssetClassification.MorningstarIndustryGroupCode ==
MorningstarIndustryGroupCode.Agriculture);
```

Industries are the finest level of classification available. They are the individual industries according to the Morningstar classification system. To get the industry of a stock, use the `MorningstarIndustryCode` property.

```
C#

// Select the US Equities in the coal industry.
var coal = fundamental.Where(x => x.AssetClassification.MorningstarIndustryCode == MorningstarIndustryCode.Coal);
```

Practical Limitations

Fundamental universes allow you to select an unlimited universe of assets to analyze. Each asset in the universe consumes approximately 5MB of RAM, so you may quickly run out of memory if your universe filter selects many assets. If you backtest your algorithms in the Algorithm Lab, familiarize yourself with the RAM capacity of your backtesting and live trading nodes . To keep your algorithm fast and efficient, only subscribe to the assets you need.

Data Availability

`Fundamental` objects can have NaN values for some of their properties. Before you sort the `Fundamental` objects by one of the properties, filter out the objects that have a NaN value for the property.

```
C#

private IEnumerable<Symbol> FundamentalFilterFunction(IEnumerable<Fundamental> fundamentals)
{
    return fundamentals
        // Select objects that have a value for the fundamental property.
        .Where(f => f.HasFundamentalData && !Double.IsNaN(f.ValuationRatios.PERatio))
        // Sort the objects by the fundamental property.
        .OrderBy(f => f.ValuationRatios.PERatio)
        .Take(10)
        .Select(x => x.Symbol);
}
```

Direct Access

To get fundamental data for Equities in your algorithm, use the `Fundamentals` property of the `Equity` objects. The fundamental data represent the company's fundamentals for the current algorithm time.

```
C#

var fundamentals = Securities[_symbol].Fundamentals;
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `Fundamentals` method. If you pass one `Symbol` , the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects. The fundamental data represents the corporate fundamentals for the current algorithm time.

```
C#

// Single asset
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);
var ibmFundamental = Fundamentals(ibm);

// Multiple assets
var nb = QuantConnect.Symbol.Create("NB", SecurityType.Equity, Market.USA);
var fundamentals = Fundamentals(new List<Symbol>{ nb, ibm }).ToList();
```

Data Availability

Some assets don't have fundamentals (for example, ETFs) and the Morningstar dataset doesn't provide fundamentals for all US Equities. To check if fundamental data is available for an asset, use the `HasFundamentalData` property.

```
C#

var hasFundamentalData = Securities[_symbol].Fundamentals.HasFundamentalData;
```

Object References

If you save a reference to the `Fundamentals` object or its properties, you can access the fundamental properties as they change over time.

```
C#

_fundamentals = Securities[_symbol].Fundamentals;
var earningRatios = _fundamentals.EarningRatios;
```

Historical Data

To get historical fundamental data, call the `History` method. The return type depends on how you call the method.

```
C#

var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);

// Fundamental objects
var fundamentalHistory = History<Fundamental>(ibm, TimeSpan.FromDays(30));

// Fundamentals objects for all US Equities (including delisted companies)
var fundamentalsHistory = History<Fundamentals>(TimeSpan.FromDays(30));

// Collection of Fundamental objects for all US Equities (including delisted companies)
var collectionHistory = History(_universe, 30, Resolution.Daily);
foreach (var fundamental in collectionHistory)
{
    // Cast to Fundamental is required
    var highestMarketCap = fundamental.OfType<Fundamental>().OrderByDescending(x => x.MarketCap).Take(5);
}
```

For more information about historical fundamental data, see Equity Fundamental Data .

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Live Trading Considerations

The live data for fundamental universe selection arrives at 6/7 AM Eastern Time (ET), so fundamental universe selection runs for live algorithms between 7 and 8 AM ET. This timing allows you to place trades before the market opens. Don't schedule anything for midnight because the universe selection data isn't ready yet.

Examples

The following examples demonstrate some common practices for fundamental universes.

Example 1: 500 Stocks >10/*Shareand* > 10M in Daily Trading Volume

The following algorithm selects the 500 most liquid US Equities above 10/*shareand*10M in daily volume.

```C#
public class LiquidNonPennyStocksUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Configure the universe to update at the start of each month. Most of the top 500 doesn't change very
        // frequently.
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        // Add a universe with custom selection rules for filtering.
        AddUniverse(fundamental => (from f in fundamental
            where f.Price > 10 && f.DollarVolume > 10000000
            orderby f.DollarVolume descending
            select f.Symbol).Take(500));
    }
}
```

Example 2: 10 Stocks Above Their 200-Day EMA With >$1B of Daily Trading Volume

Another common request is to filter the universe by a technical indicator, such as only picking stocks above their 200-day Exponential Moving Average (EMA). The `Fundamental` object has adjusted price and volume information, so you can do any price-related analysis. The following algorithm defines a separate class to contain the indicator of each asset.

```C#
using System.Collections.Concurrent;

public class UpTrendLiquidUniverseAlgorithm : QCAlgorithm
{
    // Create a concurrent dictionary to store the EMA data for universe selection.
    private ConcurrentDictionary<Symbol, SelectionData> _selectionDataBySymbol = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add the custom universe.
        AddUniverse(SelectAssets);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> fundamental)
    {
        return (from f in fundamental
            // Create/Update the EMA indicators of each stock.
            let avg = _selectionDataBySymbol.GetOrAdd(f.Symbol, sym => new SelectionData(200))
            where avg.Update(f.EndTime, f.AdjustedPrice)
            // Select the Equities that are above their EMA and have a daily volume of $1B.
            // These assets are in an uptrend and are very liquid.
            where avg.Ema.IsReady && f.Price > avg.Ema.Current.Value && f.DollarVolume > 1000000000
            // Select the 10 most liquid Equities to avoid extra slippage.
            orderby f.DollarVolume descending
            select f.Symbol).Take(10);
    }
}

// Create a separate class to contain the EMA information of each asset.
class SelectionData
{
    public readonly ExponentialMovingAverage Ema;

    // Create an EMA indicator for trend estimation and filtering.
    public SelectionData(int period)
    {
        Ema = new ExponentialMovingAverage(period);
    }

    // Update your variables and indicators with the latest data.
    // You may also want to use the History API here to warm-up the indicator.
    public bool Update(DateTime time, decimal value)
    {
        return Ema.Update(time, value);
    }
}
```

In this example, the `SelectionData` class group variables for the universe selection and updates the indicator of each asset. We highly recommend you follow this pattern to keep your algorithm tidy and bug free. The following snippet shows an example implementation of the `SelectionData` class, but you can make this whatever you need to store your custom universe filters. Note that the preceding `SelectionData` class uses a manual EMA indicator instead of the automatic version . For more information about universes that select assets based on indicators, see Indicator Universes . You need to use a `SelectionData` class instead of assigning the EMA to the `Fundamental` object because you can't create custom properties on `Fundamental` objects like you can with `Security` objects.

Example 3: 10 Stocks Furthest Above their 10-day SMA of Volume

The process to get the 10-day Simple Moving Average (SMA) stock volume is the same process as in Example 2. First, define a `SelectionData` class that performs the averaging. This class tracks the ratio of today's volume relative to historical volumes. You can use this ratio to select assets that are above their 10-day SMA and sort the results by the Equities that have had the biggest jump since yesterday.

```C#
using System.Collections.Concurrent;

public class HighRelativeVolumeUniverseAlgorithm : QCAlgorithm
{
    // Create a dictionary to store the EMA data for universe selection.
    private ConcurrentDictionary<Symbol, SelectionData> _selectionDataBySymbol = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add a universe with custom selection rules for filtering.
        AddUniverse(SelectAssets);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> fundamental)
    {
        return (from f in fundamental
            // Create/Update the volume SMA indicator of each stock.
            let avg = _selectionDataBySymbol.GetOrAdd(f.Symbol, sym => new SelectionData(f.Symbol, 10))
            where avg.Update(f.EndTime, f.Volume)
            // Select the Equities with higher trading volume than their SMA, indicating higher capital flow.
            where avg.VolumeRatio > 1
            // Select the 10 Equities with the highest relative volume, since they have the highest capactity
            // for scalp-trading or intra-day movement.
            orderby avg.VolumeRatio descending
            select f.Symbol).Take(10);
    }
}

// Define a separate class to contain and calculate the SMA of each Equity.
class SelectionData
{
    public readonly Symbol Symbol;
    public readonly SimpleMovingAverage VolumeSma;
    public decimal VolumeRatio;

    public SelectionData(Symbol symbol, int period)
    {
        // Create an SMA of volume to track the popularity of the stock.
        Symbol = symbol;
        VolumeSma = new SimpleMovingAverage(period);
    }

    public bool Update(DateTime time, decimal value)
    {
        // Update the SMA with today's data and calculate the relative volume position for filtering.
        var ready = VolumeSma.Update(time, value);
        VolumeRatio = VolumeSma.Current.Value != 0m ? value / VolumeSma.Current.Value : -1m;
        return ready;
    }
}
```

Example 4: 10 "Fastest Moving" Stocks With a 50-Day EMA > 200 Day EMA

You can construct complex universe filters with the `SelectionData` helper class pattern. To view a full example of this algorithm, see the EmaCrossUniverseSelectionAlgorithm in the LEAN GitHub repository or take the related Boot Camp lesson .

Example 5: Piotroski F-Score

To view this example, see the Piotroski F-Score Investing Research post.

Equity

ETF Constituents Universes

Introduction

An ETF constituents universe lets you select a universe of securities in an exchange traded fund. The US ETF Constituents dataset includes 2,650 US ETFs you can use to create your universe.

Create Universes

To add an ETF Constituents universe, call the `Universe.ETF` method.

```C#
public class ETFConstituentsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        AddUniverse(Universe.ETF("SPY"));
    }
}
```

The following table describes the `ETF` method arguments:

Argument: `etfTicker` The ETF ticker. To view the supported ETFs in the US ETF Constituents dataset, see Supported ETFs . Data Type: `string` | Default Value: `None`
Argument: `universeSettings` The universe settings . If you don't provide an argument, it uses the algorithm `UniverseSettings` . Data Type: `UniverseSettings` | Default Value: `null`
Argument: `universeFilterFunc` A function to select some of the ETF constituents for the universe. If you don't provide an argument, it selects all of the constituents. Data Type: `Func<IEnumerable<ETFConstituentUniverse>, IEnumerable<Symbol>>` | Default Value: `null`

To select a subset of the ETF constituents, provide a `universeFilterFunc` argument. The filter function receives `ETFConstituentUniverse` objects, which represent one of the ETF constituents. `ETFConstituentUniverse` objects have the following attributes:

```C#
public class ETFConstituentsAlgorithm : QCAlgorithm
{
    private Universe _universe;
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        _universe = Universe.ETF("SPY", UniverseSettings, ETFConstituentsFilter);
        AddUniverse(_universe);
    }

    private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Get the 10 securities with the largest weight in the index
        return constituents.OrderByDescending(c => c.Weight).Take(10).Select(c => c.Symbol);
    }
}
```

Historical Data

To get historical ETF constituents data, call the `History` method with the `Universe` object and the lookback period. The return type is a `IEnumerable<BaseDataCollection>` and you have to cast its items to `ETFConstituentUniverse` .

```C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var constituents in history)
{
    foreach (ETFConstituentUniverse constituent in constituents)
    {
        Log($"{constituent.Symbol} weight at {constituent.EndTime}: {constituent.Weight}");
    }
}
```

For more information about ETF Constituents data, see US ETF Constituents .

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Examples

The following examples demonstrate some common practices for ETF constituent universes.

Example 1: Short the Smallest ETF Constituents

A subset of the SPY constituents outperform the SPY while many of the constituents underperform the overall index. In an attempt to exclude the ETF constituents that underperform the index, the following algorithm buys the SPY and shorts the 100 assets in the index with the smallest weight in the ETF.

```C#
public class ETFConstituentsUniverseAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private Dictionary<Symbol, decimal> _etfWeightBySymbol;
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);
        Settings.MinimumOrderMarginPortfolioPercentage = 0m;
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // To avoid over-trading and high transaction costs, refilter and rebalance weekly.
        UniverseSettings.Schedule.On(DateRules.WeekEnd());
        // Add the SPY ETF.
        _spy = AddEquity("SPY").Symbol;
        // Add a universe of the SPY constituents.
        _universe = AddUniverse(Universe.ETF(_spy, universeFilterFunc: SelectAssets));
        // Create a Scheduled Event to rebalance the portfolio.
        Schedule.On(DateRules.WeekStart(), TimeRules.At(9, 0), Rebalance);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Cache the constituent weights in a dictionary for filtering and position sizing.
        _etfWeightBySymbol = constituents
            .Where(c => c.Weight.HasValue)
            .ToDictionary(c => c.Symbol, c => c.Weight.Value);
        // Select the 100 consituents with the smallest weight in the ETF.
        // They should have negative excess return.
        return _etfWeightBySymbol
            .OrderBy(x => x.Value)
            .Take(100)
            .Select(x => x.Key);
    }

    private void Rebalance()
    {
        // Get the ETF weight of all the assets currently in the universe.
        var weightBySymbol = _universe.Selected
            // To avoid trading errors, skip assets that have no price yet.
            .Where(symbol => Securities[symbol].Price != 0)
            .Select(symbol => new { Symbol = symbol, Weight = _etfWeightBySymbol[symbol] })
            .ToDictionary(x => x.Symbol, x => x.Weight);
        // Buy the SPY to eliminate systematic risk.
        var targets = new List<PortfolioTarget>
        {
            new PortfolioTarget(_spy, 1.0m-weightBySymbol.Sum(kvp => kvp.Value))
        };
        // Sell the 100 ETF constituents with the lowest weight due to expected negative excess return.
        targets.AddRange(weightBySymbol.Select(x => new PortfolioTarget(x.Key, -x.Value)));
        // Place orders to rebalance the portfolio.
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}
```

Example 2: SPY Constituents in an Uptrend

The following example chains an ETF constituents universe and a fundamental universe . It first selects all the constituents of the SPY ETF and then filters them down in the fundamental universe filter to select the assets that are trading above their average price over the last 200 days. The output of the fundamental universe selection method is the output of the chained universe. The `Fundamental` objects that the fundamental universe filter function recieves contains the prices of the ETF constituents. By chaining the ETF constituents universe into the fundamental universe, you can update the indicators with the price instead of making a history request .

```C#
public class ChainedUniverseAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, SelectionData> _selectionDataBySymbol = new();
    private Universe _universe;
```

```
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of each asset that enters the universe with its last known price so you can trade it
        // on the same morning it enters the universe without getting warnings.
        Settings.SeedInitialPrices = true;
        // Add a chained universe that selects the SPY constituents trading above their 200-day SMA.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        _universe = AddUniverse(Universe.ETF(spy), FundamentalSelection);
        // Trade daily at market open since the trading signal is generated on a daily resolution.
        Schedule.On(DateRules.EveryDay(spy), TimeRules.AfterMarketOpen(spy, 1), Rebalance);
    }

    public IEnumerable<Symbol> FundamentalSelection(IEnumerable<Fundamental> fundamental)
    {
        // Create/Update an SMA indicator for each asset that enters the ETF.
        var universeSymbols = new List<Symbol>();
        foreach (var f in fundamental)
        {
            universeSymbols.Add(f.Symbol);
            if (!_selectionDataBySymbol.ContainsKey(f.Symbol))
            {
                _selectionDataBySymbol[f.Symbol] = new SelectionData(this, f.Symbol);
            }
            _selectionDataBySymbol[f.Symbol].Update(Time, f.AdjustedPrice);
        }

        // Remove indicators for assets that are no longer in the ETF to release the computational resources.
        var symbolsToRemove = _selectionDataBySymbol.Keys.Where(symbol =>
!universeSymbols.Contains(symbol)).ToList();
        foreach (var symbol in symbolsToRemove)
        {
            _selectionDataBySymbol.Remove(symbol);
        }

        // Select the Equities trading above their SMA as we estimate them to be in uptrend and still rising.
        var selected = _selectionDataBySymbol.Where(kvp => kvp.Value.IsAboveSma)
            .Select(kvp => kvp.Key)
            .ToList();

        // Plot the results.
        Plot("Universe", "Possible", fundamental.Count());
        Plot("Universe", "Selected", selected.Count);

        return selected;
    }

    private void Rebalance()
    {
        // For an equal-weighted portfolio with the Equities that are above their SMA.
        var symbols = _universe.Selected.Where(symbol => Securities[symbol].Price > 0);
        if (symbols.Count() == 0)
        {
            return;
        }
        var weight = 1m / symbols.Count();
        SetHoldings(symbols.Select(symbol => new PortfolioTarget(symbol, weight)).ToList(),
liquidateExistingHoldings: true);
    }
}

// Define a separate class to contain the SMA indicator.
class SelectionData
{
    private SimpleMovingAverage _sma;
    public bool IsAboveSma { get; private set; }

    public SelectionData(QCAlgorithm algorithm, Symbol symbol, int period = 200)
    {
        // Create the SMA indicator for trend detection and filtering.
        _sma = new SimpleMovingAverage(period);
        // Warm up the SMA so you can immediately use it.
        algorithm.WarmUpIndicator(symbol, _sma, Resolution.Daily);
    }

    public void Update(DateTime time, decimal value)
    {
        IsAboveSma = _sma.Update(time, value) && value > _sma.Current.Value;
    }
```

```
    }
}
```

Equity

Chained Universes

Introduction

You can combine ("chain") universes together to fetch fundamental and alternative data on a specific subset of assets. Universes filter input data and return `Symbol` objects. The only requirement is that `Symbol` objects the filter returns are a subset of the input data. The source of the `Symbol` objects is unrestricted, so you can feed the output of one universe into another.

Filter Pattern

Universes filter a large set of Symbol objects by a coarse filter to quickly reduce the data processing requirement. This is often a first step before applying a second filter or requesting alternative data. For example, a strategy might only be interested in easily tradable liquid assets so quickly eliminates all stocks with less than $1M USD / day in trading volume.

The order of your filters can improve the speed of your research. By applying filters that narrow the universe the most, or are the lightest weight first, you can significantly reduce the amount of data your algorithm processes. Unless necessary, you can also not return any selections from earlier filters to further improve research speed, keeping only the universe data for later filters.

Universe Data Weights

To speed up your algorithm, request the lightest weight data first before chaining heavier filters or adding alternative data. The following table shows the size each dataset:

Name	Data Size / Weight
US Equities (Fundamental - Dollar Volume only)	Light (100 MB)
US Equities (Fundamental)	Heavy (up to 20 GB)
US Equity Options	Huge (200 TB)
US Index Options	Medium (500 GB)
US Futures	Medium (500 GB)
US Futures Options	Medium (500 GB)
Crypto	Light (1 GB)
Alternative / General	Light (100 MB - 2 GB)
Alternative / Tiingo News	Medium (200 GB)

Chain Fundamental and Alternative Data

The following example chains a fundamental universe and a QuiverCNBCsUniverse alternative universe . It first selects the 100 most liquid US Equities and then filters them down to those mentioned by CNBC commentator/trader Jim Cramer. The output of the alternative universe selection method is the output of the chained universe.

C#

```
public class ChainedUniverseAlgorithm : QCAlgorithm
{
    private List<Symbol> _fundamental = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Filter the top 100 liquid equities of the last trading day, and save the symbols for the next filtering.
        AddUniverse(fundamental =>
        {
            _fundamental = (from c in fundamental
                orderby c.DollarVolume descending
                select c.Symbol).Take(100).ToList();
            return Universe.Unchanged;
        });
        // Filter the equities being commented on by CNBC analyst Cramer, then select the ones that intersect with
the fundamental universe.
        AddUniverse<QuiverCNBCsUniverse>(altCoarse =>
        {
            var followers = from d in altCoarse.OfType<QuiverCNBCsUniverse>()
                where d.Traders.ToLower().Contains("cramer")
                select d.Symbol;
            return _fundamental.Intersect(followers);
        });
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Request CNBC data for the selected stocks.
        foreach (var added in changes.AddedSecurities)
        {
            AddData<QuiverCNBCs>(added.Symbol);
        }
    }

    public override void OnData(Slice data)
    {
        foreach (var dataPoint in data.Get<QuiverCNBCs>().SelectMany(x=> x.Value.OfType<QuiverCNBC>()))
        {
            Debug($"{dataPoint.Symbol} traders at {data.Time}: {dataPoint.Traders}");
        }
    }
}
```

Chain Fundamental and US Equity Options

The following example chains a fundamental universe and an Equity Options universe . It first selects 10 stocks with the lowest PE ratio and then selects their front-month call Option contracts. The output of both universes is the output of the chained universe.

```C#
public class ETFUniverseOptions : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        // Need to set data normalization mode to raw for options to compare the strike price fairly.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;

        // Filter for equities with fundamental data first.
        var universe = AddUniverse(FundamentalFunction);
        // Based on the filtered equities, request an option universe with them as underlying.
        AddUniverseOptions(universe, OptionFilterFunction);
    }

    private IEnumerable<Symbol> FundamentalFunction(IEnumerable<Fundamental> fundamental)
    {
        // Filter for equities with the lowest PE Ratio first.
        return fundamental
            .Where(f => !double.IsNaN(f.ValuationRatios.PERatio))
            .OrderBy(f => f.ValuationRatios.PERatio)
            .Take(10)
            .Select(x => x.Symbol);
    }

    private OptionFilterUniverse OptionFilterFunction(OptionFilterUniverse optionFilterUniverse)
    {
        // Select the front month ATM calls.
        return optionFilterUniverse.Strikes(0, 2).FrontMonth().CallsOnly();
    }

    public override void OnData(Slice data)
    {
        // Iterate through each Option chain.
        foreach (var (canonicalSymbol, chain) in data.OptionChains)
        {
            var equitySymbol = canonicalSymbol.Underlying;
            foreach (var contract in chain)
            {
                var contractSymbol = contract.Symbol;
                var price = contract.LastPrice;
            }
        }
    }
}
```

Chain ETF and Fundamental

The following example chains a fundamental universe and an ETF constituents universe . It first selects all the constituents of the QQQ ETF and then filters them down to select the 10 assets with the lowest PE ratio. The output of the fundamental universe selection method is the output of the chained universe.

```C#
public class ChainedUniverseAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        // Select QQQ constituents first, then by fundamental data.
        _universe = AddUniverse(Universe.ETF("QQQ", Market.USA, UniverseSettings, ETFConstituentsFilter),
FundamentalSelection);
    }

    private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Select all QQQ constituents.
        return constituents.Select(c => c.Symbol);
    }

    private IEnumerable<Symbol> FundamentalSelection(IEnumerable<Fundamental> fundamental)
    {
        // Filter for the lowest PE Ratio stocks among QQQ constituents for undervalued stocks.
        return fundamental
            .Where(f => !double.IsNaN(f.ValuationRatios.PERatio))
            .OrderBy(f => f.ValuationRatios.PERatio)
            .Take(10)
            .Select(x => x.Symbol);
    }

    public override void OnData(Slice data)
    {
        foreach (var symbol in _universe.Selected)
        {
            var peRatio = Securities[symbol].Fundamentals.ValuationRatios.PERatio;
        }
    }
}
```

Chain ETF and Alternative Data

The following example chains an ETF universe and a QuiverCNBCsUniverse alternative universe . It first selects all constituents of SPY and then filters them down to those mentioned by CNBC commentator/trader Jim Cramer. The output of the alternative universe selection method is the output of the chained universe.

```C#
public class ChainedUniverseAlgorithm : QCAlgorithm
{
    private List<Symbol> _etf = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;

        // Save all SPY constituents for the next filtering.
        AddUniverse(Universe.ETF("SPY", Market.USA, UniverseSettings, constituents =>
        {
            _etf = constituents.Select(c => c.Symbol).ToList();
            return Universe.Unchanged;
        }));
        // Filter the equities being commented on by CNBC analyst Cramer, then select the ones in SPY constituents.
        AddUniverse<QuiverCNBCsUniverse>(altCoarse =>
        {
            var followers = from d in altCoarse.OfType<QuiverCNBCsUniverse>()
                where d.Traders.ToLower().Contains("cramer")
                select d.Symbol;
            return _etf.Intersect(followers);
        });
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Request CNBC data for the selected stocks.
        foreach (var added in changes.AddedSecurities)
        {
            AddData<QuiverCNBCs>(added.Symbol);
        }
    }

    public override void OnData(Slice data)
    {
        foreach (var dataPoint in data.Get<QuiverCNBCs>().SelectMany(x=> x.Value.OfType<QuiverCNBC>()))
        {
            Debug($"{dataPoint.Symbol} traders at {data.Time}: {dataPoint.Traders}");
        }
    }
}
```

Chain ETF and US Equity Options

The following example chains an ETF constituents universe and an Equity Options universe . It first selects the 10 largest-weighted constituents of QQQ and then selects their front-month call Option contracts. The output of both universes is the output of the chained universe.

C#

```
public class ETFUniverseOptions : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        // Need to set the data normalization mode to raw for fair strike price comparison.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;

        // First-pass filtering from QQQ constituents.
        var etfUniverse = Universe.ETF("QQQ", Market.USA, UniverseSettings, ETFConstituentsFilter);
        AddUniverse(etfUniverse);
        // Filter for equity options from the selected QQQ constituents next.
        AddUniverseOptions(etfUniverse, OptionFilterFunction);
    }

    private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Select the top 10 weighted QQQ constituents for most liquid options.
        return constituents.OrderByDescending(c => c.Weight).Take(10).Select(c => c.Symbol);
    }

    private OptionFilterUniverse OptionFilterFunction(OptionFilterUniverse optionFilterUniverse)
    {
        // Select the front month ATM standard calls.
        return optionFilterUniverse.Strikes(0, 2).FrontMonth().CallsOnly();
    }

    public override void OnData(Slice data)
    {
        // Iterate through each Option chain.
        foreach (var (canonicalSymbol, chain) in data.OptionChains)
        {
            var equitySymbol = canonicalSymbol.Underlying;
            foreach (var contract in chain)
            {
                var contractSymbol = contract.Symbol;
                var price = contract.LastPrice;
            }
        }
    }
}
```

Equity

Legacy Fundamental Universes

Introduction

Warning: This API for Universe Selection was deprecated on November 2023. Please refer to the new Fundamental Universe API .

There are several ways to create an Equities universe. You can select a universe based on `CoarseFundamental` data or the constituents of an ETF, and then you can further filter your universe down with corporate fundamentals. The following sections explain each of these techniques in detail.

Coarse Universe Selection

A coarse universe enables you pick a set of stocks based on their trading volume, price, or whether they have fundamental data. To add a coarse universe, in the `Initialize` method, pass a filter function to the `AddUniverse` method. The coarse filter function receives a list of `CoarseFundamental` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the universe and LEAN automatically creates subscriptions for them. Don't call `AddEquity` in the filter function.

```
C#
public class MyCoarseUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        AddUniverse(CoarseFilterFunction);
    }

    private IEnumerable<Symbol> CoarseFilterFunction(IEnumerable<CoarseFundamental> coarse)
    {
        return (from c in coarse
            orderby c.DollarVolume descending
            select c.Symbol).Take(100);
    }
}
```

`CoarseFundamental` objects have the following attributes:

The total number of stocks in the US Equity Security Master dataset is 30,000 but your coarse filter function won't receive all of these at one time because the US Equity Security Master dataset is free of survivorship bias and some of the securities have delisted over time. The number of securities that are passed into your coarse filter function depends on the date of your algorithm. Currently, there are about 10,000 securities that LEAN passes into your coarse filter function.

Fundamentals Selection

A fundamental universe lets you select stocks based on corporate fundamental data. This data is powered by Morningstar® and includes approximately 8,100 tickers with 900 properties each. This universe doesn't include ETFs, ADRs, or OTC equities. Due to the sheer volume of information, fundamental selection is performed on the output of another universe filter. Think of this process as a 2-stage filter. An initial filter function selects a set of stocks and then a fine fundamental filter function selects a subset of those stocks.

QuantConnect Coarse and Fine Universe Selection

To add a fundamental universe, in the `Initialize` method, pass two filter functions to the `AddUniverse` method. The first filter function can be a coarse universe filter , dollar volume filter , or an ETF constituents filter . The second filter function receives a list of `FineFundamental` objects and must return a list of `Symbol` objects. The list of `FineFundamental` objects contains a subset of the `Symbol` objects that the first filter function returned. The `Symbol` objects you return from the second function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. Don't call `AddEquity` in the filter function.

> **Tip:** Only 8,100 assets have fundamental data. If your first filter function receives `CoarseFundamental` data, you should only select assets that have a true value for their `HasFundamentalData` property.

C#

```
public class MyUniverseAlgorithm : QCAlgorithm {
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        AddUniverse(CoarseFilterFunction, FineFundamentalFilterFunction);
    }
    // filter based on CoarseFundamental
    IEnumerable<Symbol> CoarseFilterFunction(IEnumerable<CoarseFundamental> coarse)
    {
         // In addition to further coarse universe selection, ensure the security has fundamental data
         return (from c in coarse
             where c.HasFundamentalData
             select c.Symbol);
    }
    // filter based on FineFundamental
    public IEnumerable<Symbol> FineFundamentalFilterFunction(IEnumerable<FineFundamental> fine)
    {
        // Return a list of Symbols
        return Enumerable.Empty<Symbol>();
    }
}
```

`FineFundamental` objects have the following attributes:

Example

The simplest example of accessing the fundamental object would be harnessing the iconic PE ratio for a stock. This is a ratio of the price it commands to the earnings of a stock. The lower the PE ratio for a stock, the more affordable it appears.

```
// Take the top 50 by dollar volume using coarse
// Then the top 10 by PERatio using fine
UniverseSettings.Asynchronous = true;
AddUniverse(
    coarse => {
        return (from c in coarse
            where c.Price > 10 && c.HasFundamentalData
            orderby c.DollarVolume descending
            select c.Symbol).Take(50);
    },
    fine => {
        return (from f in fine
            orderby f.ValuationRatios.PERatio ascending
            select f.Symbol).Take(10);
    });
```

Asset Categories

In addition to valuation ratios, the US Fundamental Data from Morningstar has many other data point attributes, including over 200 different categorization fields for each US stock. Morningstar groups these fields into sectors, industry groups, and industries.

Sectors are large super categories of data. To get the sector of a stock, use the `MorningstarSectorCode` property.

```
var tech = fine.Where(x => x.AssetClassification.MorningstarSectorCode == MorningstarSectorCode.Technology);
```

Industry groups are clusters of related industries that tie together. To get the industry group of a stock, use the `MorningstarIndustryGroupCode` property.

```
var ag = fine.Where(x => x.AssetClassification.MorningstarIndustryGroupCode ==
MorningstarIndustryGroupCode.Agriculture);
```

Industries are the finest level of classification available. They are the individual industries according to the Morningstar classification system. To get the industry of a stock, use the `MorningstarIndustryCode` .

```
var coal = fine.Where(x => x.AssetClassification.MorningstarIndustryCode == MorningstarSectorCode.Coal);
```

Practical Limitations

Like coarse universes, fine universes allow you to select an unlimited universe of assets to analyze. Each asset in the universe consumes approximately 5MB of RAM, so you may quickly run out of memory if your universe filter selects many assets. If you backtest your algorithms in the Algorithm Lab, familiarize yourself with the RAM capacity of your backtesting and live trading nodes . To keep your algorithm fast and efficient, only subscribe to the assets you need.

Live Trading Considerations

The live data for fundamental universe selection arrives at 6/7 AM Eastern Time (ET), so fundamental universe selection runs for live algorithms between 7 and 8 AM ET. This timing allows you to place trades before the market opens. Don't schedule anything for midnight because the universe selection data isn't ready yet.

Examples

The legacy fundamental universe is deprecated. For examples of the new fundamental universe API, see Examples .

Equity

Alternative Data Universes

Introduction

An alternative data universe lets you select a basket of Equities based on an alternative dataset that's linked to them. If you use an alternative data universe, you limit your universe to only the securities in the dataset, which avoids unnecessary subscriptions.

Supported Datasets

The following alternative datasets support universe selection:

- Brain Language Metrics on Company Filings
- Brain ML Stock Ranking
- Brain Sentiment Indicator
- Crypto Market Cap
- Upcoming Dividends
- Upcoming Earnings
- Upcoming IPOs
- Upcoming Splits
- CNBC Trading
- Corporate Lobbying
- Insider Trading
- US Congress Trading
- US Government Contracts
- WallStreetBets
- Corporate Buybacks

Examples

The following examples demonstrate some common alternative data universes.

Example 1: Brain Sentiment Universe

The following algorithm uses the Brain Sentiment Indicator dataset to create a universe of US Equities that have some article mentions and the most positive sentiment. It then forms a sentiment-weighted portfolio at the start of each month.

```C#
public class BrainSentimentUniverseAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, decimal> _sentimentBySymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add an Equity universe that updates at the start of each month.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        UniverseSettings.Schedule.On(DateRules.MonthStart(spy));
        AddUniverse<BrainSentimentIndicatorUniverse>(altData =>
        {
            _sentimentBySymbol = altData
                .Select(x => x as BrainSentimentIndicatorUniverse)
                // Select the assets with recent mentions and a sentiment score.
                .Where(x => x.TotalArticleMentions30Days > 0 && x.Sentiment30Days.HasValue)
                // Select the 10 assets with the greatest sentiment score.
                .OrderByDescending(x => x.Sentiment30Days.Value)
                .Take(10)
                .ToDictionary(x => x.Symbol, x => x.Sentiment30Days.Value);
            // Return the Symbol objects of the selected assets.
            return _sentimentBySymbol.Keys;
        });
        // Create a Scheduled Event to rebalance the portfolio at the start of each month.
        Schedule.On(DateRules.MonthStart(spy), TimeRules.At(9, 45), Rebalance);
    }

    public void Rebalance()
    {
        // To avoid trading errors, filter out the assets that don't have a price yet.
        _sentimentBySymbol = _sentimentBySymbol
            .Where(kvp => Securities[kvp.Key].Price > 0)
            .ToDictionary(kvp => kvp.Key, kvp => kvp.Value);
        // Form a sentiment-weighted portfolio.
        var sentimentScoreSum = _sentimentBySymbol.Values.Sum();
        SetHoldings(
            _sentimentBySymbol.Select(kvp => new PortfolioTarget(kvp.Key, kvp.Value / sentimentScoreSum)).ToList(),
            liquidateExistingHoldings: true
        );
    }
}
```

Example 2: Insiders Trading Universe

Insiders have more information to evaluate the overall prospect of the company, so following their trades can be useful. The following algorithm uses the Insider Trading to create a universe of US Equities that insiders have recently purchased. It then invests equally into the companies with positive insider trades, which may provide extra confidence in their expected return, and hold for 3 months.

C#

```
public class InsiderTradingUniverseAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of each asset with its last known price to
        // avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Keep each security in the universe for a minimum of 30 days to
        // digest the insiders purchase sentiment.
        UniverseSettings.MinimumTimeInUniverse = TimeSpan.FromDays(30);
        // Add the QuiverInsiderTrading dataset for insider trade
        // detection and filtering.
        _universe = AddUniverse<QuiverInsiderTradingUniverse>(SelectAssets);
        // Add a Scheduled Event to rebalance the portfolio each day.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(DateRules.EveryDay(spy), TimeRules.AfterMarketOpen(spy, 1), Rebalance);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<BaseData> altData)
    {
        // Calculate the net dollar volume of insider trades for each
        // asset.
        var dollarVolumeBySymbol = new Dictionary<Symbol, decimal?>();
        foreach (QuiverInsiderTradingUniverse data in altData)
        {
            if (data.PricePerShare == 0m || data.PricePerShare == null)
            {
                continue;
            }
            if (!dollarVolumeBySymbol.ContainsKey(data.Symbol))
            {
                dollarVolumeBySymbol[data.Symbol] = 0;
            }
            dollarVolumeBySymbol[data.Symbol] += data.Shares * data.PricePerShare;
        }
        // Select the 10 assets with the largest dollar volume of insider
        // trades.
        return dollarVolumeBySymbol
            .OrderByDescending(kvp => kvp.Value)
            .Take(10)
            .Select(kvp => kvp.Key);
    }

    public void Rebalance()
    {
        // Equally invest in insider buying companies to evenly
        // dissipate the capital risk.
        var symbols = _universe.Selected.Where(symbol => Securities[symbol].Price != 0);
        SetHoldings(symbols.Select(s => new PortfolioTarget(s, 1m / symbols.Count())).ToList(), true);
    }
}
```

Example 3: Share Buyback Universe

The following algorithm uses the Corporate Buybacks dataset to create a universe of US Equities that have announced an upcoming share buyback program:

C#

```
public class SmartInsiderIntentionUniverseAlgorithm : QCAlgorithm
{
    // A dictionary to hold the buyback size for position sizing.
    public Dictionary<Symbol, decimal> _buybackSize = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of each asset with its last known price to
        // avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe that selects assets at the start of each week.
        // The universe should select Equities that have announced a
        // material buyback plan, since they have confidence in their
        // future prospect and the reduction in supply can drive their
        // price up.
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        AddUniverse<SmartInsiderIntentionUniverse>(altData => {
            _buybackSize.Clear();
            return altData.OfType<SmartInsiderIntentionUniverse>()
                // Select assets that have a material buyback size to have
                // strong confidence.
                .Where(d => d.AmountValue.HasValue && d.AmountValue.Value > 10000000m)
                .Select(d => {
                    // Record the buyback size in the dictionary.
                    _buybackSize[d.Symbol] = d.AmountValue.Value;
                    return d.Symbol;
                });
        });
        // Add a Scheduled Event to rebalance the portfolio at the start
        // of each week. The weekly schedule allows time to capitalize
        // the market swings from the positive sentiment.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(DateRules.WeekStart(spy), TimeRules.AfterMarketOpen(spy, 1), Rebalance);
    }

    private void Rebalance()
    {
        // Ignore illiquid assets that have no price yet.
        _buybackSize = _buybackSize.Where(kvp => Securities[kvp.Key].Price != 0).ToDictionary();
        // Get the sum of all buyback size so we can scale the portfolio
        // weights based on the buyback size.
        var buybackSum = _buybackSize.Sum(x => x.Value);
        // Place the trades to rebalance the portfolio.
        SetHoldings(_buybackSize.Select(x => new PortfolioTarget(x.Key, x.Value / buybackSum)).ToList());
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Liquidate assets when they leave the universe.
        foreach (var removed in changes.RemovedSecurities)
        {
            _buybackSize.Remove(removed.Symbol);
            Liquidate(removed.Symbol);
        }
    }
}
```

Universes

Equity Options

Introduction

An Equity Options universe lets you select a basket of contracts for a single Option. LEAN models Option subscriptions as a universe of Option contracts.

Create Universes

To add a universe of Equity Option contracts, in the `Initialize` method, call the `AddOption` method. This method returns an `Option` object, which contains the canonical `Symbol` . You can't trade with the canonical Option `Symbol` , but save a reference to it so you can easily access the Option contracts in the OptionChain that LEAN passes to the `OnData` method.

C#

```
public class BasicOptionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        var option = AddOption("SPY");
        option.SetFilter(Filter);
        _symbol = option.Symbol;
    }

    private OptionFilterUniverse Filter(OptionFilterUniverse universe)
    {
        return universe.IncludeWeeklys().Expiration(0, 7).Delta(0.35m, 0.75m);
    }

    public override void OnData(Slice data)
    {
        if (data.OptionChains.TryGetValue(_symbol, out var chain))
        {
            var contract = chain.OrderBy(x => x.Greeks.Delta).FirstOrDefault();
        }
    }
}
```

The following table describes the `AddOption` method arguments:

Argument	Data Type	Description	Default Value
`ticker`	`string`	The underlying Equity ticker. To view the supported underlying Equity tickers, see Supported Assets .	
`resolution`	`Resolution?`	The resolution of the market data. To view the supported resolutions, see Resolutions . The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.	`null`
`market`	`string`	The underlying Equity market.	`null`
`fillForward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.	`true`
`leverage`	`decimal`	The leverage for this Equity.	`Security.NullLeverage`
`extendedMarketHours`	`bool`	A flag that signals if LEAN should send data during pre- and post-market trading hours.	`false`

If you add an Equity Option universe but don't have a subscription to the underlying Equity, LEAN automatically subscribes to the underlying Equity with the following settings:

Setting	Value
Fill forward	Same as the Option universe
Leverage	0
Extended Market Hours	Same as the Option universe
Data Normalization	`DataNormalizationMode.Raw`

If you already have a subscription to the underlying Equity but it's not `Raw` data normalization, LEAN automatically changes it to `Raw` .

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts of the same underlying Equity, but with different features.

```C#
// Example 1: Select a Straddle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Straddle(30, 5, 10));

// Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));

// Example 3: Select the 0DTE contracts that form an Strangle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Expiration(0, 0).Strangle(30, 5, -
10));
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`NakedCall(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`NakedPut(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`CallSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`PutSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.
`CallCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.
`PutCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.
`Strangle(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Long Strangle or Short Strangle Option strategies.
`Straddle(int minDaysTillExpiry)` Selects two contracts to form Long Straddle or Short Straddle Option strategies.
`ProtectiveCollar(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Protective Collar Option strategies.

`Conversion(int minDaysTillExpiry, decimal strikeFromAtm)` Selects two contracts to form Conversion or Reverse Conversion Option strategies.
`CallButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.
`PutButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.
`IronButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.
`IronCondor(int minDaysTillExpiry, decimal nearStrikeSpread, decimal farStrikeSpread)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`BoxSpread(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`JellyRoll(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.
`CallLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`PutLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

```
// Example 1: Select the contracts with delta between 0.25 and 0.75
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Delta(0.25m, 0.75m));

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below
20%
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below
20% that forms an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0,
30).IronCondor(30, 5, 10));
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`IV(decimal min, decimal max)`
`ImpliedVolatility(decimal min, decimal max)`
 	
Selects a contract with implied volatility within the range you set.

`D(decimal min, decimal max)`
`Delta(decimal min, decimal max)`
 	
Selects a contract with delta within the range you set.

`G(decimal min, decimal max)`
`Gamma(decimal min, decimal max)`
 	
Selects a contract with gamma within the range you set.

`R(decimal min, decimal max)`
`Rho(decimal min, decimal max)`
 	
Selects a contract with rho within the range you set.

`V(decimal min, decimal max)`
`Vega(decimal min, decimal max)`
 	
Selects a contract with vega within the range you set.

`T(decimal min, decimal max)`
`Theta(decimal min, decimal max)`
 	
Selects a contract with theta within the range you set.

`OI(long min, long max)`
`OpenInterest(decimal min, decimal max)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

To perform thorough filtering on the `OptionFilterUniverse` , define an isolated filter method.

```C#
// Select the put contracts with the lowest strike price.
option.SetFilter(Selector);

private OptionFilterUniverse Selector(OptionFilterUniverse optionFilterUniverse)
{
    return universe
        .Delta(0.5m, 1.5m)
        .Gamma(0.0001m, 0.0006m)
        .Vega(0.01m, 1.5m)
        .Theta(-2.0m, -0.5m)
        .Rho(0.5m, 3.0m)
        .ImpliedVolatility(1.0m, 3.0m)
        .OpenInterest(100, 500);
}
```

Filter by Other Contract Properties

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Option` object.

```C#
// Select contracts that have a strike price within 1 strike level above and below the underlying price
option.SetFilter(minStrike: -1, maxStrike: 1);

// Select contracts that expire within 30 days
option.SetFilter(minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select contracts that have a strike price within 1 strike level and expire within 30 days
option.SetFilter(minStrike: -1, maxStrike: 1, minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly());
```

The following table describes the available filter techniques:

`SetFilter(int minStrike, int maxStrike)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302*andtherearestrikesatevery*5. If you set `minStrike` to -1 and `maxStrike` to 1, LEAN selects the contracts that have a strike of 300*or*305. This filter runs asynchronously by default.
`SetFilter(TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`SetFilter(int minStrike, int maxStrike, TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`SetFilter(Func<OptionFilterUniverse, OptionFilterUniverse> universeFunc)` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.
`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.
`StandardsOnly()` Selects standard contracts.
`IncludeWeeklys()` Selects non-standard weeklys contracts.
`WeeklysOnly()` Selects weekly contracts.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.
`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```C#
// Example 1: Select the front month call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly().FrontMonth());

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

Navigate Intraday Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` . After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        // Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest expiration
        var contracts = chain
            .Where(x => x.Right == OptionRight.Put)
            .OrderByDescending(x => x.Expiry)
            .ThenBy(x => Math.Abs(chain.Underlying.Price - x.Strike))
            .Take(5);

        // Select the contract with the delta closest to -0.5
        var contract = contracts.OrderBy(x => Math.Abs(-0.5m - x.Greeks.Delta)).FirstOrDefault();
    }
}
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-OptionChain key-value pairs
    foreach (var kvp in slice.OptionChains)
    {
        var canoncialSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}
```

`OptionChain` objects have the following properties:

Navigate Daily Option Chains

To get the daily, pre-calculated Greeks and implied volaility of all the currently tradable contracts, call the `OptionChain` method. This method returns a collection of `OptionUniverse` objects, where each object represents a contract. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter.

```C#
// In the initialize method, create a Scheduled Event to get the Option
// chain and rebalance the portfolio.
Schedule.On(DateRules.WeekStart(_symbol), TimeRules.AfterMarketOpen(_symbol, 1), Rebalance);

public void Rebalance()
{
    foreach (var optionUniverse in OptionChain(_symbol))
    {
        var close = optionUniverse.Close;
        var oi = optionUniverse.OpenInterest;
        var delta = optionUniverse.Greeks.Delta;
    }
}
```

The `OptionChain` method was previously known as the `OptionChainProvider.GetOptionContractList` method.

`OptionUniverse` objects have the following properties:

Greeks and Implied Volatility

There are several ways to get the implied volatility and Greeks of contracts.

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```C#
public override void Initialize()
{
    var option = AddOption("SPY");
    option.SetFilter(universe => universe.IncludeWeeklys().Delta(0.3m, 0.7m).Expiration(0, 7));
}
```

To calculate the values, we use our implementation of the forward tree pricing model, which accounts for the interest rate and dividend payments.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

To override the default pricing model of the Option, set a pricing model . If you set a price model, it sets the price model of the individual contracts in the universe.

```
// Set PriceModel property to use the Crank-Nicolson finite-difference model to price the Options.
option.PriceModel = OptionPriceModels.CrankNicolsonFD();
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Historical Data

To get historical chains for an Equity Option, call the `History<OptionUniverse>` method with the canonical Option `Symbol` . This method returns the entire Option chain for each trading day, not the subset of contracts that pass your universe filter.

```
public class OptionHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var option = AddOption("SPY");
        var history = History<OptionUniverse>(option.Symbol, 5);
        foreach (var chain in history)
        {
            var endTime = chain.EndTime;
            var filteredContracts = chain.Data
                .Select(contract => contract as OptionUniverse)
                .Where(contract => contract.Greeks.Delta > 0.3m);
            foreach (var contract in filteredContracts)
            {
                var price = contract.Price;
                var iv = contract.ImpliedVolatility;
            }
        }
    }
}
```

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day. To get the intraday values or to customize the Greeks and IV calculations, create some Option indicators .

The `History<OptionUniverse>` method represents each contract with an `OptionUniverse` object, which have the following properties:

Selection Frequency

By default, Equity Option universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Equity Option universes.

Example 1: 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. The following algorithm selects 0DTE Option contracts for the SPY that fall within 3 strikes of the underlying price.

```
C#
public class ZeroDTEOptionUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var option = AddOption("SPY");
        option.SetFilter(u => u.IncludeWeeklys().Expiration(0, 0).Strikes(-3, 3));
    }
}
```

For trading full examples of Equity Option Universe, please refer to the Securities > Equity Options > Requesting Data > Universes page.

Universes

Equity CFD

Introduction

An Equity CFD universe lets you select a set of Equity CFD assets. To select the underlying Equities, you can use a fundamental universe to select assets based on corporate fundamental data, an ETF constituents universe to select the CFD versions of stocks in an exchange-traded fund, or an alternative data universe to select assets based on alternative data. This feature is powerful for European clients seeking to trade US ETF products.

Only the Interactive Brokers CFD integration supports trading Stock-CFD products. QuantConnect doesn't have historical data for Interactive Brokers CFD products; however, you can use the `LiveMode` flag to swap to the CFD equivalents for live trading. In live trading, you must include Interactive Brokers as a data provider to trade Equity-CFD products.

Create Universes Using Fundamentals

To add a fundamental universe, in the `Initialize` method, pass a filter function to the `AddUniverse` method. The filter function receives a list of `Fundamental` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. In live mode, call the `Symbol.Create` method to swap for a CFD version of the same `Symbol` . Don't call `AddCfd` in the filter function.

C#

```
// Create a universe for CFD securities based on fundamental data.
public class MyUniverseAlgorithm : QCAlgorithm {
    private Universe _universe;
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        // Pass the filter function as an argument to the AddUniverse method.
        _universe = AddUniverse(FundamentalFilterFunction);
    }

    private IEnumerable<Symbol> FundamentalFilterFunction(IEnumerable<Fundamental> fundamental)
    {
        var symbols = (from f in fundamental
                where f.HasFundamentalData
                select f.Symbol);

        if (LiveMode)
        {
            return symbols.Select(x => QuantConnect.Symbol.Create(x.Value, SecurityType.Cfd,
Market.InteractiveBrokers));
        }

        return symbols;
    }
}
```

Example

The simplest example of accessing the fundamental object would be harnessing the iconic PE ratio for a stock. This is a ratio of the price it commands to the earnings of a stock. The lower the PE ratio for a stock, the more affordable it appears.

```
// Select the top 50 by dollar volume and then select the top 10 by their PE ratio.
UniverseSettings.Asynchronous = true;
_universe = AddUniverse(
    fundamental =>
    {
        var symbols = (from f in fundamental
            where f.Price > 10 && f.HasFundamentalData && !Double.IsNaN(f.ValuationRatios.PERatio)
            orderby f.DollarVolume descending
            select f).Take(100)
            .OrderBy(f => f.ValuationRatios.PERatio).Take(10)
            .Select(f => f.Symbol);

        if (LiveMode)
        {
            return symbols.Select(x => QuantConnect.Symbol.Create(x.Value, SecurityType.Cfd,
Market.InteractiveBrokers));
        }

        return symbols;
    });
```

Practical Limitations

Fundamental universes allow you to select an unlimited universe of assets to analyze. Each asset in the universe consumes approximately 5MB of RAM, so you may quickly run out of memory if your universe filter selects many assets. If you backtest your algorithms in the Algorithm Lab, familiarize yourself with the RAM capacity of your backtesting and live trading nodes . To keep your algorithm fast and efficient, only subscribe to the assets you need.

Create Universes using ETF Constituents

To add an ETF Constituents universe, in the `Initialize` method, call the `Universe.ETF` method with a filter function, and pass it to the `AddUniverse` method. The filter function receives a list of `ETFConstituentUniverse` objects and must return a list of `Symbol` objects. The `Symbol` objects you return from the function are the constituents of the fundamental universe and LEAN automatically creates subscriptions for them. In live mode, call the `Symbol.Create` method to swap for a CFD version of the same `Symbol` . Don't call `AddCfd` in the filter function.

```
public class MyUniverseAlgorithm : QCAlgorithm {
    private Universe _universe;
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        _universe = Universe.ETF("SPY", UniverseSettings, ETFConstituentsFilter);
        AddUniverse(_universe);
    }

    private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Get the 10 securities with the largest weight in the index
        var symbols = constituents.OrderByDescending(c => c.Weight).Take(10).Select(c => c.Symbol);
        if (LiveMode)
        {
            return symbols.Select(x => QuantConnect.Symbol.Create(x.Value, SecurityType.Cfd,
Market.InteractiveBrokers));
        }

        return symbols;
    }
}
```

Selection Frequency

Equity universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Live Trading Considerations

The live data for fundamental universe selection arrives at 6/7 AM Eastern Time (ET), so fundamental universe selection runs for live algorithms between 7 and 8 AM ET. This timing allows you to place trades before the market opens. Don't schedule anything for midnight because the universe selection data isn't ready yet.

Examples

The following examples demonstrate common practices for implementing Equity CFD's universe.

Example 1: Short Bottom-Weighted SPY Constituents

A subset of the SPY constituents outperforms the SPY, while many underperform the overall index. To exclude the ETF constituents that underperform the index, the following algorithm buys the SPY CFD and shorts the CFD of the 100 constituents in the index with the smallest weight in the ETF.

C#

```
public class EquityCfdUniverseAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private Dictionary<Symbol, decimal> _etfWeightBySymbol;
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);
        Settings.MinimumOrderMarginPortfolioPercentage = 0m;
        // Request SPY to trade. In live mode, request the IB CFD
        _spy = LiveMode ? AddCfd("SPY", market: Market.InteractiveBrokers).Symbol : AddEquity("SPY").Symbol;
        // The SPY ETF provides market hours for scheduled events.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        // Refilter and rebalance weekly to avoid over-trading and high transaction costs.
        UniverseSettings.Schedule.On(DateRules.WeekEnd(spy));
        // Add a universe to select the CFD contracts of the SPY constituents.
        _universe = AddUniverse(Universe.ETF(spy, universeFilterFunc: SelectAssets));
        // Create a Scheduled Event to rebalance the portfolio.
        Schedule.On(
            DateRules.WeekStart(_spy),
            TimeRules.AfterMarketOpen(_spy, 1),
            Rebalance
        );
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Cache the constituent weights in a dictionary for filtering and position sizing.
        _etfWeightBySymbol = constituents
            .Where(c => c.Weight.HasValue)
            .ToDictionary(c => c.Symbol, c => c.Weight.Value);
        // Select the CFD contracts of the bottom-weighted 100 constituents.
        // They should have negative excess returns.
        return _etfWeightBySymbol
            .OrderBy(x => x.Value)
            .Take(100)
            .Select(x => !LiveMode ? x.Key : QuantConnect.Symbol.Create(x.Key.Value, SecurityType.Cfd,
Market.InteractiveBrokers));
    }

    private void Rebalance()
    {
        // Get the ETF weight of all the assets currently in the universe.
        var weightBySymbol = _universe.Selected.ToDictionary(symbol => symbol, symbol => _etfWeightBySymbol[symbol]);
        // Sell the CFD of the 100 ETF constituents with the lowest weight due to expected negative excess return.
        var targets = weightBySymbol.Select(x => new PortfolioTarget(x.Key, -x.Value)).ToList();
        // Buy the SPY CFD to eliminate systematic risk.
        targets.Add(new(_spy, 1.0m - weightBySymbol.Sum(kvp => kvp.Value)));
        // Place orders to rebalance the portfolio.
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}
```

Universes

Futures

Introduction

A Futures universe lets you select a basket of contracts for a single Future. LEAN models Future subscriptions as a universe of Future contracts. A Future universe is similar to an Option universe , except Future contracts don't have a strike price, so the universe filter primarily focuses on the contract expiration date.

Create Universes

To add a universe of Future contracts, in the `Initialize` method, call the `AddFuture` method. This method returns an `Future` object, which contains the continuous contract `Symbol` . The continuous contract `Symbol` is the key to access the contracts in the FutureChain that LEAN passes to the `OnData` method. The continuous contract `Mapped` property references the current contract in the continuous contract series. When you create the Future subscription, save a reference to the `Future` object so you can use it later in your algorithm.

C#

```
public class BasicFutureAlgorithm : QCAlgorithm
{
    private Future _future;
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        _future = AddFuture(Futures.Currencies.BTC,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.LastTradingDay,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        _future.SetFilter(0, 62);
    }

    public override void OnData(Slice data)
    {
        if (Portfolio.Invested)
        {
            return;
        }
        data.Bars.TryGetValue(_future.Symbol, out var continuousTradeBar);
        data.Bars.TryGetValue(_future.Mapped, out var mappedTradeBar);
        MarketOrder(_future.Mapped, 1);
    }

    // Track events when security changes its ticker, allowing the algorithm to adapt to these changes.
    public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
    {
        foreach (var (symbol, changedEvent) in symbolChangedEvents)
        {
            var oldSymbol = changedEvent.OldSymbol;
            var newSymbol = changedEvent.NewSymbol;
            var quantity = Portfolio[oldSymbol].Quantity;

            // Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped
contract
            var tag = $"Rollover - Symbol changed at {Time}: {oldSymbol} -> {newSymbol}";
            Liquidate(oldSymbol, tag: tag);
            if (quantity != 0) MarketOrder(newSymbol, quantity, tag: tag);
        }
    }
}
```

The following table describes the `AddFuture` method arguments:

Argument: `ticker`

The Future ticker. To view the supported assets in the US Futures dataset, see Supported Assets .

Data Type: `string` | Default Value: `None`

Argument: `resolution`

The resolution of the market data. To view the supported resolutions, see Resolutions . If you don't provide a value, it uses `Resolution.Minute` by default.

Data Type: `Resolution?` | Default Value: `null`

Argument: `market`

The Futures market. To view the supported markets in the US Futures dataset, see Supported Markets . If you don't provide a value, it uses the default Future market of your brokerage model .

Data Type: `string` | Default Value: `null`

Argument: `fillForward`

If true, the current slice contains the last available data even if there is no data at the current time.

Data Type: `bool` | Default Value: `true`

Argument: `leverage`

The leverage for this Future.

Data Type: `decimal` | Default Value: `Security.NullLeverage`

Argument: `extendedMarketHours`

If true, use data from the pre and post market sessions

Data Type: `bool` | Default Value: `false`

Argument: `dataMappingMode`

The contract mapping mode to use for the continuous future contract

Data Type: `DataMappingMode?` | Default Value: `null`

Argument: `dataNormalizationMode` The price scaling mode to use for the continuous future contract Data Type: `DataNormalizationMode?` | Default Value: `null`
Argument: `contractDepthOffset` The continuous future contract desired offset from the current front month. For example, 0 is the front month, 1 is the back month contract. Data Type: `int` | Default Value: `0`

Continous Contracts

By default, LEAN only subscribes to the continuous Future contract. A continuous Future contract represents a series of separate contracts stitched together to form a continuous price. If you need a lot of historical data to warm up an indicator, apply the indicator to the continuous contract price series. The `Future` object has a `Symbol` property and a `Mapped` property. The price of the `Symbol` property is the adjusted price of the continuous contract. The price of the `Mapped` property is the raw price of the currently selected contract in the continuous contract series.

```
C#

// Get the adjusted price of the continuous contract.
var adjustedPrice = Securities[_future.Symbol].Price;

// Get the raw price of the currently selected contract in the continuous contract series.
var rawPrice = Securities[_future.Mapped].Price;
```

The continuous Futures contract isn't a tradable security . You must place orders for a specific Futures contract. To access the currently selected contract in the continuous contract series, use the `Mapped` property of the `Future` object.

```
C#

// Place a market order for the currently selected contract in the continuous contract series.
MarkerOrder(_future.Mapped, 1);
```

To configure how LEAN identifies the current Future contract in the continuous series and how it forms the adjusted price between each contract, provide `dataMappingMode` , `dataNormalizationMode` , and `contractDepthOffset` arguments to the `AddFuture` method. The `Future` object that the `AddFuture` method returns contains a `Mapped` property that references the current contract in the continuous contract series. As the contracts roll over, the `Mapped` property references the next contract in the series and you receive a `SymbolChangedEvent` object in the `OnData` method. The `SymbolChangedEvent` references the old contract `Symbol` and the new contract `Symbol` . You can use `SymbolChangedEvents` to roll over contracts.

```
C#
public class BasicFutureAlgorithm : QCAlgorithm
{
    // Track when the continuous contract switches from one contract to the next.
    public override void OnSymbolChangedEvents(SymbolChangedEvents symbolChangedEvents)
    {
        foreach (var (symbol, changedEvent) in symbolChangedEvents)
        {
            var oldSymbol = changedEvent.OldSymbol;
            var newSymbol = changedEvent.NewSymbol;
            var quantity = Portfolio[oldSymbol].Quantity;

            // Rolling over: To liquidate the old mapped contract and switch to the new mapped contract.
            var tag = $"Rollover - Symbol changed at {Time}: {oldSymbol} -> {newSymbol}";
            Liquidate(oldSymbol, tag: tag);
            if (quantity != 0) MarketOrder(newSymbol, quantity, tag: tag);
        }
    }
}
```

In backtesting, the `SymbolChangedEvent` occurs at midnight Eastern Time (ET). In live trading, the live data for continuous contract mapping arrives at 6/7 AM ET, so that's when it occurs.

Data Normalization Modes

The `dataNormalizationMode` argument defines how the price series of two contracts are stitched together when the contract rollovers occur. The following `DataNormalizatoinMode` enumeration members are available for continuous contracts:

We use the entire Futures history to adjust historical prices. This process ensures you get the same adjusted prices, regardless of the backtest end date.

Data Mapping Modes

The `dataMappingMode` argument defines when contract rollovers occur. The `DataMappingMode` enumeration has the following members:

`Futures.Indices.VIX` (VX) doesn't support continous contract rolling with `DataMappingMode.OpenInterest` and `DataMappingMode.OpenInterestAnnuak` .

Contract Depth Offsets

The `contractDepthOffset` argument defines which contract to use. 0 is the front month contract, 1 is the following back month contract, and 2 is the second back month contract.

Filter Contracts

By default, LEAN doesn't add any contracts to the FuturesChain it passes to the `OnData` method.

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Future` object. The following table describes the available filter techniques:

`SetFilter(int minExpiry, int maxExpiry)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`SetFilter(Func<FutureFilterUniverse, FutureFilterUniverse> universeFunc)` Selects the contracts that a function selects.

```C#
// Select the contracts that expire within 182 days.
_future.SetFilter(0, 182);

// Select the front month contract.
_future.SetFilter(futureFilterUniverse => futureFilterUniverse.FrontMonth());
```

The following table describes the filter methods of the `FutureFilterUniverse` class:

`StandardsOnly()` Selects standard contracts
`FrontMonth()` Selects the front month contract
`BackMonths()` Selects the non-front month contracts
`BackMonth()` Selects the back month contracts
`Expiration(TimeSpan minExpiry, TimeSpan maxExpiry)` Selects contracts that expire within a range of dates relative to the current day
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects

The preceding methods return an `FutureFilterUniverse` , so you can chain the methods together.

```C#
// Select the front month standard contracts
_future.SetFilter(futureFilterUniverse => futureFilterUniverse.StandardsOnly().FrontMonth());
```

You can also define an isolated filter method.

```
// In Initialize
_future.SetFilter(Selector);

private FutureFilterUniverse Selector(FutureFilterUniverse futureFilterUniverse)
{
    return futureFilterUniverse.StandardsOnly().FrontMonth();
}
```

Navigate Futures Chains

`FuturesChain` objects represent an entire chain of contracts for a single underlying Future. They have the following properties:

To get the `FuturesChain` , index the `FuturesChains` property of the `Slice` with the continuous contract `Symbol` .

```
public override void OnData(Slice slice)
{
    if (slice.FuturesChains.TryGetValue(_symbol, out var chain))
    {
        // Example: Select the contract with the greatest open interest
        var contract = chain.OrderBy(x => x.OpenInterest).Last();
    }
}
```

You can also loop through the `FuturesChains` property to get each `FuturesChain` .

```
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.FuturesChains)
    {
        var continuousContractSymbol = kvp.Key;
        var chain = kvp.Value;
    }
}

public void OnData(FuturesChains futuresChains)
{
    foreach (var kvp in futuresChains)
    {
        var continuousContractSymbol = kvp.Key;
        var chain = kvp.Value;
    }
}
```

Historical Data

To get historical Future universe data, call the `History<FutureUniverse>` method. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter.

```C#
public class FutureHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var future = AddFuture(Futures.Indices.SP500EMini);
        var history = History<FutureUniverse>(future.Symbol, 5);
        foreach (var universe in history)
        {
            var endTime = universe.EndTime;
            foreach (FutureUniverse contract in universe)
            {
                var symbol = contract.Symbol;
                var expiry = contract.ID.Date;
                var price = contract.Close;
                var oi = contract.OpenInterest;
            }
        }
    }
}
```

The method represents each contract with a `FutureUniverse` object, which have the following properties:

Selection Frequency

By default, Futures universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Futures universes.

Example 1: Contracts Expiring On Quarter End

To reduce the need for rolling over, you can filter Future contracts that expire only on quarter ends to save transaction costs. The following example trades a simple EMA cross strategy on SP500 EMini Future contracts that expire on quarter ends.

C#

```
public class QuarterlyFuturesAlgorithm : QCAlgorithm
{
    private Future _future;
    private ExponentialMovingAverage _ema;
    // A variable to control the algorithm trading in daily frequency only, since the indicator signal is by daily.
    private int _day = -1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);

        // Request ES Future data for trading. We only use the continuous contract for indicator values.
        _future = AddFuture(
            Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest
        );
        // We only filter the ones expiring on quarter ends to reduce the transaction cost needed for rolling over
contracts.
        _future.SetFilter(futureFilterUniverse => futureFilterUniverse.ExpirationCycle(new int[] { 3, 6, 9, 12 }));

        // Create an EMA indicator to track trends for trade signal generation.
        _ema = EMA(_future.Symbol, 20, Resolution.Daily);
        // Warm up the indicator for immediate readiness.
        WarmUpIndicator(_future.Symbol, _ema, Resolution.Daily);

    }

    public override void OnData(Slice slice)
    {
        // Get the chain to trade from the filtered contracts.
        if (_day != slice.Time.Day && slice.FutureChains.TryGetValue(_future.Symbol, out var chain))
        {
            // Select the contract with the nearest expiry.
            var contract = chain.MinBy(x => x.Expiry);

            // Trade an EMA cross strategy to follow the trend.
            var quantity = Portfolio[_future.Symbol].Quantity;
            if (contract.LastPrice > _ema && quantity <= 0)
            {
                MarketOrder(contract.Symbol, 1-quantity);
            }
            else if (contract.LastPrice < _ema && quantity >= 0)
            {
                MarketOrder(contract.Symbol, -1-quantity);
            }

            _day = slice.Time.Day;
        }
    }
}
```

Example 2: Contracts Expiring Within One Week

The trading volume of Futures reaches its maximum during the last week of the trading period. The following algorithm selects contracts that expire within a week:

C#

```
public class WeeklyFuturesAlgorithm : QCAlgorithm
{
    private Future _future;
    private BollingerBands _bb;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add ES Futures for trading. The continuous contract data is
        // only used for indicator values.
        _future = AddFuture(
            Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest
        );
        // Select the contract expiring within a week since they have
        // the highest liquidity.
        _future.SetFilter(futureFilterUniverse => futureFilterUniverse.Expiration(0, 7));
        // Create a Bollinger Band indicator to identify extreme prices
        // for trade signal generation.
        _bb = BB(_future.Symbol, 60, 2);
        // Warm up the indicator for so we can trade right away.
        WarmUpIndicator(_future.Symbol, _bb);
    }

    public override void OnData(Slice slice)
    {
        // Get the current Futures chain, if there is one.
        if (!slice.FutureChains.TryGetValue(_future.Symbol, out var chain))
        {
            return;
        }
        // Select the contract with the nearest expiry.
        var contract = chain.MinBy(x => x.Expiry);
        // Trade a mean-reversal strategy based on Bollinger Band signal.
        var holding = Portfolio[contract.Symbol];
        var price = contract.LastPrice;
        int targetQuantity;
        // Case 1: Short
        if (!holding.IsShort && price > _bb.UpperBand)
        {
            targetQuantity = -1;
        }
        // Case 2: Long
        else if (!holding.IsLong && price < _bb.LowerBand)
        {
            targetQuantity = 1;
        }
        // Case 3: Exit
        else if ((holding.IsShort && price < _bb.MiddleBand) || (holding.IsLong && price > _bb.MiddleBand))
        {
            targetQuantity = 0;
        }
        // Case 4: Hold
        else
        {
            return;
        }
        MarketOrder(contract.Symbol, targetQuantity - holding.Quantity);
    }
}
```

Universes

Future Options

Introduction

A Future Option universe lets you select a basket of Option contracts on the contracts in a Futures universe .

Create Universes

To add a universe of Future Option contracts, in the `Initialize` method, define a Future universe and then pass the canonical `Symbol` to the `AddFutureOption` method.

```
C#
UniverseSettings.Asynchronous = true;
var future = AddFuture(Futures.Metals.Gold);
future.SetFilter(0, 90);
AddFutureOption(future.Symbol);
```

The following table describes the `AddFutureOption` method arguments:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The continuous Future contract Symbol. To view the supported assets in the US Future Options dataset, see Supported Assets .	
`optionFilter`	`Func<OptionFilterUniverse, OptionFilterUniverse>`	A function that selects Future Option contracts	`null`

To override the default pricing model of the Option, set a pricing model in a security initializer.

```C#
// In Initialize
var seeder = SecuritySeeder.Null;
SetSecurityInitializer(new MySecurityInitializer(BrokerageModel, seeder, this));

// Outside of the algorithm class
class MySecurityInitializer : BrokerageModelSecurityInitializer
{
    private QCAlgorithm _algorithm;

    public MySecurityInitializer(IBrokerageModel brokerageModel, ISecuritySeeder securitySeeder, QCAlgorithm
algorithm)
        : base(brokerageModel, securitySeeder)
    {
        _algorithm = algorithm;
    }

    public override void Initialize(Security security)
    {
        // First, call the superclass definition
        // This method sets the reality models of each security using the default reality models of the brokerage
model
        base.Initialize(security);

        // Next, set the price model
        if (security.Type == SecurityType.FutureOption) // Option type
        {
            security.PriceModel = OptionPriceModels.CrankNicolsonFD();
        }
    }
}
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Filter Contracts

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (weeklies and non-standard contracts are not available)
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at every time step in your algorithm. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

To set a contract filter, in the `Initialize` method, pass a filter function to the `AddFutureOption` method. The following table describes the available filter techniques:

```C#
AddFutureOption(future.Symbol, optionFilterUniverse => optionFilterUniverse.Strikes(-1, 1));
```

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.

`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.
`StandardsOnly()` Selects standard contracts.
`IncludeWeeklys()` Selects non-standard weeklys contracts. This filter doesn't currently work. To add this functionality to our roadmap , react to this GitHub Issue with a thumbs up emoji.
`WeeklysOnly()` Selects weekly contracts. This filter doesn't currently work. To add this functionality to our roadmap , react to this GitHub Issue with a thumbs up emoji.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.
`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```
AddFutureOption(future.Symbol, optionFilterUniverse => optionFilterUniverse.Strikes(-1, 1).CallsOnly());
```

To perform thorough filtering on the `OptionFilterUniverse`, define an isolated filter method.

```
# In Initialize
AddFutureOption(future.Symbol, Selector);

private OptionFilterUniverse Selector(OptionFilterUniverse optionFilterUniverse)
{
    var symbols = optionFilterUniverse.PutsOnly();
    var strike = symbols.Select(symbol => symbol.ID.StrikePrice).Min();
    symbols = symbols.Where(symbol => symbol.ID.StrikePrice == strike);
    return optionFilterUniverse.Contracts(symbols);
}
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse`.

Navigate Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain`, loop through the `OptionChains` property. After you get the `OptionChain`, you can sort and filter the Option contracts in the chain.

```
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.OptionChains)
    {
        var optionChain = kvp.Value;
        // Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest expiration
        var contracts = optionChain
            .Where(x => x.Right == OptionRight.Put)
            .OrderByDescending(x => x.Expiry)
            .ThenBy(x => Math.Abs(chain.Underlying.Price - x.Strike))
            .Take(5);

        // Select the contract with the delta closest to -0.5
        var contract = contracts.OrderBy(x => Math.Abs(-0.5m - x.Greeks.Delta)).FirstOrDefault();
    }
}
```

You can also iterate through the `FuturesChains` first.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.FuturesChains)
    {
        var continuousContractSymbol = kvp.Key;
        var futuresChain = kvp.Value;

        // Select a Future Contract and create its canonical FOP Symbol
        var futuresContract = futuresChain.First();
        var canonicalFOPSymbol = QuantConnect.Symbol.CreateCanonicalOption(futuresContract.Symbol);
        if (slice.OptionChains.TryGetValue(canonicalFOPSymbol, out var fopChain))
        {
            foreach (var contract in fopChain)
            {
                //
            }
        }
    }
}
```

`OptionChain` objects have the following properties:

Historical Data

To get historical Future Option universe data, call the `History<FutureUniverse>` method with the canoncial Option `Symbol`. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter.

```C#
public class FutureOptionHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Select a Futures contract.
        var future = AddFuture(Futures.Indices.SP500EMini);
        var futuresContract = FuturesChain(future.Symbol).First();
        // Create the canoncial Option Symbol for this Futures contract.
        var canonical = QuantConnect.Symbol.CreateCanonicalOption(futuresContract.Symbol);
        // Get the historical Option universe data for this Futures contract.
        var history = History<OptionUniverse>(canonical, 5);
        foreach (var universe in history)
        {
            var endTime = universe.EndTime;
            foreach (OptionUniverse contract in universe)
            {
                var symbol = contract.Symbol;
                var expiry = contract.ID.Date;
                var price = contract.Close;
            }
        }
    }
}
```

The method represents each contract with a `OptionUniverse` object, which have the following properties:

Selection Frequency

By default, Future Option universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Future Option universes.

Example 1: 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. The following algorithm selects 0DTE Future

Option contracts for the E-mini S&P 500 that fall within 3 strikes of the underlying price.

```C#
public class ZeroDTEFutureOptionUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        var future = AddFuture(Futures.Indices.SP500EMini);
        future.SetFilter(0, 90);
        AddFutureOption(
            future.Symbol,
            u => u.IncludeWeeklys().Expiration(0, 0).Strikes(-3, 3)
        );
    }
}
```

For full trading examples of Future Options, see Examples .

Universes

Index Options

Introduction

An Index Option universe lets you select a basket of Option contracts on an Index.

Create Universes

To add a universe of Index Option contracts, in the `Initialize` method, call the `AddIndexOption` method. This method returns an `Option` object, which contains the canonical `Symbol` . You can't trade with the canonical Option `Symbol` , but save a reference to it so you can easily access the Option contracts in the OptionChain that LEAN passes to the `OnData` method. The method to create the universe depends on if the Index Options you want require a target ticker.

Create Non-Standard Universes

Non-standard Option contracts are popular among Option traders. To create a universe of non-standard Index Options like weekly VIX contracts, pass the index Symbol and target Option ticker to the `AddIndexOption` method.

C#

```
public class WeeklyIndexOptionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        var underlying = AddIndex("VIX").Symbol;
        var option = AddIndexOption(underlying, "VIXW");
        option.SetFilter(universe => universe.IncludeWeeklys().Expiration(0, 7).Delta(0.35m, 0.75m));
        _symbol = option.Symbol;
    }

    public override void OnData(Slice data)
    {
        if (data.OptionChains.TryGetValue(_symbol, out var chain))
        {
            var contract = chain.OrderBy(x => x.Expiry).ThenBy(x => x.Greeks.Delta).FirstOrDefault();
        }
    }
}
```

The following table describes the `AddIndexOption` method arguments for non-standard universes:

Argument	Data Type	Description	Default Value
`underlying`	`Symbol`	The underlying Index `Symbol` . To view the supported indices, see Supported Assets .	
`targetOption`	`string`	The target Option ticker. To view the supported target Options, see Supported Assets .	
`resolution`	`Resolution?`	The resolution of the market data. To view the supported resolutions, see Resolutions . The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.	`null`
`market`	`string`	The Index Option market.	`Market.USA`
`fillForward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.	`true`

If you add an Option universe for an underlying Index that you don't have a subscription for, LEAN automatically subscribes to the underlying Index.

Create Standard Universes

To create a universe of Index Options based on an index like VIX, SPX, or NDX, pass the index ticker to the `AddIndexOption` method.

```
C#
var option = AddIndexOption("SPX");
option.SetFilter(universe => universe.Expiration(0, 60).Delta(0.35m, 0.75m););
 _symbol = option.Symbol;
```

The following table describes the `AddIndexOption` method arguments for standard universes:

Argument	Data Type	Description	Default Value
`ticker`	`string`	The underlying Index ticker. To view the supported indices, see Supported Assets .	
`resolution`	`Resolution?`	The resolution of the market data. To view the supported resolutions, see Resolutions .	`null`
`market`	`string`	The Index Option market.	`Market.USA`
`fillForward`	`bool`	If true, the current slice contains the last available data even if there is no data at the current time.	`true`

If you add an Option universe for an underlying Index that you don't have a subscription for, LEAN automatically subscribes to the underlying Index and sets its fill forward property to match that of the Index Option universe.

Filter by Investment Strategy

Options trading strategies consist of simultaneously buying or selling one or more Option contracts on the same underlying Index, but with different features.

```
C#
// Example 1: Select a Straddle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Straddle(30, 5, 10));

// Example 2: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));

// Example 3: Select the 0DTE contracts that form an Strangle
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Expiration(0, 0).Strangle(30, 5, -
10));
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contracts for Option strategies:

`NakedCall(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a call contract to form Naked Call , Covered Call , or Protective Call Option strategies.
`NakedPut(int minDaysTillExpiry, decimal strikeFromAtm)` Selects a put contract to form Naked Put , Covered Put , or Protective Put Option strategies.
`CallSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two call contracts to form Bull Call Spread or Bear Call Spread Option strategies.
`PutSpread(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two put contracts to form Bull Put Spread or Bear Put Spread Option strategies.

`CallCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two call contracts to form Long Call Calendar Spread or Short Call Calendar Spread Option strategies.
`PutCalendarSpread(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects two put contracts to form Long Put Calendar Spread or Short Put Calendar Spread Option strategies.
`Strangle(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Long Strangle or Short Strangle Option strategies.
`Straddle(int minDaysTillExpiry)` Selects two contracts to form Long Straddle or Short Straddle Option strategies.
`ProtectiveCollar(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects two contracts to form Protective Collar Option strategies.
`Conversion(int minDaysTillExpiry, decimal strikeFromAtm)` Selects two contracts to form Conversion or Reverse Conversion Option strategies.
`CallButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Call Butterfly or Short Call Butterfly Option strategies.
`PutButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects three contracts to form Long Put Butterfly or Short Put Butterfly Option strategies.
`IronButterfly(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Long Iron Butterfly or Short Iron Butterfly Option strategies.
`IronCondor(int minDaysTillExpiry, decimal nearStrikeSpread, decimal farStrikeSpread)` Selects four contracts to form Long Iron Condor or Short Iron Condor Option strategies.
`BoxSpread(int minDaysTillExpiry, decimal strikeSpread)` Selects four contracts to form Box Spread or Short Box Spread Option strategies.
`JellyRoll(decimal strikeFromAtm, int minNearDaysTillExpiry, int minFarDaysTillExpiry)` Selects four contracts to form Jelly Roll or Short Jelly Roll Option strategies.

`CallLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Call Ladder or Bull Call Ladder Option strategies.
`PutLadder(int minDaysTillExpiry, decimal higherStrikeFromAtm, decimal middleStrikeFromAtm, decimal lowerStrikeFromAtm)` Selects four contracts to form Bear Put Ladder or Bull Put Ladder Option strategies.

The preceding methods return an `OptionFilterUniverse`, so you can chain the methods together.

Filter by Implied Volatility and Greeks

Option price models compute the theoretical price of Option contracts, their implied volatility, and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, implied volatility can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

```C#
// Example 1: Select the contracts with delta between 0.25 and 0.75
option.SetFilter(optionFilterUniverse => optionFilterUniverse.Delta(0.25m, 0.75m));

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days with implied volatility below 20%
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days with implied volatility below 20% that forms an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().IV(0, 20).Expiration(0, 30).IronCondor(30, 5, 10));
```

The following table describes the filter methods of the `OptionFilterUniverse` class that select contract for a range of implied volatility, Greek values, and open interest:

`IV(decimal min, decimal max)`
`ImpliedVolatility(decimal min, decimal max)`
 	
Selects a contract with implied volatility within the range you set.

`D(decimal min, decimal max)`
`Delta(decimal min, decimal max)`
 	
Selects a contract with delta within the range you set.

`G(decimal min, decimal max)`
`Gamma(decimal min, decimal max)`
 	
Selects a contract with gamma within the range you set.

`R(decimal min, decimal max)`
`Rho(decimal min, decimal max)`
 	
Selects a contract with rho within the range you set.

`V(decimal min, decimal max)`
`Vega(decimal min, decimal max)`
 	
Selects a contract with vega within the range you set.

`T(decimal min, decimal max)`
`Theta(decimal min, decimal max)`
 	
Selects a contract with theta within the range you set.

`OI(long min, long max)`
`OpenInterest(decimal min, decimal max)`
 	
Selects a contract with open interest within the range you set.

The preceding methods return an `OptionFilterUniverse`, so you can chain the methods together.

To perform thorough filtering on the `OptionFilterUniverse`, define an isolated filter method.

```
C#
```

```
// Select the put contracts with the lowest strike price.
option.SetFilter(Selector);

private OptionFilterUniverse Selector(OptionFilterUniverse optionFilterUniverse)
{
    return universe
        .Delta(0.5m, 1.5m)
        .Gamma(0.0001m, 0.0006m)
        .Vega(0.01m, 1.5m)
        .Theta(-2.0m, -0.5m)
        .Rho(0.5m, 3.0m)
        .ImpliedVolatility(1.0m, 3.0m)
        .OpenInterest(100, 500);
}
```

Filter by Other Contract Properties

To set a contract filter, in the `Initialize` method, call the `SetFilter` method of the `Option` object.

```
C#
// Select contracts that have a strike price within 1 strike level above and below the underlying price
option.SetFilter(minStrike: -1, maxStrike: 1);

// Select contracts that expire within 30 days
option.SetFilter(minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select contracts that have a strike price within 1 strike level and expire within 30 days
option.SetFilter(minStrike: -1, maxStrike: 1, minExpiry: TimeSpan.FromDays(0), maxExpiry: TimeSpan.FromDays(30));

// Select call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly());
```

The following table describes the available filter techniques:

`SetFilter(int minStrike, int maxStrike)` Selects the contracts that have a strike price within a minimum and maximum strike level relative to the underlying price. For example, say the underlying price is 302*andthereare*strikes*atevery*5. If you set `minStrike` to -1 and `maxStrike` to 1, LEAN selects the contracts that have a strike of 300*or*305. This filter runs asynchronously by default.
`SetFilter(TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire within the range you set. This filter runs asynchronously by default.
`SetFilter(int minStrike, int maxStrike, TimeSpan minExpiry, TimeSpan maxExpiry)` Selects the contracts that expire and have a strike within the range you set. This filter runs asynchronously by default.
`SetFilter(Func<OptionFilterUniverse, OptionFilterUniverse> universeFunc)` Selects the contracts that a function selects.

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.
`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.

`StandardsOnly()` Selects standard contracts.
`IncludeWeeklys()` Selects non-standard weeklys contracts.
`WeeklysOnly()` Selects weekly contracts.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.
`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

```C#
// Example 1: Select the front month call contracts
option.SetFilter(optionFilterUniverse => optionFilterUniverse.CallsOnly().FrontMonth());

// Example 2: Select the contracts (including weeklys) that expire in the next 90 days
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0, 90));

// Example 3: Select the contracts (including weeklys) that expire in the next 30 days that form an Iron Condor
option.SetFilter(optionFilterUniverse => optionFilterUniverse.IncludeWeeklys().Strikes(-20, 20).Expiration(0,
30).IronCondor(30, 5, 10));
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

Default Filter

By default, LEAN subscribes to the Option contracts that have the following characteristics:

- Standard type (exclude weeklys)
- Within 1 strike price of the underlying asset price
- Expire within 35 days

To adjust the universe of contracts, set a filter. The filter usually runs at the first bar of every day. When the filter selects a contract that isn't currently in your universe, LEAN adds the new contract data to the next `Slice` that it passes to the `OnData` method.

Navigate Intraday Option Chains

`OptionChain` objects represent an entire chain of Option contracts for a single underlying security.

To get the `OptionChain` , index the `OptionChains` property of the `Slice` with the canonical `Symbol` . After you get the `OptionChain` , you can sort and filter the Option contracts in the chain.

```
C#
public override void OnData(Slice slice)
{
    // Try to get the OptionChain using the canonical symbol
    if (slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        // Example: Find 5 put contracts that are closest to at-the-money (ATM) and have the farthest expiration
        var contracts = chain
            .Where(x => x.Right == OptionRight.Put)
            .OrderByDescending(x => x.Expiry)
            .ThenBy(x => Math.Abs(chain.Underlying.Price - x.Strike))
            .Take(5);

        // Select the contract with the delta closest to -0.5
        var contract = contracts.OrderBy(x => Math.Abs(-0.5m - x.Greeks.Delta)).FirstOrDefault();
    }
}
```

You can also loop through the `OptionChains` property to get each `OptionChain` .

```
C#
public override void OnData(Slice slice)
{
    // Iterate all received Canonical Symbol-OptionChain key-value pairs
    foreach (var kvp in slice.OptionChains)
    {
        var canoncialSymbol = kvp.Key;
        var chain = kvp.Value;
        var contracts = chain.Contracts;
    }
}
```

`OptionChain` objects have the following properties:

Navigate Daily Option Chains

To get the daily, pre-calculated Greeks and implied volaility of all the currently tradable contracts, call the `OptionChain` method. This method returns a collection of `OptionUniverse` objects, where each object represents a contract. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter.

```C#
// In the initialize method, create a Scheduled Event to get the Option
// chain and rebalance the portfolio.
Schedule.On(DateRules.WeekStart(_symbol), TimeRules.AfterMarketOpen(_symbol, 1), Rebalance);

public void Rebalance()
{
    foreach (var optionUniverse in OptionChain(_symbol))
    {
        var close = optionUniverse.Close;
        var oi = optionUniverse.OpenInterest;
        var delta = optionUniverse.Greeks.Delta;
    }
}
```

The `OptionChain` method was previously known as the `OptionChainProvider.GetOptionContractList` method.

`OptionUniverse` objects have the following properties:

Greeks and Implied Volatility

There are several ways to get the implied volatility and Greeks of contracts.

The Greeks and IV values in the filter function are the daily, pre-calculated values based on the end of the previous trading day.

```C#
public override void Initialize()
{
    var option = AddIndexOption("SPX");
    option.SetFilter(universe => universe.IncludeWeeklys().Delta(0.3m, 0.7m).Expiration(0, 7));
}
```

To calculate the values, we use our implementation of the Black-Scholes pricing model, which accounts for the interest rate and dividend payments when applicable. For example, VIX doesn't have dividends. We use SPY for SPX and QQQ for NDX.

You can't customize the Greeks and IV values that the filter function receives. However, you can create indicators to customize how the Greeks and IV are calculated for the contracts already in your universe.

To override the default pricing model of the Option, set a pricing model . If you set a price model, it sets the price model of the individual contracts in the universe.

```C#
// Set PriceModel property to use the Crank-Nicolson finite-difference model to price the Options.
option.PriceModel = OptionPriceModels.CrankNicolsonFD();
```

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

Historical Data

To get historical chains for an Index Option, call the `History<OptionUniverse>` method with the canonical Option `Symbol` . This method returns the entire Option chain for each trading day, not the subset of contracts that pass your universe filter.

```
C#
public class OptionHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var option = AddIndexOption("SPX");
        var history = History<OptionUniverse>(option.Symbol, 5);
        foreach (var chain in history)
        {
            var endTime = chain.EndTime;
            var filteredContracts = chain.Data
                .Select(contract => contract as OptionUniverse)
                .Where(contract => contract.Greeks.Delta > 0.3m);
            foreach (var contract in filteredContracts)
            {
                var price = contract.Price;
                var iv = contract.ImpliedVolatility;
            }
        }
    }
}
```

The Greeks and IV values that you get from a history request of the Option universe are the daily, pre-calculated values based on the end of the previous trading day. To get the intraday values or to customize the Greeks and IV calculations, create some Option indicators .

The `History<OptionUniverse>` method represents each contract with an `OptionUniverse` object, which have the following properties:

Selection Frequency

By default, Index Option universes run at the first time step of each day to select their contracts.

Examples

The following examples demonstrate some common Index Option universes.

Example 1: 0DTE Contracts

0DTE Options are Option contracts that expire on the same day you trade them. The following algorithm selects 0DTE Option contracts for the SPX Index that fall within 3 strikes of the underlying price.

```
C#
public class ZeroDTEIndexOptionUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var index = AddIndex("SPX");
        var indexOption = AddIndexOption(index.Symbol, "SPXW");
        indexOption.SetFilter(u => u.IncludeWeeklys().Expiration(0, 0).Strikes(-3, 3));
    }
}
```

For trading full examples of Index Option Universe, please refer to the Securities > Index Options > Requesting Data > Universes page.

Universes

Crypto

Introduction

A Crypto universe lets you select a basket of Cryptocurrencies based on `CryptoUniverse` data.

Crypto Universes

To add a universe of Cryptocurrencies, in the `Initialize` method, pass a `CryptoUniverse` to the `AddUniverse` method.

```C#
private Universe _universe;
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    UniverseSettings.Resolution = Resolution.Daily;
    SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);

    // Add crypto universe selection
    _universe = AddUniverse(CryptoUniverse.Coinbase(universeDay => from x in universeDay select x.Symbol));
}
```

The following table shows the helper methods to create Crypto universes for the supported exchanges:

Brokerage Name	Helper Method	Example
`BrokerageName.Binance`	`CryptoUniverse.Binance`	Example
`BrokerageName.BinanceUS`	`CryptoUniverse.BinanceUS`	Example
`BrokerageName.Bitfinex`	`CryptoUniverse.Bitfinex`	Example
`BrokerageName.Bybit`	`CryptoUniverse.Bybit`	Example
`BrokerageName.Coinbase`	`CryptoUniverse.Coinbase`	Example
`BrokerageName.Kraken`	`CryptoUniverse.Kraken`	Example

The following table describes the `CryptoUniverse` method arguments:

Argument	Data Type	Description	Default Value
`selector`	`Func<IEnumerable<CryptoUniverse>, IEnumerable<Symbol>>`	A function to select some of the Cryptocurrencies for the universe.	
`universeSettings`	`UniverseSettings`	The universe settings .	`null`

The filter function receives `CryptoUniverse` objects, which represent one of the Cryptocurrencies in the market. The `Symbol` objects that the filter function returns represent the universe constituents. `CryptoUniverse` objects have the following attributes:

To perform thorough filtering on the `CryptoUniverse` objects, define an isolated filter method.

```
C#
private Universe _universe;
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    UniverseSettings.Resolution = Resolution.Daily;
    SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);

    // Add crypto universe selection
    _universe = AddUniverse(CryptoUniverse.Coinbase(UniverseFilter));
}

private IEnumerable<Symbol> UniverseFilter(IEnumerable< CryptoUniverse> universeDay)
{
    return universeDay.Where(cf => cf.Volume >= 100m && cf.VolumeInUsd > 10000m).Select(x => x.Symbol);
}
```

Historical Data

To get historical Cryptocurrency universe data, call the `History` method with the `Universe` object and the lookback period. The return type is a `IEnumerable<BaseDataCollection>` and you have to cast its items to `CryptoUniverse` .

```
C#
// Get 30 days of history for the Crypto universe.
var history = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in history)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Log($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

For more information about Cryptocurrency data, see Crypto .

Alternative Data Universes

An alternative data universe lets you select a basket of Cryptocurrencies based on an alternative dataset that's linked to them. If you use an alternative data universe, you limit your universe to only the securities in the dataset, which avoids unnecessary subscriptions. Currently, only the Crypto Market Cap alternative dataset supports universe selection for Crypto.

Selection Frequency

Crypto universes run on a daily basis by default. To adjust the selection schedule, see Schedule .

Live Trading Considerations

In live mode, the pipeline has a 16-hour delay. Your algorithm receives the `CryptoUniverse` objects at around 16:00-16:30 Coordinated Universal Time (UTC) each day, depending on the data processing task.

Examples

The following examples demonstrate some common Crypto universes.

Example 1: Highly Liquid Crypto Universe

To fairly compare the liquidity between Crypto pairs, use the `VolumeInUsd` property of the `CryptoUniverse` objects during universe selection. The following algorithm selects the 10 Crypto pairs with the greatest USD volume on Bitfinex:

```C#
public class HighlyLiquidCryptoUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        AddUniverse(
            CryptoUniverse.Bitfinex(data => data
                .Where(x => x.VolumeInUsd != null)
                .OrderByDescending(x => x.VolumeInUsd)
                .Take(10)
                .Select(x => x.Symbol)
            )
        );
    }
}
```

Example 2: Highly Volatile Crypto Universe

The following algorithm creates a universe of volatile Crypto pairs on Binance by selecting the pairs with the largest trading range in the previous day:

```C#
public class HighlyVolatileCryptoUniverseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        AddUniverse(
            CryptoUniverse.Binance(data => data
                .OrderByDescending(x => (x.High - x.Low) / x.Low)
                .Take(10)
                .Select(x => x.Symbol)
            )
        );
    }
}
```

Example 3: Large Cap Crypto Universe

The following algorithm uses the CoinGecko Crypto Market Cap dataset to create a universe of the largest Crypto pairs on Coinbase. To avoid trading errors, it only selects pairs that have a quote currency that matches your account currency . At noon each day, it rebalances the portfolio to give equal weight to each coin in the universe.

C#

```
public class LargeCapCryptoUniverseAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the account currency. USD is already the default value. Change it here if you want.
        SetAccountCurrency("USD");
        // Get the pairs that our brokerage supports and have a quote currency that
        // matches your account currency. We need this list in the universe selection function.
        var market = Market.Coinbase;
        var marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(market)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();
        // Add the Crypto universe and define the selection function.
        _universe = AddUniverse<CoinGeckoUniverse>(
            data => data
                .Select(c => c as CoinGecko)
                // Select the coins that the brokerage supports and have a quote currency that
                // matches our account currency.
                .Where(c => marketPairs.Contains(c.Coin + AccountCurrency))
                // Select the 10 largest coins.
                .OrderByDescending(c => c.MarketCap)
                .Take(10)
                // Create the Symbol objects of the selected coins.
                .Select(c => c.CreateSymbol(market, AccountCurrency)
            )
        );
        // Add a Sheduled Event to rebalance the portfolio.
        Schedule.On(DateRules.EveryDay(), TimeRules.At(12, 0), Rebalance);
    }

    private void Rebalance()
    {
        if (_universe.Selected == null || _universe.Selected.Count == 0)
        {
            return;
        }
        var symbols = _universe.Selected.Where(symbol => Securities[symbol].Price != 0).ToList();
        // Liquidate coins that are no longer in the universe.
        var targets = Portfolio.Values
            .Where(holding => holding.Invested && !symbols.Contains(holding.Symbol))
            .Select(holding => new PortfolioTarget(holding.Symbol, 0))
            .ToList();
        // Form an equal weighted portfolio of the coins in the universe.
        targets.AddRange(symbols.Select(symbol => new PortfolioTarget(symbol, 0.5m / symbols.Count)));
        // Place orders to rebalance the portfolio.
        SetHoldings(targets);
    }
}
```

Universes

Custom Universes

Introduction

A custom universe lets you select a basket of assets from a custom dataset.

Data Sources

You can gather your custom data from any of the following sources:

The data source should serve data in chronological order and each data point should have a unique timestamp. Each request has a 1 second overhead, so bundle samples together for fast execution.

Define Custom Universe Types

Custom universes should extend the `BaseData` class. Extensions of the `BaseData` class must implement a `GetSource` and `Reader` method.

The `GetSource` method in your custom data class instructs LEAN where to find the data. This method must return a `SubscriptionDataSource` object, which contains the data location and format (`SubscriptionTransportMedium`). You can even change source locations for backtesting and live modes. We support many different data sources.

The `Reader` method of your custom data class takes one line of data from the source location and parses it into one of your custom objects. You can add as many properties to your custom data objects as you need, but must set `Symbol` and `EndTime` properties. When there is no useable data in a line, the method should return `null` . LEAN repeatedly calls the `Reader` method until the date/time advances or it reaches the end of the file.

```C#
//Example custom universe data; it is virtually identical to other custom data types.
public class MyCustomUniverseDataClass : BaseData
{
    public int CustomAttribute1;
    public decimal CustomAttribute2;
    public override DateTime EndTime
    {
        // define end time as exactly 1 day after Time
        get { return Time + QuantConnect.Time.OneDay; }
        set { Time = value - QuantConnect.Time.OneDay; }
    }

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        return new SubscriptionDataSource(@"your-remote-universe-data", SubscriptionTransportMedium.RemoteFile);
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        var items = line.Split(",");

        // Generate required data, then return an instance of your class.
        return new MyCustomUniverseDataClass
        {
            EndTime = Parse.DateTimeExact(items[0], "yyyy-MM-dd"),
            Symbol = Symbol.Create(items[1], SecurityType.Equity, Market.USA),
            CustomAttribute1 = int.Parse(items[2]),
            CustomAttribute2 = decimal.Parse(items[3], NumberStyles.Any, CultureInfo.InvariantCulture)
        };
    }
}
```

Your `Reader` method should return objects in chronological order. If an object has a timestamp that is the same or earlier than the timestamp of the previous object, LEAN ignores it.

If you need to create multiple objects in your `Reader` method from a single `line` , follow these steps:

1. In the `GetSource` method, pass `FileFormat.UnfoldingCollection` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `Reader` method, order the objects by their timestamp and then return a `BaseDataCollection(endTime, config.Symbol, objects)` where `objects` is a list of your custom data objects.

```C#
public class MyCustomUniverseDataClass : BaseData
{
    public int CustomAttribute1 { get; set; }
    public string Ticker { get; set; }
    public DateTime Date { get; set; }

    public override DateTime EndTime
    {
        // define end time as exactly 1 day after Time
        get { return Time + QuantConnect.Time.OneDay; }
        set { Time = value - QuantConnect.Time.OneDay; }
    }

    public MyCustomUniverseDataClass()
    {
        Symbol = Symbol.Empty;
        DataType = MarketDataType.Base;
    }

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        return new SubscriptionDataSource(@"your-data-source-url",
            SubscriptionTransportMedium.RemoteFile,
            FileFormat.UnfoldingCollection);
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        var items = JsonConvert.DeserializeObject<List<MyCustomUniverseDataClass>>(line);
        var endTime = items.Last().Date;

        foreach (var item in items)
        {
            item.Symbol = Symbol.Create(item.Ticker, SecurityType.Equity, Market.USA);
            item.Time = item.Date;
            item.Value = (decimal) item.CustomAttribute1;
        }

        return new BaseDataCollection(endTime, config.Symbol, items);
    }
}
```

Initialize Custom Universes

To add a custom universe to your algorithm, in the `Initialize` method, pass your universe type and a selector function to the `AddUniverse` method. The selector function receives a list of your custom objects and must return a list of `Symbol` objects. In the selector function definition, you can use any of the properties of your custom data type. The `Symbol` objects that you return from the selector function set the constituents of the universe.

```C#
private Universe _universe;
// In Initialize
_universe = AddUniverse<MyCustomUniverseDataClass>("myCustomUniverse", Resolution.Daily, data => {
    return (from singleStockData in data
           where singleStockData.CustomAttribute1 > 0
           orderby singleStockData.CustomAttribute2 descending
           select singleStockData.Symbol).Take(5);
});
```

Historical Data

To get custom universe historical data, call the `History` method with the `Universe` object and the lookback period. The return type is a `IEnumerable<BaseDataCollection>` and you have to cast its items to `MyCustomUniverseDataClass` .

```
var history = History(_universe, 30);
foreach (var data in history)
{
    foreach (MyCustomUniverseDataClass singleStockData in data)
    {
        Log($"{singleStockData.Symbol} CustomAttribute1 at {singleStockData.EndTime}:
{singleStockData.CustomAttribute1}");
    }
}
```

Selection Frequency

Custom universes run on a schedule based on the `EndTime` of your custom data objects. To adjust the selection schedule, see Schedule .

Examples

The following examples demonstrate some common practices for Custom Universe.

Example 1: Sourcing from the Object Store

This project demonstrates how to read custom data from the Object Store , and then use it to define a universe and place trades. The following research environment file generates the demo universe data, which contains a daily set of assets and their respective signals:

```
// Load the assembly files and data types in their own cell.
#load "../Initialize.csx"
```

```
// Import the data types.
#load "../QuantConnect.csx"
using QuantConnect;
using QuantConnect.Research;
using QuantConnect.Data.Market;
using MathNet.Numerics.Distributions;

// Create a QuantBook.
var qb = new QuantBook();
// Make a history request to get a list of trading days.
var history = qb.History<TradeBar>(
    Symbol.Create("SPY", SecurityType.Equity, Market.USA),
    new DateTime(2015, 1, 1), new DateTime(2024, 12, 31), Resolution.Daily
).ToList();
// Create a variable to store the file contents.
var contents = new List<string>();
// Define the list of possible assets.
var tickers = new List<string> { "SPY", "TLT", "GLD", "USO", "IWM" };
// Loop through the list of trading days.
for (int i = 0; i < history.Count; i++)
{
    // Create a random number generator.
    var random = new Random(i);
    // Select 3 of the assets and define their target portfolio weights.
    var date = history[i].EndTime;
    var equities = tickers.OrderBy(x => random.Next()).Take(3).ToList();
    var weights = Dirichlet.Sample(random, new[] { 10d, 5d, 3d });
    // Append the target portfolio weights for this trading day to the file.
    contents.AddRange(new [] {
        $"{date:yyyy-MM-dd},{equities[0]},{weights[0]}",
        $"{date:yyyy-MM-dd},{equities[1]},{weights[1]}",
        $"{date:yyyy-MM-dd},{equities[2]},{weights[2]}"
    });
}
// Save the file to the Object Store.
Console.WriteLine(qb.ObjectStore.Save("portfolioTargets.csv", string.Join("\n", contents)));
```

The following algorithm file reads the preceding CSV file from the Object Store and uses its contents to form the daily universe and place trades:

```C#
public class CustomUniverseExampleAlgorithm : QCAlgorithm
{
    // Create a dictionary to hold the target weight of each asset.
    private Dictionary<Symbol, decimal> _weightBySymbol = new();
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add a universe that reads from the Object Store.
        _universe = AddUniverse<CustomUniverseData>("CustomUniverse", Resolution.Daily, (altCoarse) => {
            // Select the symbols that have a significant weight in the custom universe data to avoid
            // small-size trades that erode returns. Save the weight to use during the rebalance.
            _weightBySymbol = altCoarse
                .Select(d => d as CustomUniverseData)
                .Where(d => d.Weight > 0.05m)
                .ToDictionary(d => d.Symbol, d => d.Weight);
            return _weightBySymbol.Keys;
        });
        // Add a Scheduled Event to rebalanc\e the portfolio.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(
            DateRules.EveryDay(spy),
            TimeRules.AfterMarketOpen(spy, 1),
            () => SetHoldings(
                _universe.Selected.Select(symbol => new PortfolioTarget(symbol, _weightBySymbol[symbol])).ToList(),
                liquidateExistingHoldings: true
            )
        );
    }
}

public class CustomUniverseData : BaseData
{
    public decimal Weight;
    public override DateTime EndTime
    {
        // Set the data period to 1 day.
        get { return Time + QuantConnect.Time.OneDay; }
        set { Time = value - QuantConnect.Time.OneDay; }
    }

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        // Define the location and format of the data file.
        return new SubscriptionDataSource(
            "portfolioTargets.csv", SubscriptionTransportMedium.ObjectStore, FileFormat.Csv
        );
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        // Skip the header row.
        if (!Char.IsDigit(line[0]))
        {
            return null;
        }
        // Split the line by each comma.
        var items = line.Split(",");

        // Parse the data from the CSV file.
        return new CustomUniverseData
        {
            EndTime = Parse.DateTimeExact(items[0], "yyyy-MM-dd"),
            Symbol = Symbol.Create(items[1], SecurityType.Equity, Market.USA),
            Weight = decimal.Parse(items[2], NumberStyles.Any, CultureInfo.InvariantCulture)
        };
    }
}
```

Universes

Dataless Scheduled Universes

Introduction

A dataless scheduled universe let's you select a set of assets on a specific schedule. You can control which days the other types of universe run by adjusting the Schedule universe setting . However, the `Schedule` universe setting doesn't accept a `TimeRule` argument, so you can't control the time of the day they run. In contrast, a dataless scheduled universe accepts a `TimeRule` argument, but its selection function only receives the algorithm time.

Create Universes

To add a dataless scheduled universe, in the `Initialize` method, call the `AddUniverse` method with a `ScheduledUniverse` object.

```C#
public class MyUniverseAlgorithm : QCAlgorithm {
    private Universe _universe;
    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        _universe = AddUniverse(new ScheduledUniverse(DateRules.MonthStart(), TimeRules.At(8, 0), SelectSymbols));
    }

    private IEnumerable<Symbol> SelectSymbols(DateTime dt)
    {
        return new[] { QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA) };
    }
}
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`dateRule`	`IDateRule`	Date rule that defines what days the universe selection function runs	
`timeRule`	`ITimeRule`	Time rule that defines what times on each day selected by date rule the universe selection function runs	
`Func<DateTime, IEnumerable< Symbol>>`	`selector`	Selector function that accepts the current date time and returns the universe's `Symbol` objects	
`settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`null`

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`DateRules.SetDefaultTimeZone(DateTimeZone timeZone);`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`DateRules.On(int year, int month, int day)`	Trigger an event on a specific date.
`DateRules.On(params DateTime[] dates)`	Trigger an event on specific dates.
`DateRules.EveryDay()`	Trigger an event all seven days of the week.
`DateRules.EveryDay(Symbol symbol, bool extendedMarketHours = false)`	Trigger an event every day a specific symbol is trading.
`DateRules.Every(params DayOfWeek[] days)`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`DateRules.MonthStart(int daysOffset = 0)`	Trigger an event on the first day of each month plus an offset.
`DateRules.MonthStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`DateRules.MonthEnd(int daysOffset = 0)`	Trigger an event on the last day of each month minus an offset.
`DateRules.MonthEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`DateRules.WeekStart(int daysOffset = 0)`	Trigger an event on the first day of each week plus an offset.
`DateRules.WeekStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`DateRules.WeekEnd(int daysOffset = 0)`	Trigger an event on the last day of each week minus an offset.
`DateRules.WeekEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`DateRules.YearStart(int daysOffset = 0)`	Trigger an event on the first day of each year plus an offset.
`DateRules.YearStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`DateRules.YearEnd(int daysOffset = 0)`	Trigger an event on the last day of each year minus an offset.
`DateRules.YearEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`DateRules.Today`	Trigger an event once today.
`DateRules.Tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `string` and a `getDatesFunction` argument of type `Func<DateTime, DateTime, IEnumerable<DateTime>>` . The `getDatesFunction` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```C#
// Create a date rule that specifies the 10th day of each month.
var dateRule = new FuncDateRule(
    name: "10th_day_of_the_month",
    getDatesFunction: (start, end) => Enumerable.Range(start.Year, end.Year - start.Year + 1)
        .SelectMany(year => Enumerable.Range(1, 12).Select(month => new DateTime(year, month, 10)))
);
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `DateRules.EveryDay("ES")` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```C#
var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`TimeRules.SetDefaultTimeZone(DateTimeZone timeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`TimeRules.BeforeMarketOpen(Symbol symbol, double minutesBeforeOpen = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes before market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.AfterMarketOpen(Symbol symbol, double minutesAfterOpen = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.BeforeMarketClose(Symbol symbol, double minutesBeforeClose = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.AfterMarketClose(Symbol symbol, double minutesAfterClose = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes after market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.Every(TimeSpan interval)`	Trigger an event every period interval starting at midnight. This time rule triggers every period, regardless of whether or not the market is open.
`TimeRules.Now`	Trigger an event at the current time of day.
`TimeRules.Midnight`	Trigger an event at midnight.
`TimeRules.Noon`	Trigger an event at noon.
`TimeRules.At(int hour, int minute, int second = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`TimeRules.At(int hour, int minute, int second, DateTimeZone timeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

To define custom time rules, create a `FuncTimeRule` object. The `FuncTimeRule` constructor expects a `name` argument of type `string` and a `createUtcEventTimesFunction` argument of type `Func<IEnumerable<DateTime>, IEnumerable<DateTime>>` . The function receives the list of dates from the date rule and then returns a list of `DateTime` that define the time rule.

```
C#
var timeRule = new FuncTimeRule(
    name: "CustomTimeRule",
    createUtcEventTimesFunction: dates => dates.Select(d => d.AddHours(10)));
```

Some time rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `TimeRules.BeforeMarketOpen("ES", 15)` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```
C#
var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

Selection Frequency

Dataless scheduled universes run at whatever selection schedule you define by the `dateRule` and `timeRule` arguments.

Examples

The following examples demonstrate some common practices for dataless scheduled universes.

Example 1: Download External Universe Files

The following algorithm downloads a CSV file from Dropbox. The first column in the file contains the universe date. The second column in the file contains a list of Equity tickers that represents the universe for the day. The dataless scheduled universe parses the file contents each trading day and adds the universe constituents.

C#

```
public class DatalessScheduledUniverseExampleAlgorithm : QCAlgorithm
{
    // Create a dictionary for the universe data where the key is the date and
    // the value is a comma-separated string of stock tickers.
    private Dictionary<DateTime, string> _tickersByDate = new();
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Download the initial universe file.
        DownloadUniverseFile();
        // Add the custom universe.
        UniverseSettings.ExtendedMarketHours = true;
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        var dateRule = DateRules.EveryDay(spy);
        _universe = AddUniverse(new ScheduledUniverse(dateRule, TimeRules.At(8, 0), SelectAssets));
        // Schedule rebalances for market open.
        Schedule.On(dateRule, TimeRules.AfterMarketOpen(spy, 0), Rebalance);
    }

    private void DownloadUniverseFile()
    {
        // Download the universe CSV file. Dropbox links require the "dl=1" URL parameter.
        var file = Download(
            "https://www.dropbox.com/scl/fi/fbrxitk4ec3w91nse1raa/df.csv?
rlkey=7r042rukzkthp7y1srloyhkov&st=5r4sdfwd&dl=1"
        );
        // Convert the CSV file data into a dictionary where the key is the date and
        // the value is a comma-separated string of stock tickers.
        foreach (var line in file.Split('\n').Skip(1))
        {
            // Skip empty lines.
            if (line.IsNullOrEmpty())
            {
                continue;
            }
            var items = line.Split("\"");
            var date = Parse.DateTimeExact(items[0].Split(",")[0], "yyyy-MM-dd").Date;
            _tickersByDate[date] = items[1];
        }
    }

    private IEnumerable<Symbol> SelectAssets(DateTime dt)
    {
        // When live trading, re-download the CSV file each day to get the new rows.
        if (LiveMode)
        {
            DownloadUniverseFile();
        }
        // Get the current day's data from the CSV file.
        if (!_tickersByDate.TryGetValue(dt.Date, out var tickers))
        {
            // If there isn't an entry for the current date, return an empty universe.
            return Enumerable.Empty<Symbol>();
        }
        // Convert the stock tickers in the CSV file to Symbol objects.
        return tickers
            .Split(',')
            .Select(x => QuantConnect.Symbol.Create(x, SecurityType.Equity, Market.USA));
    }

    private void Rebalance()
    {
        // Form an equal-weighted portfolio of all the universe constituents.
        var weight = 1m / _universe.Selected.Count;
        SetHoldings(_universe.Selected.Select(symbol => new PortfolioTarget(symbol, weight)).ToList(),
liquidateExistingHoldings: true);
    }
}
```

Example 2: Quarter End Selection

The following algorithm selects SPY on the last month of each quarter. For the remaining months, it selects no assets.

```C#
public class DatalessScheduledUniverseDemoAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        AddUniverse(new ScheduledUniverse(
            DateRules.MonthStart(),
            TimeRules.At(8, 0),
            (dt) =>
            {
                if (dt.Month % 3 == 0)
                {
                    return new[] { QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA) };
                }
                return Enumerable.Empty<Symbol>();
            }
        ));
    }
}
```

Example 3: Third Week VIX

Standard Options expire at end of the third week of each month. The following algorithm selects VIX-related products on the third week to trade the foreseeable increase in volatility.

```C#
public class DatalessScheduledUniverseDemoAlgorithm : QCAlgorithm
{
    private int _month = -1;
    private int _week = -1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        AddUniverse(new ScheduledUniverse(
            DateRules.WeekStart(),
            TimeRules.At(8, 0),
            (dt) =>
            {
                if (dt.Month == _month)
                {
                    if (++_week == 3)
                    {
                        return new[] { QuantConnect.Symbol.Create("VXZ", SecurityType.Equity, Market.USA) };
                    }
                    return Enumerable.Empty<Symbol>();
                }
                _month = dt.Month;
                _week = 0;
                return Enumerable.Empty<Symbol>();
            }
        ));
    }
}
```

Datasets

Datasets

Overview

Introduction

It's common to use price and fundamental data points to inform trading decisions. Alternative datasets are datasets that aren't classified as market or fundamental data. Alternative data research began gaining popularity in 2007 after the financial crisis and its usage has continued to grow over the years. As usage has grown, so has the number of unique alternative datasets that are available for investors. The benefit of alternative datasets is that it’s easier to find alpha in these datasets because they receive less attention from investment researchers and these datasets contain information not found in market and fundamental datasets. Most traders research with market and fundamental datasets, so it's difficult to find alpha in them.

Methodology

The journey of raw data from its source to its integration with a trading platform can be complex. Alternative data is generally created through individuals, business processes, and sensors. Individuals create content on social media platforms, write reviews on e-commerce sites, and visit corporate Wikipedia pages. Businesses process transactions, file SEC reports, and issue company announcements. Sensors collect location data, gather satellite images, and monitor customer behavior.

Data providers can capture these forms of data for traders to inform trading decisions in ways that supplement traditional market and fundamental datasets. With over a million terabytes of data on the internet, there is virtually a limitless amount of information that can be informative for investors when analyzing a security’s performance in the marketplace.

Examples

A common example of alternative data in a trading system is using sentiment analysis on news sources to predict the future price movements of Equities. A second example is using announcements regarding corporate share buyback programs to trading Equities. A third example is using global supply and demand information for US Crude Products to inform Futures trades. To view all of the datasets we have available, see the left navigation menu.

Challenges

A challenge of working with datasets is that it can be difficult to find a reliable, high-quality, and inexpensive data source to use in live algorithms. If a data source has survivorship bias, insufficient history, or hasn’t been cleaned and processed properly, the data can cause poor trading performance. We thoroughly vet the datasets we add to the Dataset Market to ensure they are free of survivorship bias and have a reliable live feed. All of the available datasets have already been cleaned and processed, so you can just focus on the strategy research and development.

Future Outlook

The Dataset Market is still in the early phases of development. Over time, we will add more markets and alternative datasets. Alternative datasets are an ever-expanding data source, so it’s expected to continue to grow into the future. In today’s digital world, more data is created each year than in the previous year. To take advantage of the trend, we have implemented a new

onboarding process to integrate many new alternative data sources into the QuantConnect platform. With the Dataset Market, you can import a new alternative dataset into your trading algorithm with just a single line of code. The Dataset Market gives everyone the ability to access high-quality alternative datasets that were previously only accessible to major hedge funds.

Live Trading Considerations

We receive most daily alternative data at 7 AM Eastern Time (ET) and start processing it. In live trading, your algorithm receives this data within 30 minutes of 7 AM ET. In backtesting, this data has a timestamp of midnight, so your algorithm receives it about seven hours earlier than it does in live mode.

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute.

Note that there will be delay for data available to be backtested. Live feed data is available for backtesting after 24-48 hours normally. Consider using Paper live trading if close monitoring is needed.

Binance Crypto Future Margin Rate Data

Introduction

The Binance Crypto Future Margin Rate Data by QuantConnect is for crypto-currency futures margin interest data points. The data covers 718 Cryptocurrency pairs, starts in August 2020, and is delivered on a daily update frequency. This dataset is created by downloading data using Binance API.

This dataset is an important companion to the Binance Crypto Future Price Data dataset because it contains information on margin interest data to model margin costs.

For more information about the Binance Crypto Future Margin Rate Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Future Margin Rate dataset:

```C#
private Symbol _cryptoFutureSymbol;

public override void Initialize()
{
    SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin);
    //SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin);

    // perpetual futures does not have a filter function
    _cryptoFutureSymbol = AddCryptoFuture("BTCBUSD", Resolution.Minute).Symbol;
}
```

The Binance Crypto Future Margin Rate data is added to your algorithm along with the market data when you add a crypto future subscription.

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2020
Asset Coverage	718 Crypto Futures Pairs
Data Density	Regular
Resolution	Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance Crypto Future Margin Rate data to your algorithm, call the `AddCryptoFuture` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol ;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);

        // Set Account Currency to Binance Stable Coin for USD
        SetAccountCurrency("BUSD");
        SetCash(100000);

        SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin);
        SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin);

        var cryptoFuture = AddCryptoFuture("BTCBUSD", Resolution.Minute);
        // perpetual futures does not have a filter function
        _symbol = cryptoFuture.Symbol;
    }
}
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Margin Rate data, index the `MarginInterestRates` property of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.MarginInterestRates.ContainsKey(_symbol))
    {
        var interestRate = slice.MarginInterestRates[_symbol].InterestRate;
        Log($"{_symbol} price at {slice.Time}: {interestRate}");
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.MarginInterestRates)
    {
        var symbol = kvp.Key;
        var marginInterestRate = kvp.Value;
        var interestRate = marginInterestRate.InterestRate;
        Log($"{symbol} price at {slice.Time}: {interestRate}");
    }
}
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Binance Crypto Future Margin Rate data, call the `History<MarginInterestRate>` method with the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
var history = History<MarginInterestRate>(_symbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Crypto Future pairs:

Example Applications

The Binance Crypto Future Margin Rate dataset enables correct margin cost so you can accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid cryptocurrencies

Classic Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Binance exchange. When the margin interest rate is relatively low, it flips to a short position.

```C#
public class BinanceCryptoFutureDataAlgorithm : QCAlgorithm
{
    private CryptoFuture _future;
    // Add an indicator to track the low of trailing margin interest rates.
    private Minimum _lowInterestRate = new(10);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set Account Currency to USDT, since USD cannot be used to trade.
        SetCash("USDT", 100000);
        // Binance Futures Exchange accepts both Cash and Margin account types, select the one you need for the best
reality modeling.
        SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin);
        // Requesting data, we only trade on BTCUSDT Future in Binance Future exchange
        // Perpetual futures does not have a filter function.
        _future = AddCryptoFuture("BTCUSDT", Resolution.Daily);
        // Historical data
        var history = History<MarginInterestRate>(_future.Symbol, 10, Resolution.Daily);
        foreach (var dataPoint in history)
        {
            _lowInterestRate.Update(dataPoint.EndTime, dataPoint.InterestRate);
        }
    }

    public override void OnData(Slice slice)
    {
        // Note that you may want to access the margin interest of the crypto future to calculate if it would impact
a trade's PnL
        // Or you can calculate the trade size on keeping the quote currency constant
        if (!slice.MarginInterestRates.TryGetValue(_future.Symbol, out var dataPoint))
        {
            return;
        }
        var interestRate = dataPoint.InterestRate;
        Plot("Margin Interest Rate", _future.Symbol.ToString(), interestRate);
        // Short when margin interest rates are relatively low. Otherwise, long.
        if (interestRate <= _lowInterestRate)
        {
            if (!_future.Holdings.IsShort)
            {
                SetHoldings(_future.Symbol, -0.5);
            }
        }
        else if (!_future.Holdings.IsLong)
        {
            SetHoldings(_future.Symbol, 1);
        }
        // Update the indicator.
        _lowInterestRate.Update(Time, interestRate);
    }
}
```

Framework Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Binance exchange.

When the margin interest rate is relatively low, it flips to a short position.

```C#
public class BinanceCryptoFutureDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.FreePortfolioValuePercentage = 0.1m;
        // Set Account Currency to USDT, since USD cannot be used to trade.
        SetCash("USDT", 100000);
        // Binance Futures Exchange accepts both Cash and Margin account types, select the one you need for the best
reality modeling.
        SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin);

        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Leverage = 2;
        // We only trade on BTCUSDT Future in Binance Future exchange
        var symbols = new List<Symbol>{
            QuantConnect.Symbol.Create("BTCUSDT", SecurityType.CryptoFuture, Market.Binance)
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // Custom alpha model to emit insights based on the Crypto Future price data
        AddAlpha(new CryptoFutureAlphaModel());
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
    }
}

public class CryptoFutureAlphaModel : AlphaModel
{
    private Dictionary<Symbol, Minimum> _minBySymbol = new();

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();
        foreach (var kvp in _minBySymbol)
        {
            var symbol = kvp.Key;
            var lowInterestRate = kvp.Value;
            // Note that you may want to access the margin interest of the crypto future to calculate if it would
impact a trade's PnL
            // Or you can calculate the trade size on keeping the quote currency constant
            if (!slice.MarginInterestRates.TryGetValue(symbol, out var dataPoint))
                continue;
            var interestRate = dataPoint.InterestRate;
            algorithm.Plot("Margin Interest Rate", symbol.ToString(), interestRate);
            // Short when margin interest rates are relatively low. Otherwise, long.
            var direction = interestRate <= lowInterestRate.Current.Value
                ? InsightDirection.Down
                : InsightDirection.Up;
            insights.Add(Insight.Price(symbol, TimeSpan.FromDays(1), direction));
            // Update the indicator.
            lowInterestRate.Update(slice.Time, interestRate);
        }
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            var symbol = security.Symbol;
            // Add an indicator to track the low of trailing margin interest rates.
            var min = new Minimum(10);
            _minBySymbol[symbol] = min;
            // Historical data
            var history = algorithm.History<MarginInterestRate>(symbol, 10, Resolution.Daily);
            foreach (var dataPoint in history)
            {
                min.Update(dataPoint.EndTime, dataPoint.InterestRate);
            }
        }
        foreach (var security in changes.RemovedSecurities)
        {
            _minBySymbol.Remove(security.Symbol);
        }
    }
```

```
}
```

Data Point Attributes

The Binance Crypto Future Margin Rate dataset provides `MarginInterestRates` objects with the following attributes:

QuantConnect

Bybit Crypto Future Margin Rate Data

Introduction

The Bybit Crypto Future Margin Rate Data by QuantConnect is for Cryptocurrency Futures margin interest data points. The data covers 631 Cryptocurrency pairs, starts in August 2020, and is delivered on a daily update frequency. This dataset is created by downloading data using Bybit API.

This dataset is an important companion to the Bybit Crypto Future Price Data dataset because it contains information on margin interest data to model margin costs.

For more information about the Bybit Crypto Future Margin Rate Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the Bybit Crypto Future Margin Rate dataset:

```C#
private Symbol _cryptoFutureSymbol;

public override void Initialize
{
    SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

    // perpetual futures does not have a filter function
    _cryptoFutureSymbol = AddCryptoFuture("BTCBUSD", Resolution.Minute).Symbol;
}
```

The Bybit Crypto Future Margin Rate data is added to your algorithm along with the market data when you add a crypto future subscription.

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2020
Asset Coverage	631 Crypto Futures Pairs
Data Density	Regular
Resolution	Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bybit Crypto Future Margin Rate data to your algorithm, call the `AddCryptoFuture` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol ;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);

        // Set Account Currency to Tether
        SetAccountCurrency("USDT", 100000);

        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

        var cryptoFuture = AddCryptoFuture("BTCUSDT", Resolution.Minute);
        // perpetual futures does not have a filter function
        _symbol = cryptoFuture.Symbol;
    }
}
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Bybit Crypto Margin Rate data, index the `MarginInterestRates` property of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.MarginInterestRates.ContainsKey(_symbol))
    {
        var interestRate = slice.MarginInterestRates[_symbol].InterestRate;
        Log($"{_symbol} price at {slice.Time}: {interestRate}");
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.MarginInterestRates)
    {
        var symbol = kvp.Key;
        var marginInterestRate = kvp.Value;
        var interestRate = marginInterestRate.InterestRate;
        Log($"{symbol} price at {slice.Time}: {interestRate}");
    }
}
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Bybit Crypto Future Margin Rate data, call the `History<MarginInterestRate>` method with the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```
var history = History<MarginInterestRate>(_symbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Crypto Future pairs:

Pairs Available (631)

Example Applications

The Binance Crypto Future Margin Rate dataset enables correct margin cost so you can accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying Cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid Cryptocurrencies

Classic Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Bybit exchange. When the margin interest rate is relatively low, it flips to a short position.

```C#
public class BybitCryptoFutureDataAlgorithm : QCAlgorithm
{
    private CryptoFuture _future;
    // Add an indicator to track the low of trailing margin interest rates.
    private Minimum _lowInterestRate = new(10);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set Account Currency to USDT, since USD cannot be used to trade.
        SetCash("USDT", 100000);
        // Bybit  accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Requesting data, we only trade on BTCUSDT Future in Bybit  exchange
        // Perpetual futures does not have a filter function.
        _future = AddCryptoFuture("BTCUSDT", Resolution.Daily);
        // Historical data
        var history = History<MarginInterestRate>(_future.Symbol, 10, Resolution.Daily);
        foreach (var dataPoint in history)
        {
            _lowInterestRate.Update(dataPoint.EndTime, dataPoint.InterestRate);
        }
    }

    public override void OnData(Slice slice)
    {
        // Note that you may want to access the margin interest of the crypto future to calculate if it would impact
a trade's PnL
        // Or you can calculate the trade size on keeping the quote currency constant
        if (!slice.MarginInterestRates.TryGetValue(_future.Symbol, out var dataPoint))
        {
            return;
        }
        var interestRate = dataPoint.InterestRate;
        Plot("Margin Interest Rate", _future.Symbol.ToString(), interestRate);
        // Short when margin interest rates are relatively low. Otherwise, long.
        if (interestRate <= _lowInterestRate)
        {
            if (!_future.Holdings.IsShort)
            {
                SetHoldings(_future.Symbol, -0.5);
            }
        }
        else if (!_future.Holdings.IsLong)
        {
            SetHoldings(_future.Symbol, 1);
        }
        // Update the indicator.
        _lowInterestRate.Update(Time, interestRate);
    }
}
```

Framework Algorithm Example

The following example algorithm holds a long position in the BTCUSDT perpetual Future contract on the Bybit exchange. When the margin interest rate is relatively low, it flips to a short position.

```C#
public class BybitCryptoFutureDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.FreePortfolioValuePercentage = 0.1m;
        // Set Account Currency to USDT, since USD cannot be used to trade.
        SetCash("USDT", 100000);
        // Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        UniverseSettings.Resolution = Resolution.Daily;
```

```
        UniverseSettings.Leverage = 2;
        // We only trade on BTCUSDT Future in Bybit exchange
        var symbols = new List<Symbol>{
            QuantConnect.Symbol.Create("BTCUSDT", SecurityType.CryptoFuture, Market.Bybit)
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // Custom alpha model to emit insights based on the Crypto Future price data
        AddAlpha(new CryptoFutureAlphaModel());
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
    }
}

public class CryptoFutureAlphaModel : AlphaModel
{
    private Dictionary<Symbol, Minimum> _minBySymbol = new();

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();
        foreach (var kvp in _minBySymbol)
        {
            var symbol = kvp.Key;
            var lowInterestRate = kvp.Value;
            // Note that you may want to access the margin interest of the crypto future to calculate if it would
impact a trade's PnL
            // Or you can calculate the trade size on keeping the quote currency constant
            if (!slice.MarginInterestRates.TryGetValue(symbol, out var dataPoint))
                continue;
            var interestRate = dataPoint.InterestRate;
            algorithm.Plot("Margin Interest Rate", symbol.ToString(), interestRate);
            // Short when margin interest rates are relatively low. Otherwise, long.
            var direction = interestRate <= lowInterestRate.Current.Value
                ? InsightDirection.Down
                : InsightDirection.Up;
            insights.Add(Insight.Price(symbol, TimeSpan.FromDays(1), direction));
            // Update the indicator.
            lowInterestRate.Update(slice.Time, interestRate);
        }
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            var symbol = security.Symbol;
            // Add an indicator to track the low of trailing margin interest rates.
            var min = new Minimum(10);
            _minBySymbol[symbol] = min;
            // Historical data
            var history = algorithm.History<MarginInterestRate>(symbol, 10, Resolution.Daily);
            foreach (var dataPoint in history)
            {
                min.Update(dataPoint.EndTime, dataPoint.InterestRate);
            }
        }
        foreach (var security in changes.RemovedSecurities)
        {
            _minBySymbol.Remove(security.Symbol);
        }
    }
}
```

Data Point Attributes

The Binance Crypto Future Margin Rate dataset provides `MarginInterestRate` objects, which have the following attributes:

QuantConnect

CFD Data

Introduction

The CFD Data by QuantConnect serves 51 contracts for differences (CFD). The data starts as early as May 2002 and is delivered on any frequency from tick to daily. This dataset is created by QuantConnect processing raw tick data from OANDA.

CFD data does not include ask and bid sizes.

For more information about the CFD Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the CFD dataset:

```C#
_symbol = AddCfd("XAUUSD", Resolution.Daily).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	Mixed, earliest starts May 2002
Asset Coverage	51 Contracts
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	Mixed, in which the contract is listed*
Market Hours	Always Open , except from Friday 5 PM EST to Sunday 5 PM EST. Index CFDs depends on the underlying market hour*

* E.g.: DE30EUR tracks DAX30 Index, which is listed in Europe/Berlin timezone.

Requesting Data

To add CFD data to your algorithm, call the `AddCfd` method. Save a reference to the CFD `Symbol` so you can access the data later in your algorithm.

```
C#
public class CfdAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetAccountCurrency("EUR");

        SetStartDate(2019, 2, 20);
        SetEndDate(2019, 2, 21);
        SetCash("EUR", 100000);

        _symbol = AddCfd("DE30EUR").Symbol;

        SetBenchmark(_symbol);
    }
}
```

For more information about creating CFD subscriptions, see Requesting Data .

Accessing Data

To get the current CFD data, index the `QuoteBars` , or `Ticks` properties of the current `Slice` with the CFD `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing CFD data, see Handling Data .

Historical Data

To get historical CFD data, call the `History` method with the CFD `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a CFD subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings.

Supported Assets

The following table shows the available contracts:

Contract Available (51)					
AU200AUD	BCOUSD	CH20CHF	CORNUSD	DE10YBEUR	DE30EUR
EU50EUR	FR40EUR	HK33HKD	JP225USD	NAS100USD	NATGASUSD
NL25EUR	SG30SGD	SOYBNUSD	SPX500USD	SUGARUSD	UK100GBP
UK10YBGBP	US2000USD	US30USD	USB02YUSD	USB05YUSD	USB10YUSD
USB30YUSD	WHEATUSD	WTICOUSD	XAGAUD	XAGCAD	XAGCHF
XAGEUR	XAGGBP	XAGHKD	XAGJPY	XAGNZD	XAGSGD
XAGUSD	XAUAUD	XAUCAD	XAUCHF	XAUEUR	XAUGBP
XAUHKD	XAUJPY	XAUNZD	XAUSGD	XAUUSD	XAUXAG
XCUUSD	XPDUSD	XPTUSD			

Example Applications

The CFD price data enables you to trade CFD assets in your algorithm. Examples include the following strategies:

- Exploring the daily worldwide news cycles with CFDs that track international indices.
- Trading price movements of commodities with no delivery of physical goods. For example, pairs trading between gold and silver, corn and wheat, brent and crude oil, etc.

Classic Algorithm Example

The following example algorithm implements a pairs trading strategy using Gold and Silver CFDs, XAUUSD and XAGUSD, respectively. When the spread is higher than one standard deviation above its mean, the algorithm buys the spread (buy XAUUSD and sell XAGUSD). When the spread is lower than one standard deviation below its mean, it sells the spread (buy XAGUSD and sell XAUUSD).

C#

```
public class GoldSilverPairsTradingAlgorithm : QCAlgorithm
{
    // Use 500-step mean and SD indicator on determine the spread relative difference for trading signal generation
    private SimpleMovingAverage _spreadMean = new SimpleMovingAverage(500);
    private StandardDeviation _spreadStd = new StandardDeviation(500);
    private Security[] _pair = new Security[2];

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Request gold and sliver spot CFDs for trading their spread difference, assuming their spread series is
cointegrated
        AddCfd("XAUUSD", Resolution.Hour);
        AddCfd("XAGUSD", Resolution.Hour);
    }

    public override void OnData(Slice slice)
    {
        // Update the indicator with updated spread difference, such that the an updated cointegration threshold is
calculated for trade inception
        var spread = _pair[1].Price - _pair[0].Price;
        _spreadMean.Update(Time, spread);
        _spreadStd.Update(Time, spread);

        var upperthreshold = _spreadMean + _spreadStd;
        var lowerthreshold = _spreadMean - _spreadStd;

        // If the spread is higher than upper threshold, bet their spread series will revert to mean
        if (spread > upperthreshold)
        {
            SetHoldings(_pair[0].Symbol, 1);
            SetHoldings(_pair[1].Symbol, -1);
        }
        else if (spread < lowerthreshold)
        {
            SetHoldings(_pair[0].Symbol, -1);
            SetHoldings(_pair[1].Symbol, 1);
        }
        // Close positions if mean reverted
        else if ((Portfolio[_pair[0].Symbol].Quantity > 0m && spread < _spreadMean)
        || (Portfolio[_pair[0].Symbol].Quantity < 0m && spread > _spreadMean))
        {
            Liquidate();
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _pair = changes.AddedSecurities.ToArray();

        //1. Call for 500 days of history data for each symbol in the pair and save to the variable history
        var history = History(_pair.Select(x => x.Symbol), 500);

        //2. Iterate through the history tuple and update the mean and standard deviation with historical data
        foreach(var slice in history)
        {
            var spread = slice[_pair[1].Symbol].Close - slice[_pair[0].Symbol].Close;
            _spreadMean.Update(slice.Time, spread);
            _spreadStd.Update(slice.Time, spread);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm implements a pairs trading strategy using Gold and Silver CFDs, XAUUSD and XAGUSD, respectively. When the spread is higher than one standard deviation above its mean, the algorithm buys the spread (buy XAUUSD and sell XAGUSD). When the spread is lower than one standard deviation below its mean, it sells the spread (buy XAGUSD and sell XAUUSD).

C#

```
public class GoldSilverPairsTradingAlgorithm : QCAlgorithm
{
    public override void Initialize()

            _spreadMean.Update(slice.Time, spread);
            _spreadStd.Update(slice.Time, spread);
        }
    }
}
```

Data Point Attributes

The CFD dataset provides `QuoteBar` and `Tick` objects.

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

QuantConnect

Cash Indices

Introduction

The Cash Indices dataset by QuantConnect covers 125 US Indices and 3 International indices. The data starts on various dates from January 1998 and is delivered on any frequency from minute to daily.

For more information about the Cash Indices dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Live Data

The Cash Indices dataset does not provide a live data feed. To receive Cash Indices' data in your live algorithm, you must add a brokerage or a third-party data provider (see Cloud Platform > Datasets).

Getting Started

The following snippet demonstrates how to request data from the Cash Indices dataset:

```
C#
_symbol = AddIndex("VIX", Resolution.Daily).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Coverage	125 US Indices and 3 International indices (HSI, SX5E and N225)
Data Density	Dense
Resolution	Minute, Hour, & Daily
Timezone	New York for US Indices, refer to `Supported Assets` below for International indices
Market Hours	Regular Only

Requesting Data

To add Cash Indices data to your algorithm, call the `AddIndex` method. Save a reference to the Index `Symbol` so you can access the data later in your algorithm.

```C#
public class CashIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        _symbol = AddIndex("VIX").Symbol;
    }
}
```

For more information about creating Index subscriptions, see Requesting Data .

Accessing Data

To get the current Cash Indices data, index the `Bars` property of the current `Slice` with the Index `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }
}
```

For more information about accessing Index data, see Handling Data .

Historical Data

To get historical Cash Indices data, call the `History` method with the Index `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyBars = History(_symbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove an Index subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

Supported Indices

US Cash Indices

The following table shows the US Cash indices with Index Option support:

Ticker	Index	Expiry	Start Date
VIX	S&P500	30 Days	Jul 2003
SPX	S&P500	-	Jan 1998
NDX	NASDAQ-100	-	Jan 1998
RUT	Russell 2000	-	Jan 2008

VIX - CBOE Volatility Index

The Cboe Volatility Index (VIX) is a real-time index that represents the market's expectations for the relative strength of near-term price changes of the S&P 500 Index (SPX). Because it's derived from the prices of SPX index Options with near-term expiration dates, it generates a 30-day forward projection of volatility. Volatility, or how fast prices change, is often seen as a way to gauge market sentiment, and in particular, the degree of fear among market participants.

SPX - S&P 500 Index

The S&P 500 Index, or the Standard & Poor's 500 Index, is a market-capitalization-weighted index of the 500 largest publicly-traded companies in the U.S. It is not an exact list of the top 500 U.S. companies by market capitalization because there are other criteria included in the index. The index is widely regarded as the best gauge of large-cap U.S. Equities.

NDX - Nasdaq 100 Index

The Nasdaq-100 Index is a modified market-capitalization-weighted index composed of securities issued by 100 of the largest non-financial companies listed on the Nasdaq Stock Market (Nasdaq). The index includes companies from various industries except for the financial industry, like commercial and investment banks. These non-financial sectors include retail, biotechnology, industrial, technology, health care, and others.

RUT - Russell 2000 Index

The Russell 2000 Index is a small-cap U.S. stock market index that makes up the smallest 2,000 stocks in the Russell Index. It was started by the Frank Russell Company in 1984. The index is maintained by FTSE Russell, a subsidiary of the London Stock Exchange Group (LSEG).

All US Cash Indices

The following table shows all US Cash indices:

Indices Available (125). Note: QuantConnect is working on its modeling: market hours and symbol properties.					
AEX	ASX	BKX	BRR	BRTI	BXD

XEO	XMI	XNDX	XSP	XSR	

International Cash Indices

The following table shows the International Cash indices:

Ticker	Index	Start Date	Time Zone	Currency
HSI	Hang Seng Index	Dec 2006	Asia/Hong Kong	HKD
SX5E	EUREX EU STOXX	Jul 2003	Europe/Berlin	EUR
N225	Nikkei 225	Jul 2003	Asia/Tokyo	JPY

Example Applications

The Cash Indices enable you to incorporate popular indices into your trading algorithms. Examples include the following use cases:

- Exploring the difference between the Index and the ETF that tracks it
- Using these indices as the underlying asset fo Index Options strategies
- Understanding the stock market's level of expected forward-looking volatility, also known as the "fear index". When the VIX starts moving higher, it tells you that traders are getting nervous. When the VIX starts moving lower, it tells you that traders are gaining confidence.

Classic Algorithm Example

The following example algorithm tracks the 80-day EMA and 200-day EMA of SPX. When the short EMA crosses above the long EMA, the algorithm buys SPY. Otherwise, it holds cash.

```C#
public class IndexDataAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _emaSlow, _emaFast;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Request SPY data as trading vehicle for SPX
        _spy = AddEquity("SPY").Symbol;

        // Request SPX data for trade signal generation
        var spx = AddIndex("SPX").Symbol;

        // Create short and long-term EMA indicators for trend estimation to trade
        _emaFast = EMA(spx, 80, Resolution.Daily);
        _emaSlow = EMA(spx, 200, Resolution.Daily);
        SetWarmUp(200, Resolution.Daily);

        // Historical data
        var history = History(spx, 60, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        // Trade signals required indicators to be ready
        if (IsWarmingUp || !_emaSlow.IsReady)
        {
            return;
        }

        // If short-term EMA is above long-term, it indicates an up trend, so we buy SPY
        if (!Portfolio.Invested && _emaFast > _emaSlow)
        {
            SetHoldings(_spy, 1);
        }
        // If it is the reverse, it indicates a downtrend, and we liquidate any position
        else if (_emaFast < _emaSlow)
        {
            Liquidate();
        }
    }
}
```

Framework Algorithm Example

The following example algorithm tracks the 80-day EMA and 200-day EMA of SPX. When the short EMA crosses above the long EMA, the algorithm buys SPY. Otherwise, it holds cash.

C#

```
public class IndexDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Universe contains only SPY as a trading vehicle for SPX
        SetUniverseSelection(new ManualUniverseSelectionModel
        (
            QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)
        ));
        // Custom alpha model that emits insights based on SPX index data
        SetAlpha(new SpxEmaCrossAlphaModel(this));
        // Equally invests can dissipate non-systematic risky event's capital concentration risk evenly
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Expiry.EndOfMonth));
    }
}

public class SpxEmaCrossAlphaModel : AlphaModel
{
    private ExponentialMovingAverage _emaSlow, _emaFast;

    public SpxEmaCrossAlphaModel(QCAlgorithm algorithm)

QuantConnect

FOREX Data

Introduction

The FOREX Data by QuantConnect serves 71 foreign exchange (FOREX) pairs, starts on various dates from January 2007, and is delivered on any frequency from tick to daily. This dataset is created by QuantConnect processing raw tick data from OANDA.

FOREX data does not include ask and bid sizes.

For more information about the FOREX Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the FOREX dataset:

```
C#
_symbol = AddForex("EURUSD", Resolution.Daily).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2007
Asset Coverage	71 Currency pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	UTC
Market Hours	Always Open , except from Friday 5 PM EST to Sunday 5 PM EST

Requesting Data

To add FOREX data to your algorithm, call the `AddForex` method. Save a reference to the Forex `Symbol` so you can access the data later in your algorithm.

```
C#
public class ForexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2019, 2, 20);
        SetEndDate(2019, 2, 21);
        SetCash(100000);

        _symbol = AddForex("EURUSD", Resolution.Minute).Symbol;

        SetBenchmark(_symbol);
    }
}
```

For more information about creating Forex subscriptions, see Requesting Data .

Accessing Data

To get the current Forex data, index the `QuoteBars` , or `Ticks` properties of the current `Slice` with the Forex `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Forex data, see Handling Data .

Historical Data

To get historical Forex data, call the `History` method with the Forex `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a Forex pair subscription, call the `RemoveSecurity` method.

```
C#

RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings.

Supported Assets

The following table shows the available Forex pairs:

USDJPY	USDMXN	USDNOK	USDPLN	USDSAR	USDSEK
USDSGD	USDTHB	USDTRY	USDZAR	ZARJPY	

Example Applications

The FOREX price data enables you to trade currency pairs in the global market. Examples include the following strategies:

- Exploring the impact that daily worldwide news cycles have on international currencies
- Carry Trade: borrow from a lower interest currency pair to fund the purchase of a currency pair with a higher interest rate

Classic Algorithm Example

The following example algorithm implements a FOREX carry trade. It buys the FOREX pair of the country with the lowest interest rate and sells the FOREX pair of the country with the highest interest rate.

```C#
public class ForexCarryTradeAlgorithm : QCAlgorithm
{
    // Use a month counter as variable to control rebalancing
    private int _month = -1;
    private Dictionary<string, decimal> _rates;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(25000);

        // We will use hard-coded interest rates for each base currency
        _rates = new Dictionary<string, decimal>()
        {
            {"USDAUD", 1.5m},    // Australia
            {"USDCAD", 0.5m},    // Canada
            {"USDCNY", 4.35m},   // China
            {"USDEUR", 0.0m},    // Euro Area
            {"USDINR", 6.5m},    // India
            {"USDJPY", -0.1m},   // Japan
            {"USDMXN", 4.25m},   // Mexico
            {"USDTRY", 7.5m},    // Turkey
            {"USDZAR", 7.0m}     // South Africa
        };

        // Subscribe to forex data for trading
        foreach (var ticker in _rates.Keys)
        {
            AddForex(ticker, Resolution.Daily);
        }
    }

    public override void OnData(Slice slice)
    {
        // Monthly rebalance checker
        if (_month == Time.Month) return;
        _month = Time.Month;

        // Long the pair with highest interest rate and sell the pair with the lowest to earn the max monetary
inflation difference between the two
        var sortedRates = (from kvp in _rates orderby kvp.Value ascending select kvp.Key).ToArray();
        SetHoldings(sortedRates[0], -0.5);
        SetHoldings(sortedRates[sortedRates.Length-1], 0.5);
    }
}
```

Framework Algorithm Example

The following example algorithm implements a FOREX carry trade. It buys the FOREX pair of the country with the lowest interest rate and sells the FOREX pair of the country with the highest interest rate.

```C#
public class ForexCarryTradeAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(25000);

        Symbol toSymbol(string ticker)
        {
            return QuantConnect.Symbol.Create(ticker, SecurityType.Forex, Market.Oanda);
        }

        // We will use hard-coded interest rates for each base currency
        var rates = new Dictionary<Symbol, decimal>()
        {
            {toSymbol("USDAUD"), 1.5m},    // Australia
            {toSymbol("USDCAD"), 0.5m},    // Canada
            {toSymbol("USDCNY"), 4.35m},   // China
            {toSymbol("USDEUR"), 0.0m},    // Euro Area
            {toSymbol("USDINR"), 6.5m},    // India
            {toSymbol("USDJPY"), -0.1m},   // Japan
            {toSymbol("USDMXN"), 4.25m},   // Mexico
            {toSymbol("USDTRY"), 7.5m},    // Turkey
            {toSymbol("USDZAR"), 7.0m}     // South Africa
        };

        SetUniverseSelection(new ManualUniverseSelectionModel(rates.Keys));
        // A custom alpha model to emit insight according to interest rate
        SetAlpha(new IntestRatesAlphaModel(rates));
        // Equal size to capitalize the monetary value of quote currency only based on interest rate difference
        // For dollar-neutral to save margin cost
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Expiry.EndOfMonth));
    }
}

public class IntestRatesAlphaModel : AlphaModel
{
    // Variable to control the rebalancing time
    private int _month = -1;
    private Dictionary<Symbol, decimal> _rates;

    public IntestRatesAlphaModel(Dictionary<Symbol, decimal> rates)
    {
        _rates = rates;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Monthly rebalance
        if (_month == algorithm.Time.Month)
        {
            return Enumerable.Empty<Insight>();
        }
        _month = algorithm.Time.Month;

        // Long the pair with highest interest rate and sell the pair with the lowest to earn the max monetary
inflation difference between the two
        var sortedRates = (from kvp in _rates orderby kvp.Value ascending select kvp.Key).ToArray();

        return Insight.Group(
            Insight.Price(sortedRates[0], Expiry.EndOfMonth, InsightDirection.Up),
            Insight.Price(sortedRates[sortedRates.Length-1], Expiry.EndOfMonth, InsightDirection.Down)
        );
    }
}
```

Data Point Attributes

The FOREX dataset provides `QuoteBar` and `Tick` objects.

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

QuantConnect

Fear and Greed

Introduction

The Fear and Greed dataset by QuantConnect provides data points to quantify the degree of fear and greed in the US Equity market. The data starts in 2014 and is delivered on a daily frequency, delayed by two days. This dataset is created by aggregating seven indicators, including market volatility, stock market breadth, and put-call ratios.

For more information about the Fear and Greed dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the Fear and Greed dataset:

```C#
_datasetSymbol = AddData<FearGreedIndex>("FG").Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2014
Data Density	Dense
Resolution	Daily
Timezone	New York

The latest daily data points are about two days since the VIX and SPX prices are inputs into the index and their latest daily prices are also two days old. New data is available at 9 AM EST.

Requesting Data

To add Fear and Greed data to your algorithm, call the `AddData<FearGreedIndex>` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```C#
public class FearAndGreedDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<FearGreedIndex>("FG").Symbol;
    }
}
```

Accessing Data

To get the current Fear and Greed data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} value at {slice.Time}: {dataPoint.Value}");
    }
}
```

Historical Data

To get historical Fear and Greed data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
var history = History<FearGreedIndex>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscription

To remove a subscription to the Fear and Greed dataset, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Fear and Greed dataset quantifies the degree of fear and greed in the US Equity market. Example use cases include the following strategies:

- Accumulate long-term positions when the market is fearful (the index is low).
- Short risky assets when the market is greedy.
- Trade butterfly Option strategies based on the market volatility indicator.

Classic Algorithm Example

The following example algorithm buys SPY when the Fear and Greed index is less than 25 (extreme fear) and sells when it's above 75 (extreme greed).

```C#
public class FearAndGreedExampleAlgorithm : QCAlgorithm
{
    private Equity _equity;
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Add the market index to trade.
        _equity = AddEquity("SPY", Resolution.Daily);
        // Add the Fear and Greed dataset.
        _datasetSymbol = AddData<FearGreedIndex>("FG").Symbol;
    }

    public override void OnData(Slice data)
    {
        // Wait until the Fear and Greed dataset has new data
        if (!data.ContainsKey(_datasetSymbol))
        {
            return;
        }
        var value = data[_datasetSymbol].Value;
        // Buy when the market is fearful.
        if (!_equity.Invested && value < 25)
        {
            SetHoldings(_equity.Symbol, 1);
        }
        // Sell when the market is greedy.
        else if (_equity.Invested && value > 75)
        {
            Liquidate();
        }
    }
}
```

Framework Example

The following example algorithm buys SPY when the Fear and Greed index is less than 25 (extreme fear) and sells when it's above 75 (extreme greed).

```C#
public class FearAndGreedExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Trade SPY on a daily basis.
        UniverseSettings.Resolution = Resolution.Daily;
        var symbols = new[] { QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA) };
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // Add a custom Alpha model that emits insights based on the Fear and Greed dataset.
        AddAlpha(new FearAndGreedAlphaModel(this));
        // Set the equal weighted PCM so the algorithm places trades.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}

// Define the custom Alpha model.
public class FearAndGreedAlphaModel : AlphaModel
{
    // Create a list to track the current universe.
    private List<Security> _securities = new List<Security>();
    private Symbol _datasetSymbol;
```

```
    public FearAndGreedAlphaModel(QCAlgorithm algorithm)
    {
        // Add the Fear and Greed dataset.
        _datasetSymbol = algorithm.AddData<FearGreedIndex>("FG").Symbol;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice data)
    {
        // Wait until the Fear and Greed dataset has new data.
        if (!data.ContainsKey(_datasetSymbol))
        {
            return Enumerable.Empty<Insight>();
        }
        // Wait until the Fear and Greed index is extreme.
        var value = data[_datasetSymbol].Value;
        if (value >= 25 && value <= 75)
        {
            return Enumerable.Empty<Insight>();
        }

        var insights = new List<Insight>();
        foreach (var security in _securities)
        {
            InsightDirection direction;
            // Buy when the market is fearful.
            if (!security.Invested && value < 25)
            {
                direction = InsightDirection.Up;
            }
            // Sell when the market is greedy.
            else if (security.Invested && value > 75)
            {
                direction = InsightDirection.Flat;
            }
            else
            {
                continue;
            }
            insights.Add(Insight.Price(security.Symbol, TimeSpan.FromDays(2 * 365), direction));
        }
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        // When assets enter the universe, save them.
        foreach (var security in changes.AddedSecurities)
        {
            _securities.Add(security);
        }
        // When assets leave the universe, remove them.
        foreach (var security in changes.RemovedSecurities)
        {
            _securities.Remove(security);
        }
    }
}
```

Data Point Attributes

The Fear and Greed dataset provides `FearGreedIndex` objects, which have the following attributes:

QuantConnect

International Future Universe

Introduction

The International Future Universe dataset by QuantConnect lists the available International Future contracts, their daily trading volume, and Open Interest. The data covers 4 contracts (DAX, FESX, HSI, and NKD), starts in July 1998, and is delivered on daily frequency. This dataset is created by monitoring the trading activity on the EUREX, HKFE, and CME.

This dataset depends on the US Futures Security Master dataset because the US Futures Security Master dataset contains information on symbol changes of the contracts.

This dataset `does not` contain market data. For market data, see International Futures by TickData and US Futures by AlgoSeek for NKD.

For more information about the International Future Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The International Futures Universe dataset provides data for contract filtering/selection:

```C#
var hsi= AddFuture(Futures.Indices.HangSeng, Resolution.Minute)           // "HSI";
hsi.SetFilter(0, 90);
var dax = AddFuture(Futures.Indices.Dax, Resolution.Minute)               // "DAX";
dax.SetFilter(0, 90);
var fesx = AddFuture(Futures.Indices.EuroStoxx50, Resolution.Minute)      // "FESX";
fesx.SetFilter(0, 90);
var nkd = AddFuture(Futures.Indices.Nikkei225Dollar, Resolution.Minute)   // "NKD";
nkd.SetFilter(0, 90);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 1998 (for details, see `Supported Assets`)
Coverage	4 Contracts
Data Density	Dense
Resolution	Daily
Timezone	Various (for details, see `Supported Assets`)
Market Hours	Regular and Extended

Requesting Data

To add International Future Universe data to your algorithm, call the `AddFuture` method. Save a reference to the Future object so you can access the data later in your algorithm. To define which contracts should be in your universe, specify the filter when requesting the Future data.

The `AddFuture` method provides a daily stream of Future chain data. To get the most recent daily chain, call the `FuturesChain` method with the underlying Future Symbol. The `FuturesChain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```
C#
public class InternationalFuturesDataAlgorithm : QCAlgorithm
{
    private Future _future;

    public override void Initialize()
    {
        SetStartDate(2013, 12, 20);
        SetEndDate(2014, 2, 20);
        SetCash(1000000);
        UniverseSettings.Asynchronous = true;
        var future = AddFuture(Futures.Indices.HangSeng);
        // Set our contract filter for this Future chain.
        _future.SetFilter((universe) => universe.StandardsOnly().FrontMonth());
        // Get the entire Futures chain for the current day.
        var chain = FuturesChain(_future.Symbol);
    }
}
```

For more information about creating Future Universes, see Futures .

Accessing Data

For information about accessing International Future Universe data, see Futures .

Historical Data

You can get historical International Future Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical International Future Universe data in an algorithm, call the `History<FutureUniverse>` method with continuous Future `Symbol` and a lookback period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```C#
// Add the Future and save a reference to it.
var future = AddFuture(Futures.Indices.HangSeng);

// Get historical data.
var history = History<FutureUniverse>(future.Symbol, 5);
```

For more information about historical International Future Universe data in algorithms, see Contracts .

Historical Data In Research

To get historical International Future Universe data in the Research Environment, call the `History<FutureUniverse>` method with continuous Future `Symbol` and a time period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```C#
// Add the Future and save a reference to it.
var future = qb.AddFuture(Futures.Indices.HangSeng);

// Get historical data.
var history = qb.History<FutureUniverse>(future.Symbol, new DateTime(2025, 1, 1), new DateTime(2025, 4, 1));
```

For more information about historical International Future Universe data in the Research Environment, see Daily Prices History .

Supported Assets

The following table shows the available Futures:

Ticker	Future	Start Date	Time Zone	Currency
HSI	Hang Seng Index Futures	Jan 2010	Asia/Hong Kong	HKD
DAX	German Index Futures	Jan 2010	Europe/Berlin	EUR
FESX	EURO STOXX 50 Index Futures	Jul 1998	Europe/Berlin	EUR
NKD	Nikkei 225 Index Futures	Jan 2007	America/Chicago	USD

Example Applications

The International Futures Universe dataset enables you to design Futures strategies accurately. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trade speculation on an International Index
- Trading bull calendar spreads to reduce volatility and margin requirements

Classic Algorithm Example

The following example algorithm uses the ZigZag indicator to determine the trend of Hang Seng Index. It then trades the Index with HSI Futures.

```C#
public class InternationalFuturesDataAlgorithm : QCAlgorithm
{
    private Future _hsiFuture;
    private ZigZag _zz;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the time zone to HKT to make it more comparable with the exchange.
        SetTimeZone(TimeZones.HongKong);
        // Set the account currency as HKD to trade HSI Futures.
        SetAccountCurrency("HKD", 1000000);

        // Seed the last price of the contracts for filling.
        Settings.SeedInitialPrices = true;

        // Request HSI Futures to trade.
        // Note that we will trade the contract with the highest open interest for liquidity.
        _hsiFuture = AddFuture(
            Futures.Indices.HangSeng,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.LastTradingDay,
            contractDepthOffset: 0
        );
        // Adds contracts that expiry within 90 days. We will trade the farthest contract
        _hsiFuture.SetFilter(0,90);
        // Request the corresponding underlying index for feeding indicators for trade signal generation.
        var hsiIndex = AddIndex("HSI").Symbol;

        // Create a ZigZag indicator to trade Hang Seng Index price pivot points.
        _zz = ZZ(hsiIndex, 0.15m, 5, Resolution.Daily);
        // Warm up indicator for immediate readiness to trade.
        WarmUpIndicator(hsiIndex, _zz, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        // Only place trade if the Future contracts is in market opening hours to avoid stale fills.
        if (IsMarketOpen(_hsiFuture.Symbol) && _zz.IsReady)
        {
            var pivot = _zz.PivotType;
            FuturesChain chain;
            // If the last pivot point is low, the current trend is increasing after this low point.
            if (pivot == PivotPointType.Low && slice.FutureChains.TryGetValue(_hsiFuture.Symbol, out chain))
            {
                var contract = chain.OrderBy(x => x.Expiry).LastOrDefault()?.Symbol;
                SetHoldings(contract, 0.2m);
            }
            // If the last pivot point is high, the current trend decreases after this high point.
            if (pivot == PivotPointType.High && slice.FutureChains.TryGetValue(_hsiFuture.Symbol, out chain))
            {
                var contract = chain.OrderBy(x => x.Expiry).LastOrDefault()?.Symbol;
                SetHoldings(contract, -0.2m);
            }
        }
    }
}
```

Data Point Attributes

The International Future Universe dataset provides `FutureFilterUniverse` and `FutureUniverse` objects.

FutureFilterUniverse Attributes

`FutureFilterUniverse` objects have the following attributes:

FutureUniverse Attributes

`FutureUniverse` objects have the following attributes:

QuantConnect

US ETF Constituents

Introduction

The US ETF Constituents dataset by QuantConnect tracks the constituents and weighting of US Equities in 2,650 ETF listings. The data starts in June 2009 and is delivered on a daily basis (monthly basis before January 2015). This dataset is created by tracking the host ETF websites and can be delayed by up to 1 week.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US ETF Constituents dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 160,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US ETF Constituents dataset:

```C#
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    // Use the following method for a Classic Algorithm
    _universe = AddUniverse(Universe.ETF("SPY", Market.USA, UniverseSettings, ETFConstituentsFilter));

    var symbol = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
    // Use the following method for a Framework Algorithm
    AddUniverseSelection(new ETFConstituentsUniverseSelectionModel(symbol, UniverseSettings, ETFConstituentsFilter));
}
private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable <ETFConstituentUniverse> constituents)
{
    // Add all Symbols of the ETFConstituentUniverse
    return constituents.Select(x => x.Symbol);
}
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	June 2009
Asset Coverage	2,650 US ETF Listings
Data Density	Dense
Resolution	Daily (Monthly before Jan 2015)
Timezone	New York

Requesting Data

To add US ETF Constituents data to your algorithm, call the `AddUniverse` and `Universe.ETF` methods. To select which constituents occupy the universe, provide the ETF `Symbol` and a selection function.

```
C#
public class ETFConstituentUniverseAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2018, 1, 1);
        SetEndDate(2020, 8, 25);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        _universe = AddUniverse(Universe.ETF("SPY", UniverseSettings, ETFConstituentsFilter));
    }
}
```

For more information about universe settings, see Settings .

Accessing Data

To access the US ETF Constituent data, use the `ETFConstituentUniverse` objects in your selection function. The data is available in daily resolution. The `Symbol` objects you return from your selection function defines the universe constituents.

```
C#
public IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
{
    foreach (var c in constituents)
    {
        Debug($"{c.EndTime} :: {c.LastUpdate} :: {c.Weight} :: {c.SharesHeld} :: {c.MarketValue}");
    }

    return constituents.Select(c => c.Symbol);
}
```

Historical Data

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var constituents in history)
{
    foreach (ETFConstituentUniverse constituent in constituents)
    {
        Log($"{constituent.Symbol} weight at {constituent.EndTime}: {constituent.Weight}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object and the lookback period. The `UniverseHistory` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var constituents in universeHistory )
{
    foreach (ETFConstituentUniverse constituent in constituents)
    {
        Console.WriteLine($"{constituent.Symbol} weight at {constituent.EndTime}: {constituent.Weight}");
    }
}
```

You can call the `History` method in Research.

Supported ETFs

The following table shows the available ETFs:

ETF Tickers					
AADR	AAIT	AAWW	AAXJ	ABCS	ABEQ

Example Applications

The ETF Constituents dataset provides an excellent source of tradable universes for strategies without selection bias. When you use an ETF universe, the original ETF can serve as an excellent benchmark for your strategy performance. Other use cases include the following:

- Creating an index-tracking algorithm for customized passive portfolio management
- Performing statistical arbitrage with the base ETF

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 10 largest US Equities in the SPY ETF. Each day, the algorithm forms a dollar-neutral and market-neutral portfolio by buying the 10 ETF constituents and shorting the SPY ETF.

```C#
public class ETFConstituentUniverseAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Create a dictionary to store the ETF weights each day.
    private Dictionary<Symbol, decimal> _weightBySymbol = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Add the SPY to trade.
        _spy = AddEquity("SPY").Symbol;
        // Add an ETF constituents universe that selects the large caps
        // in SPY. Save the universe object so you can get history
        // for the universe.
        var universe = AddUniverse(Universe.ETF(_spy, universeFilterFunc: SelectAssets));
        // Get historical universe data.
        var history = History(universe, 30, Resolution.Daily);
        // Show an example of iterating through the historical data.
        foreach (var constituents in history)
        {
            var t = constituents.EndTime;
            foreach (ETFConstituentUniverse constituent in constituents)
            {
                var symbol = constituent.Symbol;
                var weight = constituent.Weight;
            }
        }
        // Add a Scheduled Event to rebalance the portfolio each day.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.AfterMarketOpen(_spy, 1), Rebalance);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Select the 10 largest stocks in the SPY.
        _weightBySymbol = constituents.OrderByDescending(c => c.Weight).Take(10)
            // Save the weights for position sizing.
            .ToDictionary(c => c.Symbol, c => c.Weight ?? 0m);
        // Return the selected assets.
        return _weightBySymbol.Keys;
    }

    private void Rebalance()
    {
        // Create a long-short portfolio to earn the excess return of the
        // top 10 weighted stocks from SPY.
        var spyWeight = _weightBySymbol.Values.Sum();
        var targets = new List<PortfolioTarget>() { new PortfolioTarget(_spy, -0.5m) };
        foreach (var kvp in _weightBySymbol)
        {
            targets.Add(new PortfolioTarget(kvp.Key, 0.5m * kvp.Value / spyWeight));
        }
        // Liquidate the stocks that aren't in top 10.
        SetHoldings(targets, true);
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 10 largest US Equities in the SPY ETF. Each day, the algorithm forms a dollar-neutral and market-neutral portfolio by buying the 10 ETF constituents and shorting the SPY ETF.

```C#
public class ETFConstituentUniverseFrameworkAlgorithm : QCAlgorithm
{
    public Dictionary<Symbol, decimal> WeightBySymbol = [];

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        UniverseSettings.Asynchronous = false;
        UniverseSettings.Resolution = Resolution.Minute;
```

```
        UniverseSettings.Resolution = Resolution.Minute;

        // Add universe selection on SPY's constituents to select only from large cap stocks
        // Save the universe to access its members for historical data call
        var spy = AddEquity("SPY").Symbol;
        AddUniverseSelection(new ETFConstituentsUniverseSelectionModel(spy, UniverseSettings,
ETFConstituentsFilter));

        // Add alpha model that set normalized weight as investment insight
        AddAlpha(new ETFConstituentsAlphaModel(this, spy));

        // Set up portfolio construction model that invest by the insight weights
        SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel
        {
            // Avoid excessive rebalance on insight changes
            RebalanceOnInsightChanges = false
        });

        AddRiskManagement(new NullRiskManagementModel());

        SetExecution(new ImmediateExecutionModel());
    }

    private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // The top 10 weighted securities are considered better active selections
        // Save the weights for position sizing
        WeightBySymbol = constituents.Where(c=> c.Weight.HasValue).OrderByDescending(c => c.Weight).Take(10)
            .ToDictionary(c => c.Symbol, c => c.Weight.Value);

        return WeightBySymbol.Keys;
    }
}

public class ETFConstituentsAlphaModel : AlphaModel
{
    private int _day = -1;
    private Symbol _etf;
    private ETFConstituentUniverseFrameworkAlgorithm _algorithm;

    public ETFConstituentsAlphaModel(ETFConstituentUniverseFrameworkAlgorithm algorithm, Symbol etf)
    {
        _etf = etf;
        _algorithm = algorithm;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Rebalance daily since selection is on daily basis
        if (_day == algorithm.Time.Day)
        {
            return [];
        }

        _day = algorithm.Time.Day;

        var insights = new List<Insight>();

        // Create a long-short portfolio to earn excess return of the top 10 weighted stocks from SPY
        var etfWeight = (double)_algorithm.WeightBySymbol.Values.Sum();
        if (etfWeight > 0)
        {
            // Invest half the portfolio by normalized weights of the top 10 constituents
            foreach(var kvp in _algorithm.WeightBySymbol)
            {
                insights.Add(Insight.Price(kvp.Key, Expiry.EndOfDay, InsightDirection.Up, weight:
(double)kvp.Value/etfWeight * 0.5));
            }

            // Short the other half with SPY, looking to profit from the active selection
            insights.Add(Insight.Price(_etf, Expiry.EndOfDay, InsightDirection.Down, weight: 0.5));
        }

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        // Liquidate the ones not in top 10 weights
        var symbols = changes.RemovedSecurities.Where(x => x.Invested).Select(x => x.Symbol);
        algorithm.Liquidate(symbols, tag: "Removed From Universe");
    }
```

```
    }
}
```

Research Example

The following example lists ETF constituents with the greatest weight in the SPY:

```C#
var qb = new QuantBook();

// Add the ETF
var symbol = qb.AddEquity("SPY").Symbol;

// Add ETF Universe Selection
IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
{
    // Take the top 10 weighted constituents
    return constituents
        .OrderByDescending(c => c.Weight)
        .Take(10)
        .Select(c => c.Symbol);
}

var universe = qb.AddUniverse(qb.Universe.ETF(spy, qb.UniverseSettings, ETFConstituentsFilter));

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var constituents in universeHistory )
{
    foreach (ETFConstituentUniverse constituent in constituents)
    {
        Console.WriteLine($"{constituent.Symbol} weight at {constituent.EndTime}: {constituent.Weight}");
    }
}
```

Data Point Attributes

The ETF Constituents dataset provides `ETFConstituentUniverse` objects, which have the following attributes:

QuantConnect

US Equities Short Availability

Introduction

The US Equity Short Availability dataset provides the available shares for open short positions and their borrowing cost in the US Equity market. The data covers 10,500 US Equities, starts in January 2018, and is delivered on a daily frequency. This dataset is created using information from the exchanges.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Equities Short Availability dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippets demonstrate how to request data from the US Equities Short Availability dataset.

Interactive Brokers Data

```C#
security.SetShortableProvider(new InteractiveBrokersShortableProvider());
```

Axos Clearing Data

```C#
security.SetShortableProvider(new LocalDiskShortableProvider("axos"));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2018
Asset Coverage	10,500 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add US Equities Short Availability data to your algorithm, set the shortable provider of each US Equity in your algorithm.

```
C#

public class ShortAvailabilityDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        var security = AddEquity("AAPL");
        // Set shortable provider as IB
        security.SetShortableProvider(new InteractiveBrokersShortableProvider());
        _symbol = security.Symbol;
    }
}
```

Accessing Data

To check how many shares are available for a security to short, call the `ShortableQuantity` method of the `ShortableProvider`

```
C#

var shortableProvider = Securities[_symbol].ShortableProvider;
// Get the shortable quantity of the selected symbol at the selected time
var shortableQuantity = shortableProvider.ShortableQuantity(_symbol, Time);

// Check if there are a certain quantity of shares available
var quantity = 100;
var isShortableQuantity = Shortable(_symbol, quantity);
```

To check borrowing cost, call the `FeeRate` or `RebateRate` method of the `ShortableProvider`

```
C#

var feeRate = shortableProvider.FeeRate(_symbol, Time);
var rebateRate = shortableProvider.RebateRate(_symbol, Time);
```

To get valid borrowing rates, use the InteractiveBrokersShortableProvider .

Example Applications

The US Equities Short Availability dataset enables you to accurately design strategies harnessing information about short availability. Examples include the following use cases:

- Avoiding short orders that the brokerage will reject
- Selecting securities based on how many shares are available to short

Classic Algorithm Example

The following example algorithm shorts GameStop every day there are shares available to short. If the algorithm receives a margin call, it liquidates the position and start again on the next day.

C#

```
public class ShortAvailabilityDataAlgorithm : QCAlgorithm
{
    private Equity _equity;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000);
        // Seed the security price as the last known price, such that the price data is immediately available at
initial rebalance
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =>
        {
            // Set the shortable provider as your broker for accurate short reality modeling
            security.SetShortableProvider(new InteractiveBrokersShortableProvider());
        });

        _equity = AddEquity("GME");

        // Set up daily rebalance scheduled event, since shortable quantity is updated daily
        Schedule.On(
            DateRules.EveryDay(_equity.Symbol),
            TimeRules.AfterMarketOpen(_equity.Symbol, 10),
            Rebalance);
    }

    public void Rebalance()
    {
        var symbol = _equity.Symbol;

        // You can obtain the shortable quantity to decide the submission of a short order
        // Fee and rebate rate is also available, such that you can calculate the expected return and decide if the
margin is worthwhile
        Plot("Total Shortable Quantity", symbol, _equity.ShortableProvider.ShortableQuantity(symbol, Time) ?? 0m);
        Plot("Borrowing Cost", "Fee Rate", _equity.ShortableProvider.FeeRate(symbol, Time));
        Plot("Borrowing Cost", "Rebate Rate", _equity.ShortableProvider.RebateRate(symbol, Time));

        // Test whether we can short the desired quantity
        var quantity = CalculateOrderQuantity(symbol, -1m);
        if (quantity != 0 && Shortable(symbol, quantity))
        {
            MarketOrder(symbol, quantity);
        }
    }

    public override void OnMarginCallWarning()
    {
        Liquidate();
    }
}
```

Framework Algorithm Example

The following example algorithm shorts GameStop every day there are shares available to short. If the algorithm receives a margin call, it liquidates the position and start again on the next day.

C#

```
public class ShortAvailabilityDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000);
        // Seed the security price as the last known price, such that the price data is immediately available at
initial rebalance
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =>
        {
            // Set the shortable provider as your broker for accurate short reality modeling
            security.SetShortableProvider(new InteractiveBrokersShortableProvider());
        });

        SetUniverseSelection(new ManualUniverseSelectionModel(
            QuantConnect.Symbol.Create("GME", SecurityType.Equity, Market.USA)));

        // Emit down-direction insights to short all securities in the universe
        SetAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Down, TimeSpan.FromDays(1)));
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ShortableExecutionModel());
    }

    // On Margin Call, emit flat-direction insights to liquidate the positions
    public override void OnMarginCallWarning()
    {
        EmitInsights(Securities
            .Where(kvp => kvp.Value.Invested)
            .Select(kvp => Insight.Price(kvp.Key, TimeSpan.FromDays(1), InsightDirection.Flat))
            .ToArray());
    }

    public class ShortableExecutionModel : ImmediateExecutionModel
    {
        private readonly PortfolioTargetCollection _targetsCollection = new PortfolioTargetCollection();

        public override void Execute(QCAlgorithm algorithm, IPortfolioTarget[] targets)
        {
            _targetsCollection.AddRange(targets);
            // for performance we check count value, OrderByMarginImpact and ClearFulfilled are expensive to call
            if (_targetsCollection.Count > 0)
            {
                foreach (var target in _targetsCollection.OrderByMarginImpact(algorithm))
                {
                    // calculate remaining quantity to be ordered
                    var quantity = OrderSizing.GetUnorderedQuantity(algorithm, target);
                    // If the quantity is negative, ensure that the security is shortable
                    if (quantity > 0 || algorithm.Shortable(target.Symbol, quantity))
                    {
                        algorithm.MarketOrder(target.Symbol, quantity);
                    }
                }

                _targetsCollection.ClearFulfilled(algorithm);
            }
        }
    }
}
```

Data Point Attributes

The US Equities Short Availability data is a `Symbol` /decimal pair for `ShortQuantity` , `FeeRate` , and `RebateRate` .

QuantConnect

US Equity Coarse Universe

Introduction

The US Equity Coarse Universe dataset by QuantConnect is a daily universe of all trading stocks in the US for a given day with the end of day price and volume. The data covers 30,000 US Equities in total, with approximately 8,000 Equities per day. The data starts in January 1998 and is delivered each trading day. This dataset is created by taking the closing auction price tick from the daily L1 trade and quote exchange dumps.

This dataset depends on the US Equities by AlgoSeek dataset because universe selection adds and removes market data subscriptions and on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

QuantConnect/LEAN combines the data of this dataset with MorningStar Fundamental data in runtime. You can use this dataset in local development without the Morningstar counterpart.

For more information about the US Equity Coarse Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Equity Coarse Universe dataset:

- Direct Access using the Security object

```C#
var equity = AddEquity("IBM");
var ibmFundamental = equity.Fundamentals;
```

- Direct Access using the Symbol object

```C#
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);
var ibmFundamental = Fundamentals(ibm);
```

- Universe Selection

```C#
public override void Initialize()
{
    // Universe selection
    _universe = AddUniverseSelection(new FundamentalUniverseSelectionModel(FundamentalFilterFunction));
}

public override List<Symbol> FundamentalFilterFunction(List<Fundamental> fundamental)
{
    // Sort all equities with price above $10 by dollar volume, take the top 10
    return (from f in fundamental
            where f.Price > 10
            orderby f.DollarVolume descending
            select f.Symbol).Take(10);
}
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	30,000 US Equities
Data Density	Dense
Resolution	Daily
Timezone	New York

This dataset doesn't include Over-the-Counter (OTC) stocks.

Requesting Data

You don't need any special code to request US Coarse Fundamental Data. You can access the current and historical fundamental data for any of the US Equities that this dataset includes.

```C#
public class CoarseFundamentalDataAlgorithm : QCAlgorithm
{
    private Universe _universe;
    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 7, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;

        // Option 1: Subscribe to individual US Equity assets
        AddEquity("IBM");

        // Option 2A: Create a fundamental universe (classic version)
        _universe = AddUniverse(FundamentalFilterFunction);

        // Option 2B: Create a fundamental universe (framework version)
        AddUniverseSelection(new FundamentalUniverseSelectionModel(FundamentalFilterFunction));
    }
}
```

For more information about universe settings, see Settings .

Accessing Data

If you add a fundamental universe to your algorithm, you can access fundamental data in the universe selection function.

```
C#
public IEnumerable<Symbol> FundamentalFunction(IEnumerable<Fundamental> fundamental)
{
    var sortedByDollarVolume = fundamental
        .OrderByDescending(x => x.DollarVolume)
        .Take(3).ToList();

    foreach (var cf in sortedByDollarVolume)
    {
        Debug($"{cf.EndTime} :: {cf.Symbol} : {cf.AdjustedPrice} :: {cf.DollarVolume}");
    }

    return sortedByDollarVolume.Select(x => x.Symbol);
}
```

To get fundamental data for Equities in your algorithm, use the `Fundamentals` property of the `Equity` objects. The fundamental data represent the corporate fundamentals for the current algorithm time.

```
C#
var fundamentals = Securities[symbol].Fundamentals;
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `Fundamentals` method. If you pass one `Symbol` , the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects.

```
C#
// Single asset
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);
var ibmFundamental = Fundamentals(ibm);

// Multiple assets
var nb = QuantConnect.Symbol.Create("NB", SecurityType.Equity, Market.USA);
var fundamentals = Fundamentals(new List<Symbol>{ nb, ibm }).ToList();
```

Historical Data

You can get historical fundamental data in an algorithm and in the Research Environment.

Historical Data in Algorithms

To get historical fundamental data in an algorithm, call the `History` method with `Fundamental` type and the Equity `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);

// Fundamental objects
var fundamentalHistory = History<Fundamental>(ibm, TimeSpan.FromDays(30));

// Fundamentals objects for all US Equities (including delisted companies)
var fundamentalsHistory = History<Fundamentals>(TimeSpan.FromDays(30));

// Collection of Fundamental objects for all US Equities (including delisted companies)
var collectionHistory = History(_universe, 30, Resolution.Daily);
foreach (var fundamental in collectionHistory)
{
    // Cast to Fundamental is required
    var mostLiquid = fundamental.OfType<Fundamental>().OrderByDescending(x => x.DollarVolume).Take(5);
}
```

Historical Universe Data in Research

To get historical universe data in the Research Environment, call the `UniverseHistory` method with the `Universe` object and the lookback period. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var fundamentals in universeHistory)
{
    foreach (Fundamental fundamental in fundamentals)
    {
        Console.WriteLine($"{fundamental.Symbol} dollar volume at {fundamental.EndTime}:
{fundamental.DollarVolume}");
    }
}
```

For more information about historical US Equity fundamental data, see Equity Fundamental Data .

Example Applications

The US Equity Coarse Universe dataset enables you to accurately design a universe of US Equities. Examples include the following strategies:

- Selecting securities with the largest dollar volume
- Selecting securities within a specific price range
- Selecting securities that have fundamental data available (together with MorningStar Fundamental data in `Fundamental` objects)

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the three most liquid US Equities. Each time the universe changes, the algorithm forms an equal-weighted portfolio of the three companies.

C#

```
public class USEquityCoarseUniverseConstituentsDataAlgorithm : QCAlgorithm
{
    private int _numberOfSymbols = 3;
    private SecurityChanges _changes = SecurityChanges.None;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Set Asynchronous to true to improve speed performance
        UniverseSettings.Asynchronous = true;
        // Requesting data
        var universe = AddUniverse(SelectAssets);
        // Get historical data for the universe.
        var history = History(universe, 30, Resolution.Daily);
        foreach (var fundamentals in history)
        {
            // Iterate through each asset in the universe on this day
            // and access its data point attributes.
            foreach (Fundamental f in fundamentals)
            {
                var symbol = f.Symbol;
                var t = f.EndTime;
                var dollarVolume = f.DollarVolume;
            }
        }
    }

    public IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> fundamental)
    {
        // Select the top traded stocks, since they are the most popular
        // with high capital flow.
        return fundamental.OrderByDescending(x => x.DollarVolume)
            .Take(_numberOfSymbols).Select(x => x.Symbol);
    }

    public override void OnData(Slice slice)
    {
        // If we have no changes, do nothing.
        if (slice.Bars.Count == 0 || _changes == SecurityChanges.None) return;
        // Liquidate removed securities, since they are not the most
        // popular stocks.
        foreach (var security in _changes.RemovedSecurities)
        {
            if (security.Invested)
            {
                Liquidate(security.Symbol);
            }
        }
        // We want 1/N allocation for each security in our universe to
        // evenly dissipate risk.
        foreach (var security in _changes.AddedSecurities)
        {
            SetHoldings(security.Symbol, 1m / _numberOfSymbols);
        }
        _changes = SecurityChanges.None;
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _changes = changes;
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the three most liquid US Equities and forms an equal-weighted portfolio with them.

```C#
public class USEquityCoarseUniverseConstituentsDataAlgorithm : QCAlgorithm
{
    private int _numberOfSymbols = 3;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Set Asynchronous to true to improve speed performance
        UniverseSettings.Asynchronous = true;

        // Requesting data
        SetUniverseSelection(
            new FundamentalUniverseSelectionModel(FundamentalSelectionFunction));

        // we want 1/N allocation in each security in our universe to evenly dissipate risk
        SetAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        AddRiskManagement(new NullRiskManagementModel());

        SetExecution(new ImmediateExecutionModel());
    }

    public IEnumerable<Symbol> FundamentalSelectionFunction(IEnumerable<Fundamental> fundamental)
    {
        // Select the top traded stocks, since they are the most popular with high capital flow
        return fundamental.OrderByDescending(x => x.DollarVolume)
            .Take(_numberOfSymbols).Select(x => x.Symbol);
    }
}
```

Research Example

The following example lists the three most liquid US Equities:

```C#
var qb = new QuantBook();

// Add Fundamental Universe Selection
IEnumerable<Symbol> FundamentalSelectionFunction(IEnumerable<Fundamental> fundamentals)
{
    return fundamentals.OrderByDescending(x => c.DollarVolume).Take(10).Select(x => c.Symbol);
}

var universe = qb.AddUniverse(FundamentalSelectionFunction);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var fundamentals in universeHistory)
{
    foreach (Fundamental fundamental in fundamentals)
    {
        Console.WriteLine($"{fundamental.Symbol} dollar volume at {fundamental.EndTime}:
{fundamental.DollarVolume}");
    }
}
```

Data Point Attributes

The US Equity Coarse Universe dataset provides its data within `Fundamental` objects, which have the following . The attributes from `MarketCap` to `AssetClassification` listed in the following widget are NaN until this dataset is combined with the MorningStar Fundamental dataset.

QuantConnect

US Equity Option Universe

Introduction

The US Equity Option Universe dataset by QuantConnect lists the available US Equity Options contracts and the current Implied Volatility and Greeks. The data covers 4,000 Symbols, starts in January 2012, and is delivered on a daily update frequency. To create this dataset, we use our implementation of the forward tree pricing model, which accounts for the interest rate, dividend payments, and daily closing prices. The values in this dataset are the same values you can get from daily indicators with mirror Options.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes of the underlying security.

This dataset `does not` contain market data. For market data, see US Equity Options by AlgoSeek .

For more information about the US Equity Option Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Equity Options Universe dataset:

```C#
var option = AddOption("GOOG");
_optionSymbol = option.Symbol;
option.SetFilter(universe => universe.delta(0.4m, 0.6m));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	4,000 Symbols
Data Density	Dense
Resolution	Daily
Timezone	New York

Requesting Data

To add US Equity Options Universe data to your algorithm, call the `AddOption` method. Save a reference to the Equity Option `Symbol` so you can access the data later in your algorithm. To define which contracts should be in your universe, call the `SetFilter` method of the Option object.

The `AddOption` method provides a daily stream of Option chain data. To get the most recent daily chain, call the `OptionChain` method with the underlying Equity Symbol. The `OptionChain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```C#
public class USEquityOptionsDataAlgorithm : QCAlgorithm
{
    private Symbol _optionSymbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        // Requesting data
        var option = AddOption("GOOG");
        _optionSymbol = option.Symbol;
        // Set our strike/expiry filter for this option chain
        option.SetFilter(OptionFilter);
        // Get the entire Option chain for the current day.
        var chain = OptionChain(option.Symbol.Underlying);
    }

    private OptionFilterUniverse OptionFilter(OptionFilterUniverse universe)
    {
        // Contracts can be filtered by greeks, implied volatility, open interest:
        return universe
            .Delta(0.5m, 1.5m)
            .Gamma(0.0001m, 0.0006m)
            .Vega(0.01m, 1.5m)
            .Theta(-2.0m, -0.5m)
            .Rho(0.5m, 3.0m)
            .ImpliedVolatility(1.0m, 3.0m)
            .OpenInterest(100, 500);
    }
}
```

The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.

For more information about creating US Equity Option Universes, see Equity Options .

Accessing Data

For information about accessing US Equity Options Universe data, see Equity Options .

Historical Data

You can get historical US Equity Options Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Equity Options Universe data in an algorithm, call the `History<OptionUniverse>` method with the canonical Equity Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter. If there is no data in the period you request, the history result is empty.

```C#
// OptionUniverse objects
var history = History<OptionUniverse>(_optionSymbol, TimeSpan.FromDays(3)).ToList();
```

For more information about historical Equity Options Universe data in algorithms, see Historical Data .

Historical Data In Research

To get historical US Equity Options Universe data in the Research Environment, call the `History<OptionUniverse>` method with the canonical Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter.

```
C#
var qb = new QuantBook();
var option = qb.AddOption("GOOG");
var history = qb.History<OptionUniverse>(option.Symbol, new DateTime(2020, 6, 1), new DateTime(2020, 6, 6));
foreach (var chain in history)
{
    var endTime = chain.EndTime;
    var filteredContracts = chain.Data
        .Select(contract => contract as OptionUniverse)
        .Where(contract => contract.Greeks.Delta > 0.3m);
    foreach (var contract in filteredContracts)
    {
        var price = contract.Price;
        var iv = contract.ImpliedVolatility;
    }
}
```

For more information about historical Equity Options Universe data in the Research Environment, see Universes .

Supported Assets

To view the supported assets in the US Equity Options Universe dataset, see the Data Explorer .

Example Applications

The US Equity Options Universe dataset enables you to accurately design Option strategies. Examples include the following strategies:

- Buying put Options to hedge against downward price movement in positive Equity positions
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviate from their theoretical value

Classic Algorithm Example

The following example algorithm subscribes to Google put options that fall within delta range between -1 and -0.95, open interest range between 10 and 1000, and expire within seven days. Within this Option chain, the algorithm holds the put Option contract that has the minimum delta (closest to -1) during market hour to hedge the underlying intra-day movement completely. It avoid volatility from sentiment and only earns from inter-day movement from longer-term factors. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```
C#
public class USEquityOptionsUniverseAlgorithm : QCAlgorithm
{
    private Symbol _equity, _optionSymbol, _hedge;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);
        // Asynchronous can use computational resources efficiently
        UniverseSettings.Asynchronous = true;

        // Subscribe to the underlying for the underlying position
        // Set the data normalization mode to raw for strike price comparability
        _equity = AddEquity("GOOG", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
        // Requesting option data and filter for the hedge candidates
        var option = AddOption(_equity);
```

```
        var option = AddOption(_equity);
        _optionSymbol = option.Symbol;
        option.SetFilter(OptionFilter);

        // Set scheduled event to buy a hedge option contract at market open to eliminate the intra-day movement
        Schedule.On(
            DateRules.EveryDay(_equity),
            TimeRules.AfterMarketOpen(_equity, 1),
            BuyHedgeContract
        );

        // Set a scheduled event to sell the hedge contract before market close, since we want to earn from inter-day
movement
        // Leave 2 minutes contingency to fill
        Schedule.On(
            DateRules.EveryDay(_equity),
            TimeRules.BeforeMarketClose(_equity, 2),
            SellHedgeContract
        );
    }

    private OptionFilterUniverse OptionFilter(OptionFilterUniverse universe)
    {
        // Select the contracts with delta very close to -1 and high open interest
        // This can effectively hedge most of the price change of the underlying and ensure the liquidity
        // Make sure the contract is expiring close for its tradbility
        return universe
            .IncludeWeeklys()
            .PutsOnly()
            .Expiration(2, 7)
            .Delta(-1m, -0.95m)
            .OpenInterest(10, 1000);
    }

    private void BuyHedgeContract()
    {
        if (CurrentSlice.OptionChains.TryGetValue(_optionSymbol, out var chain))
        {
            // Order the underlying if not hold, the order size should match the option contract
            // Order only if option chain data ready for hedging
            if (!Portfolio[_equity].Invested)
            {
                MarketOrder(_equity, Securities[_optionSymbol].SymbolProperties.ContractMultiplier);
            }

            // Get the contract with delta closest to -1 (lowest possible delta)
            var contract = chain.MinBy(x => x.Greeks.Delta);
            _hedge = contract.Symbol;
            // Buy 1 deep ITM put with delta close to -1 to eliminate the intraday movement
            MarketOrder(_hedge, 1);
        }
    }

    private void SellHedgeContract()
    {
        // Check if any hedge contract position, if so, liquidate before market close to expose to underlying
overnight movement
        if (_hedge != null)
        {
            Liquidate(_hedge);
            _hedge = null;
        }
    }
}
```

Framework Algorithm Example

The following example algorithm demonstrating a Gamma Scalping strategy through framework algorithm. It filters NVDA options with expiration between 30 to 90 days and open interest between 50 and 1000, due to liquidity concern and lower Gamma fluctuation. Assuming a significant upward trend is expecting, it orders a long straddle strategy from the strike price with Delta-neutral and the highest Gamma to earn the highest profit from upward underlying movement.

C#

```
public class USEquityOptionsUniverseFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
```

```
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Asynchronous can use computational resources efficiently
        UniverseSettings.Asynchronous = true;

        // Universe selection that select based on liquidity of the option contracts (by open interest)
        AddUniverseSelection(new EquityOptionsUniverseSelectionModel());
        // Custom alpha model that use Delta and Gamma to signal insights
        AddAlpha(new OptionDeltaGammaAlphaModel());
        // To maintain long-short size equal, use a PCM that order a single contract
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

class EquityOptionsUniverseSelectionModel : OptionUniverseSelectionModel
{
    // Daily update with the SelectOptionChainSymbols function
    public EquityOptionsUniverseSelectionModel()
            : base(TimeSpan.FromDays(1), SelectOptionChainSymbols) {}

    private static IEnumerable<Symbol> SelectOptionChainSymbols(DateTime utcTime)
    {
        // Select only NVDA options as our focus, which is a highly traded volatile equity with great upward momentum
        return new[] {QuantConnect.Symbol.Create("NVDA", SecurityType.Option, Market.USA)};
    }

    protected override OptionFilterUniverse Filter(OptionFilterUniverse filter)
    {
        // To ensure the liquidity and tradability, make sure the option is not 0-DTE and have a fair open interest
        // A longer TTM will have lower Gamma thus more stable in the local delta-neutral position
        return filter
            .IncludeWeeklys()
            .Expiration(30, 90)
            .OpenInterest(50, 1000);
    }
}

class OptionDeltaGammaAlphaModel : AlphaModel
{
    // A day count variable to control the alpha model only trade once a day
    private int _day = -1;

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        if (_day != slice.Time.Day)
        {
            // We open position for each option underlying as separate bet
            foreach (var kvp in slice.OptionChains)
            {
                var chain = kvp.Value;

                // For theta-neutral, select the same expiry for both call and put
                var expiry = chain.Min(x => x.Expiry);
                var contracts = chain.Where(x => x.Expiry == expiry).ToList();

                // Calculate delta and gamma per strike price group for later filtering, ensure both call and put
available for option strategy
                var deltaGammaSymbols = new List<(decimal, decimal, Symbol, Symbol)>();
                var strikes = contracts.Select(x => x.Strike)
                    .Where(x => contracts.Count(y => y.Strike == x) == 2)
                    .Distinct();
                foreach (var strike in strikes)
                {
                    // Get both call and put for their aggregated delta and gamma
                    var call = contracts.Single(x => x.Right == OptionRight.Call && x.Strike == strike);
                    var put = contracts.Single(x => x.Right == OptionRight.Put && x.Strike == strike);
                    deltaGammaSymbols.Add((call.Greeks.Delta + put.Greeks.Delta, call.Greeks.Gamma +
put.Greeks.Gamma, call.Symbol, put.Symbol));
                }

                if (deltaGammaSymbols.Count == 0)
                {
                    continue;
                }

                // We want a delta-neutral position, so it is likely to be ATM (like a long straddle)
                // Less than 2d.p. difference is non-significant, which we can pick for better reward
```

```
                // Less than 2d.p. difference is non-significant, which we can risk for better reward
                // Assuming the market direction is up in most scenario, we try to get the strike providing max
overall Gamma
                // Make sure the aggregated gamma to be positive to bet on large uptrend
                // So it will earn more when the price really go up higher and higher, but locally immune for small
noise
                var filtered = deltaGammaSymbols.Where(item => Math.Round(item.Item1, 2) <= 0.01m && item.Item2 >
0).ToList();
                if (filtered.Count == 0)
                {
                    continue;
                }
                var selected = filtered.OrderByDescending(item => item.Item2).First();

                // Provide trade signal and roll the day count to let the position stay for the whole day
                var selectedCall = selected.Item3;
                var selectedPut = selected.Item4;
                insights.AddRange(new[] {
                    Insight.Price(selectedCall, Expiry.EndOfDay, InsightDirection.Up),
                    Insight.Price(selectedPut, Expiry.EndOfDay, InsightDirection.Up)
                });
                _day = slice.Time.Day;
            }
        }

        return insights;
    }
}

class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
{
    public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
    {
        var targets = new List<PortfolioTarget>();
        foreach (var insight in insights)
        {
            if (algorithm.Securities[insight.Symbol].IsTradable)
            {
                // Use a whole number target to order the exact number of share for size-matching
                targets.Add(new PortfolioTarget(insight.Symbol, (int) insight.Direction));
            }
        }
        return targets;
    }
}
```

Data Point Attributes

The US Equity Options Universe dataset provides `OptionFilterUniverse` , `OptionUniverse` , and `OptionChain` objects.

OptionFilterUniverse Attributes

`OptionFilterUniverse` objects have the following attributes:

OptionUniverse Attributes

`OptionUniverse` objects have the following attributes:

OptionChain Attributes

`OptionChain` objects have the following attributes:

QuantConnect

US Equity Security Master

Introduction

The US Equity Security Master dataset by QuantConnect tracks US Equity corporate actions, including splits, dividends, delistings, mergers, and ticker changes through history. The data covers approximately 27,500 US Equities, starts in January 1998, and is delivered on a daily update frequency. You can easily download and install the dataset with the LEAN CLI so it's ready to use by LEAN. LEAN automatically handles all corporate actions and passes them into your algorithm as events .

This is `NOT` the underlying Equity data (US Equities dataset), which you need to purchase separately with a license from AlgoSeek. This security master dataset is required to purchase the US Equities or US Equities Options datasets.

For more information about the US Equity Security Master dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Data Summary

Data is delivered as a daily updated zip archive of map and factor files. The data is designed to be used in the LEAN Engine and cannot be consumed another way. The following table shows the dataset properties:

Property	**Value**
Start Date	January 1998
Data Points	Splits, Dividends, Mergers, IPO, & Delistings
Asset Coverage	27,500 US Equities
Resolution	Daily
Timezone	New York

This is `not` the underlying Equity data (US Equities dataset), which you need to purchase separately with a license from AlgoSeek. This security master dataset is required to purchase the US Equities or US Equities Options datasets.

Getting Started

You don't need any special code to utilize the US Equity Security Master. It automatically loads when you request US Equities data .

Accessing Splits

To get the current split data, index the `Splits` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid

issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    // Check if any splits for the symbol
    if (slice.Splits.ContainsKey(_symbol))
    {
        // If so, get the mapped split object
        var split = slice.Splits[_symbol];
        Log($"Split: {split.Symbol}\t{split.SplitFactor}\t{split.ReferencePrice}\t{split.Type}");
    }
}
```

For more information about accessing splits, see Splits .

Accessing Dividends

To get the current dividend data, index the `Dividends` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    // Check if any dividend for the symbol
    if (slice.Dividends.ContainsKey(_symbol))
    {
        // If so, get the mapped dividend object
        var dividend = slice.Dividends[_symbol];
        Log($"Dividend: {dividend.Symbol}\t{dividend.Distribution}\t{dividend.ReferencePrice}");
    }
}
```

For more information about accessing dividends, see Dividends .

Accessing Delistings

To get the current Delistings data, index the `Delistings` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    // Check if any delisting for the symbol
    if (slice.Delistings.ContainsKey(_symbol))
    {
        // If so, get the mapped delisting object
        var delisting = slice.Delistings[_symbol];
        Log($"Delistings: {delisting.Type}");
    }
}
```

For more information about accessing delistings, see Delistings .

Accessing Symbol Change Events

To get the current Symbol change events, index the `SymbolChangedEvents` property of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice){
    // Check if any symbol change event for the symbol
    if (slice.SymbolChangedEvents.ContainsKey(_symbol))
    {
        // If so, get the mapped SymbolChangeEvent object
        var symbolChangedEvent = slice.SymbolChangedEvents[_symbol];
        Log($"Symbol changed: {symbolChangedEvent.OldSymbol} -> {symbolChangedEvent.NewSymbol}");
    }
}
```

For more information about accessing Symbol change events, see Symbol Changes .

Historical Data

To get historical US Equity Security Master data, call the `History` method with the data type and the Equity `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// Splits
var splitHistory = History<Split>(_symbol, TimeSpan.FromDays(5*365));

// Dividends
var dividendHistory = History<Dividend>(_symbol, TimeSpan.FromDays(5*365));

// Symbol Changes
var symbolChangeHistory = History<SymbolChangedEvent>(_symbol, TimeSpan.FromDays(5*365));

// Delistings
var delistingHistory = History<Delisting>(_symbol, TimeSpan.FromDays(5*365));
```

For more information about historical data, see History Requests .

Live Trading Considerations

In backtesting, corporate actions occurs at midnight (ET). In live trading, the live data for corporate actions arrives at 6/7 AM ET, so that's when they occur.

Supported Assets

To view the supported assets in the US Equity Security Master dataset, see the Data Explorer . This dataset doesn't include Over-the-Counter (OTC) stocks.

Example Applications

The US Security Master enables you to accurately design strategies harnessing any core corporate actions. Examples include the following strategies:

- Post-dividend announcement trading strategies.
- Trading on new Equities by monitoring for IPOs.
- Harnessing split announcements for reverse-split announcement momentum.

Classic Algorithm Example

The following example algorithm logs the `Split` , `Dividend` , `Delisting` , and `SymbolChangedEvent` objects of Apple:

```
public class USEquitySecurityMasterAlgorithm : QCAlgorithm { private Symbol _equity; public override void Initialize() { SetStartDate(2024, 9, 1); SetEndDate(2024, 12, 31); SetCash(1000000); _equity = AddEquity("AAPL", Resolution.Daily).Symbol; } public override void OnData(Slice slice) { // Accessing Data - Splits if (slice.Splits.ContainsKey(_equity)) { var split = slice.Splits[_equity]; Debug($"Split: {split.Symbol}\t{split.SplitFactor}\t{split.ReferencePrice}\t{split.Type}"); } // Accessing Data - Dividends if (slice.Dividends.ContainsKey(_equity)) { var dividend = slice.Dividends[_equity]; Log($"Dividend: {dividend.Symbol}\t{dividend.Distribution}\t{dividend.ReferencePrice}"); } // Accessing Data - Delisting if (slice.Delistings.ContainsKey(_equity)) { var delisting = slice.Delistings[_equity]; Log($"Delistings: {delisting.Type}"); } // Accessing Data - Symbol Changed Event if (slice.SymbolChangedEvents.ContainsKey(_equity)) { var symbolChangedEvent = slice.SymbolChangedEvents[_equity]; Log($"Symbol changed: {symbolChangedEvent.OldSymbol} -> {symbolChangedEvent.NewSymbol}"); } } }
```

Framework Algorithm Example

The following algorithm demonstrates the payments for cash dividends in backtesting. When the data normalization mode is `Raw`, your portfolio receives cash dividends.

C#

```
public class PaymentsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // this will use the Tradier Brokerage open order split behavior
        // forward split will modify open order to maintain order value
        // reverse split open orders will be canceled
        SetBrokerageModel(BrokerageName.TradierBrokerage);

        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;

        // MSFT: Splits and Dividends
        // GOOG: Symbol Changed Event
        // AAA.1: Delisting
        SetUniverseSelection(new ManualUniverseSelectionModel(
            QuantConnect.Symbol.Create("MSFT", SecurityType.Equity, Market.USA)));

        SetAlpha(new PaymentAlphaModel());
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new BracketExecutionModel());
    }
}

public class PaymentAlphaModel : AlphaModel
{
    private Symbol _symbol = Symbol.Empty;

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Accessing Data - Splits
        if (slice.Splits.ContainsKey(_symbol))
        {
            var split = slice.Splits[_symbol];
            algorithm.Debug($"{split.Time.ToIso8601Invariant()} >> SPLIT >> {split.Symbol} - " +
                $"{split.SplitFactor.ToStringInvariant()} - " +
                $"{algorithm.Portfolio.Cash.ToStringInvariant()} - " +
                $"{algorithm.Portfolio[_symbol].Quantity.ToStringInvariant()}");
        }

        // Accessing Data - Dividends
        if (slice.Dividends.ContainsKey(_symbol))
        {
            var dividend = slice.Dividends[_symbol];
            algorithm.Debug($"{dividend.Time.ToStringInvariant("o")} >> DIVIDEND >> {dividend.Symbol} - " +
                $"{dividend.Distribution.ToStringInvariant("C")} - {algorithm.Portfolio.Cash} - " +
                $"{algorithm.Portfolio[_symbol].Price.ToStringInvariant("C")}");
        }

        // Accessing Data - Delisting
        if (slice.Delistings.ContainsKey(_symbol))
        {
```

```
            var delisting = slice.Delistings[_symbol];
            algorithm.Debug($"{delisting.Time.ToStringInvariant("o")} >> DELISTING >> {delisting.Type}");
        }

        // Accessing Data - Symbol Changed Event
        if (slice.SymbolChangedEvents.ContainsKey(_symbol))
        {
            var symbolChangedEvent = slice.SymbolChangedEvents[_symbol];
            algorithm.Debug($"{symbolChangedEvent.Time.ToStringInvariant("o")} >> Symbol Changed Event >> " +
                $"{symbolChangedEvent.OldSymbol} -> {symbolChangedEvent.OldSymbol}");
        }

        return slice.Bars.ContainsKey(_symbol)
            ? new [] { Insight.Price(_symbol, TimeSpan.FromDays(1), InsightDirection.Up) }
            : Enumerable.Empty<Insight>();
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        _symbol = changes.AddedSecurities.First().Symbol;
    }
}

public class BracketExecutionModel : ExecutionModel
{
    private readonly PortfolioTargetCollection _targetsCollection = new PortfolioTargetCollection();

    public override void Execute(QCAlgorithm algorithm, IPortfolioTarget[] targets)
    {
        _targetsCollection.AddRange(targets);
        // for performance we check count value, OrderByMarginImpact and ClearFulfilled are expensive to call
        if (_targetsCollection.Count > 0)
        {
            foreach (var target in _targetsCollection.OrderByMarginImpact(algorithm))
            {
                // calculate remaining quantity to be ordered
                var quantity = OrderSizing.GetUnorderedQuantity(algorithm, target);
                if (quantity != 0 && algorithm.Transactions.OrdersCount == 0)
                {
                    var bar = algorithm.Securities[target.Symbol].GetLastData() as TradeBar;
                    algorithm.MarketOrder(target.Symbol, quantity);
                    // place some orders that won't fill, when the split comes in they'll get modified to reflect the
split
                    algorithm.StopMarketOrder(target.Symbol, -quantity, bar.Low/2);
                    algorithm.LimitOrder(target.Symbol, -quantity, bar.High*2);
                }
            }

            _targetsCollection.ClearFulfilled(algorithm);
        }
    }
}
```

Data Point Attributes

The US Equity Security Master dataset provides `Split` , `Dividend` , `Delisting` , and `SymbolChangedEvent` objects.

Split Attributes

When a split or merger occurs, we pass the previous `Symbol` data into your algorithm. `Split` objects have the following attributes:

Dividend Attributes

Dividend events are triggered on the payment date. `Dividend` objects have the following attributes:

Delisting Attributes

When a security is delisted, we notify your algorithm. `Delisting` objects have the following attributes:

SymbolChangedEvent Attributes

When a security changes their ticker, we notify your algorithm. `SymbolChangedEvent` objects have the following attributes:

QuantConnect

US Future Option Universe

Introduction

The US Future Option Universe dataset by QuantConnect lists the available US Future Options contracts and the current open interest. The data covers 15 Monthly Future contracts, starts in January 2012, and is delivered on a daily update frequency. This dataset is created by monitoring the trading activity on the CME, CBOT, NYMEX, and COMEX markets.

The US Future Option Universe dataset depends on the US Future Universe dataset because the US Future Universe dataset contains the universe of underlying Futures contracts. This dataset also depends on the US Futures Security Master dataset because the US Futures Security Master dataset contains information on symbol changes of the contracts.

This dataset `does not` contain market data. For market data, see US Future Options by AlgoSeek .

For more information about the US Future Option Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Future Options Universe dataset:

```C#
var future = AddFuture(Futures.Metals.Gold, Resolution.Minute);
future.SetFilter(0, 90);
AddFutureOption(future.Symbol, universe => universe.Strikes(-1, 1));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	15 Monthly Future Contracts. Standard expires only. No weeklies or 0DTE contracts.
Data Density	Dense
Resolution	Daily
Timezone	New York
Market Hours	Regular and Extended

Requesting Data

To add US Future Options Universe data to your algorithm, call the `AddFutureOption` method. To define which contracts should be in your universe, specify the filter when requesting the Future Option data.

The `AddFutureOption` method provides a daily stream of Option chain data. To get the most recent daily chain, call the `OptionChain` method with the underlying Future Symbol. The `OptionChain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```
C#
public class USFutureOptionsDataAlgorithm : QCAlgorithm
{
    private Future _future;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;

        _future = AddFuture(Futures.Metals.Gold, Resolution.Minute);
        _future.SetFilter(0, 90);
        // Set our strike/expiry filter for this option chain
        AddFutureOption(_future.Symbol, OptionFilter);
    }

    public override void OnData(Slice slice)
    {
        // Create canonical symbol for the mapped future contract, since option chains are mapped by canonical
symbol.
        var symbol = QuantConnect.Symbol.CreateCanonicalOption(_future.Mapped);
        // Get the entire Option chain for the current day.
        var chain = OptionChain(symbol);
    }

    private OptionFilterUniverse OptionFilter(OptionFilterUniverse universe)
    {
        // Contracts can be filtered by strike, and expiration
        return universe.Strikes(-1, 1);
    }
}
```

The Future resolution must be less than or equal to the Future Option resolution. For example, if you set the Future resolution to minute, then you must set the Future Option resolution to minute, hour, or daily.

For more information about creating US Future Option universes, see Future Options .

Accessing Data

For information about accessing US Future Options Universe data, see Future Options .

Historical Data

You can get historical US Future Options Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Options Universe data in an algorithm, call the `History<OptionUniverse>` method with the canonical mapped Future Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter. If there is no data in the period you request, the history result is empty.

```
C#
var futureOptionSymbol = QuantConnect.Symbol.CreateCanonicalOption(_future.Mapped);
var history = History<OptionUniverse>(futureOptionSymbol, TimeSpan.FromDays(10)).ToList();
```

For more information about historical US Future Options Universe data in algorithms, see Historical Data .

Historical Data In Research

To get historical US Future Options Universe data in the Research Environment, call the `History<OptionUniverse>` method with the canonical Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter.

```
C#
var qb = new QuantBook();
var future = qb.AddFuture(Futures.Metals.Gold, Resolution.Minute);
var symbol = QuantConnect.Symbol.CreateCanonicalOption(future.Mapped);
var history = qb.History<OptionUniverse>(symbol, new DateTime(2020, 6, 1), new DateTime(2020, 6, 6));
foreach (var chain in history)
{
    var endTime = chain.EndTime;
    var filteredContracts = chain.Data
        .Select(contract => contract as OptionUniverse)
        .Where(contract => contract.Greeks.Delta > 0.3m);
    foreach (var contract in filteredContracts)
    {
        var price = contract.Price;
        var iv = contract.ImpliedVolatility;
    }
}
```

For more information about historical Future Options Universe data in the Research Environment, see Universes .

Supported Assets

The following list shows the available (15) Futures Options:

- `Futures.Energy.CrudeOilWTI` : Crude Oil WTI Futures (NYMEX: LO | Underlying: CL)
- `Futures.Energy.Gasoline` : Gasoline RBOB Futures (NYMEX: OB | Underlying: RB)
- `Futures.Energy.HeatingOil` : Heating Oil Futures (NYMEX: OH | Underlying: HO)
- `Futures.Energy.NaturalGas` : Natural Gas Futures (NYMEX: ON | Underlying: NG)
- `Futures.Financials.Y10TreasuryNote` : 10Y U.S. Treasury Note Futures (CBOT: OZN | Underlying: ZN)
- `Futures.Financials.Y2TreasuryNote` : 2Y U.S. Treasury Note Futures (CBOT: OZT | Underlying: ZT)
- `Futures.Financials.Y30TreasuryBond` : 30Y U.S. Treasury Bond Futures (CBOT: OZB | Underlying: ZB)
- `Futures.Grains.Corn` : Corn Futures (CBOT: OZC | Underlying: ZC)
- `Futures.Grains.Soybeans` : Soybeans Futures (CBOT: OZS | Underlying: ZS)
- `Futures.Grains.Wheat` : Default wheat contract is SRWWheat (CBOT: OZW | Underlying: ZW)
- `Futures.Indices.NASDAQ100EMini` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.SP500EMini` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Metals.Copper` : Copper Futures (COMEX: HXE | Underlying: HG)
- `Futures.Metals.Gold` : Gold Futures (COMEX: OG | Underlying: GC)
- `Futures.Metals.Silver` : Silver Futures (COMEX: SO | Underlying: SI)

Example Applications

The US Future Options dataset enables you to accurately design Future Option strategies. Examples include the following strategies:

- Selling out of the money Future Option contracts to collect the premium that the Option buyer pays
- Buying put Options to hedge against downward price movement in Future contracts you bought
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviate from their theoretical value

Classic Algorithm Example

The following example demonstrates a bull call spread Option strategy using universe filtering.

```C#
public class FutureOptionAlgorithm : QCAlgorithm
{
    private Future _underlying;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Filter the underlying continuous Futures to narrow the FOP spectrum.
        _underlying = AddFuture(Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        _underlying.SetFilter(0, 182);
        // Use CallSpread filter to obtain the 2 best-matched contracts that forms a call spread.
        // It simplifies from further filtering and reduce computation on redundant subscription.
        AddFutureOption(_underlying.Symbol, (u) => u.CallSpread(5, 5, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested)
            return;

        // Create canonical symbol for the mapped future contract, since we need that to access the option chain.
        var symbol = QuantConnect.Symbol.CreateCanonicalOption(_underlying.Mapped);

        // Get option chain data for the mapped future only.
        // It requires 2 contracts with different strikes to form a call spread, so we make sure at least 2 contracts
are present.
        if (!slice.OptionChains.TryGetValue(symbol, out var chain) || chain.Count() < 2)
            return;

        // Separate the contracts by strike, as we need to access their strike.
        var expiry = chain.Min(x => x.Expiry);
        var itmStrike = chain.Min(x => x.Strike);
        var otmStrike = chain.Max(x => x.Strike);

        // Use abstraction method to order a bull call spread to avoid manual error.
        var optionStrategy = OptionStrategies.BullCallSpread(symbol, itmStrike, otmStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Future Universe dataset:

```C#
var future = AddFuture(Futures.Metals.Gold);
future.SetFilter(0, 90);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2009
Asset Coverage	157 Futures
Data Density	Dense
Resolution	Daily
Timezone	• Chicago (CFE, CME or CBOT) • New York (ICE, NYMEX or COMEX)
Market Hours	Regular and Extended

Requesting Data

To add US Future Universe data to your algorithm, call the `AddFuture` method. Save a reference to the Future object so you can access the data later in your algorithm. To define which contracts should be in your universe, specify the filter when requesting the Future data.

The `AddFuture` method provides a daily stream of Future chain data. To get the most recent daily chain, call the `FuturesChain` method with the underlying Future Symbol. The `FuturesChain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

```
C#

public class USFutureDataAlgorithm : QCAlgorithm
{
    private Future _future;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        _future = AddFuture(Futures.Metals.Gold);
        // Set our contract filter for this Future chain.
        _future.SetFilter((universe) => universe.StandardsOnly().FrontMonth());
        // Get the entire Futures chain for the current day.
        var chain = FuturesChain(_future.Symbol);
    }
}
```

For more information about creating US Future universes, see Futures .

Accessing Data

For information about accessing US Future Universe data, see Futures .

Historical Data

You can get historical US Future Universe data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Universe data in an algorithm, call the `History<FutureUniverse>` method with continuous Future `Symbol` and a lookback period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```
C#

// Add the Future and save a reference to it.
var future = AddFuture(Futures.Metals.Gold);

// Get historical data.
var history = History<FutureUniverse>(future.Symbol, 5);
```

For more information about historical US Future Universe data in algorithms, see Contracts .

Historical Data In Research

To get historical US Future Universe data in the Research Environment, call the `History<FutureUniverse>` method with continuous Future `Symbol` and a time period. This method returns the all the available contracts for each trading day, not the subset of contracts that pass your universe filter. If there is no data for the period you requested, the history result is empty.

```
// Add the Future and save a reference to it.
var future = qb.AddFuture(Futures.Metals.Gold);

// Get historical data.
var history = qb.History<FutureUniverse>(future.Symbol, new DateTime(2025, 1, 1), new DateTime(2025, 4, 1));
```

For more information about historical US Future Universe data in the Research Environment, see Daily Prices History .

Supported Assets

The following list shows the available (157) Futures:

- `Futures.Currencies.AUD` : Australian Dollar Futures (CME: 6A)
- `Futures.Currencies.AUDCAD` : Australian Dollar/Canadian Dollar Futures (CME: ACD)
- `Futures.Currencies.AUDJPY` : Australian Dollar/Japanese Yen Futures (CME: AJY)
- `Futures.Currencies.AUDNZD` : Australian Dollar/New Zealand Dollar Futures (CME: ANE)
- `Futures.Currencies.BRL` : Brazillian Real Futures (CME: 6L)
- `Futures.Currencies.BTC` : Bitcoin Futures (CME: BTC)
- `Futures.Currencies.BTICMicroBTC` : BTIC on Micro Bitcoin Futures (CME: MIB)
- `Futures.Currencies.BTICMicroEther` : BTIC on Micro Ether Futures (CME: MRB)
- `Futures.Currencies.CAD` : Canadian Dollar Futures (CME: 6C)
- `Futures.Currencies.CADJPY` : Canadian Dollar/Japanese Yen Futures (CME: CJY)
- `Futures.Currencies.CHF` : Swiss Franc Futures (CME: 6S)
- `Futures.Currencies.ETH` : Ether Futures (CME: ETH)
- `Futures.Currencies.EUR` : Euro FX Futures (CME: 6E)
- `Futures.Currencies.EURAUD` : Euro/Australian Dollar Futures (CME: EAD)
- `Futures.Currencies.EURCAD` : Euro/Canadian Dollar Futures (CME: ECD)
- `Futures.Currencies.EuroFXEmini` : E-mini Euro FX Futures (CME: E7)
- `Futures.Currencies.EURSEK` : Euro/Swedish Krona Futures (CME: ESK)
- `Futures.Currencies.GBP` : British Pound Futures (CME: 6B)
- `Futures.Currencies.JapaneseYenEmini` : E-mini Japanese Yen Futures (CME: J7)
- `Futures.Currencies.JPY` : Japanese Yen Futures (CME: 6J)
- `Futures.Currencies.MicroAUD` : Micro AUD/USD Futures (CME: M6A)
- `Futures.Currencies.MicroBTC` : Micro Bitcoin Futures (CME: MBT)
- `Futures.Currencies.MicroCAD` : Micro USD/CAD Futures (CME: M6C)
- `Futures.Currencies.MicroCADUSD` : Micro CAD/USD Futures (CME: MCD)
- `Futures.Currencies.MicroCHF` : Micro CHF/USD Futures (CME: MSF)
- `Futures.Currencies.MicroEther` : Micro Ether Futures (CME: MET)
- `Futures.Currencies.MicroEUR` : Micro EUR/USD Futures (CME: M6E)
- `Futures.Currencies.MicroGBP` : Micro GBP/USD Futures (CME: M6B)
- `Futures.Currencies.MicroINRUSD` : Micro INR/USD Futures (CME: MIR)
- `Futures.Currencies.MicroJPY` : Micro JPY/USD Futures (CME: MJY)
- `Futures.Currencies.MicroUSDCHF` : Micro USD/CHF Futures (CME: M6S)
- `Futures.Currencies.MicroUSDCNH` : Micro USD/CNH Futures (CME: MNH)
- `Futures.Currencies.MicroUSDJPY` : Micro USD/JPY Futures (CME: M6J)
- `Futures.Currencies.MXN` : Mexican Peso Futures (CME: 6M)
- `Futures.Currencies.NZD` : New Zealand Dollar Futures (CME: 6N)

- `Futures.Currencies.RUB` : Russian Ruble Futures (CME: 6R)
- `Futures.Currencies.StandardSizeUSDOffshoreRMBCNH` : Standard-Size USD/Offshore RMB (CNH) Futures (CME: CNH)
- `Futures.Currencies.ZAR` : South African Rand Futures (CME: 6Z)
- `Futures.Energy.ArgusLLSvsWTIArgusTradeMonth` : Argus LLS vs. WTI (Argus) Trade Month Futures (NYMEX: AE5)
- `Futures.Energy.ArgusPropaneFarEastIndex` : Argus Propane Far East Index Futures (NYMEX: A7E)
- `Futures.Energy.ArgusPropaneSaudiAramco` : Argus Propane (Saudi Aramco) Futures (NYMEX: A9N)
- `Futures.Energy.BrentCrudeOilVsDubaiCrudeOilPlatts` : Brent Crude Oil vs. Dubai Crude Oil (Platts) Futures (NYMEX: ADB)
- `Futures.Energy.BrentLastDayFinancial` : Brent Last Day Financial Futures (NYMEX: BZ)
- `Futures.Energy.ChicagoEthanolPlatts` : Chicago Ethaanol (Platts) Futures (NYMEX: CU)
- `Futures.Energy.ConwayPropaneOPIS` : Conway Propane (OPIS) Futures (NYMEX: A8K)
- `Futures.Energy.CrudeOilWTI` : Crude Oil WTI Futures (NYMEX: CL)
- `Futures.Energy.DubaiCrudeOilPlattsFinancial` : Dubai Crude Oil (Platts) Financial Futures (NYMEX: DCB)
- `Futures.Energy.EastWestGasolineSpreadPlattsArgus` : East-West Gasoline Spread (Platts-Argus) Futures (NYMEX: EWG)
- `Futures.Energy.EastWestNaphthaJapanCFvsCargoesCIFNWESpreadPlatts` : East-West Naphtha: Japan C&F vs. Cargoes CIF NWE Spread (Platts) Futures (NYMEX: EWN)
- `Futures.Energy.Ethanol` : Ethanol Futures (CBOT: EH)
- `Futures.Energy.EthanolT2FOBRdamIncludingDutyPlatts` : Ethanol T2 FOB Rdam Including Duty (Platts) Futures (NYMEX: AZ1)
- `Futures.Energy.EuropeanNaphthaPlattsCrackSpread` : European Naphtha (Platts) Crack Spread Futures (NYMEX: EN)
- `Futures.Energy.EuropeanPropaneCIFARAArgus` : European Propane CIF ARA (Argus) Futures (NYMEX: APS)
- `Futures.Energy.EuropeanPropaneCIFARAArgusVsNaphthaCargoesCIFNWEPlatts` : European Propane CIF ARA (Argus) vs. Naphtha Cargoes CIF NWE (Platts) Futures (NYMEX: EPN)
- `Futures.Energy.FreightRouteTC14Baltic` : Freight Route TC14 (Baltic) Futures (NYMEX: FRC)
- `Futures.Energy.Gasoline` : Gasoline RBOB Futures (NYMEX: RB)
- `Futures.Energy.GasolineEurobobOxyNWEBargesArgus` : Gasoline Euro-bob Oxy NWE Barges (Argus) Futures (NYMEX: B7H)
- `Futures.Energy.GroupThreeSuboctaneGasolinePlattsVsRBOB` : Group Three Sub-octane Gasoliine (Platts) vs. RBOB Futures (NYMEX: AA8)
- `Futures.Energy.GroupThreeULSDPlattsVsNYHarborULSD` : Group Three ULSD (Platts) vs. NY Harbor ULSD Futures (NYMEX: AA6)
- `Futures.Energy.GulfCoastCBOBGasolineA2PlattsVsRBOBGasoline` : Gulf Coast CBOB Gasoline A2 (Platts) vs. RBOB Gasoline Futures (NYMEX: CRB)
- `Futures.Energy.GulfCoastHSFOPlattsVsEuropeanThreePointFivePercentFuelOilBargesFOBRdamPlatts` : Gulf Coast HSFO (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: GCU)
- `Futures.Energy.HeatingOil` : Heating Oil Futures (NYMEX: HO)
- `Futures.Energy.LosAngelesCARBOBGasolineOPISvsRBOBGasoline` : Los Angeles CARBOB Gasoline (OPIS) vs. RBOB Gasoline Futures (NYMEX: AJL)
- `Futures.Energy.LosAngelesCARBDieselOPISvsNYHarborULSD` : Los Angeles CARB Diesel (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AKL)
- `Futures.Energy.LosAngelesJetOPISvsNYHarborULSD` : Los Angeles Jet (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AJS)
- `Futures.Energy.MarsArgusVsWTIFinancial` : Mars (Argus) vs. WTI Financial Futures (NYMEX: AYX)
- `Futures.Energy.MarsArgusVsWTITradeMonth` : Mars (Argus) vs. WTI Trade Month Futures (NYMEX: AYV)
- `Futures.Energy.MicroCrudeOilWTI` : Micro WTI Crude Oil Futures (NYMEX: MCL)

- `Futures.Energy.MicroEuropeanFOBRdamMarineFuelZeroPointFivePercentBargesPlatts` : Micro European FOB Rdam Marine Fuel 0.5% Barges (Platts) Futures (NYMEX: R5O)
- `Futures.Energy.MicroEuropeanThreePointFivePercentOilBargesFOBRdamPlatts` : Micro European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: MEF)
- `Futures.Energy.MicroGasoilZeroPointOnePercentBargesFOBARAPlatts` : Micro Gasoil 0.1% Barges FOB ARA (Platts) Futures (NYMEX: M1B)
- `Futures.Energy.MicroSingaporeFOBMarineFuelZeroPointFivePercetPlatts` : Micro Singapore FOB Marine Fuel 0.5% (Platts) Futures (NYMEX: S5O)
- `Futures.Energy.MicroSingaporeFuelOil380CSTPlatts` : Micro Singapore Fuel Oil 380CST (Platts) Futures (NYMEX: MAF)
- `Futures.Energy.MiniEuropeanThreePointPercentFiveFuelOilBargesPlatts` : Mini European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: A0D)
- `Futures.Energy.MiniSingaporeFuelOil180CstPlatts` : Mini Singapore Fuel Oil 180 cst (Platts) Futures (NYMEX: A0F)
- `Futures.Energy.MontBelvieuEthaneOPIS` : Mont Belvieu Ethane (OPIS) Futures (NYMEX: AC0)
- `Futures.Energy.MontBelvieuLDHPropaneOPIS` : Mont Belvieu LDH Propane (OPIS) Futures (NYMEX: B0)
- `Futures.Energy.MontBelvieuNaturalGasolineOPIS` : Mont Belvieu Natural Gasoline (OPIS) Futures (NYMEX: A7Q)
- `Futures.Energy.MontBelvieuNormalButaneOPIS` : Mont Belvieu Normal Butane (OPIS) Futures (NYMEX: AD0)
- `Futures.Energy.NaturalGas` : Natural Gas Futures (NYMEX: NG)
- `Futures.Energy.NaturalGasHenryHubLastDayFinancial` : Natural Gas (Henry Hub) Last-day Financial Futures (NYMEX: HH)
- `Futures.Energy.NaturalGasHenryHubPenultimateFinancial` : Natural Gas (Henry Hub) Penultimate Financial Futures (NYMEX: HP)
- `Futures.Energy.OnePercentFuelOilCargoesFOBNWEPlattsVsThreePointFivePercentFuelOilBargesFOBRdamPlatts` : 1% Fuel Oil Cargoes FOB NWE (Platts) vs. 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: FSS)
- `Futures.Energy.PremiumUnleadedGasoline10ppmFOBMEDPlatts` : Premium Unleaded Gasoline 10 ppm FOB MED (Platts) Futures (NYMEX: A3G)
- `Futures.Energy.PropaneNonLDHMontBelvieuOPIS` : Propane Non-LDH Mont Belvieu (OPIS) Futures (NYMEX: A1R)
- `Futures.Energy.RBOBGasolineCrackSpread` : RBOB Gasoline Crack Spread Futures (NYMEX: ARE)
- `Futures.Energy.RBOBGasolineVsEurobobOxyNWEBargesArgusThreeHundredFiftyThousandGallons` : RBOB Gasoline vs. Euro-bob Oxy NWE Barges (Argus) (350,000 gallons) Futures (NYMEX: EXR)
- `Futures.Energy.SingaporeFuelOil380cstPlattsVsEuropeanThreePointFivePercentFuelOilBargesFOBRdamPlatts` : Singapore Fuel Oil 380 cst (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: EVC)
- `Futures.Energy.SingaporeGasoilPlattsVsLowSulphurGasoilFutures` : Singapore Gasoil (Platts) vs. Low Sulphur Gasoil Futures (NYMEX: AGA)
- `Futures.Energy.SingaporeMogas92UnleadedPlattsBrentCrackSpread` : Singapore Mogas 92 Unleaded (Platts) Brent Crack Spread Futures (NYMEX: D1N)
- `Futures.Energy.ThreePointFivePercentFuelOilBargesFOBRdamPlattsCrackSpread` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread Futures (NYMEX: FO)
- `Futures.Energy.ThreePointFivePercentFuelOilBargesFOBRdamPlattsCrackSpread1000mt` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread (1000mt) Futures (NYMEX: BOO)
- `Futures.Energy.WTIBrentFinancial` : WTI-Brent Financial Futures (NYMEX: BK)
- `Futures.Energy.WTIFinancial` : WTI Financial Futures (NYMEX: CSX)
- `Futures.Energy.WTIHoustonArgusVsWTITradeMonth` : WTI Houston (Argus) vs. WTI Trade Month Futures (NYMEX: HTT)
- `Futures.Energy.WTIHoustonCrudeOil` : WTI Houston Crude Oil Futures (NYMEX: HCL)
- `Futures.Financials.EuroDollar` : EuroDollar Futures (CME: GE)
- `Futures.Financials.FiveYearUSDMACSwap` : 5-Year USD MAC Swap Futures (CBOT: F1U)

- `Futures.Financials.MicroY10TreasuryNote` : Micro 10-Year Yield Futures (CBOT: 10Y)
- `Futures.Financials.MicroY2TreasuryBond` : Micro 2-Year Yield Futures (CBOT: 2YY)
- `Futures.Financials.MicroY30TreasuryBond` : Micro 30-Year Yield Futures (CBOT: 30Y)
- `Futures.Financials.MicroY5TreasuryBond` : Micro 5-Year Yield Futures (CBOT: 5YY)
- `Futures.Financials.UltraTenYearUSTreasuryNote` : Ultra 10-Year U.S. Treasury Note Futures (CBOT: TN)
- `Futures.Financials.UltraUSTreasuryBond` : Ultra U.S. Treasury Bond Futures (CBOT: UB)
- `Futures.Financials.Y10TreasuryNote` : 10Y U.S. Treasury Note Futures (CBOT: ZN)
- `Futures.Financials.Y2TreasuryNote` : 2Y U.S. Treasury Note Futures (CBOT: ZT)
- `Futures.Financials.Y30TreasuryBond` : 30Y U.S. Treasury Bond Futures (CBOT: ZB)
- `Futures.Financials.Y5TreasuryNote` : 5Y U.S. Treasury Note Futures (CBOT: ZF)
- `Futures.Forestry.Lumber` : Lumber Futures (CME: LBR)
- `Futures.Forestry.RandomLengthLumber` : Random Length Lumber Futures (CME: LBS)
- `Futures.Grains.BlackSeaCornFinanciallySettledPlatts` : Black Sea Corn Financially Settled (Platts) Futures (CBOT: BCF)
- `Futures.Grains.BlackSeaWheatFinanciallySettledPlatts` : Black Sea Wheat Financially Settled (Platts) Futures (CBOT: BWF)
- `Futures.Grains.Corn` : Corn Futures (CBOT: ZC)
- `Futures.Grains.HRWWheat` : KC HRW Wheat Futures (CBOT: KE)
- `Futures.Grains.Oats` : Oats Futures (CBOT: ZO)
- `Futures.Grains.Soybeans` : Soybeans Futures (CBOT: ZS)
- `Futures.Grains.SoybeanMeal` : Soybean Meal Futures (CBOT: ZM)
- `Futures.Grains.SoybeanOil` : Soybean Oil Futures (CBOT: ZL)
- `Futures.Grains.Wheat` : Default wheat contract is SRWWheat (CBOT: ZW)
- `Futures.Indices.BloombergCommodityIndex` : Bloomberg Commodity Index Futures (CBOT: AW)
- `Futures.Indices.Dow30EMini` : E-mini Dow Indu 30 Futures (CBOT: YM)
- `Futures.Indices.DowJonesRealEstate` : Dow Jones Real Estate futures on CME (CME: RX)
- `Futures.Indices.FTSEEmergingEmini` : E-mini FTSE Emerging Index Futures (CME: EI)
- `Futures.Indices.MicroDow30EMini` : Micro E-mini Dow Jones Industrial Average Index Futures (CBOT: MYM)
- `Futures.Indices.MicroNASDAQ100EMini` : Micro E-mini Nasdaq-100 Index Futures (CME: MNQ)
- `Futures.Indices.MicroRussell2000EMini` : Micro E-mini Russell 2000 Index Futures (CME: M2K)
- `Futures.Indices.MicroSP500EMini` : Micro E-mini S&P 500 Index Futures (CME: MES)
- `Futures.Indices.NASDAQ100BiotechnologyEMini` : E-mini Nasdaq-100 Biotechnology Index Futures (CME: BIO)
- `Futures.Indices.NASDAQ100EMini` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.Nikkei225Dollar` : Nikkei-225 Dollar Futures (CME: NKD)
- `Futures.Indices.Nikkei225YenCME` : Nikkei-225 Yen denominated Futures on CME (CME: NIY)
- `Futures.Indices.Russell1000EMini` : E-mini Russell 1000 futures on CME (CME: RS1)
- `Futures.Indices.Russell2000EMini` : E-mini Russell 2000 Futures (CME: RTY)
- `Futures.Indices.SPGSCICommodity` : S&P-GSCI Commodity Index Futures (CME: GD)
- `Futures.Indices.SP400MidCapEmini` : E-mini S&P MidCap 400 Futures (CME: EMD)
- `Futures.Indices.SP500AnnualDividendIndex` : (CME: SDA)
- `Futures.Indices.SP500EMini` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Indices.TOPIXYEN` : YEN Denominated Topix Index Futures on CME (CME: TPY)
- `Futures.Indices.USDDenominatedIbovespa` : USD-Denominated Ibovespa Index Futures (CME: IBV)
- `Futures.Indices.VIX` : CBOE Volatility Index Futures (CFE: VX)
- `Futures.Meats.FeederCattle` : Feeder Cattle Futures (CME: GF)

- `Futures.Meats.LeanHogs` : Lean Hogs Futures (CME: HE)
- `Futures.Meats.LiveCattle` : Live Cattle Futures (CME: LE)
- `Futures.Metals.AluminiumEuropeanPremiumDutyPaidMetalBulletin` : Aluminium European Premium Duty-Paid (Metal Bulletin) Futures (COMEX: EDP)
- `Futures.Metals.AluminumMWUSTransactionPremiumPlatts25MT` : Aluminum MW U.S. Transaction Premium Platts (25MT) Futures (COMEX: AUP)
- `Futures.Metals.Copper` : Copper Futures (COMEX: HG)
- `Futures.Metals.Gold` : Gold Futures (COMEX: GC)
- `Futures.Metals.MicroGold` : Micro Gold Futures (COMEX: MGC)
- `Futures.Metals.MicroGoldTAS` : Micro Gold TAS Futures (COMEX: MGT)
- `Futures.Metals.MicroPalladium` : Micro Palladium Futures (NYMEX: PAM)
- `Futures.Metals.MicroSilver` : Micro Silver Futures (COMEX: SIL)
- `Futures.Metals.Palladium` : Palladium Futures (NYMEX: PA)
- `Futures.Metals.Platinum` : Platinum Futures (NYMEX: PL)
- `Futures.Metals.Silver` : Silver Futures (COMEX: SI)
- `Futures.Metals.USMidwestDomesticHotRolledCoilSteelCRUIndex` : U.S. Midwest Domestic Hot-Rolled Coil Steel (CRU) Index Futures (NYMEX: HRC)
- `Futures.Softs.Sugar11` : Sugar #11 Futures ICE (ICE: SB)
- `Futures.Softs.Sugar11CME` : Sugar #11 Futures CME (NYMEX: YO)

Example Applications

The US Future Universe dataset enables you to accurately design Futures strategies. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trading bull calendar spreads to reduce volatility and margin requirements
- Trading bull calendar spreads to speculate contango

Classic Algorithm Example

The following example algorithm selects and buys the front-month Mini Gold Futures contract and sells the front-month Micro Gold Futures contract. When the front-month contract changes, the algorithm rebalances the portfolio.

C#

```
public class USFuturesDataAlgorithm : QCAlgorithm
{
    private Future _miniGold;
    private Future _microGold;
    // Save a cache of the mapped symbol to trade.
    private Dictionary<Symbol, FuturesContract?> _contract = new ();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        UniverseSettings.Asynchronous = true;

        // Requesting data on gold and micro-gold contracts.
        // Filter the universe to trade only the contracts expiring within 90 days to ensure liquidity.
        _miniGold = AddFuture(Futures.Metals.Gold);
        _miniGold.SetFilter(0, 90);
        _contract.Add(_miniGold.Symbol, null);

        _microGold = AddFuture(Futures.Metals.MicroGold);
        _microGold.SetFilter(0, 90);
        _contract.Add(_microGold.Symbol, null);
    }

    public override void OnData(Slice slice)
    {
        foreach (var (symbol, chain) in slice.FutureChains)
        {
            if (_contract.ContainsKey(symbol))
            {
                // Select the contract with the greatest open interest to trade with the most efficiency.
                var mostLiquidContract = chain.OrderBy(x => x.OpenInterest).Last();

                if (_contract[symbol] == null || mostLiquidContract.Symbol != _contract[symbol].Symbol)
                {
                    // Liquidate any unmapped contracts.
                    if (_contract[symbol] != null)
                    {
                        Liquidate(_contract[symbol].Symbol);
                    }
                    _contract[symbol] = mostLiquidContract;

                    // Buy mini-gold and short micro-gold contracts as planned.
                    if (symbol == _miniGold.Symbol)
                    {
                        MarketOrder(_contract[symbol].Symbol, 1);
                    }
                    else if (symbol == _microGold.Symbol)
                    {
                        MarketOrder(_contract[symbol].Symbol, -1);
                    }
                }
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm selects and buys the front-month Mini Gold Futures contract and sells the front-month Micro Gold Futures contract. When the front-month contract changes, the algorithm rebalances the portfolio.

C#

```
public class USFuturesDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        UniverseSettings.Asynchronous = true;
        // Set up an universe selection model that selects the front month contract
        SetUniverseSelection(new FrontMonthFutureUniverseSelectionModel());
        SetAlpha(new ConstantFuturesAlphaModel());
```

```
        SetAlpha(new ConstantFuturesAlphaModel());
        // A portfolio construction model that only order a single share per insight signal
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

class FrontMonthFutureUniverseSelectionModel : FutureUniverseSelectionModel
{
    // Daily updating with select_future_chain_symbols function
    public FrontMonthFutureUniverseSelectionModel()
        : base(TimeSpan.FromDays(1), SelectFutureChainSymbols) {}

QuantConnect

US Futures Security Master

Introduction

The US Futures Security Master dataset by QuantConnect provides mapping reference data for the most liquid contracts of the CME Group exchanges, calculated with popular rolling techniques. The data covers 157 root Future contracts, starts in May 2009, and is delivered on a daily frequency with a zip file with all the contract mappings. This dataset is created by daily processing of the US historical Future chains.

This dataset, paired with the US Futures dataset, supports the following rolling techniques: forward panama canal, backwards panama canal, and backwards ratio. You can set the specific rolling date to occur on the last trading day, first day month, or the day when the contract with the greatest open interest changes.

VIX Futures don't support continous contract rolling with open interest.

This is `NOT` the underlying Futures data (US Futures dataset), which you need to purchase separately with a license from AlgoSeek. This security master dataset is required to purchase the US Futures or US Future Options datasets.

For more information about the US Futures Security Master dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

You don't need any special code to utilize the US Futures Security Master. It automatically loads when you request US Futures data .

Data Summary

The following table describes the dataset properties:

Property	**Value**
Start Date	May 2009
Asset Coverage	157 Liquid Futures
Data Density	Regular
Resolution	Daily

VIX Futures don't support continous contract rolling with open interest.

Key Concept

The US Futures Security Master lets you to construct continuous Futures, allowing the access of normalized historical data of the underlying assets, as well as trading the “lead” Future contracts for those assets.

Continuous Futures refer to sets of rolling lead Future contracts during their actively trading periods. Since Future contracts expire at their maturities, to analyze the historical price of a Future and to apply technical indicators, you need the continuous Future price series.

To access the continuous Future, use the Future's `Symbol` property.

```C#
// Set the data normalization mode and data mapping mode to select the contract as the continuous contract with price
adjustment for smooth price series
var future = AddFuture(Futures.Energy.CrudeOilWTI,
    dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
    dataMappingMode: DataMappingMode.OpenInterest,
    contractDepthOffset: 0
);
_continuousFutureSymbol = future.Symbol;
```

The `dataNormalizationMode` and `dataMappingMode` arguments makes the transition of the underlying contracts seemless. However, the Future `Symbol` doesn't map to an underlying Future contract. It works fine to trade within backtests, but could be subjected to friction costs during live trading since the order price could be a normalized price. For more information about this topic, see the `Live Trading Considerations` section.

Data Normalization Modes

The data normalization mode defines how the price series of two contracts are stitched together when the contract rollovers occur. The `DataNormalizatoinMode` enumeration has the following members available for continuous contracts:

If you use a data normalization mode that's not in the preceding list, LEAN automatically converts it to `DataNormalizationMode.BackwardsRatio` .

Data Mapping Modes

The data mapping mode defines when contract rollovers occur. The `DataMappingMode` enumeration has the following members:

VIX Futures don't support continous contract rolling with `DataMappingMode.OpenInterest` and `DataMappingMode.OpenInterestAnnuak` .

Tracking Contract Changes

As the contracts roll over, the `Mapped` property of the `Future` object references the next contract in the series and you receive a `SymbolChangedEvent` . To get the current `Symbol` change events, index the `SymbolChangedEvents` property of the current `Slice` with the continuous Futures `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Future at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    // Get Symbol Change Event of the Continuous Future (change in mapped contract)
    if (slice.SymbolChangedEvents.TryGetValue(_continuousFutureSymbol, out var changedEvent))
    {
        var oldSymbol = changedEvent.OldSymbol;
        var newSymbol = AddFutureContract(changedEvent.NewSymbol).Symbol;
        var tag = $"Rollover - Symbol changed at {Time}: {oldSymbol} -> {newSymbol}";
        var quantity = Portfolio[oldSymbol].Quantity;
        // Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped contract
        Liquidate(oldSymbol, tag: tag);
        if (quantity != 0) MarketOrder(newSymbol, quantity, tag: tag);
        Log(tag);
    }
}
```

`SymbolChangedEvent` objects have the following attributes:

Live Trading Considerations

You can trade continuous Futures, but the continuous Future `Symbol` doesn't map to a single underlying Future contract. Instead, it represents a set of rolling contracts. Thus, the prices could be frictional during a contract rollover, which could be catastrophic in live trading! For live trading, you should place your orders directly on the underlying contracts. To get the current underlying contract in the continuous Future series, use the `Mapped` property.

```C#
// Get the mapped symbol
var currentContract = _continuousContract.Mapped;
Buy(currentContract, 1);
```

Data Format

If you download the files in the US Futures Security Master, you get a factor file and a map file for each of the exchanges with supported continuous Futures. To view the files, see the *|data|future|<exchange_name>* directory under your LEAN CLI base directory.

For the factor file, it is a `.zip` collection of REST API styled `.csv` files for each Future `Symbol`, including the date, scaling factors for each type of data normalization and the data mapping mode that indicates the Symbol changing event is on that day for that mapping mode. The following line is an example line in the `.csv` file:

{"Date":"2009-10-31T00:00:00","BackwardsRatioScale":[0.99141630901287553648068669 53,1.0,1.0],"BackwardsPanamaCanalScale":[-2.0,0.0,0.0],"ForwardPanamaCanalScale":[0.0,0.0,0.0],"DataMappingMode":1}

For the map file, it is a `.zip` collection of `.csv` files for each Future `Symbol`, including the date, new underlying contract Symbol, the exchange code, and the data mapping mode that indicates the Symbol changing event is on that day for that mapping mode. The following line is an example line in the `.csv` file:

```
20091130,aw uii3j0m6zbj9,CBOT,1
```

Historical Data

You can get historical US Future Security Master data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Security Master data in an algorithm, call the `History<SymbolChangedEvent>` method with continuous Future `Symbol` and a lookback period. This method returns the old and new contract of each rollover. If there is no data for the period you requested, the history result is empty.

```
// Add the Future and define its rollover settings.
var future = AddFuture(
    Futures.Indices.SP500EMini,
    dataMappingMode: DataMappingMode.OpenInterest,
    dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
    contractDepthOffset: 0
);

// Get historical data.
var history = History<SymbolChangedEvent>(future.Symbol, TimeSpan.FromDays(365));
```

For more information about historical US Future Security Master data in algorithms, see Symbol Changes .

Historical Data In Research

To get historical US Future Security Master data in the Research Environment, call the `History<SymbolChangedEvent>` method with continuous Future `Symbol` and a time period. This method returns the old and new contract of each rollover. If there is no data for the period you requested, the history result is empty.

```
// Add the Future and define its rollover settings.
var future = qb.AddFuture(
    Futures.Indices.SP500EMini,
    dataMappingMode: DataMappingMode.OpenInterest,
    dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
    contractDepthOffset: 0
);

// Get historical data.
var history = qb.History<SymbolChangedEvent>(future.Symbol, new DateTime(2023, 1, 1), new DateTime(2025, 1, 1));
```

For more information about historical US Future Security Master data in the Research Environment, see Symbol Changes History .

Supported Assets

The following list shows the available (157) Futures:

- `Futures.Currencies.AUD` : Australian Dollar Futures (CME: 6A)
- `Futures.Currencies.AUDCAD` : Australian Dollar/Canadian Dollar Futures (CME: ACD)
- `Futures.Currencies.AUDJPY` : Australian Dollar/Japanese Yen Futures (CME: AJY)
- `Futures.Currencies.AUDNZD` : Australian Dollar/New Zealand Dollar Futures (CME: ANE)
- `Futures.Currencies.BRL` : Brazillian Real Futures (CME: 6L)
- `Futures.Currencies.BTC` : Bitcoin Futures (CME: BTC)
- `Futures.Currencies.BTICMicroBTC` : BTIC on Micro Bitcoin Futures (CME: MIB)
- `Futures.Currencies.BTICMicroEther` : BTIC on Micro Ether Futures (CME: MRB)
- `Futures.Currencies.CAD` : Canadian Dollar Futures (CME: 6C)
- `Futures.Currencies.CADJPY` : Canadian Dollar/Japanese Yen Futures (CME: CJY)
- `Futures.Currencies.CHF` : Swiss Franc Futures (CME: 6S)
- `Futures.Currencies.ETH` : Ether Futures (CME: ETH)
- `Futures.Currencies.EUR` : Euro FX Futures (CME: 6E)
- `Futures.Currencies.EURAUD` : Euro/Australian Dollar Futures (CME: EAD)
- `Futures.Currencies.EURCAD` : Euro/Canadian Dollar Futures (CME: ECD)
- `Futures.Currencies.EuroFXEmini` : E-mini Euro FX Futures (CME: E7)
- `Futures.Currencies.EURSEK` : Euro/Swedish Krona Futures (CME: ESK)

- `Futures.Currencies.GBP` : British Pound Futures (CME: 6B)
- `Futures.Currencies.JapaneseYenEmini` : E-mini Japanese Yen Futures (CME: J7)
- `Futures.Currencies.JPY` : Japanese Yen Futures (CME: 6J)
- `Futures.Currencies.MicroAUD` : Micro AUD/USD Futures (CME: M6A)
- `Futures.Currencies.MicroBTC` : Micro Bitcoin Futures (CME: MBT)
- `Futures.Currencies.MicroCAD` : Micro USD/CAD Futures (CME: M6C)
- `Futures.Currencies.MicroCADUSD` : Micro CAD/USD Futures (CME: MCD)
- `Futures.Currencies.MicroCHF` : Micro CHF/USD Futures (CME: MSF)
- `Futures.Currencies.MicroEther` : Micro Ether Futures (CME: MET)
- `Futures.Currencies.MicroEUR` : Micro EUR/USD Futures (CME: M6E)
- `Futures.Currencies.MicroGBP` : Micro GBP/USD Futures (CME: M6B)
- `Futures.Currencies.MicroINRUSD` : Micro INR/USD Futures (CME: MIR)
- `Futures.Currencies.MicroJPY` : Micro JPY/USD Futures (CME: MJY)
- `Futures.Currencies.MicroUSDCHF` : Micro USD/CHF Futures (CME: M6S)
- `Futures.Currencies.MicroUSDCNH` : Micro USD/CNH Futures (CME: MNH)
- `Futures.Currencies.MicroUSDJPY` : Micro USD/JPY Futures (CME: M6J)
- `Futures.Currencies.MXN` : Mexican Peso Futures (CME: 6M)
- `Futures.Currencies.NZD` : New Zealand Dollar Futures (CME: 6N)
- `Futures.Currencies.RUB` : Russian Ruble Futures (CME: 6R)
- `Futures.Currencies.StandardSizeUSDOffshoreRMBCNH` : Standard-Size USD/Offshore RMB (CNH) Futures (CME: CNH)
- `Futures.Currencies.ZAR` : South African Rand Futures (CME: 6Z)
- `Futures.Energy.ArgusLLSvsWTIArgusTradeMonth` : Argus LLS vs. WTI (Argus) Trade Month Futures (NYMEX: AE5)
- `Futures.Energy.ArgusPropaneFarEastIndex` : Argus Propane Far East Index Futures (NYMEX: A7E)
- `Futures.Energy.ArgusPropaneSaudiAramco` : Argus Propane (Saudi Aramco) Futures (NYMEX: A9N)
- `Futures.Energy.BrentCrudeOilVsDubaiCrudeOilPlatts` : Brent Crude Oil vs. Dubai Crude Oil (Platts) Futures (NYMEX: ADB)
- `Futures.Energy.BrentLastDayFinancial` : Brent Last Day Financial Futures (NYMEX: BZ)
- `Futures.Energy.ChicagoEthanolPlatts` : Chicago Ethaanol (Platts) Futures (NYMEX: CU)
- `Futures.Energy.ConwayPropaneOPIS` : Conway Propane (OPIS) Futures (NYMEX: A8K)
- `Futures.Energy.CrudeOilWTI` : Crude Oil WTI Futures (NYMEX: CL)
- `Futures.Energy.DubaiCrudeOilPlattsFinancial` : Dubai Crude Oil (Platts) Financial Futures (NYMEX: DCB)
- `Futures.Energy.EastWestGasolineSpreadPlattsArgus` : East-West Gasoline Spread (Platts-Argus) Futures (NYMEX: EWG)
- `Futures.Energy.EastWestNaphthaJapanCFvsCargoesCIFNWESpreadPlatts` : East-West Naphtha: Japan C&F vs. Cargoes CIF NWE Spread (Platts) Futures (NYMEX: EWN)
- `Futures.Energy.Ethanol` : Ethanol Futures (CBOT: EH)
- `Futures.Energy.EthanolT2FOBRdamIncludingDutyPlatts` : Ethanol T2 FOB Rdam Including Duty (Platts) Futures (NYMEX: AZ1)
- `Futures.Energy.EuropeanNaphthaPlattsCrackSpread` : European Naphtha (Platts) Crack Spread Futures (NYMEX: EN)
- `Futures.Energy.EuropeanPropaneCIFARAArgus` : European Propane CIF ARA (Argus) Futures (NYMEX: APS)
- `Futures.Energy.EuropeanPropaneCIFARAArgusVsNaphthaCargoesCIFNWEPlatts` : European Propane CIF ARA (Argus) vs. Naphtha Cargoes CIF NWE (Platts) Futures (NYMEX: EPN)
- `Futures.Energy.FreightRouteTC14Baltic` : Freight Route TC14 (Baltic) Futures (NYMEX: FRC)
- `Futures.Energy.Gasoline` : Gasoline RBOB Futures (NYMEX: RB)
- `Futures.Energy.GasolineEurobobOxyNWEBargesArgus` : Gasoline Euro-bob Oxy NWE Barges (Argus) Futures (NYMEX:

B7H)

- `Futures.Energy.GroupThreeSuboctaneGasolinePlattsVsRBOB` : Group Three Sub-octane Gasoliine (Platts) vs. RBOB Futures (NYMEX: AA8)
- `Futures.Energy.GroupThreeULSDPlattsVsNYHarborULSD` : Group Three ULSD (Platts) vs. NY Harbor ULSD Futures (NYMEX: AA6)
- `Futures.Energy.GulfCoastCBOBGasolineA2PlattsVsRBOBGasoline` : Gulf Coast CBOB Gasoline A2 (Platts) vs. RBOB Gasoline Futures (NYMEX: CRB)
- `Futures.Energy.GulfCoastHSFOPlattsVsEuropeanThreePointFivePercentFuelOilBargesFOBRdamPlatts` : Gulf Coast HSFO (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: GCU)
- `Futures.Energy.HeatingOil` : Heating Oil Futures (NYMEX: HO)
- `Futures.Energy.LosAngelesCARBOBGasolineOPISvsRBOBGasoline` : Los Angeles CARBOB Gasoline (OPIS) vs. RBOB Gasoline Futures (NYMEX: AJL)
- `Futures.Energy.LosAngelesCARBDieselOPISvsNYHarborULSD` : Los Angeles CARB Diesel (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AKL)
- `Futures.Energy.LosAngelesJetOPISvsNYHarborULSD` : Los Angeles Jet (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AJS)
- `Futures.Energy.MarsArgusVsWTIFinancial` : Mars (Argus) vs. WTI Financial Futures (NYMEX: AYX)
- `Futures.Energy.MarsArgusVsWTITradeMonth` : Mars (Argus) vs. WTI Trade Month Futures (NYMEX: AYV)
- `Futures.Energy.MicroCrudeOilWTI` : Micro WTI Crude Oil Futures (NYMEX: MCL)
- `Futures.Energy.MicroEuropeanFOBRdamMarineFuelZeroPointFivePercentBargesPlatts` : Micro European FOB Rdam Marine Fuel 0.5% Barges (Platts) Futures (NYMEX: R5O)
- `Futures.Energy.MicroEuropeanThreePointFivePercentOilBargesFOBRdamPlatts` : Micro European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: MEF)
- `Futures.Energy.MicroGasoilZeroPointOnePercentBargesFOBARAPlatts` : Micro Gasoil 0.1% Barges FOB ARA (Platts) Futures (NYMEX: M1B)
- `Futures.Energy.MicroSingaporeFOBMarineFuelZeroPointFivePercetPlatts` : Micro Singapore FOB Marine Fuel 0.5% (Platts) Futures (NYMEX: S5O)
- `Futures.Energy.MicroSingaporeFuelOil380CSTPlatts` : Micro Singapore Fuel Oil 380CST (Platts) Futures (NYMEX: MAF)
- `Futures.Energy.MiniEuropeanThreePointPercentFiveFuelOilBargesPlatts` : Mini European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: A0D)
- `Futures.Energy.MiniSingaporeFuelOil180CstPlatts` : Mini Singapore Fuel Oil 180 cst (Platts) Futures (NYMEX: A0F)
- `Futures.Energy.MontBelvieuEthaneOPIS` : Mont Belvieu Ethane (OPIS) Futures (NYMEX: AC0)
- `Futures.Energy.MontBelvieuLDHPropaneOPIS` : Mont Belvieu LDH Propane (OPIS) Futures (NYMEX: B0)
- `Futures.Energy.MontBelvieuNaturalGasolineOPIS` : Mont Belvieu Natural Gasoline (OPIS) Futures (NYMEX: A7Q)
- `Futures.Energy.MontBelvieuNormalButaneOPIS` : Mont Belvieu Normal Butane (OPIS) Futures (NYMEX: AD0)
- `Futures.Energy.NaturalGas` : Natural Gas Futures (NYMEX: NG)
- `Futures.Energy.NaturalGasHenryHubLastDayFinancial` : Natural Gas (Henry Hub) Last-day Financial Futures (NYMEX: HH)
- `Futures.Energy.NaturalGasHenryHubPenultimateFinancial` : Natural Gas (Henry Hub) Penultimate Financial Futures (NYMEX: HP)
- `Futures.Energy.OnePercentFuelOilCargoesFOBNWEPlattsVsThreePointFivePercentFuelOilBargesFOBRdamPlatts` : 1% Fuel Oil Cargoes FOB NWE (Platts) vs. 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: FSS)
- `Futures.Energy.PremiumUnleadedGasoline10ppmFOBMEDPlatts` : Premium Unleaded Gasoline 10 ppm FOB MED (Platts) Futures (NYMEX: A3G)
- `Futures.Energy.PropaneNonLDHMontBelvieuOPIS` : Propane Non-LDH Mont Belvieu (OPIS) Futures (NYMEX: A1R)
- `Futures.Energy.RBOBGasolineCrackSpread` : RBOB Gasoline Crack Spread Futures (NYMEX: ARE)

- `Futures.Energy.RBOBGasolineVsEurobobOxyNWEBargesArgusThreeHundredFiftyThousandGallons` : RBOB Gasoline vs. Euro-bob Oxy NWE Barges (Argus) (350,000 gallons) Futures (NYMEX: EXR)
- `Futures.Energy.SingaporeFuelOil380cstPlattsVsEuropeanThreePointFivePercentFuelOilBargesFOBRdamPlatts` : Singapore Fuel Oil 380 cst (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: EVC)
- `Futures.Energy.SingaporeGasoilPlattsVsLowSulphurGasoilFutures` : Singapore Gasoil (Platts) vs. Low Sulphur Gasoil Futures (NYMEX: AGA)

- `Futures.Energy.ThreePointFivePercentFuelOilBargesFOBRdamPlattsCrackSpread` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread Futures (NYMEX: FO)
- `Futures.Energy.ThreePointFivePercentFuelOilBargesFOBRdamPlattsCrackSpread1000mt` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread (1000mt) Futures (NYMEX: BOO)
- `Futures.Energy.WTIBrentFinancial` : WTI-Brent Financial Futures (NYMEX: BK)
- `Futures.Energy.WTIFinancial` : WTI Financial Futures (NYMEX: CSX)
- `Futures.Energy.WTIHoustonArgusVsWTITradeMonth` : WTI Houston (Argus) vs. WTI Trade Month Futures (NYMEX: HTT)
- `Futures.Energy.WTIHoustonCrudeOil` : WTI Houston Crude Oil Futures (NYMEX: HCL)
- `Futures.Financials.EuroDollar` : EuroDollar Futures (CME: GE)
- `Futures.Financials.FiveYearUSDMACSwap` : 5-Year USD MAC Swap Futures (CBOT: F1U)
- `Futures.Financials.MicroY10TreasuryNote` : Micro 10-Year Yield Futures (CBOT: 10Y)
- `Futures.Financials.MicroY2TreasuryBond` : Micro 2-Year Yield Futures (CBOT: 2YY)
- `Futures.Financials.MicroY30TreasuryBond` : Micro 30-Year Yield Futures (CBOT: 30Y)
- `Futures.Financials.MicroY5TreasuryBond` : Micro 5-Year Yield Futures (CBOT: 5YY)
- `Futures.Financials.UltraTenYearUSTreasuryNote` : Ultra 10-Year U.S. Treasury Note Futures (CBOT: TN)
- `Futures.Financials.UltraUSTreasuryBond` : Ultra U.S. Treasury Bond Futures (CBOT: UB)
- `Futures.Financials.Y10TreasuryNote` : 10Y U.S. Treasury Note Futures (CBOT: ZN)
- `Futures.Financials.Y2TreasuryNote` : 2Y U.S. Treasury Note Futures (CBOT: ZT)
- `Futures.Financials.Y30TreasuryBond` : 30Y U.S. Treasury Bond Futures (CBOT: ZB)
- `Futures.Financials.Y5TreasuryNote` : 5Y U.S. Treasury Note Futures (CBOT: ZF)
- `Futures.Forestry.Lumber` : Lumber Futures (CME: LBR)
- `Futures.Forestry.RandomLengthLumber` : Random Length Lumber Futures (CME: LBS)
- `Futures.Grains.BlackSeaCornFinanciallySettledPlatts` : Black Sea Corn Financially Settled (Platts) Futures (CBOT: BCF)
- `Futures.Grains.BlackSeaWheatFinanciallySettledPlatts` : Black Sea Wheat Financially Settled (Platts) Futures (CBOT: BWF)
- `Futures.Grains.Corn` : Corn Futures (CBOT: ZC)
- `Futures.Grains.HRWWheat` : KC HRW Wheat Futures (CBOT: KE)
- `Futures.Grains.Oats` : Oats Futures (CBOT: ZO)
- `Futures.Grains.Soybeans` : Soybeans Futures (CBOT: ZS)
- `Futures.Grains.SoybeanMeal` : Soybean Meal Futures (CBOT: ZM)
- `Futures.Grains.SoybeanOil` : Soybean Oil Futures (CBOT: ZL)
- `Futures.Grains.Wheat` : Default wheat contract is SRWWheat (CBOT: ZW)
- `Futures.Indices.BloombergCommodityIndex` : Bloomberg Commodity Index Futures (CBOT: AW)
- `Futures.Indices.Dow30EMini` : E-mini Dow Indu 30 Futures (CBOT: YM)
- `Futures.Indices.DowJonesRealEstate` : Dow Jones Real Estate futures on CME (CME: RX)
- `Futures.Indices.FTSEEmergingEmini` : E-mini FTSE Emerging Index Futures (CME: EI)

- `Futures.Indices.MicroDow30EMini` : Micro E-mini Dow Jones Industrial Average Index Futures (CBOT: MYM)
- `Futures.Indices.MicroNASDAQ100EMini` : Micro E-mini Nasdaq-100 Index Futures (CME: MNQ)
- `Futures.Indices.MicroRussell2000EMini` : Micro E-mini Russell 2000 Index Futures (CME: M2K)
- `Futures.Indices.MicroSP500EMini` : Micro E-mini S&P 500 Index Futures (CME: MES)
- `Futures.Indices.NASDAQ100BiotechnologyEMini` : E-mini Nasdaq-100 Biotechnology Index Futures (CME: BIO)
- `Futures.Indices.NASDAQ100EMini` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.Nikkei225Dollar` : Nikkei-225 Dollar Futures (CME: NKD)
- `Futures.Indices.Nikkei225YenCME` : Nikkei-225 Yen denominated Futures on CME (CME: NIY)
- `Futures.Indices.Russell1000EMini` : E-mini Russell 1000 futures on CME (CME: RS1)
- `Futures.Indices.Russell2000EMini` : E-mini Russell 2000 Futures (CME: RTY)
- `Futures.Indices.SPGSCICommodity` : S&P-GSCI Commodity Index Futures (CME: GD)
- `Futures.Indices.SP400MidCapEmini` : E-mini S&P MidCap 400 Futures (CME: EMD)
- `Futures.Indices.SP500AnnualDividendIndex` : (CME: SDA)
- `Futures.Indices.SP500EMini` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Indices.TOPIXYEN` : YEN Denominated Topix Index Futures on CME (CME: TPY)
- `Futures.Indices.USDDenominatedIbovespa` : USD-Denominated Ibovespa Index Futures (CME: IBV)
- `Futures.Indices.VIX` : CBOE Volatility Index Futures (CFE: VX)
- `Futures.Meats.FeederCattle` : Feeder Cattle Futures (CME: GF)
- `Futures.Meats.LeanHogs` : Lean Hogs Futures (CME: HE)
- `Futures.Meats.LiveCattle` : Live Cattle Futures (CME: LE)
- `Futures.Metals.AluminiumEuropeanPremiumDutyPaidMetalBulletin` : Aluminium European Premium Duty-Paid (Metal Bulletin) Futures (COMEX: EDP)
- `Futures.Metals.AluminumMWUSTransactionPremiumPlatts25MT` : Aluminum MW U.S. Transaction Premium Platts (25MT) Futures (COMEX: AUP)
- `Futures.Metals.Copper` : Copper Futures (COMEX: HG)
- `Futures.Metals.Gold` : Gold Futures (COMEX: GC)
- `Futures.Metals.MicroGold` : Micro Gold Futures (COMEX: MGC)
- `Futures.Metals.MicroGoldTAS` : Micro Gold TAS Futures (COMEX: MGT)
- `Futures.Metals.MicroPalladium` : Micro Palladium Futures (NYMEX: PAM)
- `Futures.Metals.MicroSilver` : Micro Silver Futures (COMEX: SIL)
- `Futures.Metals.Palladium` : Palladium Futures (NYMEX: PA)
- `Futures.Metals.Platinum` : Platinum Futures (NYMEX: PL)
- `Futures.Metals.Silver` : Silver Futures (COMEX: SI)
- `Futures.Metals.USMidwestDomesticHotRolledCoilSteelCRUIndex` : U.S. Midwest Domestic Hot-Rolled Coil Steel (CRU) Index Futures (NYMEX: HRC)
- `Futures.Softs.Sugar11` : Sugar #11 Futures ICE (ICE: SB)
- `Futures.Softs.Sugar11CME` : Sugar #11 Futures CME (NYMEX: YO)

Example Applications

The US Futures Security Master enables you to design strategies harnessing continuous Futures contracts. Examples include the following strategies:

- Trading cyclical patterns in commodity Futures.
- Buying gold Futures as an inflation hedge with automatic contract roll-overs.
- Detecting arbitrage opportunities between index Futures and Equities.

Classic Algorithm Example

The following example algorithm buys the continuous Future contract for Crude Oil when its price rises above its simple moving average. When its price drops below its simple moving average, the algorithm sells the continuous contract. Each time the continuous Future contract rolls over, the algorithm logs the event.

C#

```
public class USFuturesSecurityMasterDataClassicAlgorithm  : QCAlgorithm
{
    private Future _future;
    // Define a threshold for the SMA cross.
    private decimal _threshold = 0.01m;
    private SimpleMovingAverage _sma;

    public override void Initialize()
    {
        SetCash(1000000);
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of each asset with its last known price to
        // avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a Future. Set the continuous contract mapping criteria to
        // the contract with highest open interest to provide the best
        // price information for trend estimation.
        _future = AddFuture(
            Futures.Energy.CrudeOilWTI,

            Liquidate(oldSymbol, tag: tag);
            MarketOrder(newSymbol, quantity, tag: tag);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buys the continuous Future contract for Crude Oil when its price rises above its simple moving average. When its price drops below its simple moving average, the algorithm sells the continuous contract. Each time the contract rolls over, the algorithm logs the event.

C#

```
public class USFuturesSecurityMasterDataFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetCash(1000000);
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Setting the continuous contract mapping criteria, the contract with highest open interest provide the best
price information for trend estimation
        AddFuture(Futures.Energies.CrudeOilWTI,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0
        );
        AddAlpha(new ContinuousFuturesAlphaModel());
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }

    class ContinuousFuturesAlphaModel : AlphaModel
    {
        private Future _continuousContract;
        private Symbol _symbol;
        // 1% margin to reassure trend direction
        private decimal _threshold = 0.01m;
        private SimpleMovingAverage _sma;

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            //  Check if contract data available, since all trades are based on that only
            if (_symbol == null || _continuousContract == null)
            {
                return insights;
            }

            // Up-to-date handling of switching the mapped contract for trade liquidity
            foreach (var (symbol, changedEvent) in slice.SymbolChangedEvents)
            {
                var oldSymbol = changedEvent.OldSymbol;
                if (algorithm.Insights.HasActiveInsights(oldSymbol, algorithm.UtcTime))
                {
                    var newSymbol = changedEvent.NewSymbol;
                    var tag = $"Rollover - Symbol changed at {algorithm.Time}: {oldSymbol} -> {newSymbol}";
                    var lastInsight = algorithm.Insights[oldSymbol].OrderBy(x => x.CloseTimeUtc).LastOrDefault();
                    insights.Add(Insight.Price(newSymbol, lastInsight.CloseTimeUtc, lastInsight.Direction, tag:
tag));
                    algorithm.Insights.Clear(new Symbol[] { oldSymbol });
                    algorithm.Log(tag);
                }
            }
```

```
            var mappedSymbol = _continuousContract.Mapped;
            // Make sure trade decisions are based on newly received data
            if (!slice.Bars.ContainsKey(_symbol) || !_sma.IsReady || mappedSymbol == null)
            {
                return insights;
            }

            // Long if trend up by threshold to follow the trend
            if (slice.Bars[_symbol].Price > _sma.Current.Value * (1+_threshold) &&
!algorithm.Portfolio[mappedSymbol].IsLong)
            {
                insights.Add(Insight.Price(mappedSymbol, TimeSpan.FromDays(14), InsightDirection.Up));
            }
            // Short if trend down by threshold to follow the trend
            else if (slice.Bars[_symbol].Price < _sma.Current.Value * (1-_threshold) &&
!algorithm.Portfolio[mappedSymbol].IsShort)
            {
                insights.Add(Insight.Price(mappedSymbol, TimeSpan.FromDays(14), InsightDirection.Down));
            }

            return insights;
        }

        public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
        {
            foreach (var security in changes.AddedSecurities)
            {
                var symbol = security.Symbol;
                // Set up SMA indicator for trend direction estimator, only for the canonical symbol
                if (symbol.IsCanonical())
                {
                    _continuousContract = (Future)security;
                    _symbol = symbol;
                    _sma = algorithm.SMA(_symbol, 10, Resolution.Daily);

                    // Historical data
                    var history = algorithm.History(symbol, 60*24*10, Resolution.Minute);
                    algorithm.Debug($"We got {history.Count()} from our history request for {symbol}");

                    // Warm up the SMA indicator for its readiness for immediate use
                    foreach (var bar in history)
                    {
                        _sma.Update(new IndicatorDataPoint(bar.Time, bar.Close));
                    }
                }
            }
        }
    }

    class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
    {
        public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
        {
            var targets = new List<PortfolioTarget>();
            foreach (var insight in insights)
            {
                if (algorithm.Securities[insight.Symbol].IsTradable)
                {
                    targets.Add(new PortfolioTarget(insight.Symbol, (int) insight.Direction));
                }
            }
            return targets;
        }
    }
}
```

Data Point Attributes

The US Futures Security Master dataset provides `SymbolChangedEvent` objects, which have the following attributes:

QuantConnect

US Index Option Universe

Introduction

The US Index Option Universe dataset by QuantConnect lists the available US Index Options contracts and the current Implied Volatility and Greeks. The data covers European Option contracts for 3 US Indices: SPX, VIX, and NDX. It starts in January 2012 and is delivered on a daily update frequency. To create this dataset, we use our implementation of the forward tree pricing model, which accounts for the interest rate, dividend payments, and daily closing prices. The values in this dataset are the same values you can get from daily indicators with mirror Options.

This dataset `does not` contain market data. For market data, see US Index Options by AlgoSeek .

For more information about the US Index Option Universe dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

QuantConnect was founded in 2012 to serve quants everywhere with the best possible algorithmic trading technology. Seeking to disrupt a notoriously closed-source industry, QuantConnect takes a radically open-source approach to algorithmic trading. Through the QuantConnect web platform, more than 50,000 quants are served every month.

Getting Started

The following snippet demonstrates how to request data from the US Index Options Universe dataset:

```C#
var option = AddIndexOption("VIX");
option.SetFilter(universe => universe.delta(0.4m, 0.6m));
_optionSymbol = option.Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	7 Index Options
Data Density	Dense
Resolution	Daily
Timezone	New York

Specification Over Time

According to the SPX Options contract specification , some SPX contracts expire every month and SPXW contracts expires every day. Before 2021, you could only trade SPX contracts with the following expiration dates:

- Expires within the next 4 months
- Expires in September within the next 14 months
- Expires in January, March, or June within the next 2 years
- Expires in December within the next 3 years

During this time, SPXW didn't have 0DTE every day.

`Sources` :

- Cboe Options Exchange to List Three Long-Dated SPX Options Expirations, Beginning November 1, 2021

- S&P 500 Weekly Options Now Expire Five Days a Week

Requesting Data

To add US Index Options Universe data to your algorithm, call the `AddIndexOption` method. Save a reference to the Index Option `Symbol` so you can access the data later in your algorithm. To define which contracts should be in your universe, call the `SetFilter` method of the `IndexOption` object.

The `AddIndexOption` method provides a daily stream of Option chain data. To get the most recent daily chain, call the `OptionChain` method with the canonical Index Option Symbol. The `OptionChain` method returns data on all the tradable contracts, not just the contracts that pass your universe filter.

C#

```
public class IndexOptionsDataAlgorithm : QCAlgorithm
{
    private Symbol _indexSymbol, _standardOptionSymbol, _weeklyOptionSymbol;

    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        _indexSymbol = AddIndex("VIX").Symbol;

        var standardOption = AddIndexOption(_indexSymbol);
        standardOption.SetFilter(OptionFilter);
        _standardOptionSymbol = standardOption.Symbol;
        var standardChain = OptionChain(_standardOptionSymbol);

        var weeklyOption = AddIndexOption(_indexSymbol, "VIXW");
        weeklyOption.SetFilter(OptionFilter);
        _weeklyOptionSymbol = weeklyOption.Symbol;
        var weeklyChain = OptionChain(_weeklyOptionSymbol)
            .Where(contract => !IndexOptionSymbol.IsStandard(contract.Symbol));
    }

    private OptionFilterUniverse OptionFilter(OptionFilterUniverse universe)
    {
        // Contracts can be filtered by greeks, implied volatility, open interest:
        return universe
            .Delta(0.5m, 1.5m)
            .Gamma(0.0001m, 0.0006m)
            .Vega(0.01m, 1.5m)
            .Theta(-2.0m, -0.5m)
            .Rho(0.5m, 3.0m)
            .ImpliedVolatility(1.0m, 3.0m)
            .OpenInterest(100, 500);
    }
}
```

The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.

For more information about creating US Index Option subscriptions, see Index Options .

Accessing Data

For information about accessing US Equity Options data, see Handling Data .

Historical Data

You can get historical US Index Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Index Options Universe data in an algorithm, call the `History<OptionUniverse>` method with the canonical Index Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter. If there is no data in the period you request, the history result is empty.

```C#
// OptionUniverse objects
var history = History<OptionUniverse>(_standardOptionSymbol, TimeSpan.FromDays(3)).ToList();
```

For more information about Index Options Universe data in algorithms, see Historical Data .

Historical Data In Research

To get historical US Index Options Universe data in the Research Environment, call the `History<OptionUniverse>` method with the canonical Option `Symbol` . This method returns data on all of the tradable contracts, not just the contracts that pass your universe filter.

```C#
var qb = new QuantBook();
var indexSymbol = qb.AddIndex("VIX").Symbol;
var option = qb.AddIndexOption(indexSymbol); // or qb.AddIndexOption(indexSymbol, "VIXW");
var history = qb.History<OptionUniverse>(option.Symbol, new DateTime(2020, 6, 1), new DateTime(2020, 6, 6));
foreach (var chain in history)
{
    var endTime = chain.EndTime;
    var filteredContracts = chain.Data
        .Select(contract => contract as OptionUniverse)
        .Where(contract => contract.Greeks.Delta > 0.3m);
    foreach (var contract in filteredContracts)
    {
        var price = contract.Price;
        var iv = contract.ImpliedVolatility;
    }
}
```

For more information about historical Index Options Universe data in the Research Environment, see Universes .

Supported Assets

The following table shows the available Index Options:

Underlying Index	Underlying Ticker	Target Ticker	Standard Contracts	Weekly Contracts	Tradable on Expiry Day
NASDAQ-100	NDX		✓		
NASDAQ-100	NDX	NDXP	✓		✓
NASDAQ-100	NDX	NQX	✓	✓	✓
Russell 2000	RUT		✓		
Russell 2000	RUT	RUTW		✓	✓
S&P500	SPX		✓		
S&P500	SPX	SPXW		✓	✓
S&P500	VIX		✓		
S&P500	VIX	VIXW		✓	

For more information about each underlying Index, see Supported Indices .

Example Applications

The US Index Options Universe dataset enables you to accurately design strategies for Index Options. Examples include the following strategies:

- Buying VIX call Options to hedge against upcoming volatility
- Buying VIX put Options to capture the natural downward price movement in the VIX index
- Buying SPX put Options to protect against downward price movement in the S&P 500

Classic Algorithm Example

The following example algorithm subscribes to SPX put options that fall within delta range between -1 and -0.95, open interest range between 10 and 1000, and expire within seven days. Within this Option chain, the algorithm holds the put Option contract that has the minimum delta (closest to -1) during market hour to hedge the underlying intra-day movement completely. It avoid volatility from sentiment and only earns from inter-day movement from longer-term factors. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```
from AlgorithmImports import * class IndexOptionsUniverseAlgorithm(QCAlgorithm): def initialize(self) -&GT; None: self.set_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) self.set_cash(10000000) # Asynchronous can use computational resources efficiently self.universe_settings.asynchronous = True # Subscribe to the underlying for the underlying position # Set the data normalization mode to raw for strike price comparability self.index = self.add_index("SPX").symbol # Requesting option data and filter for the hedge candidates option = self.add_index_option(self.index) option.set_filter(self.option_filter) self.option_symbol = option.symbol # Set scheduled event to buy a hedge option contract at market open to eliminate the intra-day movement self.schedule.on( self.date_rules.every_day(self.index), self.time_rules.after_market_open(self.index, 1), self.buy_hedge_contract ) # Set a scheduled event to sell the hedge contract before market close, since we want to earn from inter-day movement # Leave 2 minutes contingency to fill self.schedule.on( self.date_rules.every_day(self.index), self.time_rules.before_market_close(self.index, 2), self.sell_hedge_contract ) self.hedge = None def option_filter(self, universe: OptionFilterUniverse) -&GT; OptionFilterUniverse: # Select the contracts with delta very close to -1 and high open interest # This can effectively hedge most of the price change of the underlying and ensure the liquidity # Make sure the contract is expiring close for its tradbility return universe.include_weeklys().puts_only().expiration(2, 7).delta(-1, -0.95).open_interest(10, 1000) def buy_hedge_contract(self) -&GT; None: chain = self.current_slice.option_chains.get(self.option_symbol) if chain: # Order the underlying if not hold, the order size should match the option contract # Order only if option chain data ready for hedging if not self.portfolio[self.index].invested: self.market_order(self.index, self.securities[self.option_symbol].symbol_properties.contract_multiplier) # Get the contract with delta closest to -1 (lowest possible delta) contract = sorted(chain, key=lambda x: x.greeks.delta)[0] self.hedge = contract.symbol # Buy 1 deep ITM put with delta close to -1 to eliminate the intraday movement self.market_order(self.hedge, 1) def sell_hedge_contract(self) -&GT; None: # Check if any hedge contract position, if so, liquidate before market close to expose to underlying overnight movement if self.hedge: self.liquidate(self.hedge) self.hedge = None
```

```
public class IndexOptionsUniverseAlgorithm : QCAlgorithm { private Symbol _index, _optionSymbol, _hedge; public override void Initialize() { SetStartDate(2024, 9, 1); SetEndDate(2024, 12, 31); SetCash(10000000); // Asynchronous can use computational resources efficiently UniverseSettings.Asynchronous = true; // Subscribe to the underlying for the underlying position // Set the data normalization mode to raw for strike price comparability _index = AddIndex("SPX").Symbol; // Requesting option data and filter for the hedge candidates var option = AddIndexOption(_index); _optionSymbol = option.Symbol; option.SetFilter(OptionFilter); // Set scheduled event to buy a hedge option contract at market open to eliminate the intra-day movement Schedule.On( DateRules.EveryDay(_index), TimeRules.AfterMarketOpen(_index, 1), BuyHedgeContract ); // Set a scheduled event to sell the hedge contract before market close, since we want to earn from inter-day movement // Leave 2 minutes contingency to fill Schedule.On( DateRules.EveryDay(_index), TimeRules.BeforeMarketClose(_index, 2), SellHedgeContract ); } private OptionFilterUniverse OptionFilter(OptionFilterUniverse universe) { // Select the contracts with delta very close to -1 and high open interest // This can effectively hedge most of the price change of the underlying and ensure the liquidity // Make sure the contract is expiring close for its tradbility return universe .IncludeWeeklys() .PutsOnly() .Expiration(2, 7) .Delta(-1m, -0.95m) .OpenInterest(10, 1000); } private void BuyHedgeContract() { if (CurrentSlice.OptionChains.TryGetValue(_optionSymbol, out var chain)) { // Order the underlying if not hold, the order size should match the option contract // Order only if option chain data ready for hedging if (!Portfolio[_index].Invested) { MarketOrder(_index, Securities[_optionSymbol].SymbolProperties.ContractMultiplier); } // Get the contract with delta closest to -1 (lowest possible delta) var contract = chain.MinBy(x =&GT; x.Greeks.Delta); _hedge = contract.Symbol; // Buy 1 deep ITM put with delta close to -1 to eliminate the intraday movement MarketOrder(_hedge, 1); } } private void SellHedgeContract() { // Check if any hedge contract position, if so, liquidate before market close to expose to underlying overnight movement if (_hedge != null) { Liquidate(_hedge); _hedge = null; } } }
```

Framework Algorithm Example

The following example algorithm demonstrating a Gamma Scalping strategy through framework algorithm. It filters SPX options with expiration between 30 to 90 days and open interest between 50 and 1000, due to liquidity concern and lower Gamma fluctuation. Assuming a significant upward trend is expecting, it orders a long straddle strategy from the strike price with Delta-neutral and the highest Gamma to earn the highest profit from upward underlying movement.

C#

```
public class IndexOptionsUniverseFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
```

```
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        // Asynchronous can use computational resources efficiently
        UniverseSettings.Asynchronous = true;

        // Universe selection that select based on liquidity of the option contracts (by open interest)
        AddUniverseSelection(new IndexOptionsUniverseSelectionModel());
        // Custom alpha model that use Delta and Gamma to signal insights
        AddAlpha(new OptionDeltaGammaAlphaModel());
        // To maintain long-short size equal, use a PCM that order a single contract
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

class IndexOptionsUniverseSelectionModel : OptionUniverseSelectionModel
{
    // Daily update with the SelectOptionChainSymbols function
    public IndexOptionsUniverseSelectionModel()
            : base(TimeSpan.FromDays(1), SelectOptionChainSymbols) {}

    private static IEnumerable<Symbol> SelectOptionChainSymbols(DateTime utcTime)
    {
        // Select only SPX options as our focus, which is a highly traded volatile index with great upward momentum
        return new[] {QuantConnect.Symbol.Create("SPX", SecurityType.IndexOption, Market.USA)};
    }

    protected override OptionFilterUniverse Filter(OptionFilterUniverse filter)
    {
        // To ensure the liquidity and tradability, make sure the option is not 0-DTE and have a fair open interest
        // A longer TTM will have lower Gamma thus more stable in the local delta-neutral position
        return filter
            .IncludeWeeklys()
            .Expiration(30, 90)
            .OpenInterest(50, 1000);
    }
}

class OptionDeltaGammaAlphaModel : AlphaModel

                var expiry = chain.Min(x => x.Expiry);
                var contracts = chain.Where(x => x.Expiry == expiry).ToList();

                // Calculate delta and gamma per strike price group for later filtering, ensure both call and put
available for option strategy
                var deltaGammaSymbols = new List<(decimal, decimal, Symbol, Symbol)>();
                var strikes = contracts.Select(x => x.Strike)
                    .Where(x => contracts.Count(y => y.Strike == x) == 2)
                    .Distinct();
                foreach (var strike in strikes)
                {
                    // Get both call and put for their aggregated delta and gamma
                    var call = contracts.Single(x => x.Right == OptionRight.Call && x.Strike == strike);
                    var put = contracts.Single(x => x.Right == OptionRight.Put && x.Strike == strike);
                    deltaGammaSymbols.Add((call.Greeks.Delta + put.Greeks.Delta, call.Greeks.Gamma +
put.Greeks.Gamma, call.Symbol, put.Symbol));
                }

                if (deltaGammaSymbols.Count == 0)
                {
                    continue;
                }

                // We want a delta-neutral position, so it is likely to be ATM (like a long straddle)
                // Less than 0.1 p.d. difference is non-significant, which we can risk for better reward
```

```
                // Less than 2d.p. difference is non-significant, which we can risk for better reward
                // Assuming the market direction is up in most scenario, we try to get the strike providing max
overall Gamma
                // Make sure the aggregated gamma to be positive to bet on large uptrend
                // So it will earn more when the price really go up higher and higher, but locally immune for small
noise
                var filtered = deltaGammaSymbols.Where(item => Math.Round(item.Item1, 2) <= 0.01m && item.Item2 >
0).ToList();
                if (filtered.Count == 0)
                {
                    continue;
                }
                var selected = filtered.OrderByDescending(item => item.Item2).First();

                // Provide trade signal and roll the day count to let the position stay for the whole day
                var selectedCall = selected.Item3;
                var selectedPut = selected.Item4;
                insights.AddRange(new[] {
                    Insight.Price(selectedCall, Expiry.EndOfDay, InsightDirection.Up),
                    Insight.Price(selectedPut, Expiry.EndOfDay, InsightDirection.Up)
                });
                _day = slice.Time.Day;
            }
        }

        return insights;
    }
}

class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
{
    public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
    {
        var targets = new List<PortfolioTarget>();

US Equities

Introduction

The US Equities dataset by AlgoSeek is survivorship bias-free daily coverage of every stock traded in the US Securities Information Processors (SIP) CTA/UTP feed since 1998. The dataset covers approximately 27,500 securities, starts in January 1998, and is delivered in any resolution from tick to daily. The Data is collected from the full SIP feed via our Equinix co-located servers, including all trades and quotes published to every exchange as well as FINRA. Over-the-Counter (OTC) trades are not included.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Equities dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

AlgoSeek is the default US Equities dataset on QuantConnect. The following snippet demonstrates how to request data from the US Equities dataset:

```C#
_aapl = AddEquity("AAPL", Resolution.Daily).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	27,500 US Equities
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular and Extended

Requesting Data

To add US Equities data to your algorithm, call the `AddEquity` method. Save a reference to the Equity `Symbol` so you can access the data later in your algorithm.

```
C#
public class USEquityDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2018, 1, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);
        // Subscribe to AAPL data
        _symbol = AddEquity("AAPL", Resolution.Minute).Symbol;
    }
}
```

For more information about creating US Equity subscriptions, see Requesting Data or US Equity Universes .

Accessing Data

To get the current US Equities data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Equity `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    // Access data: TradeBar data
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    // Access data: QuoteBar data
    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    // Access data: Ticks data
    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    // Iterate all TradeBar received
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    // Iterate all QuoteBar received
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    // Iterate all Ticks received
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing US Equities data, see Handling Data .

Historical Data

To get historical US Equity data, call the `History` method with the Equity `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Universe Selection

To select a universe of US Equities, see Equity Universes .

Remove Subscriptions

To unsubscribe from a US Equity that you added with the `AddEquity` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings.

Supported Assets

To view the supported assets in the US Equities dataset, see the Data Explorer . This dataset doesn't include Over-the-Counter

(OTC) stocks.

Example Applications

The US Equities dataset enables you to accurately design Equity trading strategies. Examples include the following strategies:

- Momentum strategies using historical returns on the premise that the momentum will continue
- Value strategies using fundamental factors on the premise that the price of undervalued securities will rise
- Factor investing with periodic rebalancing

Classic Algorithm Example

The following example algorithm buys and holds Apple stock:

```C#
public class USEquityDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Requesting single equity data, since we only trade AAPL
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;

        // Historical data
        var history = History(_symbol, 60, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        // Check if the current slice containing AAPL and if we hold any position
        // As we make use of the most updated price data to decide the order size
        if (slice.ContainsKey(_symbol) && slice[_symbol] != null && !Portfolio.Invested)
        {
            SetHoldings(_symbol, 1);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buys and holds Apple stock:

```C#
public class USEquityDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        UniverseSettings.Resolution = Resolution.Daily;
        // To select only AAPL, use a manual selection universe
        var symbols = new[] {QuantConnect.Symbol.Create("AAPL", SecurityType.Equity, Market.USA)};
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));

        // Constant investment signal
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7), 0.025, null));

        // Invest in all members equally
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}
```

Data Point Attributes

The US Equities dataset provides `TradeBar` , `QuoteBar` , and `Tick` objects.

`Tick` objects have the following attributes:

AlgoSeek

US Equity Options

Introduction

The US Equity Options data by AlgoSeek provides Option data, including prices, strikes, expires, and open interest. The data covers 4,000 Symbols, starts in January 2012, and is delivered on a minute frequency. This dataset is created by monitoring Options Price Reporting Authority (OPRA) data feed, which consolidates last sale and quotation information originating from the national securities exchanges that have been approved by the Securities and Exchange Commission.

This dataset depends on the following datasets:

- US Equity Security Master - data on splits, dividends, and symbol changes for the underlying Equities.
- US Equity Option Universe - data on the available contracts and their daily Greeks and implied volatility values.
- US Equities - trade and quote data on the underlying Equities.

For more information about the US Equity Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek was in 2014 with the goal of providing the highest quality, most accurate, ready-to-use data in the financial data industry. AlgoSeek provides access to Equities, ETFs, ETNs, Equity Indices, Equity Options, Futures, and Future Options for quantitative firms and traders.

Getting Started

The following snippet demonstrates how to request data from the US Equity Options dataset:

```C#
var option = AddOption("GOOG");
_optionSymbol = option.Symbol;
option.SetFilter(-2, +2, 0, 180);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012*
Asset Coverage	4,000 Symbols
Data Density	Dense
Resolution	Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular Only

* Some data is available before this date. In 2012, AlgoSeek started to fetch data from 48 OPRA channels instead of 24, increasing the quality of the data.

Requesting Data

To add US Equity Options data to your algorithm, call the `AddOption` method. Save a reference to the Equity Option `Symbol` so you can access the data later in your algorithm.

```
C#
public class USEquityOptionsDataAlgorithm : QCAlgorithm
{
    private Symbol _optionSymbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        // Request GOOG option data
        var option = AddOption("GOOG");
        _optionSymbol = option.Symbol;
        // Set our strike/expiry filter for this option chain
        option.SetFilter(-2, +2, 0, 180);
    }
}
```

The Equity resolution must be less than or equal to the Equity Option resolution. For example, if you set the Equity resolution to minute, then you must set the Equity Option resolution to minute, hour, or daily.

For more information about creating US Equity Option subscriptions, see Requesting Data or Equity Options Universes .

Accessing Data

To get the current US Equity Options data, index the `OptionChains` property of the current `Slice` with the canonical Equity Option `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Index Option at every time step. To avoid issues, call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    // Get the wanted option chain with the canonical symbol
    if (slice.OptionChains.TryGetValue(_optionSymbol, out var chain))
    {
        // Iterate the option contracts in chain
        foreach (var contract in chain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }
}
```

You can also iterate through all of the `OptionChain` objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    // Iterate all option chains of all symbols
    foreach (var kvp in slice.OptionChains)
    {
        var canonicalSymbol = kvp.Key;
        var chain = kvp.Value;
        // Iterate the option contracts in chain
        foreach (var contract in chain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }
}
```

For more information about accessing US Equity Options data, see Handling Data .

Historical Data

You can get historical US Equity Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Equity Options data in an algorithm, call the `History` method with the Equity Option contract `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(contract.Symbol, 100, Resolution.Minute);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(contract.Symbol, 100, Resolution.Minute);

// OpenInterest objects
var historyOpenInterest = History<OpenInterest>(contract.Symbol, 100, Resolution.Minute);
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Equity Options data in the Research Environment, call the `History` or `OptionHistory` method. The `History` method returns the price, volume, and open interest history for some given Option contract(s). The `OptionHistory` method returns the price and volume history for the contracts that pass your daily universe filter.

```C#
var qb = new QuantBook();
var option = qb.AddOption("GOOG");
option.SetFilter(-2, 2, 0, 90);
var history = qb.OptionHistory(option.Symbol, new DateTime(2020, 6, 1), new DateTime(2020, 6, 5));

var contracts = history
    .SelectMany(x => x.OptionChains.SelectMany(y => y.Value.Contracts.Keys))
    .Distinct().ToList();
var expiries = contracts.Select(x => x.ID.Date).Distinct().ToList();
var strikes = contracts.Select(x => x.ID.StrikePrice).Distinct().ToList();
```

To get historical data for arbitrary US Equity Option contracts instead of just the that pass your universe filter, call the `History` method like you would in an algorithm, but on the `QuantBook` object. For more information about historical data in the Research Environment, see Key Concepts .

Historical Greeks and IV Data

To get historical data for the Greeks and implied volatility of Equity Options, see the US Equity Option Universe dataset.

Supported Assets

To view the supported assets in the US Equity Options dataset, see the Data Explorer .

Example Applications

The US Equity Options dataset enables you to accurately design Option strategies. Examples include the following strategies:

- Buying put Options to hedge against downward price movement in positive Equity positions
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviates from their theoretical value

Classic Algorithm Example

The following example algorithm subscribes to Google Options that fall within two strikes of the underlying stock price and expire within seven days. Within this Option chain, the algorithm buys the call Option contract that has the furthest expiry and has its strike price closest to the underlying stock price. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```C#
public class USEquityOptionsDataAlgorithm : QCAlgorithm
{
    private Symbol _underlying, _optionSymbol;
    private OptionContract? _contract = null;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        // Requesting data
        _underlying = AddEquity("GOOG").Symbol;
        var option = AddOption("GOOG");
        _optionSymbol = option.Symbol;
        // To speculate trade the underlying with a low cost, filter for the ATM calls that expiring in the current
week
        // -2/+2 strike buffer is given for small price change
        option.SetFilter((u) => u.IncludeWeeklys().CallsOnly().Strikes(-2, +2).Expiration(0, 7));
    }

    public override void OnData(Slice slice)
    {
        // If the Option contract is exercised, close the underlying position.
        if (Portfolio[_underlying].Invested)
        {
            Liquidate(_underlying);
        }
        // If the Option contract expires, rollover to the next contract.
        if (_contract != null && !Portfolio[_contract.Symbol].Invested)
        {
            _contract = null;
        }
        // Select with the lastest option chain data only
        if (_contract == null && slice.OptionChains.TryGetValue(_optionSymbol, out var chain))
        {
            // Select the call contracts with the furthest expiration (week end)
            var furthestExpiry = chain.Max(c => c.Expiry);
            var furthestExpiryCalls = chain.Where(c => c.Expiry == furthestExpiry);
            // Get the ATM call for speculate trade with low cost and limited loss
            _contract = furthestExpiryCalls.OrderByDescending(x => Math.Abs(chain.Underlying.Price -
x.Strike)).Last();
            MarketOrder(_contract.Symbol, 1);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 100, Resolution.Minute);
            Debug($"We got {history.Count()} from our history request for {security.Symbol}");
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buys a call Option contract for Google that falls within one strike of the underlying stock price and expires within seven days. When the contract expires, the algorithm rolls over to the next contract that meets this criteria.

```C#
public class USEquityOptionsDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        // Requesting data
        SetUniverseSelection(new EarliestExpiringWeeklyAtTheMoneyCallOptionUniverseSelectionModel());

        SetAlpha(new ConstantOptionsAlphaModel());
```

```
        SetAlpha(new ConstantOptionsAlphaModel());

        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

class EarliestExpiringWeeklyAtTheMoneyCallOptionUniverseSelectionModel : OptionUniverseSelectionModel
{
    // Daily update with the SelectOptionChainSymbols function
    public EarliestExpiringWeeklyAtTheMoneyCallOptionUniverseSelectionModel()
            : base(TimeSpan.FromDays(1), SelectOptionChainSymbols) {}

    private static IEnumerable<Symbol> SelectOptionChainSymbols(DateTime utcTime)
    {
        // Select only GOOG options as our focus
        return new[] {QuantConnect.Symbol.Create("GOOG", SecurityType.Option, Market.USA)};
    }

    protected override OptionFilterUniverse Filter(OptionFilterUniverse filter)
    {
        // To speculate trade the underlying with a low cost, filter for the ATM calls that expiring in the current
week
        // -2/+2 strike buffer is given for small price change
        return filter
            .Strikes(-1, -1)
            .Expiration(0, 7)
            .WeeklysOnly()
            .CallsOnly();
    }
}

class ConstantOptionsAlphaModel : AlphaModel
{
    private Symbol? _underlying = null;
    private OptionContract? _contract = null;

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        // Liquidate the underlying if the option is being exercised/assigned
        if (algorithm.Portfolio[_underlying].Invested)
        {
            insights.Add(Insight.Price(_underlying, TimeSpan.FromDays(7), InsightDirection.Flat));
        }

        if (_contract != null && algorithm.Portfolio[_contract.Symbol].Invested)
        {
            return insights;
        }

        // Get the ATM call for speculate trade with low cost and limited loss that expires at week end
        foreach (var kvp in slice.OptionChains)
        {
            var chain = kvp.Value;
            var expiry = chain.Max(x => x.Expiry);
            _contract = chain.Where(x => x.Expiry == expiry)
                .OrderBy(x => Math.Abs(x.Strike - x.UnderlyingLastPrice))
                .First();
            insights.Add(Insight.Price(_contract.Symbol, _contract.Expiry + TimeSpan.FromDays(1),
InsightDirection.Up));
        }
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            if (security.Type == SecurityType.Equity)
            {
                _underlying = security.Symbol;
            }
            else {
                // Historical data
                var history = algorithm.History(security.Symbol, 100, Resolution.Minute);
                algorithm.Debug($"We got {history.Count()} from our history request for {security.Symbol}");
            }
        }
    }
}
```

```
class SinglePortfolioConstructionModel : PortfolioConstructionModel
{
    public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
    {
        var targets = new List<PortfolioTarget>();
        foreach (var insight in insights)
        {
            if (algorithm.Securities[insight.Symbol].IsTradable)
            {
                targets.Add(new PortfolioTarget(insight.Symbol, (int) insight.Direction));
            }
        }
        return targets;
    }
}
```

Data Point Attributes

The US Equity Options dataset provides `TradeBar` , `QuoteBar` , and `OpenInterest` objects.

AlgoSeek

US Future Options

Introduction

The US Future Options dataset by AlgoSeek provides Option data on US Future contracts, including prices, strikes, and expires. The data covers 15 Monthly Future contracts, starts in January 2012, and is delivered on a minute frequency. This dataset is created by monitoring the trading activity on the CME, CBOT, NYMEX, and COMEX markets.

This dataset depends on the following datasets:

- US Future Option Universe - data on the available US Future Options contracts and their current Open Interest.
- US Futures Security Master - data to construct continuous Futures.
- US Future Universe - data on the available US Future contracts, their daily trading volume, and Open Interest.
- US Futures - data on the underlying Futures contracts, including price, volume, Open Interest, and expiry.

For more information about the US Future Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering equities, futures, options, cash forex, and cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Future Options dataset:

```C#
var future = AddFuture(Futures.Metals.Gold, Resolution.Minute);
future.SetFilter(0, 90);
AddFutureOption(future.Symbol, universe => universe.Strikes(-5, +5));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	15 Monthly Future Contracts. Standard expires only*.
Data Density	Dense
Resolution	Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular and Extended

* No weeklies or 0DTE contracts.

Requesting Data

To add US Future Options data to your algorithm, call the `AddFutureOption` method.

```
C#
public class FutureOptionDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2020, 1, 28);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        var future = AddFuture(Futures.Metals.Gold, Resolution.Minute);
        future.SetFilter(0, 90);
        AddFutureOption(future.Symbol, universe => universe.Strikes(-5, +5));
    }
}
```

The Future resolution must be less than or equal to the Future Option resolution. For example, if you set the Future resolution to minute, then the Future Option resolution must be minute, hour, or daily.

For more information about creating Future Options subscriptions, see Requesting Data or Future Options Universes .

Accessing Data

To get the current Future Options data, iterate through the `OptionChains` property of the current `Slice` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Future Options at every time step.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.OptionChains)
    {
        var canonicalFOPSymbol = kvp.Key;
        var chain = kvp.Value;
        foreach (var contract in chain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }
}
```

You can also iterate through the `FuturesChains` in the current `Slice` first.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.FuturesChains)
    {
        var continuousContractSymbol = kvp.Key;
        var futuresChain = kvp.Value;

        // Select a Future Contract and create its canonical FOP Symbol
        var futuresContract = futuresChain.First();
        var canonicalFOPSymbol = QuantConnect.Symbol.CreateCanonicalOption(futuresContract.Symbol);
        if (slice.OptionChains.TryGetValue(canonicalFOPSymbol, out var optionChain))
        {
            foreach (var fopContract in optionChain)
            {
                Log($"{fopContract.Symbol} price at {slice.Time}: {fopContract.LastPrice}");
            }
        }
    }
}
```

For more information about accessing Future Options data, see Handling Data .

Historical Data

You can get historical US Future Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Future Options data in an algorithm, call the `History` method with the Future Option contract `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(contract.Symbol, 100, Resolution.Minute);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(contract.Symbol, 100, Resolution.Minute);

// OpenInterest objects
var historyOpenInterest = History<OpenInterest >(contract.Symbol, 100, Resolution.Minute);
```

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Future Options data in the Research Environment, call the `History` or `OptionHistory` method. The `History` method returns the price, volume, and open interest history for some given Future Option contract(s). The `OptionHistory` method returns the price and volume history for the contracts that pass your daily universe filter.

```C#
var qb = new QuantBook();
var future = qb.AddFuture(Futures.Indices.SP500EMini);
var startDate = new DateTime(2024, 1, 2);
var futureContractSymbol = qb.FutureChainProvider.GetFutureContractList(future.Symbol, startDate)
    .OrderBy(x => x.ID.Date)
    .First();
var history = qb.OptionHistory(
    futureContractSymbol, startDate, futureContractSymbol.ID.Date, Resolution.Hour
);

var contracts = history
    .SelectMany(x => x.OptionChains.SelectMany(y => y.Value.Contracts.Keys))
    .Distinct().ToList();
var expiries = contracts.Select(x => x.ID.Date).Distinct().ToList();
var strikes = contracts.Select(x => x.ID.StrikePrice).Distinct().ToList();
```

To get historical data for arbitrary US Equity Option contracts instead of just the that pass your universe filter, call the `History` method like you would in an algorithm, but on the `QuantBook` object. For more information about historical data in the Research Environment, see Key Concepts .

Supported Assets

The following list shows the available (15) Futures Options:

- `Futures.Energy.CrudeOilWTI` : Crude Oil WTI Futures (NYMEX: LO | Underlying: CL)
- `Futures.Energy.Gasoline` : Gasoline RBOB Futures (NYMEX: OB | Underlying: RB)
- `Futures.Energy.HeatingOil` : Heating Oil Futures (NYMEX: OH | Underlying: HO)
- `Futures.Energy.NaturalGas` : Natural Gas Futures (NYMEX: ON | Underlying: NG)
- `Futures.Financials.Y10TreasuryNote` : 10Y U.S. Treasury Note Futures (CBOT: OZN | Underlying: ZN)
- `Futures.Financials.Y2TreasuryNote` : 2Y U.S. Treasury Note Futures (CBOT: OZT | Underlying: ZT)

- `Futures.Financials.Y30TreasuryBond` : 30Y U.S. Treasury Bond Futures (CBOT: OZB | Underlying: ZB)
- `Futures.Grains.Corn` : Corn Futures (CBOT: OZC | Underlying: ZC)
- `Futures.Grains.Soybeans` : Soybeans Futures (CBOT: OZS | Underlying: ZS)
- `Futures.Grains.Wheat` : Default wheat contract is SRWWheat (CBOT: OZW | Underlying: ZW)
- `Futures.Indices.NASDAQ100EMini` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.SP500EMini` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Metals.Copper` : Copper Futures (COMEX: HXE | Underlying: HG)
- `Futures.Metals.Gold` : Gold Futures (COMEX: OG | Underlying: GC)
- `Futures.Metals.Silver` : Silver Futures (COMEX: SO | Underlying: SI)

Example Applications

The US Future Options dataset enables you to accurately design Future Option strategies. Examples include the following strategies:

- Selling out of the money Future Option contracts to collect the premium that the Option buyer pays
- Buying put Options to hedge against downward price movement in Future contracts you bought
- Exploiting arbitrage opportunities that arise when the price of Option contracts deviates from their theoretical value

Classic Algorithm Example

The following example demonstrates a weekly-renewing covered call strategy to collect credit of selling the option. It filters the ATM call contract that expires within the current week at week start using `SetFilter` filtering function.

```C#
public class FutureOptionExampleAlgorithm : QCAlgorithm
{
    private Future _underlying;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(5000000);
        // Subscribe the underlying since the updated price is needed for filtering
        _underlying = AddFuture(Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        // Filter the underlying continuous Futures to narrow the FOP spectrum
        _underlying.SetFilter(0, 182);
        // Filter for the current-week-expiring calls to formulate a covered call that expires at the end of week
        AddFutureOption(_underlying.Symbol, (u) => u.IncludeWeeklys().CallsOnly().Expiration(0, 5));
    }

    public override void OnData(Slice slice)
    {
        // Create canonical symbol for the mapped future contract, since option chains are mapped by canonical symbol
        var symbol = QuantConnect.Symbol.CreateCanonicalOption(_underlying.Mapped);

        // Get option chain data for the mapped future, as both the underlying and FOP have the highest liquidity
among all other contracts
        if (!Portfolio.Invested &&
            slice.OptionChains.TryGetValue(symbol, out var chain))
        {
            // Obtain the ATM call that expires at the end of week, such that both underlying and the FOP expires the
same time
            var expiry = chain.Max(x => x.Expiry);
            var atmCall = chain.Where(x => x.Expiry == expiry)
                .OrderBy(x => Math.Abs(x.Strike - x.UnderlyingLastPrice))
                .First();

            // Use abstraction method to order a covered call to avoid manual error
            var optionStrategy = OptionStrategies.CoveredCall(symbol, atmCall.Strike, expiry);
            Buy(optionStrategy, 1);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            if (security.Type == SecurityType.FutureOption)
            {
                // Historical data
                var history = History(security.Symbol, 10, Resolution.Minute);
            }
        }
    }
}
```

Framework Algorithm Example

The following example demonstrates a daily renewing speculation trade on upward movement of Gold with FOP using algorithm framework. Using FOP, traders can achieve lower cost to get similar absolute profit, given the FOP is selected to be deep ITM with high Delta value.

```C#
public class FutureOptionDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Override an option universe selection model to select the FOPs
        AddUniverseSelection(new GoldFOPUniverseSelectionModel(this));
        // Handle the FOP trading logic in an alpha model
```

```
        SetAlpha(new ConstantFutureOptionsAlphaModel());
        // To order a single contract per insight, use a custom portfolio construction model
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

public class GoldFOPUniverseSelectionModel : OptionUniverseSelectionModel
{
    // Daily renewed universe since option contract list is updated on a daily basis
    public GoldFOPUniverseSelectionModel(QCAlgorithm algorithm)
        : base(TimeSpan.FromDays(1), _ => OptionChainSymbolSelector(algorithm, _))
    {
    }

    private static IEnumerable<Symbol> OptionChainSymbolSelector(QCAlgorithm algorithm, DateTime utcTime)
    {
        // Create the underlying symbol to get the FOP contracts later
        var futureSymbol = QuantConnect.Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX);
        // Get all gold FOP contracts of the front month gold contract expiring within 3 months, since their
liquidity is the highest
        return algorithm.FutureChainProvider.GetFutureContractList(futureSymbol, algorithm.Time)
            .Where(futureContractSymbol => futureContractSymbol.ID.Date <= algorithm.Time + TimeSpan.FromDays(90))
            .Select(futureContractSymbol => QuantConnect.Symbol.CreateCanonicalOption(futureContractSymbol));
    }

    protected override OptionFilterUniverse Filter(OptionFilterUniverse optionFilterUniverse)
    {
        // Filter for the ATM calls that expires latest (same expiry as the underlying)
        // +/-5 strike range buffer for price movement
        return optionFilterUniverse.BackMonth().Strikes(-5, +5).CallsOnly();
    }
}

class ConstantFutureOptionsAlphaModel : AlphaModel
{
    // A dictionary to cache the mapped FOP of the underlying Future for filtering wanted option chain data and check
if invested
    private Dictionary<Symbol, OptionContract> optionContractByUnderlyingFutureContract = new Dictionary<Symbol,
OptionContract>();

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        foreach (var kvp in slice.OptionChains)
        {
            // Liquidate underlying Future contract after Option assignment
            var underlyingFutureContract = kvp.Key.Underlying;
            if (algorithm.Portfolio[underlyingFutureContract].Invested)
            {
                algorithm.Insights.Cancel(new[] { underlyingFutureContract });
                optionContractByUnderlyingFutureContract.Remove(underlyingFutureContract);
            }

            // Do not repeatly invest in the same underlying's FOP
            var chain = kvp.Value.Where(contract => algorithm.Securities[contract.Symbol].IsTradable);
            if (chain.Count() == 0 || optionContractByUnderlyingFutureContract.ContainsKey(underlyingFutureContract))
            {
                continue;
            }

            // Select the Option contract with the lowest strike price to speculate trade the underlying with lowest
cost and highest delta
            var contract = chain.MinBy(contract => contract.Strike);
            insights.Add(Insight.Price(contract.Symbol, contract.Expiry.AddDays(1), InsightDirection.Up));
            optionContractByUnderlyingFutureContract.Add(kvp.Key.Underlying, contract);
        }
        return insights;
    }
}

class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
{
    public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
    {
        var targets = new List<PortfolioTarget>();
        foreach (var insight in insights)
        {
            if (algorithm.Securities[insight.Symbol].IsTradable)
```

```
                {
                    // Use integer target to create a portfolio target to trade a single contract
                    targets.Add(new PortfolioTarget(insight.Symbol, (int) insight.Direction));
                }
            }
            return targets;
        }
    }
```

AlgoSeek

US Futures

Introduction

The US Futures dataset by AlgoSeek provides Futures data, including price, volume, open interest, and expiry. The data covers the 157 most liquid contracts, starts in May 2009, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on the CFE *, CBOT, CME, COMEX, NYMEX, and ICE *.

This dataset also depends on the US Futures Security Master because the US Futures Security Master dataset contains information to construct continuous Futures.

For more information about the US Futures dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering equities, futures, options, cash forex, and cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Futures dataset:

```C#
var future = AddFuture(Futures.Metals.Gold);
future.SetFilter(0, 90);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2009
Asset Coverage	157 Futures
Data Density	Dense
Resolution	Tick, Second, Minute, Hour, & Daily
Timezone	• Chicago (CFE, CME or CBOT) • New York (ICE, NYMEX or COMEX)
Market Hours	Regular and Extended

This dataset only includes Sugar (SB) from the ICE exchange.

This data provider doesn't include a live data feed for the CFE market (VIX).

LBS (Random Length Lumber) was deprecated for LBR (Lumber).

Volume Discrepancies

The volume of the daily trade bars from this dataset is different from the daily volume that CME and other platforms like Yahoo Finance report because the CME includes pit trades in their daily volume calculation. In contrast, the volume of the daily trade bars in this dataset (from AlgoSeek) doesn't include pit trades because pit trades are over-the-counter, which algorithms can't trade.

Another discrepancy occurs from the start and end times of the daily bars. Daily bars from the CME and Yahoo Finance span from 5 PM Central Time (CT) to 4 PM CT on the following day. In contrast, QuantConnect consolidates daily bars from from 12 AM Eastern Time (ET) to 12 AM ET the following day. Therefore, to calculate the daily volume in the same way that CME does (excluding the pit trades), sum the volume of intraday bars that span 5 PM CT to 4 PM CT on the following day. For an example implementation, see Examples .

Requesting Data

To add US Futures data to your algorithm, call the `AddFuture` method. Save a reference to the Future so you can access the data later in your algorithm.

```
C#
public class USFuturesDataAlgorithm : QCAlgorithm
{
    private Symbol _futureSymbol;

    public override void Initialize()
    {
        SetStartDate(2013, 12, 20);
        SetEndDate(2014, 2, 20);
        SetCash(1000000);
        UniverseSettings.Asynchronous = true;
        // Request Gold Future data
        var future = AddFuture(Futures.Metals.Gold);
        // Set filter to obtain the contracts expire within 90 days
        future.SetFilter(0, 90);
        _futureSymbol = future.Symbol;
    }
}
```

For more information about creating Future subscriptions, see Requesting Data or Futures Universes .

Accessing Data

To get the current US Futures data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Future `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    // Access data: TradeBar data
    if (slice.Bars.TryGetValue(_futureSymbol, out var tradeBar))
    {
        Log($"{_futureSymbol} price at {slice.Time}: {tradeBar.Close}");
    }

    // Access data: QuoteBar data
    if (slice.QuoteBars.TryGetValue(_futureSymbol, out var quoteBar))
    {
        Log($"{_futureSymbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    // Access data: Ticks data
    if (slice.Ticks.TryGetValue(_futureSymbol, out var ticks))
    {
        foreach (var tick in ticks)
        {
            Log($"{_futureSymbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    // Iterate all TradeBar received
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    // Iterate all QuoteBar received
    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    // Iterate all Ticks received
    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing US Futures data, see Handling Data .

Historical Data

You can get historical US Futures data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Futures data in an algorithm, call the `History` method with the canonical Futures `Symbol` or a Futures contract `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var contractHistoryTradeBars = History(contract.Symbol, 100, Resolution.Minute);
var continuousHistoryTradeBars = History(
    symbols: new[] {_futureSymbol},
    start: Time - TimeSpan.FromDays(15),
    end: Time,
    resolution: Resolution.Minute,
    fillForward: false,
    extendedMarketHours: false,
    dataMappingMode: DataMappingMode.OpenInterest,
    dataNormalizationMode: DataNormalizationMode.Raw,
    contractDepthOffset: 0);

// QuoteBar objects
var contractHistoryQuoteBars = History<QuoteBar>(contract.Symbol, 100, Resolution.Minute);
var continuousHistoryQuoteBars = History<QuoteBar>(_futureSymbol, 100, Resolution.Minute);

// Tick objects
var contractHistoryTicks = History<Tick>(contract.Symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
var continuousHistoryTicks = History<Tick>(_futureSymbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data in algorithms, see History Requests . For more information about the price adjustments for continuous contracts, see Continous Contracts .

Historical Data In Research

To get historical US Futures data in the Research Environment for an entire Futures chain, call the `FutureHistory` method with the canonical Future `Symbol` .

```C#
var qb = new QuantBook();
var future = qb.AddFuture(Futures.Metals.Gold);
future.SetFilter(0, 90);
var history = qb.FutureHistory(future.Symbol, new DateTime(2020, 6, 1), new DateTime(2020, 6, 5));

var contracts = history.SelectMany(x => x.OptionChains.SelectMany(y => y.Value.Contracts.Keys)).Distinct().ToList();
var expiries = contracts.Select(x => x.ID.Date).Distinct().ToList();
```

To get historical data for a single US Futures contract or the continuous Futures contract, call the `History` method like you would in an algorithm but on the `QuantBook` object. For more information about historical data in the Research Environment, see Futures .

Supported Assets

The following list shows the available (157) Futures:

- `Futures.Currencies.AUD` : Australian Dollar Futures (CME: 6A)
- `Futures.Currencies.AUDCAD` : Australian Dollar/Canadian Dollar Futures (CME: ACD)
- `Futures.Currencies.AUDJPY` : Australian Dollar/Japanese Yen Futures (CME: AJY)
- `Futures.Currencies.AUDNZD` : Australian Dollar/New Zealand Dollar Futures (CME: ANE)
- `Futures.Currencies.BRL` : Brazillian Real Futures (CME: 6L)
- `Futures.Currencies.BTC` : Bitcoin Futures (CME: BTC)
- `Futures.Currencies.BTICMicroBTC` : BTIC on Micro Bitcoin Futures (CME: MIB)
- `Futures.Currencies.BTICMicroEther` : BTIC on Micro Ether Futures (CME: MRB)
- `Futures.Currencies.CAD` : Canadian Dollar Futures (CME: 6C)
- `Futures.Currencies.CADJPY` : Canadian Dollar/Japanese Yen Futures (CME: CJY)
- `Futures.Currencies.CHF` : Swiss Franc Futures (CME: 6S)
- `Futures.Currencies.ETH` : Ether Futures (CME: ETH)

- `Futures.Currencies.EUR` : Euro FX Futures (CME: 6E)
- `Futures.Currencies.EURAUD` : Euro/Australian Dollar Futures (CME: EAD)
- `Futures.Currencies.EURCAD` : Euro/Canadian Dollar Futures (CME: ECD)
- `Futures.Currencies.EuroFXEmini` : E-mini Euro FX Futures (CME: E7)
- `Futures.Currencies.EURSEK` : Euro/Swedish Krona Futures (CME: ESK)
- `Futures.Currencies.GBP` : British Pound Futures (CME: 6B)
- `Futures.Currencies.JapaneseYenEmini` : E-mini Japanese Yen Futures (CME: J7)
- `Futures.Currencies.JPY` : Japanese Yen Futures (CME: 6J)
- `Futures.Currencies.MicroAUD` : Micro AUD/USD Futures (CME: M6A)
- `Futures.Currencies.MicroBTC` : Micro Bitcoin Futures (CME: MBT)
- `Futures.Currencies.MicroCAD` : Micro USD/CAD Futures (CME: M6C)
- `Futures.Currencies.MicroCADUSD` : Micro CAD/USD Futures (CME: MCD)
- `Futures.Currencies.MicroCHF` : Micro CHF/USD Futures (CME: MSF)
- `Futures.Currencies.MicroEther` : Micro Ether Futures (CME: MET)
- `Futures.Currencies.MicroEUR` : Micro EUR/USD Futures (CME: M6E)
- `Futures.Currencies.MicroGBP` : Micro GBP/USD Futures (CME: M6B)
- `Futures.Currencies.MicroINRUSD` : Micro INR/USD Futures (CME: MIR)
- `Futures.Currencies.MicroJPY` : Micro JPY/USD Futures (CME: MJY)
- `Futures.Currencies.MicroUSDCHF` : Micro USD/CHF Futures (CME: M6S)
- `Futures.Currencies.MicroUSDCNH` : Micro USD/CNH Futures (CME: MNH)
- `Futures.Currencies.MicroUSDJPY` : Micro USD/JPY Futures (CME: M6J)
- `Futures.Currencies.MXN` : Mexican Peso Futures (CME: 6M)
- `Futures.Currencies.NZD` : New Zealand Dollar Futures (CME: 6N)
- `Futures.Currencies.RUB` : Russian Ruble Futures (CME: 6R)
- `Futures.Currencies.StandardSizeUSDOffshoreRMBCNH` : Standard-Size USD/Offshore RMB (CNH) Futures (CME: CNH)
- `Futures.Currencies.ZAR` : South African Rand Futures (CME: 6Z)
- `Futures.Energy.ArgusLLSvsWTIArgusTradeMonth` : Argus LLS vs. WTI (Argus) Trade Month Futures (NYMEX: AE5)
- `Futures.Energy.ArgusPropaneFarEastIndex` : Argus Propane Far East Index Futures (NYMEX: A7E)
- `Futures.Energy.ArgusPropaneSaudiAramco` : Argus Propane (Saudi Aramco) Futures (NYMEX: A9N)
- `Futures.Energy.BrentCrudeOilVsDubaiCrudeOilPlatts` : Brent Crude Oil vs. Dubai Crude Oil (Platts) Futures (NYMEX: ADB)
- `Futures.Energy.BrentLastDayFinancial` : Brent Last Day Financial Futures (NYMEX: BZ)
- `Futures.Energy.ChicagoEthanolPlatts` : Chicago Ethaanol (Platts) Futures (NYMEX: CU)
- `Futures.Energy.ConwayPropaneOPIS` : Conway Propane (OPIS) Futures (NYMEX: A8K)
- `Futures.Energy.CrudeOilWTI` : Crude Oil WTI Futures (NYMEX: CL)
- `Futures.Energy.DubaiCrudeOilPlattsFinancial` : Dubai Crude Oil (Platts) Financial Futures (NYMEX: DCB)
- `Futures.Energy.EastWestGasolineSpreadPlattsArgus` : East-West Gasoline Spread (Platts-Argus) Futures (NYMEX: EWG)
- `Futures.Energy.EastWestNaphthaJapanCFvsCargoesCIFNWESpreadPlatts` : East-West Naphtha: Japan C&F vs. Cargoes CIF NWE Spread (Platts) Futures (NYMEX: EWN)
- `Futures.Energy.Ethanol` : Ethanol Futures (CBOT: EH)
- `Futures.Energy.EthanolT2FOBRdamIncludingDutyPlatts` : Ethanol T2 FOB Rdam Including Duty (Platts) Futures (NYMEX: AZ1)
- `Futures.Energy.EuropeanNaphthaPlattsCrackSpread` : European Naphtha (Platts) Crack Spread Futures (NYMEX: EN)
- `Futures.Energy.EuropeanPropaneCIFARAArgus` : European Propane CIF ARA (Argus) Futures (NYMEX: APS)

- `Futures.Energy.EuropeanPropaneCIFARAArgusVsNaphthaCargoesCIFNWEPlatts` : European Propane CIF ARA (Argus) vs. Naphtha Cargoes CIF NWE (Platts) Futures (NYMEX: EPN)
- `Futures.Energy.FreightRouteTC14Baltic` : Freight Route TC14 (Baltic) Futures (NYMEX: FRC)
- `Futures.Energy.Gasoline` : Gasoline RBOB Futures (NYMEX: RB)
- `Futures.Energy.GasolineEurobobOxyNWEBargesArgus` : Gasoline Euro-bob Oxy NWE Barges (Argus) Futures (NYMEX: B7H)
- `Futures.Energy.GroupThreeSuboctaneGasolinePlattsVsRBOB` : Group Three Sub-octane Gasoliine (Platts) vs. RBOB Futures (NYMEX: AA8)
- `Futures.Energy.GroupThreeULSDPlattsVsNYHarborULSD` : Group Three ULSD (Platts) vs. NY Harbor ULSD Futures (NYMEX: AA6)
- `Futures.Energy.GulfCoastCBOBGasolineA2PlattsVsRBOBGasoline` : Gulf Coast CBOB Gasoline A2 (Platts) vs. RBOB Gasoline Futures (NYMEX: CRB)
- `Futures.Energy.GulfCoastHSFOPlattsVsEuropeanThreePointFivePercentFuelOilBargesFOBRdamPlatts` : Gulf Coast HSFO (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: GCU)
- `Futures.Energy.HeatingOil` : Heating Oil Futures (NYMEX: HO)
- `Futures.Energy.LosAngelesCARBOBGasolineOPISvsRBOBGasoline` : Los Angeles CARBOB Gasoline (OPIS) vs. RBOB Gasoline Futures (NYMEX: AJL)
- `Futures.Energy.LosAngelesCARBDieselOPISvsNYHarborULSD` : Los Angeles CARB Diesel (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AKL)
- `Futures.Energy.LosAngelesJetOPISvsNYHarborULSD` : Los Angeles Jet (OPIS) vs. NY Harbor ULSD Futures (NYMEX: AJS)
- `Futures.Energy.MarsArgusVsWTIFinancial` : Mars (Argus) vs. WTI Financial Futures (NYMEX: AYX)
- `Futures.Energy.MarsArgusVsWTITradeMonth` : Mars (Argus) vs. WTI Trade Month Futures (NYMEX: AYV)
- `Futures.Energy.MicroCrudeOilWTI` : Micro WTI Crude Oil Futures (NYMEX: MCL)
- `Futures.Energy.MicroEuropeanFOBRdamMarineFuelZeroPointFivePercentBargesPlatts` : Micro European FOB Rdam Marine Fuel 0.5% Barges (Platts) Futures (NYMEX: R5O)
- `Futures.Energy.MicroEuropeanThreePointFivePercentOilBargesFOBRdamPlatts` : Micro European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: MEF)
- `Futures.Energy.MicroGasoilZeroPointOnePercentBargesFOBARAPlatts` : Micro Gasoil 0.1% Barges FOB ARA (Platts) Futures (NYMEX: M1B)
- `Futures.Energy.MicroSingaporeFOBMarineFuelZeroPointFivePercetPlatts` : Micro Singapore FOB Marine Fuel 0.5% (Platts) Futures (NYMEX: S5O)
- `Futures.Energy.MicroSingaporeFuelOil380CSTPlatts` : Micro Singapore Fuel Oil 380CST (Platts) Futures (NYMEX: MAF)
- `Futures.Energy.MiniEuropeanThreePointPercentFiveFuelOilBargesPlatts` : Mini European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: A0D)
- `Futures.Energy.MiniSingaporeFuelOil180CstPlatts` : Mini Singapore Fuel Oil 180 cst (Platts) Futures (NYMEX: A0F)
- `Futures.Energy.MontBelvieuEthaneOPIS` : Mont Belvieu Ethane (OPIS) Futures (NYMEX: AC0)
- `Futures.Energy.MontBelvieuLDHPropaneOPIS` : Mont Belvieu LDH Propane (OPIS) Futures (NYMEX: B0)
- `Futures.Energy.MontBelvieuNaturalGasolineOPIS` : Mont Belvieu Natural Gasoline (OPIS) Futures (NYMEX: A7Q)
- `Futures.Energy.MontBelvieuNormalButaneOPIS` : Mont Belvieu Normal Butane (OPIS) Futures (NYMEX: AD0)
- `Futures.Energy.NaturalGas` : Natural Gas Futures (NYMEX: NG)
- `Futures.Energy.NaturalGasHenryHubLastDayFinancial` : Natural Gas (Henry Hub) Last-day Financial Futures (NYMEX: HH)
- `Futures.Energy.NaturalGasHenryHubPenultimateFinancial` : Natural Gas (Henry Hub) Penultimate Financial Futures (NYMEX: HP)
- `Futures.Energy.OnePercentFuelOilCargoesFOBNWEPlattsVsThreePointFivePercentFuelOilBargesFOBRdamPlatts` : 1%

Fuel Oil Cargoes FOB NWE (Platts) vs. 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: FSS)

- `Futures.Energy.PremiumUnleadedGasoline10ppmFOBMEDPlatts` : Premium Unleaded Gasoline 10 ppm FOB MED (Platts) Futures (NYMEX: A3G)
- `Futures.Energy.PropaneNonLDHMontBelvieuOPIS` : Propane Non-LDH Mont Belvieu (OPIS) Futures (NYMEX: A1R)
- `Futures.Energy.RBOBGasolineCrackSpread` : RBOB Gasoline Crack Spread Futures (NYMEX: ARE)
- `Futures.Energy.RBOBGasolineVsEurobobOxyNWEBargesArgusThreeHundredFiftyThousandGallons` : RBOB Gasoline vs. Euro-bob Oxy NWE Barges (Argus) (350,000 gallons) Futures (NYMEX: EXR)
- `Futures.Energy.SingaporeFuelOil380cstPlattsVsEuropeanThreePointFivePercentFuelOilBargesFOBRdamPlatts` : Singapore Fuel Oil 380 cst (Platts) vs. European 3.5% Fuel Oil Barges FOB Rdam (Platts) Futures (NYMEX: EVC)
- `Futures.Energy.SingaporeGasoilPlattsVsLowSulphurGasoilFutures` : Singapore Gasoil (Platts) vs. Low Sulphur Gasoil Futures (NYMEX: AGA)
- `Futures.Energy.SingaporeMogas92UnleadedPlattsBrentCrackSpread` : Singapore Mogas 92 Unleaded (Platts) Brent Crack Spread Futures (NYMEX: D1N)
- `Futures.Energy.ThreePointFivePercentFuelOilBargesFOBRdamPlattsCrackSpread` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread Futures (NYMEX: FO)
- `Futures.Energy.ThreePointFivePercentFuelOilBargesFOBRdamPlattsCrackSpread1000mt` : 3.5% Fuel Oil Barges FOB Rdam (Platts) Crack Spread (1000mt) Futures (NYMEX: BOO)
- `Futures.Energy.WTIBrentFinancial` : WTI-Brent Financial Futures (NYMEX: BK)
- `Futures.Energy.WTIFinancial` : WTI Financial Futures (NYMEX: CSX)
- `Futures.Energy.WTIHoustonArgusVsWTITradeMonth` : WTI Houston (Argus) vs. WTI Trade Month Futures (NYMEX: HTT)
- `Futures.Energy.WTIHoustonCrudeOil` : WTI Houston Crude Oil Futures (NYMEX: HCL)
- `Futures.Financials.EuroDollar` : EuroDollar Futures (CME: GE)
- `Futures.Financials.FiveYearUSDMACSwap` : 5-Year USD MAC Swap Futures (CBOT: F1U)
- `Futures.Financials.MicroY10TreasuryNote` : Micro 10-Year Yield Futures (CBOT: 10Y)
- `Futures.Financials.MicroY2TreasuryBond` : Micro 2-Year Yield Futures (CBOT: 2YY)
- `Futures.Financials.MicroY30TreasuryBond` : Micro 30-Year Yield Futures (CBOT: 30Y)
- `Futures.Financials.MicroY5TreasuryBond` : Micro 5-Year Yield Futures (CBOT: 5YY)
- `Futures.Financials.UltraTenYearUSTreasuryNote` : Ultra 10-Year U.S. Treasury Note Futures (CBOT: TN)
- `Futures.Financials.UltraUSTreasuryBond` : Ultra U.S. Treasury Bond Futures (CBOT: UB)
- `Futures.Financials.Y10TreasuryNote` : 10Y U.S. Treasury Note Futures (CBOT: ZN)
- `Futures.Financials.Y2TreasuryNote` : 2Y U.S. Treasury Note Futures (CBOT: ZT)
- `Futures.Financials.Y30TreasuryBond` : 30Y U.S. Treasury Bond Futures (CBOT: ZB)
- `Futures.Financials.Y5TreasuryNote` : 5Y U.S. Treasury Note Futures (CBOT: ZF)
- `Futures.Forestry.Lumber` : Lumber Futures (CME: LBR)
- `Futures.Forestry.RandomLengthLumber` : Random Length Lumber Futures (CME: LBS)
- `Futures.Grains.BlackSeaCornFinanciallySettledPlatts` : Black Sea Corn Financially Settled (Platts) Futures (CBOT: BCF)
- `Futures.Grains.BlackSeaWheatFinanciallySettledPlatts` : Black Sea Wheat Financially Settled (Platts) Futures (CBOT: BWF)
- `Futures.Grains.Corn` : Corn Futures (CBOT: ZC)
- `Futures.Grains.HRWWheat` : KC HRW Wheat Futures (CBOT: KE)
- `Futures.Grains.Oats` : Oats Futures (CBOT: ZO)
- `Futures.Grains.Soybeans` : Soybeans Futures (CBOT: ZS)
- `Futures.Grains.SoybeanMeal` : Soybean Meal Futures (CBOT: ZM)
- `Futures.Grains.SoybeanOil` : Soybean Oil Futures (CBOT: ZL)

- `Futures.Grains.Wheat` : Default wheat contract is SRWWheat (CBOT: ZW)
- `Futures.Indices.BloombergCommodityIndex` : Bloomberg Commodity Index Futures (CBOT: AW)
- `Futures.Indices.Dow30EMini` : E-mini Dow Indu 30 Futures (CBOT: YM)
- `Futures.Indices.DowJonesRealEstate` : Dow Jones Real Estate futures on CME (CME: RX)
- `Futures.Indices.FTSEEmergingEmini` : E-mini FTSE Emerging Index Futures (CME: EI)
- `Futures.Indices.MicroDow30EMini` : Micro E-mini Dow Jones Industrial Average Index Futures (CBOT: MYM)
- `Futures.Indices.MicroNASDAQ100EMini` : Micro E-mini Nasdaq-100 Index Futures (CME: MNQ)
- `Futures.Indices.MicroRussell2000EMini` : Micro E-mini Russell 2000 Index Futures (CME: M2K)
- `Futures.Indices.MicroSP500EMini` : Micro E-mini S&P 500 Index Futures (CME: MES)
- `Futures.Indices.NASDAQ100BiotechnologyEMini` : E-mini Nasdaq-100 Biotechnology Index Futures (CME: BIO)
- `Futures.Indices.NASDAQ100EMini` : E-mini NASDAQ 100 Futures (CME: NQ)
- `Futures.Indices.Nikkei225Dollar` : Nikkei-225 Dollar Futures (CME: NKD)
- `Futures.Indices.Nikkei225YenCME` : Nikkei-225 Yen denominated Futures on CME (CME: NIY)
- `Futures.Indices.Russell1000EMini` : E-mini Russell 1000 futures on CME (CME: RS1)
- `Futures.Indices.Russell2000EMini` : E-mini Russell 2000 Futures (CME: RTY)
- `Futures.Indices.SPGSCICommodity` : S&P-GSCI Commodity Index Futures (CME: GD)
- `Futures.Indices.SP400MidCapEmini` : E-mini S&P MidCap 400 Futures (CME: EMD)
- `Futures.Indices.SP500AnnualDividendIndex` : (CME: SDA)
- `Futures.Indices.SP500EMini` : E-mini S&P 500 Futures (CME: ES)
- `Futures.Indices.TOPIXYEN` : YEN Denominated Topix Index Futures on CME (CME: TPY)
- `Futures.Indices.USDDenominatedIbovespa` : USD-Denominated Ibovespa Index Futures (CME: IBV)
- `Futures.Indices.VIX` : CBOE Volatility Index Futures (CFE: VX)
- `Futures.Meats.FeederCattle` : Feeder Cattle Futures (CME: GF)
- `Futures.Meats.LeanHogs` : Lean Hogs Futures (CME: HE)
- `Futures.Meats.LiveCattle` : Live Cattle Futures (CME: LE)
- `Futures.Metals.AluminiumEuropeanPremiumDutyPaidMetalBulletin` : Aluminium European Premium Duty-Paid (Metal Bulletin) Futures (COMEX: EDP)
- `Futures.Metals.AluminumMWUSTransactionPremiumPlatts25MT` : Aluminum MW U.S. Transaction Premium Platts (25MT) Futures (COMEX: AUP)
- `Futures.Metals.Copper` : Copper Futures (COMEX: HG)
- `Futures.Metals.Gold` : Gold Futures (COMEX: GC)
- `Futures.Metals.MicroGold` : Micro Gold Futures (COMEX: MGC)
- `Futures.Metals.MicroGoldTAS` : Micro Gold TAS Futures (COMEX: MGT)
- `Futures.Metals.MicroPalladium` : Micro Palladium Futures (NYMEX: PAM)
- `Futures.Metals.MicroSilver` : Micro Silver Futures (COMEX: SIL)
- `Futures.Metals.Palladium` : Palladium Futures (NYMEX: PA)
- `Futures.Metals.Platinum` : Platinum Futures (NYMEX: PL)
- `Futures.Metals.Silver` : Silver Futures (COMEX: SI)
- `Futures.Metals.USMidwestDomesticHotRolledCoilSteelCRUIndex` : U.S. Midwest Domestic Hot-Rolled Coil Steel (CRU) Index Futures (NYMEX: HRC)
- `Futures.Softs.Sugar11` : Sugar #11 Futures ICE (ICE: SB)
- `Futures.Softs.Sugar11CME` : Sugar #11 Futures CME (NYMEX: YO)

Example Applications

The US Futures dataset enables you to accurately design Futures strategies. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trading bull calendar spreads to reduce volatility and margin requirements

Classic Algorithm Example

The following example algorithm buys the Mini Gold Futures contract with the greatest open interest and sells the Micro Gold Futures contract with the greatest open interest. When the open interest of a different contract exceeds the open interest of a contract in the portfolio, the algorithm rebalances the portfolio.

```
C#
public class USFuturesDataAlgorithm : QCAlgorithm
{
    private Future _gold, _microGold;
    private decimal _goldMulitplier, _microGoldMulitplier;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        // Setting the continuous contract mapping criteria for both Gold and Micro Gold contracts, since we want to
order the highest liquidity contracts
        Settings.SeedInitialPrices = true;
        _gold = AddFuture(Futures.Metals.Gold,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        _microGold = AddFuture(Futures.Metals.MicroGold,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0);
        // The contract multiplier is cached in the Security SymbolProperties property from the symbol properties
database
        _goldMulitplier = _gold.SymbolProperties.ContractMultiplier;
        _microGoldMulitplier = _microGold.SymbolProperties.ContractMultiplier;
    }

    public override void OnData(Slice slice)
    {
        // Make sure to calculate the order size by the most updated price data of both contracts
        if (!Portfolio.Invested && slice.Bars.ContainsKey(_gold.Symbol) && slice.Bars.ContainsKey(_microGold.Symbol))
        {
            // Calculate the order size for $500k
            // Get the quotient after dividing the contract multiplier since the order size must be whole number
            var goldQuantity = Math.Floor(500000m / slice.Bars[_gold.Symbol].Close / _goldMulitplier);
            var microGoldQuantity = Math.Floor(500000m / slice.Bars[_microGold.Symbol].Close / _microGoldMulitplier);

            MarketOrder(_gold.Mapped, goldQuantity);
            MarketOrder(_microGold.Mapped, microGoldQuantity);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 100, Resolution.Minute);
            Debug($"We got {history.Count()} from our history request for {security.Symbol}");
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buys the front-month Mini Gold Futures contract and sells the front-month Micro Gold Futures contract. When the front-month contract changes, the algorithm rebalances the portfolio.

```
C#
public class USFuturesDataAlgorithm : QCAlgorithm
```

```
public class GoldMicroFuturesDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        UniverseSettings.Asynchronous = true;
        // Set up an universe selection model that selects the front month contract
        SetUniverseSelection(new FrontMonthFutureUniverseSelectionModel());
        SetAlpha(new ConstantFuturesAlphaModel());
        // A portfolio construction model that only order a single share per insight signal
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

class FrontMonthFutureUniverseSelectionModel : FutureUniverseSelectionModel
{
    // Daily updating with select_future_chain_symbols function
    public FrontMonthFutureUniverseSelectionModel()
        : base(TimeSpan.FromDays(1), SelectFutureChainSymbols) {}

    private static IEnumerable<Symbol> SelectFutureChainSymbols(DateTime utcTime)
    {
        //Select gold and micro gold contracts for the strategy need
        return new List<Symbol> {
            QuantConnect.Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX),
            QuantConnect.Symbol.Create(Futures.Metals.MicroGold, SecurityType.Future, Market.COMEX)
        };
    }

    protected override FutureFilterUniverse Filter(FutureFilterUniverse filter)
    {
        // Filter only front month contract for liquidity and most informed information
        return filter.FrontMonth().OnlyApplyFilterAtMarketOpen();
    }
}

class ConstantFuturesAlphaModel : AlphaModel
{
    // Long gold and short micro gold in this strategy
    private Symbol
        _longSymbol = QuantConnect.Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX),
        _shortSymbol = QuantConnect.Symbol.Create(Futures.Metals.MicroGold, SecurityType.Future, Market.COMEX);

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        if (algorithm.Portfolio.Invested)
        {
            return insights;
        }

        // For both gold and micro gold, select the front month contract (only contract) in the chain
        foreach (var kvp in slice.FutureChains)
        {
            var symbol = kvp.Key;
            var chain = kvp.Value;
            var contract = chain.First();

            // Long gold and short micro gold as planned
            if (symbol == _longSymbol)
            {
                insights.Add(Insight.Price(contract.Symbol, contract.Expiry + TimeSpan.FromDays(1),
InsightDirection.Up));
            }
            else if (symbol == _shortSymbol)
            {
                insights.Add(Insight.Price(contract.Symbol, contract.Expiry + TimeSpan.FromDays(1),
InsightDirection.Down));
            }
        }

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
```

```
            {
                // Historical data
                var history = algorithm.History(security.Symbol, 100, Resolution.Minute);
                algorithm.Debug($"We got {history.Count()} from our history request for {security.Symbol}");
            }
        }
    }

    class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
    {
        public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
        {
            var targets = new List<PortfolioTarget>();
            foreach (var insight in insights)
            {
                if (algorithm.Securities[insight.Symbol].IsTradable)
                {
                    // Single share only using integer portfolio target
                    targets.Add(new PortfolioTarget(insight.Symbol, (int) insight.Direction));
                }
            }
            return targets;
        }
    }
```

Data Point Attributes

The US Futures dataset provides `FuturesChain` , `Future` , and `OpenInterest` objects. To configure the continuous Future settings, use the `DataNormalizationMode` and `DataMappingMode` enumerations.

DataNormalizationMode Values

The `DataNormalizationMode` enumeration has the following values:

DataMappingMode Values

The `DataMappingMode` enumeration has the following values:

Future Attributes

`Future` objects have the following attributes:

FuturesChain Attributes

`FuturesChain` objects have the following attributes:

OpenInterest Attributes

`OpenInterest` objects have the following attributes:

AlgoSeek

US Index Options

Introduction

The US Index Options dataset by AlgoSeek provides Option data, including prices, strikes, expires, and open interest. The data covers European Option contracts for 3 US Indices: SPX, VIX, and NDX. It starts from January 2012 and is delivered on minute resolution. This dataset is created by monitoring the Options Price Reporting Authority (OPRA) data feed, which consolidates last sale and quotation information originating from the national securities exchanges that have been approved by the Securities and Exchange Commission.

The US Index Options dataset depends on the US Index Option Universe dataset because the US Index Options Universe dataset contains information on the available contracts, including their daily Greeks and implied volatility values.

For more information about the US Index Options dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

AlgoSeek is a leading historical intraday US market data provider offering the most comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cryptocurrencies. AlgoSeek data is built for quantitative trading and machine learning. For more information about AlgoSeek, visit algoseek.com .

Getting Started

The following snippet demonstrates how to request data from the US Index Options dataset:

```C#
_indexSymbol = AddIndex("VIX").Symbol;
var option = AddIndexOption(_indexSymbol);
option.SetFilter(-2, 2, 0, 90);
_optionSymbol = option.Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2012
Asset Coverage	7 Index Options
Data Density	Regular
Resolution	Minute, Hourly, & Daily
Timezone	New York
Market Hours	Regular Only

Specification Over Time

According to the SPX Options contract specification , some SPX contracts expire every month and SPXW contracts expires every day. Before 2021, you could only trade SPX contracts with the following expiration dates:

- Expires within the next 4 months
- Expires in September within the next 14 months
- Expires in January, March, or June within the next 2 years
- Expires in December within the next 3 years

During this time, SPXW didn't have 0DTE every day.

`Sources` :

- Cboe Options Exchange to List Three Long-Dated SPX Options Expirations, Beginning November 1, 2021

- S&P 500 Weekly Options Now Expire Five Days a Week

Requesting Data

To add US Index Options data to your algorithm, call the `AddIndexOption` method. Save a reference to the Index Option `Symbol` so you can access the data later in your algorithm.

```
C#
public class IndexOptionsDataAlgorithm : QCAlgorithm
{
    private Symbol _indexSymbol, _standardOptionSymbol, _weeklyOptionSymbol;

    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;
        _indexSymbol = AddIndex("VIX").Symbol;

        var standardOption = AddIndexOption(_indexSymbol);
        standardOption.SetFilter(-2, 2, 0, 90);
        _standardOptionSymbol = standardOption.Symbol;

        var weeklyOption = AddIndexOption(_indexSymbol, "VIXW");
        weeklyOption.SetFilter(-2, 2, 0, 90);
        _weeklyOptionSymbol = weeklyOption.Symbol;
    }
}
```

The Index resolution must be less than or equal to the Index Option resolution. For example, if you set the Index resolution to minute, then you must set the Index Option resolution to minute, hour, or daily.

For more information about creating US Index Option subscriptions, see Requesting Data or Index Options Universes .

Accessing Data

To get the current US Index Options data, index the `OptionChains` property of the current `Slice` with the canonical Index Option `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Index Option at every time step.

```
public override void OnData(Slice slice)
{
    if (slice.OptionChains.ContainsKey(_standardOptionSymbol))
    {
        var standardChain = slice.OptionChains[_standardOptionSymbol];
        foreach (var contract in standardChain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }

    if (slice.OptionChains.ContainsKey(_weeklyOptionSymbol))
    {
        var weeklyChain = slice.OptionChains[_weeklyOptionSymbol];
        foreach (var contract in weeklyChain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }
}
```

C#

You can also iterate through all of the `OptionChain` objects in the current `Slice` .

```
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.OptionChains)
    {
        var canonicalSymbol = kvp.Key;
        var chain = kvp.Value;
        foreach (var contract in chain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }
}
```

C#

For more information about accessing US Index Options data, see Handling Data .

Historical Data

You can get historical US Index Options data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical US Index Options data in an algorithm, call the `History` method with the Index Option contract `Symbol` . If there is no data in the period you request, the history result is empty.

```
// TradeBar objects
var historyTradeBars = History(contract.Symbol, 100, Resolution.Minute);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(contract.Symbol, 100, Resolution.Minute);

// OpenInterest objects
var historyOpenInterest = History<OpenInterest>(contract.Symbol, 100, Resolution.Minute);
```

C#

For more information about historical data in algorithms, see History Requests .

Historical Data In Research

To get historical US Index Options data in the Research Environment, call the `History` or `OptionHistory` method. The `History` method returns the price, volume, and open interest history for some given Option contract(s). The `OptionHistory` method

returns the price and volume history for the contracts that pass your daily universe filter.

```
C#
var qb = new QuantBook();
var indexSymbol = qb.AddIndex("VIX").Symbol;
var option = qb.AddIndexOption(indexSymbol); // or qb.AddIndexOption(indexSymbol, "VIXW");
option.SetFilter(-2, 2, 0, 90);
var history = qb.OptionHistory(option.Symbol, new DateTime(2020, 6, 1), new DateTime(2020, 6, 5));

var contracts = history
    .SelectMany(x => x.OptionChains.SelectMany(y => y.Value.Contracts.Keys))
    .Distinct().ToList();
var expiries = contracts.Select(x => x.ID.Date).Distinct().ToList();
var strikes = contracts.Select(x => x.ID.StrikePrice).Distinct().ToList();
```

To get historical data for arbitrary US Index Option contracts instead of just the that pass your universe filter, call the `History` method like you would in an algorithm, but on the `QuantBook` object. For more information about historical data in the Research Environment, see Key Concepts .

Historical Greeks and IV Data

To get historical data for the Greeks and implied volatility of Index Options, see the US Index Option Universe dataset.

Supported Assets

The following table shows the available Index Options:

Underlying Index	Underlying Ticker	Target Ticker	Standard Contracts	Weekly Contracts	Tradable on Expiry Day
NASDAQ-100	NDX		✓		
NASDAQ-100	NDX	NDXP	✓		✓
NASDAQ-100	NDX	NQX	✓	✓	✓
Russell 2000	RUT		✓		
Russell 2000	RUT	RUTW		✓	✓
S&P500	SPX		✓		
S&P500	SPX	SPXW		✓	✓
S&P500	VIX		✓		
S&P500	VIX	VIXW		✓	

For more information about each underlying Index, see Supported Indices .

Example Applications

The US Index Options dataset enables you to accurately design strategies for Index Options. Examples include the following strategies:

- Buying VIX call Options to hedge against upcoming volatility
- Buying VIX put Options to capture the natural downward price movement in the VIX index
- Buying SPX put Options to protect against downward price movement in the S&P 500

Classic Algorithm Example

The following example algorithm buys the VIX Index Option Bull Call Spread with the furthest expiration:

C#

```
public class IndexOptionsDataAlgorithm : QCAlgorithm
{
    private Symbol _optionSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(200000);
        // Asynchronous can use computational resources efficiently
        UniverseSettings.Asynchronous = true;
        // Filter to get ATM calls expiring in 180 days to form the Bull Call Spread
        var option = AddIndexOption("SPX");
        option.SetFilter((u) => u.CallsOnly().Strikes(-2, +2).Expiration(0, 180));
        _optionSymbol = option.Symbol;
    }

    public override void OnData(Slice slice)
    {
        if (!Portfolio.Invested && IsMarketOpen(_optionSymbol))
        {
            // Make sure getting the updated VIX option chain
            if (slice.OptionChains.TryGetValue(_optionSymbol, out var chain))
            {
                var expiry = chain.Max(x => x.Expiry);
                var callContracts = chain
                    .Where(x => x.Expiry == expiry)
                    .OrderBy(x => x.Strike)
                    .ToList();

                // Need 2 contracts to form a call spread
                if (callContracts.Count < 2)
                {
                    return;
                }

                // Obtain 2 call contracts with different strike price to form the call spread
                var longCall = callContracts.First();
                var shortCall = callContracts.First(contract => contract.Strike > longCall.Strike);

                // Use all the buying power, but need to ensure the order size of the long and short call are the
same
                var quantity = new[] {
                    CalculateOrderQuantity(shortCall.Symbol, -1m),
                    CalculateOrderQuantity(longCall.Symbol, 1m) }
                    .Min(x=> Math.Abs(x));
                if (quantity == 0) return;

                // Bull call spread consists of long a lower-strike call and short a higher-strike call
                MarketOrder(shortCall.Symbol, -quantity);
                MarketOrder(longCall.Symbol, quantity);

                var expectedMarginUsage = Math.Max((longCall.Strike - shortCall.Strike) *
Securities[longCall.Symbol].SymbolProperties.ContractMultiplier * quantity, 0);
                if (expectedMarginUsage != Portfolio.TotalMarginUsed)
                {
                    throw new Exception("Unexpect margin used!");
                }
            }
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            if (security.Type == SecurityType.IndexOption)
            {
                // Historical data
                var history = History(security.Symbol, 10, Resolution.Minute);
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buys the VIX Index Option Bull Call Spread with the furthest expiration:

C#

```
public class IndexOptionsDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(200000);
        UniverseSettings.Asynchronous = true;
        SetUniverseSelection(new VIXIndexOptionUniverseSelectionModel());

        SetAlpha(new BullCallSpreadAlphaModel());

        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

public class VIXIndexOptionUniverseSelectionModel : OptionUniverseSelectionModel
{
    // Only interest in VIX options
    public VIXIndexOptionUniverseSelectionModel()
        : base(TimeSpan.FromDays(1),
            _ => new[] {QuantConnect.Symbol.Create("VIX", SecurityType.IndexOption, Market.USA)})
    {
    }

    protected override OptionFilterUniverse Filter(OptionFilterUniverse optionFilterUniverse)
    {
        // Filter to get ATM calls expiring in 180 days to form the Bull Call Spread
        return optionFilterUniverse.CallsOnly().Strikes(-2, +2).Expiration(0, 180);
    }
}

public class BullCallSpreadAlphaModel : AlphaModel
{
    public BullCallSpreadAlphaModel()
    {
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = Enumerable.Empty<Insight>();
        if (algorithm.Portfolio.Invested)
        {
            return insights;
        }

        foreach (var kvp in slice.OptionChains)
        {
            var canoncialSymbol = kvp.Key;
            var chain = kvp.Value;
            if (chain.IsNullOrEmpty())
            {
                return insights;
            }
            // Bull call spread legs are having the same expiry
            var expiry = chain.Max(contract => contract.Expiry);
            var callContracts = chain
                .Where(contract => contract.Expiry == expiry)
                .OrderBy(x => x.Strike)
                .ToList();

            // Need 2 contracts to form a call spread
            if (callContracts.Count < 2)
            {
                return insights;
            }

            // Obtain 2 call contracts with different strike price to form the call spread
            var longCall = callContracts.First();
            var shortCall = callContracts.First(contract => contract.Strike > longCall.Strike);

            // Bull call spread consists of long a lower-strike call and short a higher-strike call
            return Insight.Group(
                Insight.Price(longCall.Symbol, expiry.AddDays(1), InsightDirection.Up),
                Insight.Price(shortCall.Symbol, expiry.AddDays(1), InsightDirection.Down));
        }
        return insights;
```

```
            return insights;
        }
    }

    public class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
    {
        public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
        {
            if (insights.Count() == 0)
            {
                return Enumerable.Empty<PortfolioTarget>();
            }
            // Only a single contract toi ensure both legs size is equal
            var quantity = insights
                .Select(i => Math.Abs(algorithm.CalculateOrderQuantity(i.Symbol, (decimal)i.Direction)))
                .Min();

            return insights.Select(i => new PortfolioTarget(i.Symbol, quantity * (decimal)i.Direction));
        }
    }
```

Data Point Attributes

The US Index Options dataset provides `TradeBar` , `QuoteBar` , and `OpenInterest` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

OpenInterest Attributes

`OpenInterest` objects have the following attributes:

Datasets

Morningstar

Morningstar was founded by Joe Mansueto in 1984 with the goal of empowering investors by connecting people to the investing information and tools they need. Morningstar provides access extensive line of products and services for individual investors, financial advisors, asset managers, and retirement plan providers. Morningstar provides data on approximately 525,000 investment offerings including stocks, mutual funds, and similar vehicles, along with real-time global market data on nearly 18 million equities, indexes, futures, options, commodities, and precious metals, in addition to foreign exchange and Treasury markets. Morningstar also offers investment management services through its investment advisory subsidiaries, with $244 billion in assets under advisement or management as of 2021.

US Fundamental Data

Morningstar

US Fundamental Data

Introduction

The US Fundamental Data by Morningstar tracks US Equity fundamentals. The data covers 8,000 US Equities, starts in January 1998, and is delivered on a daily frequency. The data does not include ETFs, ADRs, or OTC equities. This dataset is created by using a combination of string matching, Regular Expressions, and Machine Learning to gather the fundamental data published by companies.

For older symbols, the file date is approximated 45 days after the as of date. When a filing date is present on the Morningstar data, it is used. As we are a quant platform, all the data is loaded using "As Original Reported" figures. If there was a mistake reporting the figure, this will not be fixed later. The market typically responds quickly to these initially reported figures. Data is available for multiple periods depending on the property. Periods available include: 1 mo, 2 mo, 3 mo, 6 mo, 9 mo, 12 mo, 1 Yr, 2 Yr, 3 Yr, and 5 Yr. Morningstar symbols cover the NYSE, NASDAQ, AMEX, and BATS exchanges.

In live trading, Morningstar data is delivered to your algorithm at approximately 6 am each day. The majority of the fundamental data update occurs once per month. This includes updates to all of the key information for each security Morningstar supports. On top of this monthly update, there are daily updates of the financial ratios.

As Morningstar data arrives, it updates the master copy and is passed into your algorithm, similar to how TradeBars are fill-forwarded in your data feed. If there have been no updates for a day, you'll receive the same fundamental data.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

QuantConnect/LEAN combines the data of this dataset with US Coarse Universe data in runtime.

For more information about the US Fundamental Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Morningstar was founded by Joe Mansueto in 1984 with the goal of empowering investors by connecting people to the investing information and tools they need. Morningstar provides access extensive line of products and services for individual investors, financial advisors, asset managers, and retirement plan providers. Morningstar provides data on approximately 525,000 investment offerings including stocks, mutual funds, and similar vehicles, along with real-time global market data on nearly 18 million equities, indexes, futures, options, commodities, and precious metals, in addition to foreign exchange and Treasury markets. Morningstar also offers investment management services through its investment advisory subsidiaries, with $244 billion in assets under advisement or management as of 2021.

Getting Started

The following snippets demonstrate how to request data from the US Fundamental dataset:

- Direct Access using the Security object

```C#
var equity = AddEquity("IBM");
var ibmFundamental = equity.Fundamentals;
```

- Direct Access using the Symbol object

```
C#
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);
var ibmFundamental = Fundamentals(ibm);
```

- Universe Selection

```
C#
public override void Initialize()
{
    _universe = AddUniverseSelection(new FundamentalUniverseSelectionModel(FundamentalFilterFunction));
}

public override List<Symbol> FundamentalFilterFunction(List<Fundamental> fundamental)
{
    return (from f in fundamental
            where f.HasFundamentalData && f.Price > 10 && !Double.IsNaN(f.ValuationRatios.PERatio)
            orderby f.ValuationRatios.PERatio
            select f.Symbol).Take(10);
}
```

Data Summary

The following table describes the dataset properties:

Property	**Value**
Start Date	January 1998
Asset Coverage	8,000 US Equities *
Corporate Indicators / Tracked Fields	900 Fields
Data Density	Sparse
Resolution	Daily
Timezone	New York

* The data does not include ETFs, ADRs, or OTC equities.

Requesting Data

You don't need any special code to request US Fundamental Data. You can access the current and historical fundamental data for any of the US Equities that this dataset includes.

```C#
public class MorningStarDataAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 7, 1);
        SetCash(100000);
        UniverseSettings.Asynchronous = true;

        // Option 1: Subscribe to individual US Equity assets
        AddEquity("IBM");

        // Option 2A: Create a fundamental universe (classic version)
        _universe = AddUniverse(FundamentalFilterFunction);

        // Option 2B: Create a fundamental universe (framework version)
        AddUniverseSelection(new FundamentalUniverseSelectionModel(FundamentalFilterFunction));
    }
}
```

For more information about universe settings, see Settings .

Accessing Data

If you add a fundamental universe to your algorithm, you can access fundamental data in the universe selection function.

```C#
public IEnumerable<Symbol> FundamentalFunction(IEnumerable<Fundamental> fundamental)
{
    return fundamental.Where(f => f.Price > 10 && f.ValuationRatios.PERatios > 30).Select(f => f.Symbol);
}
```

To get fundamental data for Equities in your algorithm, use the `Fundamentals` property of the `Equity` objects. The fundamental data represent the corporate fundamentals for the current algorithm time.

```C#
var fundamentals = Securities[symbol].Fundamentals;
```

To get fundamental data for Equities, regardless of whether or not you have subscribed to them in your algorithm, call the `Fundamentals` method. If you pass one `Symbol` , the method returns a `Fundamental` object. If you pass a list of `Symbol` objects, the method returns a list of `Fundamental` objects.

```C#
// Single asset
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);
var ibmFundamental = Fundamentals(ibm);

// Multiple assets
var nb = QuantConnect.Symbol.Create("NB", SecurityType.Equity, Market.USA);
var fundamentals = Fundamentals(new List<Symbol>{ nb, ibm }).ToList();
```

Historical Data

You can get historical fundamental data in an algorithm and in the Research Environment.

Historical Data in Algorithms

To get historical fundamental data in an algorithm, call the `History` method with `Fundamental` type and the Equity `Symbol` or the `Universe` object. If there is no data in the period you request, the history result is empty.

```C#
var ibm = QuantConnect.Symbol.Create("IBM", SecurityType.Equity, Market.USA);

// Fundamental objects
var fundamentalHistory = History<Fundamental>(ibm, TimeSpan.FromDays(30));

// Fundamentals objects for all US Equities (including delisted companies)
var fundamentalsHistory = History<Fundamentals>(TimeSpan.FromDays(30));

// Collection of Fundamental objects for all US Equities (including delisted companies)
var collectionHistory = History(_universe, 30, Resolution.Daily);
foreach (var fundamental in collectionHistory)
{
    // Cast to Fundamental is required
    var highestMarketCap = fundamental.OfType<Fundamental>().OrderByDescending(x => x.MarketCap).Take(5);
}
```

Historical Data in the Research Environment

To get historical data in the Research Environment, call any of the preceding methods or call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. Alternatively, call the `GetFundamental` method with the Equity `Symbol` , a `Fundamental` property, a start date, and an end date. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var fundamentals in universeHistory)
{
    foreach (Fundamental fundamental in fundamentals)
    {
        Console.WriteLine($"{fundamental.Symbol} market cap at {fundamental.EndTime}: {fundamental.MarketCap}");
    }
}

var history = qb.GetFundamental(symbol, "ValuationRatios.PERatios", new DateTime(2021, 1, 1), new DateTime(2021, 7,
1));
```

For more information about historical US Equity fundamental data, see Equity Fundamental Data .

Example Applications

The US Fundamentals dataset enables you to design strategies harnessing fundamental data points. Examples include the following strategies:

- Ranking a universe of securities by a value factor like the Piotroski F-score and buying a subset of the universe with the best factor ranking
- Using the Morningstar asset classification to target specific industries or to ensure your strategy is diversified across several sectors
- Trading securities that recently performed an IPO

Classic Algorithm Example

The following example algorithm creates a dynamic universe of US Equities. The first stage filter selects the 100 most liquid US Equities and the second stage filter selects the 10 assets with the greatest PE ratio. The algorithm then forms an equal-weighted portfolio with the 10 assets in the universe.

C#

```
public class MorningStarDataAlgorithm : QCAlgorithm
{
    private int _universeSize = 10;
    private SecurityChanges _changes = SecurityChanges.None;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Requesting data
        UniverseSettings.Resolution = Resolution.Daily;
        // Add universe selection to filter with fundamental data
        AddUniverse(FundamentalSelectionFunction);
    }

    public IEnumerable<Symbol> FundamentalSelectionFunction(IEnumerable<Fundamental> fundamental)
    {
        // Make sure fundamental data and PE ratio available
        // To avoid penny stocks with high volatility, set price above $1
        // Filter the top 100 high dollar volume equities to ensure liquidity
        // Get the top 10 PE Ratio stocks to follow speculations of a large number of capital
        return fundamental
            .Where(x => x.HasFundamentalData && x.Price > 1 && !Double.IsNaN(x.ValuationRatios.PERatio))
            .OrderByDescending(x => x.DollarVolume)
            .Take(100)
            .OrderByDescending(x => x.ValuationRatios.PERatio)
            .Take(_universeSize)
            .Select(x => x.Symbol);
    }

    public override void OnData(Slice slice)
    {
        // if we have no changes, do nothing
        if (_changes == SecurityChanges.None || slice.Bars.Count == 0) return;

        // liquidate removed securities, as not being the most popular stocks anymore
        foreach (var security in _changes.RemovedSecurities)
        {
            if (security.Invested)
            {
                Liquidate(security.Symbol);
            }
        }

        // we want 1/N allocation in each security in our universe to evenly dissipate risk
        foreach (var security in _changes.AddedSecurities)
        {
            SetHoldings(security.Symbol, 1m / _universeSize);
        }

        _changes = SecurityChanges.None;
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _changes = changes;
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities. The first stage filter selects the 100 most liquid US Equities and the second stage filter selects the 10 assets with the greatest PE ratio. The algorithm then forms an equal-weighted portfolio with the 10 assets in the universe.

```C#
public class MorningStarDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Add universe selection to filter with fundamental data
        UniverseSettings.Resolution = Resolution.Daily;
        AddUniverseSelection(new CustomFundamentalUniverseSelectionModel());

        SetAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));

        // we want 1/N allocation in each security in our universe to evenly dissipate risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        AddRiskManagement(new NullRiskManagementModel());

        SetExecution(new ImmediateExecutionModel());
    }
}

public class CustomFundamentalUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamental)
    {
        return fundamental
            // Make sure fundamental data and PE ratio available
            // To avoid penny stocks with high volatility, set price above $1
            .Where(x => x.HasFundamentalData && x.Price > 1 && !Double.IsNaN(x.ValuationRatios.PERatio))
            // Filter the top 100 high dollar volume equities to ensure liquidity
            .OrderByDescending(x => x.DollarVolume)
            .Take(100)
            // Get the top 10 PE Ratio stocks to follow speculations of a large number of capital
            .OrderByDescending(x => x.ValuationRatios.PERatio)
            .Take(10)
            .Select(x => x.Symbol);
    }
}
```

Research Example

The following example selects the 100 most liquid US Equities and lists the 10 assets with the greatest PE ratio.:

```C#
var qb = new QuantBook();

// Add Fundamental Universe Selection
IEnumerable<Symbol> FundamentalSelectionFunction(IEnumerable<Fundamental> fundamentals)
{
    return fundamentals
        .Where(x => !Double.IsNaN(x.ValuationRatios.PERatio))
        .OrderByDescending(x => x.DollarVolume).Take(100)
        .OrderByDescending(x => x.ValuationRatios.PERatio).Take(10)
        .Select(x => x.Symbol);
}

var universe = qb.AddUniverse(FundamentalSelectionFunction);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var fundamentals in universeHistory)
{
    foreach (Fundamental fundamental in fundamentals)
    {
        Console.WriteLine($"{fundamental.Symbol} PE ratio at {fundamental.EndTime}:
{fundamental.ValuationRatios.PERatio}");
    }
}
```

Data Point Attributes

The US Fundamentals dataset provides `Fundamental` objects. To filter `Fundamental` objects, you can use the `MorningstarSectorCode` , `MorningstarIndustryGroupCode` , and `MorningstarIndustryCode` enumeration values.

Fundamental Attributes

`Fundamental` objects have the following attributes:

MorningstarSectorCode Enumeration

Sectors are large super categories of data. To access the sector of an Equity, use the `MorningstarSectorCode` property.

```C#
filteredFundamentals = fundamental.Where(x =>
    x.AssetClassification.MorningstarSectorCode == MorningstarSectorCode.Technology);
```

The `MorningstarSectorCode` enumeration has the following members:

MorningstarIndustryGroupCode Enumeration

Industry groups are clusters of related industries that tie together. To access the industry group of an Equity, use the `MorningstarIndustryGroupCode` property.

```C#
filteredFundamentals = fundamental.Where(x =>
    x.AssetClassification.MorningstarIndustryGroupCode == MorningstarIndustryGroupCode.Software);
```

The `MorningstarIndustryGroupCode` enumeration has the following members:

MorningstarIndustryCode Enumeration

Industries are the finest classification level available and are the individual industries according to the Morningstar classification system. To access the industry group of an Equity, use the `MorningstarIndustryCode` property.

```C#
filteredFundamentals = fundamental.Where(x =>
    x.AssetClassification.MorningstarIndustryCode == MorningstarIndustryCode.SoftwareApplication);
```

The `MorningstarIndustryCode` enumeration has the following members:

Exchange ID Values

The exchange ID represents the exchange that lists the Equity. To access the exchange ID of an Equity, use the `PrimaryExchangeID` property.

```C#
filteredFundamentals = fundamental.Where(x =>
    x.CompanyReference.PrimaryExchangeID == "NAS");
```

The exchanges are represented by the following string values:

String Representation	Exchange
NYS	New York Stock Exchange (NYSE)

NAS	NASDAQ
ASE	American Stock Exchange (AMEX)
TSE	Tokyo Stock Exchange
AMS	Amsterdam Internet Exchange
SGO	Santiago Stock Exchange
XMAD	Madrid Stock Exchange
ASX	Australian Securities Exchange
BVMF	B3 (stock exchange)
LON	London Stock Exchange
TKS	Istanbul Stock Exchange Settlement and Custody Bank
SHG	Shanghai Exchange
LIM	Lima Stock Exchange
FRA	Frankfurt Stock Exchange
JSE	Johannesburg Stock Exchange
MIL	Milan Stock Exchange
TAE	Tel Aviv Stock Exchange
STO	Stockholm Stock Exchange
ETR	Deutsche Boerse Xetra Core
PAR	Paris Stock Exchange
BUE	Buenos Aires Stock Exchange
KRX	Korea Exchange
SWX	SIX Swiss Exchange
PINX	Pink Sheets (OTC)
CSE	Canadian Securities Exchange
PHS	Philippine Stock Exchange
MEX	Mexican Stock Exchange
TAI	Taiwan Stock Exchange
IDX	Indonesia Stock Exchange

OSL	Oslo Stock Exchange
BOG	Colombia Stock Exchange
NSE	National Stock Exchange of India
HEL	Nasdaq Helsinki
MISX	Moscow Exchange
HKG	Hong Kong Stock Exchange
IST	Istanbul Stock Exchange
BOM	Bombay Stock Exchange
TSX	Toronto Stock Exchange
BRU	Brussels Stock Exchange
BATS	BATS Global Markets
ARCX	NYSE Arca
GREY	Grey Market (OTC)
DUS	Dusseldorf Stock Exchange
BER	Berlin Stock Exchange
ROCO	Taipei Exchange
CNQ	Canadian Trading and Quotation System Inc.
BSP	Bangko Sentral ng Pilipinas
NEOE	NEO Exchange

Datasets

TickData

TickData was founded by a futures broker and a programmer in 1984 as the first company in the world to offer historical tick-by-tick prices on the futures and index markets. TickData provides access to comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cash Indices.

International Futures

TickData

International Futures

Introduction

The International Futures dataset by TickData provides Futures data, including price, volume, open interest, and expiry. The data covers the 4 contracts, DAX, FESX, HSI, and NKD, starting in July 1998 and is delivered on any frequency from tick to daily. This dataset is created by TickData, which negotiates directly with exchanges for their official archive and partners with real-time data providers with direct exchange connections and multiple redundant ticker plants.

This dataset also depends on the US Futures Security Master because the US Futures Security Master dataset contains information to construct continuous Futures.

For more information about the International Futures dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

TickData was founded by a futures broker and a programmer in 1984 as the first company in the world to offer historical tick-by-tick prices on the futures and index markets. TickData provides access to comprehensive and detailed market data and analytics products in the financial industry covering Equities, Futures, Options, cash FOREX, and Cash Indices.

Getting Started

The following snippet demonstrates how to request data from the International Futures dataset:

```C#
var hsi= AddFuture(Futures.Indices.HangSeng, Resolution.Minute).Symbol           // "HSI";
var dax = AddFuture(Futures.Indices.Dax, Resolution.Minute).Symbol               // "DAX";
var fesx = AddFuture(Futures.Indices.EuroStoxx50, Resolution.Minute).Symbol      // "FESX";
var nkd = AddFuture(Futures.Indices.Nikkei225Dollar, Resolution.Minute).Symbol   // "NKD";
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 1998, see `Supported Assets` below for details
Coverage	4 Contracts
Data Density	Dense
Resolution	Minute, Hour, & Daily
Timezone	Various, refer to `Supported Assets` below
Market Hours	Regular and Extended

Volume Discrepancies

For Futures contracts trading in the US, for example, NKD, see US Futures .

Requesting Data

To add International Futures data to your algorithm, call the `AddFuture` method. Save a reference to the Future so you can access the data later in your algorithm.

```
C#
public class InternationalFuturesDataAlgorithm : QCAlgorithm
{
    private Symbol _futureSymbol;

    public override void Initialize()
    {
        SetStartDate(2013, 12, 20);
        SetEndDate(2014, 2, 20);
        SetCash(1000000);
        UniverseSettings.Asynchronous = true;
        // Request Hang Seng Index Futures data
        var future = AddFuture(Futures.Indices.HangSeng);
        // Set filter to obtain the contracts expire within 90 days
        future.SetFilter(0, 90);
        _futureSymbol = future.Symbol;
    }
}
```

For more information about creating Future subscriptions, see Requesting Data or Futures Universes .

Accessing Data

To get the current International Futures data, index the `FuturesChains` property of the current `Slice` with the canonical Futures `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your Future at every time step.

```
C#
public override void OnData(Slice slice)
{
    // Get future chain of the canonical symbol
    if (slice.FuturesChains.TryGetValue(_futureSymbol, out var chain))
    {
        // Iterate each contract in the future chain
        foreach (var contract in chain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }
}
```

You can also iterate through all of the `FuturesChain` objects in the current `Slice` .

```
C#
public override void OnData(Slice slice)
{
    // Iterate all future chains
    foreach (var kvp in slice.FuturesChains)
    {
        var canonicalSymbol = kvp.Key;
        var chain = kvp.Value;
        // Iterate each contract in the future chain
        foreach (var contract in chain)
        {
            Log($"{contract.Symbol} price at {slice.Time}: {contract.LastPrice}");
        }
    }
}
```

For more information about accessing Futures data, see Handling Data .

Historical Data

You can get historical International Futures data in an algorithm and the Research Environment.

Historical Data In Algorithms

To get historical International Futures data in an algorithm, call the `History` method with the canonical Futures `Symbol` or a Futures contract `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var contractHistoryTradeBars = History(contract.Symbol, 100, Resolution.Minute);
var continuousHistoryTradeBars = History(
    symbols: new[] {_futureSymbol},
    start: Time - TimeSpan.FromDays(15),
    end: Time,
    resolution: Resolution.Minute,
    fillForward: false,
    extendedMarketHours: false,
    dataMappingMode: DataMappingMode.OpenInterest,
    dataNormalizationMode: DataNormalizationMode.Raw,
    contractDepthOffset: 0);

// QuoteBar objects
var contractHistoryQuoteBars = History<QuoteBar>(contract.Symbol, 100, Resolution.Minute);
var continuousHistoryQuoteBars = History<QuoteBar>(_futureSymbol, 100, Resolution.Minute);

// Tick objects
var contractHistoryTicks = History<Tick>(contract.Symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
var continuousHistoryTicks = History<Tick>(_futureSymbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data in algorithms, see History Requests . For more information about the price adjustments for continuous contracts, see Continous Contracts .

Historical Data In Research

To get historical International Futures data in the Research Environment for an entire Futures chain, call the `FutureHistory` method with the canonical Future `Symbol` .

```C#
var qb = new QuantBook();
var future = qb.AddFuture(Futures.Indices.HangSeng);
future.SetFilter(0, 90);
var history = qb.FutureHistory(future.Symbol, new DateTime(2020, 6, 1), new DateTime(2020, 6, 5));

var contracts = history.SelectMany(x => x.OptionChains.SelectMany(y => y.Value.Contracts.Keys)).Distinct().ToList();
var expiries = contracts.Select(x => x.ID.Date).Distinct().ToList();
```

To get historical data for a single International Futures contract or the continuous Futures contract, call the `History` method like you would in an algorithm but on the `QuantBook` object. For more information about historical data in the Research Environment, see Futures .

Supported Assets

The following table shows the available Futures:

Ticker	Future	Start Date	Time Zone	Currency
HSI	Hang Seng Index Futures	Jan 2010	Asia/Hong Kong	HKD
DAX	German Index Futures	Jan 2010	Europe/Berlin	EUR
FESX	EURO STOXX 50 Index Futures	Jul 1998	Europe/Berlin	EUR
NKD	Nikkei 225 Index Futures	Jan 2007	America/Chicago	USD

Example Applications

The International Futures dataset enables you to design Futures strategies accurately. Examples include the following strategies:

- Buying the Futures contract with the most open interest to reduce slippage and market impact
- Trade speculation on an International Index
- Trading bull calendar spreads to reduce volatility and margin requirements

Classic Algorithm Example -- HSI Futures

The following example algorithm uses ZigZag to determine the trend of Hang Seng Index. To trade the Indices, we make use of the HSI Futures.

C#

```
public class InternationalFuturesDataAlgorithm : QCAlgorithm
{
    private Future _hsiFuture;
    private ZigZag _zz;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the time zone to HKT to make it more comparable with the exchange.
        SetTimeZone(TimeZones.HongKong);
        // Set the account currency as HKD to trade HSI Futures.
        SetAccountCurrency("HKD", 1000000);

        // Seed the last price of the contracts for filling.
        Settings.SeedInitialPrices = true;

        // Request HSI Futures to trade.
        // Note that we will trade the contract with the highest open interest for liquidity.
        _hsiFuture = AddFuture(
            Futures.Indices.HangSeng,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.LastTradingDay,
            contractDepthOffset: 0
        );
        // Request the corresponding underlying index for feeding indicators for trade signal generation.
        var hsiIndex = AddIndex("HSI").Symbol;

        // Create a ZigZag indicator to trade Hang Seng Index price pivot points.
        _zz = ZZ(hsiIndex, 0.15m, 5, Resolution.Daily);
        // Warm up indicator for immediate readiness to trade.
        WarmUpIndicator(hsiIndex, _zz, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        // Only place trade if the Future contracts is in market opening hours to avoid stale fills.
        if (IsMarketOpen(_hsiFuture.Symbol) && _zz.IsReady)
        {
            var pivot = _zz.PivotType;
            // If the last pivot point is low, the current trend is increasing after this low point.
            if (pivot == PivotPointType.Low && !Portfolio[_hsiFuture.Symbol].IsLong)
            {
                SetHoldings(_hsiFuture.Mapped, 0.2m);
            }
            // If the last pivot point is high, the current trend decreases after this high point.
            else if (pivot == PivotPointType.High && !Portfolio[_hsiFuture.Symbol].IsShort)
            {
                SetHoldings(_hsiFuture.Mapped, -0.2m);
            }
        }

        // Handle rollover in case the current mapped contract changes.
        foreach (var (_, changedEvent) in slice.SymbolChangedEvents)
        {
            var oldSymbol = changedEvent.OldSymbol;
            var newSymbol = AddFutureContract(changedEvent.NewSymbol).Symbol;
            var quantity = Portfolio[oldSymbol].Quantity;
            // Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped
contract
            Liquidate(oldSymbol);
            if (quantity != 0)
            {
                MarketOrder(newSymbol, quantity);
            }
        }
    }
}
```

Classic Algorithm Example -- FESX Futures

The following example algorithm uses the MACD indicator to determine the trend of the EuroStoxx50 Index. To trade the Index, we make use of the FESX Futures.

```C#
public class InternationalFuturesDataAlgorithm : QCAlgorithm
{
    private Future _fesxFuture;
    private MovingAverageConvergenceDivergence _macd;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the time zone to Berlin to make it more comparable with the exchange.
        SetTimeZone(TimeZones.Berlin);
        // Set the account currency as EUR to trade FSX Futures.
        SetAccountCurrency("EUR", 1000000);
        // Seed the last price of the contracts for filling.
        Settings.SeedInitialPrices = true;

        // Request FESX Futures to trade.
        // Note that we will trade the contract with the highest open interest for liquidity.
        _fesxFuture = AddFuture(
            Futures.Indices.EuroStoxx50,
            extendedMarketHours: true,
            dataMappingMode: DataMappingMode.LastTradingDay,
            contractDepthOffset: 0
        );
        // Request the corresponding underlying Index for feeding indicator for trade signal generation.
        var fesxIndex = AddIndex("SX5E").Symbol;

        // Create a MACD indicator to trade EuroStoxx trend changes on the fast-slow term trend convergence.
        _macd = MACD(fesxIndex, 12, 26, 9, resolution: Resolution.Daily);
        // Warm up indicator for immediate readiness to trade.
        WarmUpIndicator(fesxIndex, _macd, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        // Only place trade if the Future contracts is in market opening hours to avoid stale fills.
        if (IsMarketOpen(_fesxFuture.Symbol) && _macd.IsReady)
        {
            // To identify a sensitive change in trend, use the change in the histogram value of the MACD.
            var histogram = _macd.Histogram;
            var histogramChg = histogram - histogram.Previous;
            // Positive histogram value increasing means the fast trend is rising faster than the slow trend,
indicating a strong uptrend.
            if (histogramChg > 0 && histogram > 0 && !Portfolio[_fesxFuture.Symbol].IsLong)
            {
                SetHoldings(_fesxFuture.Mapped, 0.2m);
            }
            // Negative histogram value decreasing means the slow trend is dropping faster than the fast trend,
indicating a strong downtrend.
            else if (histogramChg < 0 && histogram < 0 && !Portfolio[_fesxFuture.Symbol].IsShort)
            {
                SetHoldings(_fesxFuture.Mapped, -0.2m);
            }
        }

        // Handle rollover in case the current mapped contract changes.
        foreach (var (_, changedEvent) in slice.SymbolChangedEvents)
        {
            var oldSymbol = changedEvent.OldSymbol;
            var newSymbol = AddFutureContract(changedEvent.NewSymbol).Symbol;
            var quantity = Portfolio[oldSymbol].Quantity;
            // Rolling over: to liquidate any position of the old mapped contract and switch to the newly mapped
contract
            Liquidate(oldSymbol);
            if (quantity != 0)
            {
                MarketOrder(newSymbol, quantity);
            }
        }
    }
}
```

Data Point Attributes

The International Futures dataset provides `Future` , `FuturesChain` , and `OpenInterest` objects. To configure the continuous

Future settings, use the `DataNormalizationMode` and `DataMappingMode` enumerations.

Future Attributes

`Future` objects have the following attributes:

FuturesChain Attributes

`FuturesChain` objects have the following attributes:

OpenInterest Attributes

`OpenInterest` objects have the following attributes:

DataNormalizationMode Values

The `DataNormalizationMode` enumeration has the following values:

DataMappingMode Values

The `DataMappingMode` enumeration has the following values:

Binance Crypto Future Price Data

Introduction

The Binance Crypto Future Price Data by CoinAPI is for Crypto-currency futures price and volume data points. The data covers 718 Cryptocurrency pairs, starts in August 2020, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance.

The Binance Crypto Future Margin Rate Data dataset provides margin interest data to model margin costs.

For more information about the Binance Crypto Future Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Future Price dataset:

```C#
private Symbol _cryptoFutureSymbol;

public override void Initialize
{
    SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin);
    //SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin);

    // perpetual futures does not have a filter function
    _cryptoFutureSymbol = AddCryptoFuture("BTCBUSD", Resolution.Minute).Symbol;
}
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2020
Asset Coverage	718 Crypto Futures Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance Crypto Future Price data to your algorithm, call the `AddCryptoFuture` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol ;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);

        // Set Account Currency to Binance Stable Coin for USD
        SetAccountCurrency("BUSD");
        SetCash(100000);

        SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin);
        SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin);

        var cryptoFuture = AddCryptoFuture("BTCBUSD", Resolution.Minute);
        // perpetual futures does not have a filter function
        _symbol = cryptoFuture.Symbol;
    }
}
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Future Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Binance Crypto Future Price data, call the `History` method with the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto Future contract that you added with the `AddCryptoFuture` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your Crypto Future holdings.

Supported Assets

The following table shows the available Crypto Future pairs:

Example Applications

The Binance Crypto Future Price dataset enables you to accurately design strategies for Cryptocurrencies with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid cryptocurrencies

Classic Algorithm Example

The following example algorithm buys BTCUSDT perpetual future contract if the last day's close price was close to ask close price than bid close price, sells short of that in opposite, through the Binance exchange:

```
from AlgorithmImports import * class BinanceCryptoFutureDataAlgorithm(QCAlgorithm): def initialize(se
lf) -> None: self.set_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account curren
cy to USDT, since you can't trade with # USD and the algorithm doesn't automatically convert USD & US
DT # holdings. self.set_account_currency("USDT", 100000) # Binance Futures Exchange accepts both Cash
and Margin account # types. Select the one you need for the best reality modeling. self.set_brokerage
_model(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN) # Add BTCUSDT data from the Binance Future
exchange. # Perpetual futures does not have a filter function. self._btc = self.add_crypto_future("BT
CUSDT", Resolution.DAILY) # Historical data history = self.history(self._btc, 10, Resolution.DAILY) d
ef on_data(self, slice: Slice) -> None: # Trade only based on updated price data. if self._btc.symbol
not in slice.bars or self._btc.symbol not in slice.quote_bars: return # Scalp-trade the bid-ask sprea
d based on the supply-demand strength if self._btc.price - self._btc.bid_price > self._btc.ask_price
- self._btc.price: self.set_holdings(self._btc, -0.5) else: self.set_holdings(self._btc, 1)
```

```
public class BinanceCryptoFutureDataAlgorithm : QCAlgorithm { public CryptoFuture _btc; public overri
de void Initialize() { SetStartDate(2024, 9, 1); SetEndDate(2024, 12, 31); // Set the account currenc
y to USDT, since you can't trade with // USD and the algorithm doesn't automatically convert USD & US
DT // holdings. SetAccountCurrency("USDT", 100000); // Binance Futures Exchange accepts both Cash and
Margin account // types. Select the one you need for the best reality modeling. SetBrokerageModel(Bro
kerageName.BinanceFutures, AccountType.Margin); // Add BTCUSDT data from the Binance Future exchange.
// Perpetual futures does not have a filter function. _btc = AddCryptoFuture("BTCUSDT", Resolution.Da
ily); // Historical data var history = History(_btc, 10, Resolution.Daily); } public override void On
Data(Slice slice) { // Trade only based on updated price data. if (!slice.Bars.ContainsKey(_btc) || !
slice.QuoteBars.ContainsKey(_btc)) { return; } // Scalp-trade the bid-ask spread based on the supply-
demand strength if (_btc.Price - _btc.BidPrice > _btc.AskPrice - _btc.Price) { SetHoldings(_btc, -0.5
m); } else { SetHoldings(_btc, 1m); } } }
```

Framework Algorithm Example

The following example algorithm hold a long BTCUSDT Future portfolio if the last day's close price was close to ask close price than bid close price, while hold short of that in opposite, through the Binance exchange using the algorithm framework implementation:

```
from AlgorithmImports import * class BinanceCryptoFutureDataAlgorithm(QCAlgorithm): def initialize(se
lf) -> None: self.set_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account curren
cy to USDT, since you can't trade with # USD and the algorithm doesn't automatically convert USD & US
DT # holdings. self.set_account_currency("USDT", 100000) # Binance Futures Exchange accepts both Cash
and Margin account types, select the one you need for the best reality modeling. self.set_brokerage_m
odel(BrokerageName.BINANCE_FUTURES, AccountType.MARGIN) self.universe_settings.resolution = Resolutio
n.DAILY self.universe_settings.leverage = 2 # We only trade on BTCUSDT Future in Binance Future excha
nge symbols = Symbol.create("BTCUSDT", SecurityType.CRYPTO_FUTURE, Market.BINANCE) self.add_universe_
selection(ManualUniverseSelectionModel(symbols)) # Custom alpha model to emit insights based on the C
rypto Future price data self.add_alpha(CryptoFutureAlphaModel()) # Equally invest to evenly dissipate
the capital concentration risk of inidividual crypto pair self.set_portfolio_construction(EqualWeight
ingPortfolioConstructionModel()) self.set_execution(ImmediateExecutionModel()) class CryptoFutureAlph
aModel(AlphaModel): def __init__(self) -> None: self.symbols = [] def update(self, algorithm: QCAlgor
ithm, slice: Slice) -> List[Insight]: insights = [] for symbol in self.symbols: # Trade only based on
updated price data if not slice.bars.contains_key(symbol) or not slice.quote_bars.contains_key(symbol
): continue quote = slice.quote_bars[symbol] price = slice.bars[symbol].price # Scalp-trade the bid-a
sk spread based on the supply-demand strength if price - quote.bid.close > quote.ask.close - price: d
irection = InsightDirection.DOWN else: direction = InsightDirection.UP insights.append(Insight.price(
symbol, timedelta(1), direction)) return insights def on_securities_changed(self, algorithm: QCAlgori
thm, changes: SecurityChanges) -> None: for security in changes.added_securities: symbol = security.s
ymbol self.symbols.append(symbol) # Historical data history = algorithm.history(symbol, 10, Resolutio
n.DAILY) for security in changes.removed_securities: symbol = security.symbol if symbol in self.symbo
ls: self.symbols.remove(symbol)
```

```
public class BinanceCryptoFutureDataAlgorithm : QCAlgorithm { public Symbol _symbol; public override
void Initialize() { SetStartDate(2024, 9, 1); SetEndDate(2024, 12, 31); // Set the account currency t
o USDT, since you can't trade with // USD and the algorithm doesn't automatically convert USD & USDT
// holdings. SetAccountCurrency("USDT", 100000); // Binance Futures Exchange accepts both Cash and Ma
rgin account types, select the one you need for the best reality modeling. SetBrokerageModel(Brokerag
eName.BinanceFutures, AccountType.Margin); UniverseSettings.Resolution = Resolution.Daily; UniverseSe
ttings.Leverage = 2; // We only trade on BTCUSDT Future in Binance Future exchange var symbols = new
List<Symbol> { QuantConnect.Symbol.Create("BTCUSDT", SecurityType.CryptoFuture, Market.Binance) }; Ad
dUniverseSelection(new ManualUniverseSelectionModel(symbols)); // Custom alpha model to emit insights
based on the Crypto Future price data AddAlpha(new CryptoFutureAlphaModel()); // Equally invest to ev
enly dissipate the capital concentration risk of inidividual crypto pair SetPortfolioConstruction(new
EqualWeightingPortfolioConstructionModel()); SetExecution(new ImmediateExecutionModel()); } } public
class CryptoFutureAlphaModel : AlphaModel { private List<Symbol> _symbols = new(); public override IE
numerable<Insight> Update(QCAlgorithm algorithm, Slice slice) { var insights = new List<Insight>(); f
oreach (var symbol in _symbols) { // Trade only based on updated price data if (!slice.Bars.ContainsK
ey(symbol) || !slice.QuoteBars.TryGetValue(symbol, out var quote)) { continue; } var price = slice.Ba
rs[symbol].Price; // Scalp-trade the bid-ask spread based on the supply-demand strength InsightDirect
ion direction; if (price - quote.Bid.Close > quote.Ask.Close - price) { direction = InsightDirection.
Down; } else { direction = InsightDirection.Up; } insights.Add(Insight.Price(symbol, TimeSpan.FromDay
s(1), direction)); } return insights; } public override void OnSecuritiesChanged(QCAlgorithm algorith
m, SecurityChanges changes) { foreach (var security in changes.AddedSecurities) { var symbol = securi
ty.Symbol; _symbols.Add(symbol); // Historical data var history = algorithm.History(symbol, 10, Resol
ution.Daily); } foreach (var security in changes.RemovedSecurities) { _symbols.Remove(security.Symbol
); } } }
```

Data Point Attributes

The Binance Crypto Future Price dataset provides `TradeBar` , `QuoteBar` , and `Tick` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CoinAPI

Binance Crypto Price Data

Introduction

The Binance Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 3,320 Cryptocurrency pairs, starts in July 2017, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance.

For more information about the Binance Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Binance Crypto Price dataset:

```C#
// Binance accepts both Cash and Margin account types only.
SetBrokerageModel(BrokerageName.Binance, AccountType.Cash);
//SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);

_symbol = AddCrypto("BTCBUSD", Resolution.Minute, Market.Binance).Symbol;

_universe = AddUniverse(CryptoUniverse.Binance(UniverseSelectionFilter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2017
Asset Coverage	3,320 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance Crypto Price data to your algorithm, call the `AddCrypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);

        // Set Account Currency to Binance Stable Coin for USD
        SetAccountCurrency("BUSD");
        SetCash(100000);

        // Binance accepts both Cash and Margin account types.
        SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);

        _symbol = AddCrypto("BTCBUSD", Resolution.Minute, Market.Binance).Symbol;
    }
}
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Binance Crypto Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Binance Crypto Price data, call the `History` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Binance Crypto pairs, call the `AddUniverse` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
C#
using QuantConnect.Data.UniverseSelection;

public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);
    _universe = AddUniverse(CryptoUniverse.Binance(UniverseSelectionFilter));
}

private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return from c in universeDay
           where c.Volume >= 100m && c.VolumeInUsd > 10000m
           select c.Symbol;
}
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```
C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in history)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Log($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, and the lookback period. The `UniverseHistory` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Console.WriteLine($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

You can call the `History` method in Research.

Remove Subcriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (3320)

Example Applications

The Binance Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Binance exchange:

```
from AlgorithmImports import * class CoinAPIDataAlgorithm(QCAlgorithm): def initialize(self) -> None: self.set_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account currency to USDT, since you can't trade with # USD and the algorithm doesn't automatically convert USD & USDT # holdings. self.set_account_currency("USDT", 100000) self.universe_settings.asynchronous = True # Binance accepts both Cash and Margin account types. Select the # one you need for the best reality modeling. self.set_brokerage_model(BrokerageName.BINANCE, AccountType.MARGIN) # Add BTCUSDT data. self._btc = self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BINANCE) # Historical data history = self.history(self._btc.symbol, 30, Resolution.DAILY) # Add a Crypto universe that selects trading pairs on Binance. universe = self.add_universe(CryptoUniverse.binance(self._select_assets)) # Historical Universe data universe_history = self.history(universe, 30, Resolution.DAILY) for (universe_symbol, time), universe_day in universe_history.items(): for universe_item in universe_day: symbol = universe_item.symbol price = universe_item.close def _select_assets(self, universe_day): # Filter for materially traded Crypto pairs with significant # size and dollar volume, assuming higher capital flow in for # higher return. return [universe_item.symbol for universe_item in universe_day if universe_item.volume >= 100 and universe_item.volume_in_usd > 10_000_000] def on_data(self, slice: Slice) -> None: # Speculate-invest all available free cash on BTCUSDT, repecting # the order quantity restrictions to avoid invalid orders. if self.portfolio.cash_book['BTC'].amount != 0: return # Define a buffer so that we can scale down the order size, # avoiding trading errors. buffer = max( BinanceFeeModel.TAKER_TIER_1_FEE, self.settings.free_portfolio_value_percentage ) quantity = ( self.portfolio.cash_book['USDT'].amount / self._btc.ask_price * (1-buffer) ) # Check if the quantity exceeds the minimum order size. On # Binance, the minimum order size is measured in the quote # currency (USDT in this case). minimum_order_size = ( self._btc.symbol_properties.minimum_order_size / self._btc.ask_price ) if abs(quantity) < minimum_order_size: return self.market_order(self._btc, quantity)
```

```
public class CoinAPIDataAlgorithm : QCAlgorithm { private Crypto _btc; public override void Initialize() { SetStartDate(2024, 9, 1); SetEndDate(2024, 12, 31); // Set the account currency to USDT, since you can't trade with // USD and the algorithm doesn't automatically convert USD & USDT // holdings. SetAccountCurrency("USDT", 100000); UniverseSettings.Asynchronous = true; // Binance accepts both Cash and Margin account types. Select the // one you need for the best reality modeling. SetBrokerageModel(BrokerageName.Binance, AccountType.Margin); // Add BTCUSDT data. _btc = AddCrypto("BTCUSDT", Resolution.Minute, Market.Binance); // Historical data var history = History(_btc.Symbol, 30, Resolution.Daily); // Add a Crypto universe that selects trading pairs on Binance. var universe = AddUniverse(CryptoUniverse.Binance(SelectAssets)); // Historical Universe data var universeHistory = History(universe, 30, Resolution.Daily); foreach (var universeDay in universeHistory) { foreach (CryptoUniverse universeItem in universeDay) { var symbol = universeItem.Symbol; var price = universeItem.Close; } } } private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay) { // Filter for materially traded Crypto pairs with significant // size and dollar volume, assuming higher capital flow in for // higher return. return from universeItem in universeDay where universeItem.Volume >= 100m && universeItem.VolumeInUsd > 10000000m select universeItem.Symbol; } public override void OnData(Slice slice) { // Speculate-invest all available free cash on BTCUSDT, repecting // the order quantity restrictions to avoid invalid orders. if (Portfolio.CashBook["BTC"].Amount != 0) { return; } // Define a buffer so that we can scale down the order size, // avoiding trading errors. var buffer = Math.Max(BinanceFeeModel.TakerTier1Fee, Settings.FreePortfolioValuePercentage); var quantity = Portfolio.CashBook["USDT"].Amount / _btc.AskPrice * (1-buffer); // Check if the quantity exceeds the minimum order size. On // Binance, the minimum order size is measured in the quote // currency (USDT in this case). var minimumOrderSize = _btc.SymbolProperties.MinimumOrderSize / _btc.AskPrice; if (Math.Abs(quantity) < minimumOrderSize) { return; } MarketOrder(_btc, quantity); } }
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Binance exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

C#

```
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private List<string> _marketPairs;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.FreePortfolioValuePercentage = 0.05m;

        // Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        SetAccountCurrency("USDT", 100000);
        // Binance accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);

        // Warm up the security with the last known price to avoid conversion error
        Settings.SeedInitialPrices = true;
        UniverseSettings.Asynchronous = true;
        UniverseSettings.Resolution = Resolution.Minute;
        // Add Crypto Universe Selection that select crypto pairs in Binance exchange
        AddUniverse(CryptoUniverse.Binance(UniverseSelectionFilter));
        // Get the pairs on Binance that have USDT as the quote currency.
        _marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(Market.Binance)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();

        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromMinutes(20), 0.025,
null));
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
    {
        // Select pairs where the quote currency is USDT.
        return universeDay.Where(c => _marketPairs.Contains(c.Symbol.Value))
            // Filter for materially traded crypto pairs with significant size and dollar volume, assuming higher
capital flow in for higher return
            .OrderBy(c => c.VolumeInUsd)
            .TakeLast(3)
            .Select(c => c.Symbol);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 30, Resolution.Daily);
        }
    }
}
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Binance exchange:

```C#
var qb = new QuantBook();

// Add Cryptocurrency pair
var symbol = qb.AddCrypto("BTCUSDT", market:Market.Binance).Symbol;

// Historical data
var history = qb.History(symbol, 30, Resolution.Daily);
foreach (var bar in history)
{
    Console.WriteLine($"{bar.EndTime} {bar}");
}

// Add Crypto Universe Selection
IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return universeDay
        .Where(x => x.VolumeInUsd != null && x.VolumeInUsd > 10000m)
        .OrderByDescending(x => x.VolumeInUsd)
        .Take(5)
        .Select(x => x.Symbol);
}
var universe = qb.AddUniverse(CryptoUniverse.Binance(UniverseSelectionFilter));

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    Console.WriteLine($"=== {universeDay.First().EndTime} ===");
    foreach (CryptoUniverse universeItem in universeDay.OrderByDescending(x => x.VolumeInUsd))
    {
        Console.WriteLine($"{universeItem.Symbol}: {universeItem.VolumeInUsd}");
    }
}
```

Data Point Attributes

The Binance Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Binance US Crypto Price Data

Introduction

The Binance US Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 604 Cryptocurrency pairs, starts in October 2019, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Binance US.

For more information about the Binance US Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippets demonstrates how to set the brokerage model, request data, and perform universe selection with the Binance US dataset:

```C#
// Binance US only accepts cash accounts
SetBrokerageModel(BrokerageName.BinanceUS, AccountType.Cash);

_symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.BinanceUS).Symbol;

_universe = AddUniverse(CryptoUniverse.BinanceUS(UniverseSelectionFilter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 2019
Asset Coverage	604 Cryptocurrency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Binance US Crypto Price data to your algorithm, call the `AddCrypto` method. Save a reference to the Crypto `Symbol` so

you can access the data later in your algorithm.

```C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        // BinanceUS accepts Cash account type only, AccountType.Margin will result in an exception.
        SetBrokerageModel(BrokerageName.BinanceUS, AccountType.Cash);

        _symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.BinanceUS).Symbol;
    }
}
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Binance US Crypto Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Binance US Crypto Price data, call the `History` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Binance US Crypto pairs, call the `AddUniverse` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
C#
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    SetBrokerageModel(BrokerageName.BinanceUS, AccountType.Cash);
    _universe = AddUniverse(CryptoUniverse.BinanceUS(UniverseSelectionFilter));
}

private IEnumerable<Symol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return from c in universeDay
           where c.Volume >= 100m && c.VolumeInUsd > 10000m
           select c.Symbol;
}
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in history)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Log($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, and the lookback period. The `UniverseHistory` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Console.WriteLine($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (604)					
1000MOGUSDT	1000REKTUSDT	1INCHUSD	1INCHUSD4	1INCHUSDT	A2ZUSDT

Example Applications

The Binance US Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Binance US exchange:

C#

```
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Crypto _btc;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set USDT as the account currency so we can trade BTCUSDT.
        SetAccountCurrency("USDT", 100000);
        UniverseSettings.Asynchronous = true;
        // Binance US accepts Cash account type only. AccountType.Margin
        // results in an exception.
        SetBrokerageModel(BrokerageName.BinanceUS, AccountType.Cash);
        // Add BTCUSDT data.
        _btc = AddCrypto("BTCUSDT", Resolution.Minute, Market.BinanceUS);
        // Historical data
        var history = History(_btc.Symbol, 30, Resolution.Daily);
        // Add a Crypto universe that selects trading pairs on Binance US.
        var universe = AddUniverse(CryptoUniverse.BinanceUS(SelectAssets));
        // Historical Universe data
        var universeHistory = History(universe, 30, Resolution.Daily);
        foreach (var universeDay in universeHistory)
        {
            foreach (CryptoUniverse universeItem in universeDay)
            {
                var symbol = universeItem.Symbol;
                var price = universeItem.Close;
            }
        }
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay)
    {
        // Filter for materially traded Crypto pairs with significant
        // size and dollar volume, assuming higher capital flow in for
        // higher return.
        return from universeItem in universeDay
                where universeItem.Volume >= 100m
                && universeItem.VolumeInUsd > 10000000m
                select universeItem.Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Speculate-invest all available free cash on BTCUSDT, repecting
        // the order quantity restrictions to avoid invalid orders.
        if (Portfolio.CashBook["BTC"].Amount != 0)
        {
            return;
        }
        // Define a buffer so that we can scale down the order size,
        // avoiding trading errors.
        var buffer = Math.Max(BinanceFeeModel.TakerTier1Fee, Settings.FreePortfolioValuePercentage);
        var quantity = Portfolio.CashBook["USDT"].Amount / _btc.AskPrice * (1-buffer);
        // Check if the quantity exceeds the minimum order size. On
        // Binance US, the minimum order size is measured in the quote
        // currency (USDT in this case).
        var minimumOrderSize = _btc.SymbolProperties.MinimumOrderSize / _btc.AskPrice;
        if (Math.Abs(quantity) < minimumOrderSize)
        {
            return;
        }
        MarketOrder(_btc, quantity);
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Binance US exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _btcusd;
    private List<string> _marketPairs;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        Settings.FreePortfolioValuePercentage = 0.05m;
        // Warm up the security with the last known price to avoid conversion error
        Settings.SeedInitialPrices = true;
        UniverseSettings.Asynchronous = true;
        UniverseSettings.Resolution = Resolution.Minute;
        // Add Crypto Universe Selection that select crypto pairs in BinanceUS exchange
        AddUniverse(CryptoUniverse.BinanceUS(UniverseSelectionFilter));
        // Get the pairs on Binance US that have USD as the quote currency.
        _marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(Market.BinanceUS)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();
        AddAlpha( new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromMinutes(20), 0.025,
null) );
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
    {
        // Select pairs where the quote currency is USD.
        return universeDay.Where(c => _marketPairs.Contains(c.Symbol.Value))
            // Filter for materially traded crypto pairs with significant size and dollar volume, assuming higher
capital flow in for higher return
            .OrderBy(c => c.VolumeInUsd)
            .TakeLast(3)
            .Select(c => c.Symbol);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 30, Resolution.Daily);
            Debug($"We got {history.Count()} items from our history request");
        }
    }
}
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the BinanceUS exchange:

```C#
var qb = new QuantBook();

// Add Cryptocurrency pair
var symbol = qb.AddCrypto("BTCUSDT", market:Market.BinanceUS).Symbol;

// Historical data
var history = qb.History(symbol, 30, Resolution.Daily);
foreach (var bar in history)
{
    Console.WriteLine($"{bar.EndTime} {bar}");
}

// Add Crypto Universe Selection
IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return universeDay
        .Where(x => x.VolumeInUsd != null && x.VolumeInUsd > 10000m)
        .OrderByDescending(x => x.VolumeInUsd)
        .Take(5)
        .Select(x => x.Symbol);
}
var universe = qb.AddUniverse(CryptoUniverse.BinanceUS(UniverseSelectionFilter));

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    Console.WriteLine($"=== {universeDay.First().EndTime} ===");
    foreach (CryptoUniverse universeItem in universeDay.OrderByDescending(x => x.VolumeInUsd))
    {
        Console.WriteLine($"{universeItem.Symbol}: {universeItem.VolumeInUsd}");
    }
}
```

Data Point Attributes

The Binance US Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Bitfinex Crypto Price Data

Introduction

The Bitfinex Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 570 Cryptocurrency pairs, starts in January 2013, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Bitfinex.

For more information about the Bitfinex Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Bitfinex Crypto Price dataset:

```C#
// Bitfinex accepts both Cash and Margin type account.
SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Cash);
//SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin);

_symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.Bitfinex).Symbol;

_universe = AddUniverse(CryptoUniverse.Bitfinex(UniverseSelectionFilter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2013
Asset Coverage	570 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bitfinex Crypto Price data to your algorithm, call the `AddCrypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        // Bitfinex accepts both Cash and Margin type account.
        SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin);

        _symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.Bitfinex).Symbol;
    }
}
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Bitfinex Crypto Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Bitfinex Crypto Price data, call the `History` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Bitfinex Crypto pairs, call the `AddUniverse` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```
C#
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin);
    _universe = AddUniverse(CryptoUniverse.Bitfinex(UniverseSelectionFilter));
}

private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return from c in universeDay
           where c.Volume >= 100m && c.VolumeInUsd > 10000m
           select c.Symbol;
}
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in history)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Log($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, and the lookback period. The `UniverseHistory` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Console.WriteLine($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Data Points Attributes

The Bitfinex Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

Supported Assets

Example Applications

The Bitfinex Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Bitfinex exchange:

C#

```
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Crypto _btc;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        UniverseSettings.Asynchronous = true;
        SetCash(100000);
        // Bitfinex accepts both Cash and Margin account types. Select the
        // one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin);
        // Add BTCUSD data.
        _btc = AddCrypto("BTCUSD", Resolution.Minute, Market.Bitfinex);
        // Historical data
        var history = History(_btc.Symbol, 30, Resolution.Daily);
        // Add a Crypto universe that selects trading pairs on Bitfinex.
        var universe = AddUniverse(CryptoUniverse.Bitfinex(SelectAssets));
        // Historical Universe data
        var universeHistory = History(universe, 30, Resolution.Daily);
        foreach (var universeDay in universeHistory)
        {
            foreach (CryptoUniverse universeItem in universeDay)
            {
                var symbol = universeItem.Symbol;
                var price = universeItem.Close;
            }
        }
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay)
    {
        // Filter for materially traded Crypto pairs with significant
        // size and dollar volume, assuming higher capital flow in for
        // higher return.
        return from universeItem in universeDay
                where universeItem.Volume >= 100m
                && universeItem.VolumeInUsd > 10000000m
                select universeItem.Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Speculate-invest all available free cash on BTCUSD, repecting
        // the order quantity restrictions to avoid invalid orders.
        if (Portfolio.CashBook["BTC"].Amount != 0)
        {
            return;
        }
        // Define a buffer so that we can scale down the order size,
        // avoiding trading errors.
        var buffer = Math.Max(BitfinexFeeModel.TakerFee, Settings.FreePortfolioValuePercentage);
        var quantity = Portfolio.CashBook["USD"].Amount / _btc.AskPrice * (1-buffer);
        // Check if the quantity exceeds the minimum order size. On
        // Bitfinex, the minimum order size is measured in the base
        // currency (BTC in this case).
        if (Math.Abs(quantity) < _btc.SymbolProperties.MinimumOrderSize)
        {
            return;
        }
        MarketOrder(_btc, quantity);
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Bitfinex exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private List<string> _marketPairs;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        Settings.FreePortfolioValuePercentage = 0.05m;
        // Bitfinex accepts both Cash and Margin account types, select the one you need for the best reality
modeling.
        SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin);

        // Warm up the security with the last known price to avoid conversion error
        Settings.SeedInitialPrices = true;
        UniverseSettings.Asynchronous = true;
        UniverseSettings.Resolution = Resolution.Minute;
        // Add Crypto Universe Selection that select crypto pairs in Bitfinex exchange
        AddUniverse(CryptoUniverse.Bitfinex(SelectAssets));
        // Get the pairs on Bitfinex that have USD as the quote currency.
        _marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(Market.Bitfinex)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();
        AddAlpha( new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromHours(4), 0.025, null)
);
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay)
    {
        // Select pairs where the quote currency is USD.
        return universeDay.Where(c => _marketPairs.Contains(c.Symbol.Value))
            // Filter for materially traded crypto pairs with significant size and dollar volume, assuming higher
capital flow in for higher return
            .OrderBy(c => c.VolumeInUsd)
            .TakeLast(3)
            .Select(c => c.Symbol);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 30, Resolution.Daily);
            Debug($"We got {history.Count()} items from our history request");
        }
    }
}
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Bitfinex exchange:

```C#
var qb = new QuantBook();

// Add Cryptocurrency pair
var symbol = qb.AddCrypto("BTCUSDT", market:Market.Bitfinex).Symbol;

// Historical data
var history = qb.History(symbol, 30, Resolution.Daily);
foreach (var bar in history)
{
    Console.WriteLine($"{bar.EndTime} {bar}");
}

// Add Crypto Universe Selection
IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return universeDay
        .Where(x => x.VolumeInUsd != null && x.VolumeInUsd > 10000m)
        .OrderByDescending(x => x.VolumeInUsd)
        .Take(5)
        .Select(x => x.Symbol);
}
var universe = qb.AddUniverse(CryptoUniverse.Bitfinex(UniverseSelectionFilter));

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    Console.WriteLine($"=== {universeDay.First().EndTime} ===");
    foreach (CryptoUniverse universeItem in universeDay.OrderByDescending(x => x.VolumeInUsd))
    {
        Console.WriteLine($"{universeItem.Symbol}: {universeItem.VolumeInUsd}");
    }
}
```

Data Point Attributes

The Bitfinex Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Bybit Crypto Future Price Data

Introduction

The Bybit Crypto Future Price Data by CoinAPI is for Cryptocurrency Futures price and volume data points. The data covers 631 Cryptocurrency pairs, starts in August 2020, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Bybit.

The Bybit Crypto Future Margin Rate Data dataset provides margin interest rate data to model margin costs.

For more information about the Bybit Crypto Future Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Bybit Crypto Future Price dataset:

```C#
private Symbol _cryptoFutureSymbol;

public override void Initialize
{
    SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

    _cryptoFutureSymbol = AddCryptoFuture("BTCUSDT", Resolution.Minute).Symbol;
}
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 2019
Asset Coverage	631 Crypto Futures Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bybit Crypto Future Price data to your algorithm, call the `AddCryptoFuture` method. Save a reference to the Crypto Future `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);

        // Set Account Currency to Tether
        SetAccountCurrency("USDT", 100000);

        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

        var cryptoFuture = AddCryptoFuture("BTCUSDT", Resolution.Minute);
        _symbol = cryptoFuture.Symbol;
    }
}
```

For more information about creating Crypto Future subscriptions, see Requesting Data .

Accessing Data

To get the current Bybit Crypto Future Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto Future `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto Future data, see Handling Data .

Historical Data

To get historical Bybit Crypto Future Price data, call the `History` method with the Crypto Future `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To unsubscribe from a Crypto Future contract that you added with the `AddCryptoFuture` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your Crypto Future holdings.

Supported Assets

The following table shows the available Crypto Future pairs:

Example Applications

The Bybit Crypto Future Price dataset enables you to accurately design strategies for Crypto Futures with term structure. Examples include the following strategies:

- Horizontal/Diagonal arbitrage with the underlying Cryptocurrencies
- Trade Contango/Backwardation predictions
- Hedge for illiquid Cryptocurrencies

Classic Algorithm Example

The following example algorithm buys BTCUSDT perpetual future contract if the last day's close price was close to ask close

price than bid close price, sells short of that in opposite, through the Bybit exchange:

```C#
public class BybitCryptoFutureDataAlgorithm : QCAlgorithm
{
    public Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        SetAccountCurrency("USDT", 100000);
        // Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

        // Requesting data, we only trade on BTCUSDT Future in Bybit exchange
        var cryptoFuture = AddCryptoFuture("BTCUSDT", Resolution.Daily);
        // perpetual futures does not have a filter function
        _symbol = cryptoFuture.Symbol;

        // Historical data
        var history = History(_symbol, 10, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        // Trade only based on updated price data
        if (!slice.QuoteBars.TryGetValue(_symbol, out var quote) || !slice.Bars.ContainsKey(_symbol))
        {
            return;
        }
        var price = slice.Bars[_symbol].Price;

        // Scalp-trade the bid-ask spread based on the supply-demand strength
        if (price - quote.Bid.Close > quote.Ask.Close - price)
        {
            SetHoldings(_symbol, -1m);
        }
        else
        {
            SetHoldings(_symbol, 1m);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm hold a 100% long BTCUST future portfolio if the last day's close price was close to ask close price than bid close price, while hold short of that in opposite, through the Bybit exchange using the algorithm framework implementation:

```C#
public class BybitCryptoFutureDataAlgorithm : QCAlgorithm
{
    public Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        SetAccountCurrency("USDT", 100000);
        // Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Leverage = 2;
        // We only trade on BTCUSDT Future in Bybit exchange
        var symbols = new []{
            QuantConnect.Symbol.Create("BTCUSDT", SecurityType.CryptoFuture, Market.Bybit)
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // Custom alpha model to emit insights based on the Crypto Future price data
```

```
        AddAlpha(new CryptoFutureAlphaModel());
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
    }
}

public class CryptoFutureAlphaModel : AlphaModel
{
    private List<Symbol> _symbols = new();

    public override List<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        foreach (var symbol in _symbols)
        {
            // Trade only based on updated price data
            if (!slice.Bars.ContainsKey(symbol) || !slice.QuoteBars.TryGetValue(symbol, out var quote))
            {
                continue;
            }
            var price = slice.Bars[symbol].Price;

            // Scalp-trade the bid-ask spread based on the supply-demand strength
            if (price - quote.Bid.Close > quote.Ask.Close - price)
            {
                insights.Add(
                    Insight.Price(symbol, TimeSpan.FromDays(1), InsightDirection.Down)
                );
            }
            else
            {
                insights.Add(
                    Insight.Price(symbol, TimeSpan.FromDays(1), InsightDirection.Up)
                );
            }
        }

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            var symbol = security.Symbol;
            _symbols.Add(symbol);

            // Historical data
            var history = algorithm.History(symbol, 10, Resolution.Daily);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            _symbols.Remove(security.Symbol);
        }
    }
}
```

Data Point Attributes

The Bybit Crypto Future Price dataset provides `TradeBar` , `QuoteBar` , and `Tick` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CoinAPI

Bybit Crypto Price Data

Introduction

The Bybit Crypto Price Data by CoinAPI is for Cryptocurrency price and volume data points. The data covers 956 Cryptocurrency pairs, starts in July 2017, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Bybit.

For more information about the Bybit Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Bybit Crypto Price dataset:

```C#
// Bybit accepts both Cash and Margin account types only.
SetBrokerageModel(BrokerageName.Bybit, AccountType.Cash);
//SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

_symbol = AddCrypto("BTCUSDT", Resolution.Minute, Market.Bybit).Symbol;

_universe = AddUniverse(CryptoUniverse.Bybit(UniverseSelectionFilter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	April 2022
Asset Coverage	956 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Bybit Crypto Price data to your algorithm, call the `AddCrypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);

        // Set Account Currency to Tether
        SetAccountCurrency("USDT", 100000);

        // Bybit accepts both Cash and Margin account types.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

        _symbol = AddCrypto("BTCUSDT", Resolution.Minute, Market.Bybit).Symbol;
    }
}
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Bybit Crypto Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Bybit Crypto Price data, call the `History` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Bybit Crypto pairs, call the `AddUniverse` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```C#
using QuantConnect.Data.UniverseSelection;

public override void Initialize()
{
    SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);
    UniverseSettings.Asynchronous = true;
    _universe = AddUniverse(CryptoUniverse.Bybit(UniverseSelectionFilter));
}

private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return from c in universeDay
           where c.Volume >= 100m && c.VolumeInUsd > 10000m
           select c.Symbol;
}
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in history)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Log($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, and the lookback period. The `UniverseHistory` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Console.WriteLine($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (956)

Example Applications

The Bybit Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Bybit exchange:

```
from AlgorithmImports import * class CoinAPIDataAlgorithm(QCAlgorithm): def initialize(self) -> None: self.set_start_date(2024, 9, 1) self.set_end_date(2024, 12, 31) # Set the account currency to USDT, since you can't trade with # USD and the algorithm doesn't automatically convert USD & USDT # holdings. self.set_account_currency("USDT", 100_000) self.universe_settings.asynchronous = True # Bybit accepts both Cash and Margin account types. Select the # one you need for the best reality modeling. self.set_brokerage_model(BrokerageName.BYBIT, AccountType.MARGIN) # Add BTCUSDT data. self._btc = self.add_crypto("BTCUSDT", Resolution.MINUTE, Market.BYBIT) # Historical data history = self.history(self._btc.symbol, 30, Resolution.DAILY) # Add a Crypto universe that selects trading pairs on Bybit. universe = self.add_universe(CryptoUniverse.bybit(self._select_assets)) # Historical Universe data universe_history = self.history(universe, 30, Resolution.DAILY) for (universe_symbol, time), universe_day in universe_history.items(): for universe_item in universe_day: symbol = universe_item.symbol price = universe_item.close def _select_assets(self, universe_day): # Filter for materially traded Crypto pairs with significant # size and dollar volume, assuming higher capital flow in for # higher return. return [universe_item.symbol for universe_item in universe_day if universe_item.volume >= 100 and universe_item.volume_in_usd > 10_000_000] def on_data(self, slice: Slice) -> None: # Speculate-invest all available free cash on BTCUSDT, repecting # the order quantity restrictions to avoid invalid orders. if self.portfolio.cash_book['BTC'].amount != 0: return # Define a buffer so that we can scale down the order size, # avoiding trading errors. buffer = max( BybitFeeModel.TAKER_NON_VIP_FEE, self.settings.free_portfolio_value_percentage ) quantity = ( self.portfolio.cash_book['USDT'].amount / self._btc.ask_price * (1-buffer) ) # Check if the quantity exceeds the minimum order size. On # Bybit, the minimum order size is measured in the base # currency (BTC in this case). if abs(quantity) < self._btc.symbol_properties.minimum_order_size: return self.market_order(self._btc, quantity)
```

```
public class CoinAPIDataAlgorithm : QCAlgorithm { private Crypto _btc; public override void Initialize() { SetStartDate(2024, 9, 1); SetEndDate(2024, 12, 31); // Set the account currency to USDT, since you can't trade with // USD and the algorithm doesn't automatically convert USD & USDT // holdings. SetAccountCurrency("USDT", 100000); UniverseSettings.Asynchronous = true; // Bybit accepts both Cash and Margin account types. Select the // one you need for the best reality modeling. SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin); // Add BTCUSDT data. _btc = AddCrypto("BTCUSDT", Resolution.Minute, Market.Bybit); // Historical data var history = History(_btc.Symbol, 30, Resolution.Daily); // Add a Crypto universe that selects trading pairs on Bybit. var universe = AddUniverse(CryptoUniverse.Bybit(SelectAssets)); // Historical Universe data var universeHistory = History(universe, 30, Resolution.Daily); foreach (var universeDay in universeHistory) { foreach (CryptoUniverse universeItem in universeDay) { var symbol = universeItem.Symbol; var price = universeItem.Close; } } } private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay) { // Filter for materially traded Crypto pairs with significant // size and dollar volume, assuming higher capital flow in for // higher return. return from universeItem in universeDay where universeItem.Volume >= 100m && universeItem.VolumeInUsd > 10000000m select universeItem.Symbol; } public override void OnData(Slice slice) { // Speculate-invest all available free cash on BTCUSDT, repecting // the order quantity restrictions to avoid invalid orders. if (Portfolio.CashBook["BTC"].Amount != 0) { return; } // Define a buffer so that we can scale down the order size, // avoiding trading errors. var buffer = Math.Max(BybitFeeModel.TakerNonVIPFee, Settings.FreePortfolioValuePercentage); var quantity = Portfolio.CashBook["USDT"].Amount / _btc.AskPrice * (1-buffer); // Check if the quantity exceeds the minimum order size. On // Bybit, the minimum order size is measured in the base // currency (BTC in this case). if (Math.Abs(quantity) < _btc.SymbolProperties.MinimumOrderSize) { return; } MarketOrder(_btc, quantity); } }
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Bybit exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private List<string> _marketPairs;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.FreePortfolioValuePercentage = 0.05m;

        // Set Account Currency to Tether, since USD and USDT will not auto-convert and USD cannot be used to trade
        SetAccountCurrency("USDT", 100000);
        // Bybit accepts both Cash and Margin account types, select the one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);

        // Warm up the security with the last known price to avoid conversion error
        Settings.SeedInitialPrices = true;
        UniverseSettings.Asynchronous = true;
        UniverseSettings.Resolution = Resolution.Minute;
        // Add Crypto Universe Selection that select crypto pairs in Bybit exchange
        AddUniverse(CryptoUniverse.Bybit(UniverseSelectionFilter));
        // Get the pairs on Bybit that have USDT as the quote currency.
        _marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(Market.Bybit)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();

        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromMinutes(20), 0.025,
null));
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
    {
        // Select pairs where the quote currency is USDT.
        return universeDay.Where(c => _marketPairs.Contains(c.Symbol.Value))
            // Filter for materially traded crypto pairs with significant size and dollar volume, assuming higher
capital flow in for higher return
            .OrderBy(c => c.VolumeInUsd)
            .TakeLast(3)
            .Select(c => c.Symbol);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 30, Resolution.Daily);
            Debug($"We got {history.Count()} items from our history request");
        }
    }
}
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Bybit exchange:

```C#
var qb = new QuantBook();

// Add Cryptocurrency pair
var symbol = qb.AddCrypto("BTCUSDT", market:Market.Bybit).Symbol;

// Historical data
var history = qb.History(symbol, 30, Resolution.Daily);
foreach (var bar in history)
{
    Console.WriteLine($"{bar.EndTime} {bar}");
}

// Add Crypto Universe Selection
IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return universeDay
        .Where(x => x.VolumeInUsd != null && x.VolumeInUsd > 10000m)
        .OrderByDescending(x => x.VolumeInUsd)
        .Take(5)
        .Select(x => x.Symbol);
}
var universe = qb.AddUniverse(CryptoUniverse.Bybit(UniverseSelectionFilter));

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    Console.WriteLine($"=== {universeDay.First().EndTime} ===");
    foreach (CryptoUniverse universeItem in universeDay.OrderByDescending(x => x.VolumeInUsd))
    {
        Console.WriteLine($"{universeItem.Symbol}: {universeItem.VolumeInUsd}");
    }
}
```

Data Point Attributes

The Bybit Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Coinbase Crypto Price Data

Introduction

The Coinbase Crypto Price Data by CoinAPI provides Cryptocurrency price and volume data points. The data covers 970 Cryptocurrency pairs, starts in January 2015, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on Coinbase.

For more information about the Coinbase Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Coinbase Crypto Price dataset:

```C#
// Coinbase only accepts Cash account type
SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);

_symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.Coinbase).Symbol;

_universe = AddUniverse(CryptoUniverse.Coinbase(UniverseSelectionFilter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2015
Asset Coverage	970 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Coinbase Crypto Price data to your algorithm, call the `AddCrypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        // Coinbase accepts Cash account type only, AccountType.Margin will result in an exception.
        SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);

        _symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.Coinbase).Symbol;
    }
}
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Coinbase Crypto Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Coinbase Crypto Price data, call the `History` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Coinbase Crypto pairs, call the `AddUniverse` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```C#
using QuantConnect.Data.UniverseSelection;

public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);
    _universe = AddUniverse(CryptoUniverse.Coinbase(UniverseSelectionFilter));
}

private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return from c in universeDay
           where c.Volume >= 100m && c.VolumeInUsd > 10000m
           select c.Symbol;
}
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in history)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Log($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, and the lookback period. The `UniverseHistory` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Console.WriteLine($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (970)					
00USD	00USDC	1INCHBTC	1INCHEUR	1INCHGBP	1INCHUSD

Example Applications

The Coinbase Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Coinbase exchange:

C#

```
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Crypto _btc;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        UniverseSettings.Asynchronous = true;
        SetCash(100000);
        // Coinbase accepts Cash account type only. AccountType.Margin
        // results in an exception.
        SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);
        // Add BTCUSD data.
        _btc = AddCrypto("BTCUSD", Resolution.Minute, Market.Coinbase);
        // Historical data
        var history = History(_btc.Symbol, 30, Resolution.Daily);
        // Add a Crypto universe that selects trading pairs on Coinbase.
        var universe = AddUniverse(CryptoUniverse.Coinbase(SelectAssets));
        // Historical Universe data
        var universeHistory = History(universe, 30, Resolution.Daily);
        foreach (var universeDay in universeHistory)
        {
            foreach (CryptoUniverse universeItem in universeDay)
            {
                var symbol = universeItem.Symbol;
                var price = universeItem.Close;
            }
        }
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay)
    {
        // Filter for materially traded Crypto pairs with significant
        // size and dollar volume, assuming higher capital flow in for
        // higher return.
        return from universeItem in universeDay
                where universeItem.Volume >= 100m
                && universeItem.VolumeInUsd > 10000000m
                select universeItem.Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Speculate-invest all available free cash on BTCUSD, repecting
        // the order quantity restrictions to avoid invalid orders.
        if (Portfolio.CashBook["BTC"].Amount != 0)
        {
            return;
        }
        // Define a buffer so that we can scale down the order size,
        // avoiding trading errors.
        var buffer = Math.Max(CoinbaseFeeModel.TakerAdvanced1, Settings.FreePortfolioValuePercentage);
        var quantity = Portfolio.CashBook["USD"].Amount / _btc.AskPrice * (1-buffer);
        // Check if the quantity exceeds the minimum order size. On
        // Coinbase, the minimum order size is measured in the base
        // currency (BTC in this case).
        if (Math.Abs(quantity) < _btc.SymbolProperties.MinimumOrderSize)
        {
            return;
        }
        MarketOrder(_btc, quantity);
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Coinbase exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private List<string> _marketPairs;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 2, 1);
        SetCash(100000);
        Settings.FreePortfolioValuePercentage = 0.05m;
        // Warm up the security with the last known price to avoid conversion error
        Settings.SeedInitialPrices = true;
        UniverseSettings.Asynchronous = true;
        UniverseSettings.Resolution = Resolution.Minute;
        // Add Crypto Universe Selection that select crypto pairs in Coinbase exchange
        AddUniverse(CryptoUniverse.Coinbase(SelectAssets));
        // Get the pairs on Coinbase that have USD as the quote currency.
        _marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(Market.Coinbase)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();
        AddAlpha( new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromHours(4), 0.025, null)
);
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay)
    {
        // Select pairs where the quote currency is USD.
        return universeDay.Where(c => _marketPairs.Contains(c.Symbol.Value))
            // Filter for materially traded crypto pairs with significant size and dollar volume, assuming higher
capital flow in for higher return
            .OrderBy(c => c.VolumeInUsd)
            .TakeLast(3)
            .Select(c => c.Symbol);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 30, Resolution.Daily);
            Debug($"We got {history.Count()} items from our history request");
        }
    }
}
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Coinbase exchange:

```C#
var qb = new QuantBook();

// Add Cryptocurrency pair
var symbol = qb.AddCrypto("BTCUSDT", market:Market.Coinbase).Symbol;

// Historical data
var history = qb.History(symbol, 30, Resolution.Daily);
foreach (var bar in history)
{
    Console.WriteLine($"{bar.EndTime} {bar}");
}

// Add Crypto Universe Selection
IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return universeDay
        .Where(x => x.VolumeInUsd != null && x.VolumeInUsd > 10000m)
        .OrderByDescending(x => x.VolumeInUsd)
        .Take(5)
        .Select(x => x.Symbol);
}
var universe = qb.AddUniverse(CryptoUniverse.Coinbase(UniverseSelectionFilter));

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    Console.WriteLine($"=== {universeDay.First().EndTime} ===");
    foreach (CryptoUniverse universeItem in universeDay.OrderByDescending(x => x.VolumeInUsd))
    {
        Console.WriteLine($"{universeItem.Symbol}: {universeItem.VolumeInUsd}");
    }
}
```

Data Point Attributes

The Coinbase Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

CoinAPI

Kraken Crypto Price Data

Introduction

The Kraken Crypto Price Data by CoinAPI provides Cryptocurrency price and volume data points. The data covers 1,262 Cryptocurrency pairs, starts in October 2013, and is delivered on any frequency from tick to daily. This dataset is created by monitoring the trading activity on the Cryptocurrency markets/exchanges supported by QuantConnect.

For more information about the Kraken Crypto Price Data dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinAPI was founded by Artur Pietrzyk in 2016 with the goal of providing real-time and historical cryptocurrency market data, collected from hundreds of exchanges. CoinAPI provides access to Cryptocurrencies for traders, market makers, and developers building third-party applications.

Getting Started

The following snippet demonstrates how to request data from the Kraken Crypto Price dataset:

```C#
// Kraken accepts both Cash and Margin type account.
SetBrokerageModel(BrokerageName.Kraken, AccountType.Cash);
//SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin);

_symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.Kraken).Symbol;

_universe = AddUniverse(CryptoUniverse.Kraken(UniverseSelectionFilter));
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 2013
Asset Coverage	1,262 Currency Pairs
Data Density	Dense
Resolution	Tick, Second, Minute, Hourly, & Daily
Timezone	UTC
Market Hours	Always Open

Requesting Data

To add Kraken Crypto Price data to your algorithm, call the `AddCrypto` method. Save a reference to the Crypto `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2020, 6, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        // Kraken accepts both Cash and Margin type account.
        SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin);

        _symbol = AddCrypto("BTCUSD", Resolution.Minute, Market.Kraken).Symbol;
    }
}
```

For more information about creating Crypto subscriptions, see Requesting Data .

Accessing Data

To get the current Kraken Crypto Price data, index the `Bars` , `QuoteBars` , or `Ticks` properties of the current `Slice` with the Crypto `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.Bars.ContainsKey(_symbol))
    {
        var tradeBar = slice.Bars[_symbol];
        Log($"{_symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    if (slice.QuoteBars.ContainsKey(_symbol))
    {
        var quoteBar = slice.QuoteBars[_symbol];
        Log($"{_symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    if (slice.Ticks.ContainsKey(_symbol))
    {
        var ticks = slice.Ticks[_symbol];
        foreach (var tick in ticks)
        {
            Log($"{_symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

You can also iterate through all of the data objects in the current `Slice` .

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Bars)
    {
        var symbol = kvp.Key;
        var tradeBar = kvp.Value;
        Log($"{symbol} price at {slice.Time}: {tradeBar.Close}");
    }

    foreach (var kvp in slice.QuoteBars)
    {
        var symbol = kvp.Key;
        var quoteBar = kvp.Value;
        Log($"{symbol} bid at {slice.Time}: {quoteBar.Bid.Close}");
    }

    foreach (var kvp in slice.Ticks)
    {
        var symbol = kvp.Key;
        var ticks = kvp.Value;
        foreach (var tick in ticks)
        {
            Log($"{symbol} price at {slice.Time}: {tick.Price}");
        }
    }
}
```

For more information about accessing Crypto data, see Handling Data .

Historical Data

To get historical Kraken Crypto Price data, call the `History` method with the Crypto `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// TradeBar objects
var historyTradeBars = History(_symbol, 100, Resolution.Daily);

// QuoteBar objects
var historyQuoteBars = History<QuoteBar>(_symbol, 100, Resolution.Minute);

// Tick objects
var historyTicks = History<Tick>(_symbol, TimeSpan.FromSeconds(10), Resolution.Tick);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Kraken Crypto pairs, call the `AddUniverse` method with a `CryptoUniverse` object. A Crypto universe uses a selection function to select Crypto pairs based on their OHLCV and dollar volume of the previous day as of midnight Coordinated Universal Time (UTC).

```C#
using QuantConnect.Data.UniverseSelection;

public override void Initialize()
{
    SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin);
    UniverseSettings.Asynchronous = true;
    _universe = AddUniverse(CryptoUniverse.Kraken(UniverseSelectionFilter));
}

private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return from c in universeDay
           where c.Volume >= 100m && c.VolumeInUsd > 10000m
           select c.Symbol;
}
```

For more information about universe settings, see Settings .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object, and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var history = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in history)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Log($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, and the lookback period. The `UniverseHistory` returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (CryptoUniverse universeItem in universeDay)
    {
        Console.WriteLine($"{universeItem.Symbol} price at {universeItem.EndTime}: {universeItem.Close}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To unsubscribe from a Crypto pair that you added with the `AddCrypto` method, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_symbol);
```

The `RemoveSecurity` method cancels your open orders for the security and liquidates your holdings in the virtual pair .

Supported Assets

The following table shows the available Cryptocurrency pairs:

Pairs Available (1262)					
1INCHEUR	1INCHUSD	AAVEAUD	AAVEBTC	AAVEETH	AAVEEUR

Example Applications

The Kraken Crypto Price dataset enables you to accurately design strategies for Cryptocurrencies. Examples include the following strategies:

- Buy and hold
- Trading Cryptocurrency volatility and price action
- Allocating a small portion of your portfolio to Cryptocurrencies to hedge against inflation

Classic Algorithm Example

The following example algorithm buys and holds Bitcoin through the Kraken exchange:

C#

```
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private Crypto _btc;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        UniverseSettings.Asynchronous = true;
        SetCash(100000);
        // Kraken accepts both Cash and Margin account types. Select the
        // one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin);
        // Add BTCUSD data.
        _btc = AddCrypto("BTCUSD", Resolution.Minute, Market.Kraken);
        // Historical data
        var history = History(_btc.Symbol, 30, Resolution.Daily);
        // Add a Crypto universe that selects trading pairs on Kraken.
        var universe = AddUniverse(CryptoUniverse.Kraken(SelectAssets));
        // Historical Universe data
        var universeHistory = History(universe, 30, Resolution.Daily);
        foreach (var universeDay in universeHistory)
        {
            foreach (CryptoUniverse universeItem in universeDay)
            {
                var symbol = universeItem.Symbol;
                var price = universeItem.Close;
            }
        }
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<CryptoUniverse> universeDay)
    {
        // Filter for materially traded Crypto pairs with significant
        // size and dollar volume, assuming higher capital flow in for
        // higher return.
        return from universeItem in universeDay
                where universeItem.Volume >= 100m
                && universeItem.VolumeInUsd > 10000000m
                select universeItem.Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Speculate-invest all available free cash on BTCUSD, repecting
        // the order quantity restrictions to avoid invalid orders.
        if (Portfolio.CashBook["BTC"].Amount != 0)
        {
            return;
        }
        // Define a buffer so that we can scale down the order size,
        // avoiding trading errors.
        var buffer = Math.Max(KrakenFeeModel.TakerTier1CryptoFee, Settings.FreePortfolioValuePercentage);
        var quantity = Portfolio.CashBook["USD"].Amount / _btc.AskPrice * (1-buffer);
        // Check if the quantity exceeds the minimum order size. On
        // Kraken, the minimum order size is measured in the base
        // currency (BTC in this case).
        if (Math.Abs(quantity) < _btc.SymbolProperties.MinimumOrderSize)
        {
            return;
        }
        MarketOrder(_btc, quantity);
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of Crypto pairs on the Kraken exchange and then forms a equal-weighted portfolio of all the pairs in the universe:

```C#
public class CoinAPIDataAlgorithm : QCAlgorithm
{
    private List<string> _marketPairs;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        Settings.FreePortfolioValuePercentage = 0.05m;

        // Kraken accepts both Cash and Margin type account, select the one you need for the best reality modeling.
        SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin);

        // Warm up the security with the last known price to avoid conversion error
        Settings.SeedInitialPrices = true;

        // Get the pairs on Kraken that have USD as the quote currency.
        _marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(Market.Kraken)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();
        // Add Crypto Universe Selection that select crypto pairs in Kraken exchange
        AddUniverse(CryptoUniverse.Kraken(UniverseSelectionFilter));

        AddAlpha( new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromHours(4), 0.025, null)
);
        // Equally invest to evenly dissipate the capital concentration risk of inidividual crypto pair
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
    {
        // Select pairs where the quote currency is USD.
        return universeDay.Where(c => _marketPairs.Contains(c.Symbol.Value))
            // Filter for materially traded crypto pairs with significant size and dollar volume, assuming higher
capital flow in for higher return
            .OrderBy(c => c.VolumeInUsd)
            .TakeLast(3)
            .Select(c => c.Symbol);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(var security in changes.AddedSecurities)
        {
            // Historical data
            var history = History(security.Symbol, 30, Resolution.Daily);
            Debug($"We got {history.Count()} items from our history request");
        }
    }
}
```

Research Example

The following example lists crypto-currency pairs with the greatest dollar volume in the Kraken exchange:

```C#
var qb = new QuantBook();

// Add Cryptocurrency pair
var symbol = qb.AddCrypto("BTCUSDT", market:Market.Kraken).Symbol;

// Historical data
var history = qb.History(symbol, 30, Resolution.Daily);
foreach (var bar in history)
{
    Console.WriteLine($"{bar.EndTime} {bar}");
}

// Add Crypto Universe Selection
IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<CryptoUniverse> universeDay)
{
    return universeDay
        .Where(x => x.VolumeInUsd != null && x.VolumeInUsd > 10000m)
        .OrderByDescending(x => x.VolumeInUsd)
        .Take(5)
        .Select(x => x.Symbol);
}
var universe = qb.AddUniverse(CryptoUniverse.Kraken(UniverseSelectionFilter));

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    Console.WriteLine($"=== {universeDay.First().EndTime} ===");
    foreach (CryptoUniverse universeItem in universeDay.OrderByDescending(x => x.VolumeInUsd))
    {
        Console.WriteLine($"{universeItem.Symbol}: {universeItem.VolumeInUsd}");
    }
}
```

Data Point Attributes

The Kraken Crypto Price dataset provides `TradeBar` , `QuoteBar` , `Tick` , and `CryptoUniverse` objects.

TradeBar Attributes

`TradeBar` objects have the following attributes:

QuoteBar Attributes

`QuoteBar` objects have the following attributes:

Tick Attributes

`Tick` objects have the following attributes:

CryptoUniverse Attributes

`CryptoUniverse` objects have the following attributes:

Datasets

Benzinga

Benzinga was founded by Jason Raznick in 2010 with goal of connecting the world with news, data, and education that makes the path to financial prosperity easier for everyone, everyday. Benzinga provides access to real-time news for individual investors.

Benzinga News Feed

Benzinga

Benzinga News Feed

Introduction

The Benzinga News Feed dataset by Benzinga tracks US Equity news releases. The data covers about 1,250 articles per day across 8,000 Equities, starts in January 2016, and is delivered on a second frequency. This dataset is created by structuring the content produced by Benzinga's editorial team.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Benzinga News Feed dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Benzinga was founded by Jason Raznick in 2010 with goal of connecting the world with news, data, and education that makes the path to financial prosperity easier for everyone, everyday. Benzinga provides access to real-time news for individual investors.

Getting Started

The following snippet demonstrates how to request data from the Benzinga News Feed dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<BenzingaNews>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	September 2017
Asset Coverage	8,000 Equities
Data Density	Sparse
Resolution	Second (1,250 Articles/Day)
Timezone	New York

Requesting Data

To add Benzinga News Feed data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class BenzingaNewsDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Minute).Symbol;
        _datasetSymbol = AddData<BenzingaNews>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Benzinga News Feed data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var article = slice[_datasetSymbol];
        Log($"{_datasetSymbol} title at {slice.Time}: {article.Mentions}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<BenzingaNews>())
    {
        var datasetSymbol = kvp.Key;
        var article = kvp.Value;
        Log($"{datasetSymbol} title at {slice.Time}: {article.Title}");
    }
}
```

Historical Data

To get historical Benzinga News Feed data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<BenzingaNews>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to Benzinga News Feed data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Benzinga News Feed enables you to accurately design strategies harnessing real-time news releases. Examples include the following strategies:

- Creating a dictionary of sentiment scores for various words and assigning a sentiment score to the content of each news release
- Calculating the sentiment of news releases with Natural Language Processing (NLP)
- Trading securities when their news releases that Benzinga tags with current buzzwords

Classic Algorithm Example

The following example algorithm parses the Benzinga news articles related to Apple. If the sentiment is positive, the algorithm buys Apple. Otherwise, it holds cash.

```C#
using System.Text.RegularExpressions;

public class BenzingaNewsDataAlgorithm : QCAlgorithm
{
    private Symbol _aapl;
    private Symbol _benzingaSymbol;
    private int _currentHoldings = 0;
    private int _targetHoldings = 0;
    //  A custom word-score map for calculating the total sentiment score
    private Dictionary<string, int> _wordScores = new Dictionary<string, int>(){
        {"good", 1}, {"great", 1}, {"best", 1}, {"growth", 1},
        {"bad", -1}, {"terrible", -1}, {"worst", -1}, {"loss", -1}
    };

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Requesting data to obtain the updated news for sentiment score calculation
        _aapl = AddEquity("AAPL", Resolution.Minute).Symbol;
        _benzingaSymbol = AddData<BenzingaNews>(_aapl).Symbol;

        // Historical data
        var history = History<BenzingaNews>(_benzingaSymbol, 14, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        if (slice.ContainsKey(_benzingaSymbol))
        {
            // Assign a sentiment score to the news article by specific word appearance scoring
            var contentWords = slice[_benzingaSymbol].Contents.ToLower();
            var score = 0;
            foreach (KeyValuePair<string, int> entry in _wordScores)
            {
                score += (Regex.Matches(contentWords, entry.Key).Count * entry.Value);
            }
            _targetHoldings = Convert.ToInt32(score > 0);
        }

        // Ensure we have AAPL data in the current Slice to avoid stale filling
        if (!(slice.ContainsKey(_aapl) && slice[_aapl] != null && !slice[_aapl].IsFillForward))
        {
            return;
        }

        // Buy or sell if the sentiment has changed from our current holdings
        if (_currentHoldings != _targetHoldings)
        {
            SetHoldings(_aapl, _targetHoldings);
            _currentHoldings = _targetHoldings;
        }
    }
}
```

Framework Algorithm Example

The following example algorithm parses the Benzinga news articles related to Apple. If the sentiment is positive, the algorithm buys Apple. Otherwise, it holds cash.

```C#
using System.Text.RegularExpressions;

public class BenzingaNewsDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        AddUniverseSelection(
```

```
        AddUniverseSelection(
            new ManualUniverseSelectionModel(
                QuantConnect.Symbol.Create("AAPL", SecurityType.Equity, Market.USA)
        ));

        AddAlpha(new BenzingaAlphaModel());

        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        AddRiskManagement(new NullRiskManagementModel());

        SetExecution(new ImmediateExecutionModel());
    }
}

public class BenzingaAlphaModel : AlphaModel
{
    private Dictionary<Symbol, SymbolData> _symbolDataBySymbol = new Dictionary<Symbol, SymbolData>();
    // A custom word-score map for calculating the total sentiment score
    private Dictionary<string, int> _wordScores = new Dictionary<string, int>(){
        {"good", 1}, {"great", 1}, {"best", 1}, {"growth", 1},
        {"bad", -1}, {"terrible", -1}, {"worst", -1}, {"loss", -1}
    };

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        foreach (var kvp in _symbolDataBySymbol)
        {
            var symbol = kvp.Key;
            var symbolData = kvp.Value;

            if (slice.ContainsKey(symbolData.benzingaSymbol))
            {
                // Assign a sentiment score to the news article by specific word appearance scoring
                var contentWords = slice[symbolData.benzingaSymbol].Contents.ToLower();
                var score = 0;
                foreach (var entry in _wordScores)
                {
                    score += (Regex.Matches(contentWords, entry.Key).Count * entry.Value);
                }
                symbolData.targetDirection = score > 0 ? InsightDirection.Up : InsightDirection.Flat;
            }

            // Ensure we have security data in the current Slice to avoid stale filling
            if (!(slice.ContainsKey(symbol) && slice[symbol] != null && !slice[symbol].IsFillForward))
            {
                continue;
            }

            // Buy or sell if the sentiment has changed from our current holdings
            if (symbolData.currentDirection != symbolData.targetDirection)
            {
                insights.Add(Insight.Price(symbol, TimeSpan.FromDays(14), symbolData.targetDirection));
                symbolData.currentDirection = symbolData.targetDirection;
            }
        }
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            var symbol = security.Symbol;
            _symbolDataBySymbol.Add(symbol, new SymbolData(algorithm, symbol));
        }

        foreach (var security in changes.RemovedSecurities)
        {
            var symbol = security.Symbol;
            if (_symbolDataBySymbol.ContainsKey(symbol))
            {
                _symbolDataBySymbol[symbol].dispose();
                _symbolDataBySymbol.Remove(symbol);
            }
        }
    }
}
```

```
public class SymbolData
{
    private QCAlgorithm _algorithm;
    public Symbol benzingaSymbol;
    public InsightDirection currentDirection = InsightDirection.Flat;
    public InsightDirection targetDirection = InsightDirection.Flat;

    public SymbolData(QCAlgorithm algorithm, Symbol symbol)
    {
        _algorithm = algorithm;

        // Requesting data to obtain the updated news for sentiment score calculation
        benzingaSymbol = algorithm.AddData<BenzingaNews>(symbol).Symbol;

        // Historical data
        var history = algorithm.History<BenzingaNews>(benzingaSymbol, 14, Resolution.Daily);
        algorithm.Debug($"We got {history.Count()} items from our history request");
    }

    public void dispose()
    {
        // Unsubscribe from the Benzinga feed for this security to release computational resources
        _algorithm.RemoveSecurity(benzingaSymbol);
    }
}
```

Data Point Attributes

The Benzinga News Feed dataset provides `BenzingaNews` objects, which have the following attributes:

Datasets

Blockchain

Blockchain is a website that publishes data related to Bitcoin. It has been online since 2011 and publishes the Bitcoin Metadata history back to 2009.

Bitcoin Metadata

Blockchain

Bitcoin Metadata

Introduction

The Bitcoin Metadata dataset by Blockchain provides 23 fundamental metadata of Bitcoin directly fetched from the Bitcoin blockchain. The data starts in January 2009 and delivered on a daily frequency. This dataset contains mining statistics like hash rate and miner revenue; transaction metadata like transaction per block, transaction fee, and number of addresses; and blockchain metadata like blockchain size and block size.

For more information about the Bitcoin Metadata dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Blockchain is a website that publishes data related to Bitcoin. It has been online since 2011 and publishes the Bitcoin Metadata history back to 2009.

Getting Started

The following snippet demonstrates how to request data from the Bitcoin Metadata dataset:

```C#
_symbol = AddCrypto("BTCUSD", Resolution.Daily, Market.Bitfinex).Symbol;
_datasetSymbol = AddData<BitcoinMetadata>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2009
Coverage	Bitcoin blockchain
Data Density	Regular
Resolution	Daily
Timezone	UTC

Requesting Data

To add Bitcoin Metadata data to your algorithm, call the `AddData` method with the BTCUSD `Symbol` . Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class BlockchainBitcoinMetadataAlgorithm: QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _symbol = AddCrypto("BTCUSD", Resolution.Daily, Market.Bitfinex).Symbol;
        _datasetSymbol = AddData<BitcoinMetadata>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Bitcoin Metadata data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} miner revenue at {slice.Time}: {dataPoint.MinersRevenue}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<BlockchainBitcoinData>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} miner revenue at {slice.Time}: {dataPoint.MinersRevenue}");
    }
}
```

Historical Data

To get historical Bitcoin Metadata data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<BlockchainBitcoinData>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Bitcoin Metadata dataset enables you to incorporate metadata from the Bitcoin blockchain into your strategies. Examples include the following strategies:

- Comparing mining and transaction statistics to provide insight on the supply-demand relationship of the Bitcoin blockchain service.
- Measuring the activity and popularity of the Bitcoin blockchain to predict the price movements of the Cryptocurrency.

Classic Algorithm Example

The following example algorithm tracks the transaction-to-hash-rate ratio of the Bitcoin network. The algorithm holds Bitcoin when the ratio increases. Otherwise, it holds dollars.

C#

```
public class BlockchainBitcoinMetadataAlgorithm : QCAlgorithm
{
    private Symbol _bitcoinMetadataSymbol, _btcSymbol;
    // Cache the last supply-demand ratio for comparison
    private decimal? _lastDemandSupply = null;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Request BTCUSD as the trading vehicle on Bitcoin Metadata
        _btcSymbol = AddCrypto("BTCUSD", Resolution.Minute, Market.Bitfinex).Symbol;
        // Request Bitcoin Metadata for trade signal generation
        _bitcoinMetadataSymbol = AddData<BitcoinMetadata>(_btcSymbol).Symbol;

        // Historical data
        var history = History(new[]{_bitcoinMetadataSymbol}, 60, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request for {_btcSymbol} Blockchain Bitcoin
Metadata");
    }

    public override void OnData(Slice slice)
    {
        // Trade only based on updated Bitcoin Metadata
        var data = slice.Get<BitcoinMetadata>();
        if (!data.IsNullOrEmpty())
        {
            // Calculate the supply-demand ratio to estimate the microeconomy structure of Bitcoin for scalp-trading
            // Transaction number as demand, hash production rate as supply
            if (data[_bitcoinMetadataSymbol].HashRate == 0)
            {
                return;
            }
            var currentDemandSupply = data[_bitcoinMetadataSymbol].NumberofTransactions /
data[_bitcoinMetadataSymbol].HashRate;

            // Comparing the average transaction-to-hash-rate ratio changes, buy Bitcoin if demand is higher than
supply, sell vice versa
            if (_lastDemandSupply != null && currentDemandSupply > _lastDemandSupply)
            {
                SetHoldings(_btcSymbol, 1);
            }
            else
            {
                SetHoldings(_btcSymbol, 0);
            }

            _lastDemandSupply = currentDemandSupply;
        }
    }
}
```

Framework Algorithm Example

The following example algorithm tracks the transaction-to-hash-rate ratio of the Bitcoin network. The algorithm holds Bitcoin when the ratio increases. Otherwise, it holds dollars.

C#

```
public class BlockchainBitcoinMetadataFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Universe contains only BTCUSD as the trading vehicle on Bitcoin Metadata
        AddUniverseSelection(
            new ManualUniverseSelectionModel(
            QuantConnect.Symbol.Create("BTCUSD", SecurityType.Crypto, Market.Bitfinex)
        ));
        // Custom alpha model that emit insights based on Bitcoin Metadata
        AddAlpha(new BlockchainBitcoinMetadataAlphaModel());
        // Equally invest to evenly dissipate the capital concentration risk from non-sysmtematic risky events
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}

public class BlockchainBitcoinMetadataAlphaModel: AlphaModel
{
    private Dictionary<Symbol, Symbol> _bitcoinMetadataSymbolBySymbol = new Dictionary<Symbol, Symbol>();
    // Cache the last supply-demand ratio for comparison
    private Dictionary<Symbol, decimal> _lastDemandSupply = new Dictionary<Symbol, decimal>();

    public BlockchainBitcoinMetadataAlphaModel(){}

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        // Trade only based on updated Bitcoin Metadata
        var data = slice.Get<BitcoinMetadata>();
        if (!data.IsNullOrEmpty())
        {
            foreach(var kvp in _bitcoinMetadataSymbolBySymbol)
            {
                var symbol = kvp.Key;
                var bitcoinMetadataSymbol = kvp.Value;

                // Calculate the supply-demand ratio to estimate the microeconomy structure of the crypto pair for
scalp-trading
                // Transaction number as demand, hash production rate as supply
                if (data[bitcoinMetadataSymbol].HashRate == 0) continue;
                var currentDemandSupply = data[bitcoinMetadataSymbol].NumberofTransactions /
data[bitcoinMetadataSymbol].HashRate;

                // Comparing the average transaction-to-hash-rate ratio changes, buy coin if demand is higher than
supply
                if (_lastDemandSupply.ContainsKey(symbol) && currentDemandSupply > _lastDemandSupply[symbol])
                {
                    insights.Add(Insight.Price(symbol, TimeSpan.FromDays(1), InsightDirection.Up));
                }

                _lastDemandSupply[symbol] = currentDemandSupply;
            }
        }

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            var symbol = security.Symbol;
            // Request Bitcoin Metadata for trade signal generation
            var bitcoinMetadataSymbol = algorithm.AddData<BitcoinMetadata>(symbol).Symbol;

            _bitcoinMetadataSymbolBySymbol.Add(symbol, bitcoinMetadataSymbol);

            // Historical data
            var history = algorithm.History(new[]{bitcoinMetadataSymbol}, 60, Resolution.Daily);
        }
    }
}
```

Data Point Attributes

The Bitcoin Metadata dataset provides `BitcoinMetadata` objects, which have the following attributes:

Brain Language Metrics on Company Filings

Introduction

The Brain Language Metrics on Company Filings dataset provides the results of an NLP system that monitors several language metrics on 10-K and 10-Q company reports for US Equities. The data covers 5,000 US Equities, starts in January 2010, and is delivered on a daily frequency. The dataset is made of two parts; the first one includes the language metrics of the most recent 10-K or 10-Q report for each firm, namely:

1. Financial sentiment
2. Percentage of words belonging to financial domain classified by language types (e.g. “litigious” or “constraining” language)
3. Readability score
4. Lexical metrics such as lexical density and richness
5. Text statistics such as the report length and the average sentence length

The second part includes the differences between the two most recent 10-Ks or 10-Qs reports of the same period for each company, namely:

1. Difference of the various language metrics (e.g. delta sentiment, delta readability score, delta percentage of a specific language type etc.)
2. Similarity metrics between documents, also with respect to a specific language type (for example similarity with respect to “litigious” language or “uncertainty” language)

The analysis is available for the whole report and for specific sections of the report (e.g. Risk Factors and MD&A).

For more information, refer to Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain Language Metrics on Company Filings dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain Language Metrics on Company Filings dataset:

```
C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_dataset10KSymbol = AddData<BrainCompanyFilingLanguageMetrics10K>(_symbol).Symbol;
_datasetAllSymbol = AddData<BrainCompanyFilingLanguageMetricsAll>(_symbol).Symbol;

_universe10k = AddUniverse<BrainCompanyFilingLanguageMetricsUniverse10K>(UniverseSelection);
_universeAll = AddUniverse<BrainCompanyFilingLanguageMetricsUniverseAll>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2010
Asset Coverage*	5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

The coverage includes all assets since the start date. It increases over time.

Requesting Data

To add Brain Language Metrics on Company Filings data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class BrainCompanyFilingNLPDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _dataset10KSymbol, _datasetAllSymbol;

    public override void Initialize()
    {
        SetStartDate(2010, 1, 1);
        SetEndDate(2021, 7, 8);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _dataset10KSymbol= AddData<BrainCompanyFilingLanguageMetrics10K>(_symbol).Symbol;
        _datasetAllSymbol= AddData<BrainCompanyFilingLanguageMetricsAll>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Brain Language Metrics on Company Filings data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_dataset10KSymbol))
    {
        var dataPoint = slice[_dataset10KSymbol];
        Log($"{_dataset10KSymbol} report sentiment at {slice.Time}: {dataPoint.ReportSentiment.Sentiment}");
    }

    if (slice.ContainsKey(_datasetAllSymbol))
    {
        var dataPoint = slice[_datasetAllSymbol];
        Log($"{_datasetAllSymbol} report sentiment at {slice.Time}: {dataPoint.ReportSentiment.Sentiment}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<BrainCompanyFilingLanguageMetrics10K>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} report sentiment at {slice.Time}: {dataPoint.ReportSentiment.Sentiment}");
    }

    foreach (var kvp in slice.Get<BrainCompanyFilingLanguageMetricsAll>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} report sentiment at {slice.Time}: {dataPoint.ReportSentiment.Sentiment}");
    }
}
```

Historical Data

To get historical Brain Language Metrics on Company Filings data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
// Dataset objects
var tenKHistory = History<BrainCompanyFilingLanguageMetrics10K>(_dataset10KSymbol, 100, Resolution.Daily);
var allHistory = History<BrainCompanyFilingLanguageMetricsAll>(_datasetAllSymbol, 100, Resolution.Daily);

// Slice objects
var history = History(new[] {_dataset10KSymbol, _datasetAllSymbol}, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain Language Metrics on Company Filings data, call the `AddUniverse` method with the `BrainCompanyFilingLanguageMetricsUniverseAll` class or the `BrainCompanyFilingLanguageMetricsUniverse10K` class and a selection function.

```C#
private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<BrainCompanyFilingLanguageMetricsUniverseAll>(altCoarse =>
    {
        return from d in altCoarse.OfType<BrainCompanyFilingLanguageMetricsUniverseAll>()
            where d.ReportSentiment.Sentiment > 0m &&
                      d.ManagementDiscussionAnalyasisOfFinancialConditionAndResultsOfOperations.Sentiment > 0m
            select d.Symbol;
    });
}
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = History(_universe, 30, Resolution.Daily);
foreach (var universeDay in universeHistory)
{
    foreach (BrainCompanyFilingLanguageMetricsUniverse10K languageMetrics in universeDay)
    {
        Log($"{languageMetrics.Symbol} sentiment at {languageMetrics.EndTime}:
{languageMetrics.ReportSentiment.Sentiment}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (BrainCompanyFilingLanguageMetricsUniverse10K languageMetrics in universeDay)
    {
        Console.WriteLine($"{languageMetrics.Symbol} sentiment at {languageMetrics.EndTime}:
{languageMetrics.ReportSentiment.Sentiment}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_dataset10KSymbol);
RemoveSecurity(_datasetAllSymbol);
```

If you subscribe to Brain Language Metrics on Company Filings data for assets in a dynamic universe, remove the dataset

subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain Language Metrics on Company Filings dataset enables you to test strategies using language metrics and their differences gathered from 10K and 10Q reports. Examples include the following strategies:

- Using the similarity among reports to determine position sizing of securities. Some examples are discussed in Lazy Prices, Cohen et al. 2018 and The Positive Similarity of Company Filings and the Cross-section of Stock Returns, M. Padyšák 2020 .
- Using the sentiment of the latest report to determine the portfolio allocation to give to each security in the universe.
- Using levels of uncertainty, readability, or litigious language in the report to determine position sizing of securities.

Classic Algorithm Example

The following example algorithm buys Apple when the sentiment of their 10K report is positive. Otherwise, it holds cash.

```C#
public class BrainCompanyFilingNLPDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Requesting data -- we aim to obtain a sentiment score from the company filings
        // Combining both fundamental and sentiment factor, as well as past performance and future provision
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<BrainCompanyFilingLanguageMetrics10K>(_symbol).Symbol;

        // Historical data
        var history = History<BrainCompanyFilingLanguageMetrics10K>(_datasetSymbol, 365, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request for {_datasetSymbol}");
    }

    public override void OnData(Slice slice)
    {
        // Trade base on the updated report sentiment
        if (slice.ContainsKey(_datasetSymbol))
        {
            // Buy for a positive sentiment score for the positive return projection
            var sentiment = slice[_datasetSymbol].ReportSentiment.Sentiment;
            SetHoldings(_symbol, sentiment > 0 ? 1 : 0);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have positive sentiment in their 10K report and then forms an equal-weighted portfolio:

C#

```
public class BrainCompanyFilingNLPDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        Settings.FreePortfolioValuePercentage = 0.1m;
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;

        // Filter based on company filing data
        UniverseSettings.Resolution = Resolution.Daily;
        AddUniverse<BrainCompanyFilingLanguageMetricsUniverse10K>(altCoarse =>
        {
            // Filter for the stocks with positive sentiment score for the positive return projection
            // Combining both fundamental and sentiment factor, as well as past performance and future provision
            return from d in altCoarse.OfType<BrainCompanyFilingLanguageMetricsUniverse10K>()
                where d.ReportSentiment.Sentiment > 0m
                select d.Symbol;
        });

        AddAlpha(new BrainCompanyFilingNLPAlphaModel());

        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        AddRiskManagement(new NullRiskManagementModel());

        SetExecution(new ImmediateExecutionModel());
    }
}

public class BrainCompanyFilingNLPAlphaModel : AlphaModel
{
    private List<Security> _securities = new();

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Signal to invest in the selected universe, which are expected to have a positive return due to positive
fundamentals and future prospect
        return _securities
            .Where(security => security.Price != 0 && security.IsTradable)
            .Select(security => Insight.Price(security.Symbol, TimeSpan.FromDays(1), InsightDirection.Up));
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes) {
        foreach (var security in changes.AddedSecurities)
        {
            _securities.Add(security);
        }
        foreach (var security in changes.RemovedSecurities)
        {
            if (_securities.Contains(security))
            {
                _securities.Remove(security);
            }
        }
    }
}
```

Research Example

The following example lists US Equities having the highest 2-day rank.

```
C#
#r "../QuantConnect.DataSource.BrainSentiment.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<BrainCompanyFilingLanguageMetrics10K>(aapl).Symbol;

// Historical data
var history = qb.History<BrainCompanyFilingLanguageMetrics10K>(symbol, 180, Resolution.Daily);
foreach (BrainCompanyFilingLanguageMetrics10K languageMetrics in history)
{
    Console.WriteLine($"{languageMetrics} at {languageMetrics.EndTime}");
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    var symbols = (from d in altCoarse.OfType<BrainCompanyFilingLanguageMetricsUniverse10K>()
        orderby d.ReportSentiment.Sentiment descending select d.Symbol).Take(10);
    return symbols;
}
var universe = qb.AddUniverse<BrainCompanyFilingLanguageMetricsUniverse10K>(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-10), qb.Time);
foreach (var universeDay in universeHistory)
{
    foreach (BrainCompanyFilingLanguageMetricsUniverse10K languageMetrics in universeDay)
    {
        Console.WriteLine($"{languageMetrics.Symbol} sentiment at {languageMetrics.EndTime}:
{languageMetrics.ReportSentiment.Sentiment}");
    }
}
```

Data Point Attributes

The Brain Language Metrics on Company Filings dataset provides `BrainCompanyFilingLanguageMetrics` and `BrainCompanyFilingLanguageMetricsUniverse` objects.

BrainCompanyFilingLanguageMetrics Attributes

`BrainCompanyFilingLanguageMetrics` objects have the following attributes:

BrainCompanyFilingLanguageMetricsUniverse Attributes

`BrainCompanyFilingLanguageMetricsUniverse` objects have the following attributes:

Brain

Brain ML Stock Ranking

Introduction

The Brain ML Stock Ranking dataset by Brain generates a daily ranking for US Equities based on their predicted ranking of future returns relative to the universe median across four-time horizons: next 2, 3, 5, 10, and 21 days (one trading month). The data covers 1,000 US Equities (universe updated yearly by including the largest 1,000 US companies of the previous year), starts in January 2010, and is delivered on a daily frequency. This dataset is created by a voting scheme of machine learning classifiers that non-linearly combine a variety of features with a series of techniques aimed at mitigating the well-known overfitting problem for financial data with a low signal-to-noise ratio. Examples of features are time-varying stock-specific features like price and volume-related metrics or fundamentals; time-fixed stock-specific features like the sector and other database information; market regime features such as volatility and other financial stress indicators; calendar features representing possible anomalies, for example, the month of the year.

More precisely the ML Stock Ranking score is related to the confidence of a Machine Learning classifier in predicting top or bottom quintile returns for the next N trading days (e.g. next 21 trading days) for a stock with the respect to the median of the universe and ranges from -1 to +1.

A negative score means that the system is more confident that the stock belongs to the lower returns quintile, a positive score means that the system is more confident that the stock belongs to the higher returns quintile. It is important to note that the score has a meaning only if used to compare different stocks to perform a ranking.

Typical use is to download the score for a large stock universe for a given day, e.g. 500 stocks or the full universe of 1000 stocks, order the stocks by mlAlpha score and go long the top K stocks, or build a long-short strategy going long the top K and short the bottom K stocks.

For more information, refer to Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain ML Stock Ranking dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain ML Stock Ranking dataset:

C#

```
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<BrainStockRanking2Day>(_symbol).Symbol;

_universe = AddUniverse<BrainStockRankingUniverse>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2010
Asset Coverage*	1,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

The coverage includes all assets since the start date. It increases over time.

Requesting Data

To add Brain ML Stock Ranking data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class BrainMLRankingDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _2DaySymbol, _3DaySymbol, _5DaySymbol, _10DaySymbol, _monthSymbol;

    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 7, 8);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _2DaySymbol = AddData<BrainStockRanking2Day>(_symbol).Symbol;
        _3DaySymbol = AddData<BrainStockRanking3Day>(_symbol).Symbol;
        _5DaySymbol = AddData<BrainStockRanking5Day>(_symbol).Symbol;
        _10DaySymbol = AddData<BrainStockRanking10Day>(_symbol).Symbol;
        _monthSymbol = AddData<BrainStockRanking21Day>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Brain ML Stock Ranking data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_2DaySymbol))
    {
        var dataPoint = slice[_2DaySymbol];
        Log($"{_2DaySymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    if (slice.ContainsKey(_3DaySymbol))
    {
        var dataPoint = slice[_3DaySymbol];
        Log($"{_3DaySymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    if (slice.ContainsKey(_5DaySymbol))
    {
        var dataPoint = slice[_5DaySymbol];
        Log($"{_5DaySymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    if (slice.ContainsKey(_10DaySymbol))
    {
        var dataPoint = slice[_10DaySymbol];
        Log($"{_10DaySymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    if (slice.ContainsKey(_monthSymbol))
    {
        var dataPoint = slice[_monthSymbol];
        Log($"{_monthSymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<BrainStockRanking2Day>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    foreach (var kvp in slice.Get<BrainStockRanking3Day>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    foreach (var kvp in slice.Get<BrainStockRanking5Day>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    foreach (var kvp in slice.Get<BrainStockRanking10Day>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }

    foreach (var kvp in slice.Get<BrainStockRanking21Day>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} rank at {slice.Time}: {dataPoint.Rank}");
    }
}
```

Historical Data

To get historical Brain ML Stock Ranking data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#

// Dataset objects
var twoDayHistory = History<BrainStockRanking2Day>(_2DaySymbol, 100, Resolution.Daily);
var threeDayHistory = History<BrainStockRanking3Day>(_3DaySymbol, 100, Resolution.Daily);
var fiveDayHistory = History<BrainStockRanking5Day>(_5DaySymbol, 100, Resolution.Daily);
var tenDayHistory = History<BrainStockRanking10Day>(_10DaySymbol, 100, Resolution.Daily);
var monthHistory = History<BrainStockRanking21Day>(_monthSymbol, 100, Resolution.Daily);

// Slice objects
var history = History(new[] {_2DaySymbol, _3DaySymbol, _5DaySymbol,
                             _10DaySymbol, _monthSymbol}, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain ML Stock Ranking data, call the `AddUniverse` method with the `BrainStockRankingUniverse` class and a selection function.

```
C#

private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<BrainStockRankingUniverse>(altCoarse =>
    {
        return from d in altCoarse.OfType<BrainStockRankingUniverse>()
            where d.Rank2Days > 0m && d.Rank3Days > 0m  && d.Rank5Days > 0m
            select d.Symbol;
    })
};
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
C#

var universeHistory = History(_universe, 30, Resolution.Daily);
foreach (var ranks in universeHistory)
{
    foreach (BrainStockRankingUniverse rank in ranks)
    {
        Log($"{rank.Symbol} 2-day rank at {rank.EndTime}: {rank.Rank2Days}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var ranks in universeHistory)
{
    foreach (BrainStockRankingUniverse rank in ranks)
    {
        Console.WriteLine($"{rank.Symbol} 2-day rank at {rank.EndTime}: {rank.Rank2Days}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
RemoveSecurity(_2DaySymbol);
RemoveSecurity(_3DaySymbol);
RemoveSecurity(_5DaySymbol);
RemoveSecurity(_10DaySymbol);
RemoveSecurity(_monthSymbol);
```

If you subscribe to Brain ML Stock Ranking data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain ML Stock Ranking dataset enables you to test strategies using the machine learning ranking provided by Brain. Examples include the following strategies:

- Constructing a portfolio of securities with each security's weight in the portfolio reflecting its Brain ML Stock Ranking
- Buying stocks with the largest Brain ML Stock Ranking
- Building a market-neutral strategy based on the top N and bottom N stocks in the Brain ML Stock Ranking

Classic Algorithm Example

The following example algorithm constructs a portfolio where the weight of each security in the portfolio is scaled based on its Brain ML Ranking. It gives a larger allocation to securities that have a higher Brain ML Ranking.

```C#
public class BrainMLRankingDataAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, Symbol> _symbolByDatasetSymbol = new Dictionary<Symbol, Symbol>();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // We cherry picked 5 largest stocks, high trading volume provides better information and credibility for ML
ranking
        var tickers = new List<string>() {"AAPL", "TSLA", "MSFT", "F", "KO"};
        foreach (var ticker in tickers)
        {
            // Requesting data to get 2 days estimated relative ranking
            var symbol = AddEquity(ticker, Resolution.Daily).Symbol;
            var datasetSymbol = AddData<BrainStockRanking2Day>(symbol).Symbol;
            _symbolByDatasetSymbol.Add(datasetSymbol, symbol);

            // Historical data
            var history = History<BrainStockRanking2Day>(datasetSymbol, 365, Resolution.Daily);
            Debug($"We got {history.Count()} items from our history request for {symbol}");
        }
    }

    public override void OnData(Slice slice)
    {
        // Collect rankings for all symbols for ranking them
        var points = slice.Get<BrainStockRanking2Day>();
        if (points == null)
        {
            return;
        }
        var symbols = new List<Symbol>();
        var ranks = new List<decimal>();
        foreach (var point in points.Values)
        {
            symbols.Add(_symbolByDatasetSymbol[point.Symbol]);
            ranks.Add(point.Rank);
        }

        // Rank each symbol's Brain ML ranking relative to the other symbols for positional sizing
        if (ranks.Count() == 0) return;
        var sortedRanksTemp = new List<decimal>(ranks);
        sortedRanksTemp.Sort();
        var sortedRanks = new List<decimal>();
        for (var i = 0; i < symbols.Count(); i++)
        {
            sortedRanks.Add(sortedRanksTemp.IndexOf(ranks[i]) + 1);
        }

        // Place orders, the better the rank, the higher the estimated return and hence weight
        for (var i = 0; i < symbols.Count(); i++)
        {
            var rank = sortedRanks[i];
            var weight = rank / sortedRanks.Sum();
            SetHoldings(symbols[i], weight);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm constructs a portfolio where the weight of each security in the portfolio is scaled based on its Brain ML Ranking. It gives a larger allocation to securities that have a higher Brain ML Ranking.

```C#
public class BrainMLRankingDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
```

```
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Select based on ML ranking data
        AddUniverse<BrainStockRankingUniverse>(altCoarse =>
        {
            // Select the ones that expected to out-perform the median of the whole market in 2-3 days
            return from d in altCoarse.OfType<BrainStockRankingUniverse>()
                where d.Rank2Days > 0.2m && d.Rank3Days > 0.2m
                select d.Symbol;
        });

Research Example

The following example lists US Equities having the highest 2-day rank.

C#

```
#r "../QuantConnect.DataSource.BrainSentiment.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<BrainStockRanking2Day>(aapl).Symbol;

// Historical data
var history = qb.History<BrainStockRanking2Day>(symbol, 30, Resolution.Daily);
foreach (BrainStockRanking2Day rank in history)
{
    Console.WriteLine($"{rank} at {rank.EndTime}");
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return (from d in altCoarse.OfType<BrainStockRankingUniverse>()
        orderby d.Rank2Days descending select d.Symbol).Take(10);
}
var universe = qb.AddUniverse<BrainStockRankingUniverse>(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-5), qb.Time);
foreach (var ranks in universeHistory)
{
    foreach (BrainStockRankingUniverse rank in ranks)
    {
        Console.WriteLine($"{rank.Symbol} 2-day rank at {rank.EndTime}: {rank.Rank2Days}");
    }
}
```

Brain Sentiment Indicator

Introduction

The Brain Sentiment Indicator dataset by Brain tracks the public sentiment around US Equities. The data covers 4,500 US Equities, starts in August 2016, and is delivered on a daily frequency. This dataset is created by analyzing financial news using Natural Language Processing techniques while taking into account the similarity and repetition of news on the same topic. The sentiment score assigned to each stock ranges from -1 (most negative) to +1 (most positive). The sentiment score corresponds to the average sentiment for each piece of news. The score is updated daily and is available on two time scales: 7 days and 30 days. For more information, see Brain's summary paper .

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Brain Sentiment Indicator dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. The founders share a common academic background of research in Physics as well as extensive experience in Financial markets.

Getting Started

The following snippet demonstrates how to request data from the Brain Sentiment Indicator dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_dataset7DaySymbol = AddData<BrainSentimentIndicator7Day>(_symbol).Symbol;
_dataset30DaySymbol = AddData<BrainSentimentIndicator30Day>(_symbol).Symbol;

_universe = AddUniverse<BrainSentimentIndicatorUniverse>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2016
Asset Coverage*	4,500 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

The coverage includes all assets since the start date. It increases over time.

Requesting Data

To add Brain Sentiment Indicator data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class BrainSentimentDataAlgorithm : QCAlgorithm
{
    private Symbol _dataset7DaySymbol, _dataset30DaySymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2021, 7, 8);
        SetCash(100000);

        var symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _dataset7DaySymbol = AddData<BrainSentimentIndicator7Day>(symbol).Symbol;
        _dataset30DaySymbol = AddData<BrainSentimentIndicator30Day>(symbol).Symbol;
    }
}
```

Accessing Data

To get the current Brain Sentiment Indicator data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_dataset7DaySymbol))
    {
        var dataPoint = slice[_dataset7DaySymbol];
        Log($"{_dataset7DaySymbol} sentiment at {slice.Time}: {dataPoint.Sentiment}");
    }

    if (slice.ContainsKey(_dataset30DaySymbol))
    {
        var dataPoint = slice[_dataset30DaySymbol];
        Log($"{_dataset30DaySymbol} sentiment at {slice.Time}: {dataPoint.Sentiment}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<BrainSentimentIndicator7Day>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} sentiment at {slice.Time}: {dataPoint.Sentiment}");
    }

    foreach (var kvp in slice.Get<BrainSentimentIndicator30Day>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} sentiment at {slice.Time}: {dataPoint.Sentiment}");
    }
}
```

Historical Data

To get historical Brain Sentiment Indicator data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
// Dataset objects
var weekHistory = History<BrainSentimentIndicator7Day>(_dataset7DaySymbol, 100, Resolution.Daily);
var monthHistory = History<BrainSentimentIndicator30Day>(_dataset30DaySymbol, 100, Resolution.Daily);

// Slice objects
var history = History(new[] {_dataset7DaySymbol, _dataset30DaySymbol}, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Brain Sentiment Indicator data, call the `AddUniverse` method with the `BrainSentimentIndicatorUniverse` class and a selection function.

```
C#
private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<BrainSentimentIndicatorUniverse>(altCoarse=>
    {
        return from d in altCoarse.OfType<BrainSentimentIndicatorUniverse>()
            where d.TotalArticleMentions7Days > 0m && d.Sentiment7Days > 0m
            select d.Symbol;
    });
}
```

The Brain Sentiment Indicator universe runs at 7 AM Eastern Time (ET) in live trading. For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
C#
var universeHistory = History(_universe, 30, Resolution.Daily);
foreach (var sentiments in universeHistory)
{
    foreach (BrainSentimentIndicatorUniverse sentiment in sentiments)
    {
        Log($"{sentiment.Symbol} 7-day sentiment at {sentiment.EndTime}: {sentiment.Sentiment7Days}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var sentiments in universeHistory)
{
    foreach (BrainSentimentIndicatorUniverse sentiment in sentiments)
    {
        Console.WriteLine($"{sentiment.Symbol} 7-day sentiment at {sentiment.EndTime}: {sentiment.Sentiment7Days}");
    }
}
```

C#

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
RemoveSecurity(_dataset7DaySymbol);
RemoveSecurity(_dataset30DaySymbol);
```

C#

If you subscribe to Brain Sentiment Indicator data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Brain Sentiment Indicator dataset enables you to incorporate sentiment from financial news sources into your strategies. Examples include the following strategies:

- Buying when the public sentiment for a security is increasing
- Short selling when the public sentiment for a security is decreasing
- Scaling the position sizing of securities based on how many times they are mentioned in financial news articles
- Sector rotation based on news sentiment

Classic Algorithm Example

The following example algorithm buys Apple when the 30-day Brain Sentiment indicator increases. Otherwise, it remains in cash.

```C#
public class BrainSentimentDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Symbol _datasetSymbol;
    private decimal? _latestSentimentValue = null;
    private int _targetHoldings = 0;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Requesting the processed longer term (30-day) sentiment score data for sentiment trading
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<BrainSentimentIndicator30Day>(_symbol).Symbol;

        // Historical data
        var history = History<BrainSentimentIndicator30Day>(_datasetSymbol, 100, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request for {_datasetSymbol}");

        // Warm up historical sentiment values, cache for comparing last sentiment score to trade, making it
immediately tradable signal
        var previousSentimentValues = history.Select(x => x.Sentiment);
        foreach (var sentiment in previousSentimentValues)
        {
            Update(sentiment);
        }
    }

    public void Update(decimal sentiment)
    {
        // Comparing the last sentiment score and decide to buy if the sentiment increases to ride the popularity
        if (_latestSentimentValue != null)
        {
            _targetHoldings = sentiment > _latestSentimentValue ? 1 : 0;
        }
        _latestSentimentValue = sentiment;
    }

    public override void OnData(Slice slice)
    {
        // Update trade direction based on updated data
        if (slice.ContainsKey(_datasetSymbol))
        {
            var sentiment = slice[_datasetSymbol].Sentiment;
            Update(sentiment);
        }

        // Ensure we have security data in the current slice to avoid stale fill
        // Buy if sentiment increase, liquidate otherwise to ride on the popularity of the equity
        if (slice.Bars.ContainsKey(_symbol) && _targetHoldings == 1 != Portfolio.Invested)
        {
            SetHoldings(_symbol, _targetHoldings);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have been mentioned in an article over the last seven days. It then buys the subset of Equities that have increasing sentiment and forms an equal-weighted portfolio.

```C#
public class BrainSentimentDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 10);
        SetCash(100000);

        Settings.MinimumOrderMarginPortfolioPercentage = 0;
        UniverseSettings.Resolution = Resolution.Daily;
```

```
        UniverseSettings.Resolution = Resolution.Daily;
        // Filter by sentiment data
        AddUniverse<BrainSentimentIndicatorUniverse>(altCoarse =>
        {
            // Filter for any sentiment on last 7 days to trade on sentiment news
            return from d in altCoarse.OfType<BrainSentimentIndicatorUniverse>()
                where d.SentimentalArticleMentions7Days > 0m
                select d.Symbol;
        });

        AddAlpha(new BrainSentimentAlphaModel());

        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        AddRiskManagement(new NullRiskManagementModel());

        SetExecution(new ImmediateExecutionModel());
    }
}

public class BrainSentimentAlphaModel : AlphaModel
{
    private Dictionary<Symbol, SymbolData> _symbolDataBySymbol = new Dictionary<Symbol, SymbolData>();

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        foreach (var entry in _symbolDataBySymbol)
        {
            var symbol = entry.Key;
            var symbolData = entry.Value;

            // Update trade direction based on updated data
            if (slice.ContainsKey(symbolData.datasetSymbol)   && slice[symbolData.datasetSymbol] != null)
            {
                var sentiment = slice[symbolData.datasetSymbol].Sentiment;
                symbolData.Update(sentiment);
            }

            // Ensure we have security data in the current slice to avoid stale fill
            if (!(slice.ContainsKey(symbol)  && slice[symbol] != null))
            {
                continue;
            }

            // Buy if sentiment increase, liquidate otherwise to ride on the popularity of the equity
            if (symbolData.targetDirection == InsightDirection.Up  && !algorithm.Portfolio[symbol].Invested)
            {
                insights.Add(Insight.Price(symbol, TimeSpan.FromDays(100), symbolData.targetDirection));
            }
        }

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            var symbol = security.Symbol;
            _symbolDataBySymbol.Add(symbol, new SymbolData(algorithm, symbol));
        }

        foreach (var security in changes.RemovedSecurities)
        {
            var symbol = security.Symbol;
            if (_symbolDataBySymbol.ContainsKey(symbol))
            {
                _symbolDataBySymbol[symbol].dispose();
                _symbolDataBySymbol.Remove(symbol);
            }
        }
    }
}

public class SymbolData
{
    public Symbol datasetSymbol;
    public InsightDirection targetDirection = InsightDirection.Flat;
```

```
    public InsightDirection targetDirection = InsightDirection.Flat;
    private QCAlgorithm _algorithm;
    private decimal? _latestSentimentValue = null;

    public SymbolData(QCAlgorithm algorithm, Symbol symbol)
    {
        _algorithm = algorithm;

        // Requesting the processed longer term (30-day) sentiment score data for sentiment trading
        datasetSymbol = algorithm.AddData<BrainSentimentIndicator30Day>(symbol).Symbol;

        // Historical data
        var history = algorithm.History<BrainSentimentIndicator30Day>(datasetSymbol, 100, Resolution.Daily);
        if (history.Count() == 0)
        {
            return;
        }

        // Warm up historical sentiment values, cache for comparing last sentiment score to trade, making it
immediately tradable signal
        var previousSentimentValues = history.Select(x => x.Sentiment);
        foreach (var sentiment in previousSentimentValues)
        {
            Update(sentiment);
        }
    }

    public void dispose()
    {
        // Unsubscribe from the Brain Sentiment feed for this security to release computational resources
        _algorithm.RemoveSecurity(datasetSymbol);
    }

    public void Update(decimal sentiment)
    {
        // Comparing the last sentiment score and decide to buy if the sentiment increases to ride the popularity
        if (_latestSentimentValue != null)
        {
            targetDirection = sentiment > _latestSentimentValue ? InsightDirection.Up : InsightDirection.Flat;
        }
        _latestSentimentValue = sentiment;
    }
}
```

Research Example

The following example lists US Equities having the highest 7-day sentiment.

```
C#
#r "../QuantConnect.DataSource.BrainSentiment.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<BrainSentimentIndicator30Day>(aapl).Symbol;

// Historical data
var history = qb.History<BrainSentimentIndicator30Day>(symbol, 30, Resolution.Daily);
foreach (BrainSentimentIndicator30Day sentiment in history)
{
    Console.WriteLine($"{sentiment} at {sentiment.EndTime}");
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return (from d in altCoarse.OfType<BrainSentimentIndicatorUniverse>()
        orderby d.Sentiment7Days descending select d.Symbol).Take(10);
}
var universe = qb.AddUniverse<BrainSentimentIndicatorUniverse>(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-5), qb.Time);
foreach (var sentiments in universeHistory)
{
    foreach (BrainSentimentIndicatorUniverse sentiment in sentiments)
    {
        Console.WriteLine($"{sentiment.Symbol} 7-day sentiment at {sentiment.EndTime}: {sentiment.Sentiment7Days}");
    }
}
```

Brain Wikipedia Page Views

Introduction

The Brain Wikipedia Page Views dataset by Brain tracks investor attention toward large U.S. equities by monitoring traffic on company Wikipedia pages. The dataset covers approximately 1,000 of the largest U.S. companies, broadly corresponding to the Russell 1000, and is available starting from February 2023. Data is delivered at a daily frequency.

The dataset is constructed by analyzing the number of views on each company's Wikipedia page, including both the main page and any secondary pages that redirect to it. Only English-language Wikipedia pages are considered. The data is published daily, typically by 12:00 PM UTC, and reflects attention metrics calculated relative to the reporting date.

In addition to raw page-view counts, the dataset includes buzz metrics, which normalize current attention levels relative to historical behavior. Buzz scores are computed as the distance between current page views and the company's own historical average over the previous six months, expressed in units of standard deviations. As a result, positive buzz values indicate unusually high attention, while negative values indicate lower-than-normal attention.

Metrics are provided across multiple time horizons, including 1-day, 7-day, and 30-day rolling windows, enabling users to study short-term spikes in attention as well as more persistent trends. These features make the dataset well-suited for research into investor attention, behavioral finance signals, event-driven strategies, and alpha models that incorporate information demand.

This dataset depends on the US Equity Security Master dataset, which provides essential information such as symbol mappings, corporate actions, and identifier consistency required for accurate historical analysis and backtesting.

For more information about the Brain Wikipedia Page Views dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Brain is a Research Company that creates proprietary datasets and algorithms for investment strategies, combining experience in financial markets with strong competencies in Statistics, Machine Learning, and Natural Language Processing. Getting Started

The following snippet demonstrates how to request data from the Brain Wikipedia Page Views dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<BrainWikipediaPageViews>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	February 2023
Asset Coverage*	~1,000 US Equities (approximately Russell 1000)
Data Density	Sparse
Resolution	Daily
Timezone	UTC

* The coverage includes the largest U.S. equities since the start date and may evolve over time.

Requesting Data

To add Brain Wikipedia Page Views Indicator data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class BrainWikipediaPageViews: QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 7, 8);
        SetCash(100000);
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<BrainWikipediaPageViews>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Brain Wikipedia Page Views Indicator data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} report sentiment at {slice.Time}: {dataPoint. NumberViews1}, {dataPoint. Buzz1}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<BrainWikipediaPageViews>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} metric at {slice.Time}: {data_point. NumberViews1}, {data_point. Buzz1}");
    }
}
```

Historical Data

To get historical Brain Wikipedia Page Views data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
var history = History<BrainWikipediaPageViews>(_datasetSymbol, 100, Resolution.Daily);
```

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Brain Wikipedia Page Views dataset enables you to incorporate investor attention signals derived from Wikipedia traffic into your strategies. Examples include the following strategies:

- Buying securities that experience unusually high spikes in Wikipedia page views, indicating elevated public interest.
- Avoiding or reducing exposure to securities with declining or abnormally low attention relative to their historical baseline.
- Scaling position sizes based on short-term or long-term attention intensity using page view and buzz metrics.
- Building cross-sectional ranking strategies that favor stocks with sustained increases in public visibility.

Classic Algorithm Example

The following example algorithm ranks large-cap U.S. stocks daily using Brain Wikipedia Page Views attention and buzz metrics, then allocates portfolio weights proportionally to each stock's relative attention score.

C#

```
public class BrainWikipediaPageViewsRankingAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2025, 1, 1);
        SetEndDate(2025, 11, 23);
        SetCash(100000);

        // Seed prices so we don't get "no price" trading errors
        Settings.SeedInitialPrices = true;

        // We cherry picked 5 largest stocks, high trading volume provides better information and credibility for ML
ranking
        var tickers = new[] { "AAPL", "TSLA", "MSFT", "F", "KO" };

        foreach (var ticker in tickers)
        {
            // Requesting data to get 2 days estimated relative ranking
            var symbol = AddEquity(ticker, Resolution.Daily).Symbol;
            var datasetSymbol = AddData<BrainWikipediaPageViews>(symbol).Symbol;

            // Historical data (request dataset symbol)
            var history = History(datasetSymbol, 365, Resolution.Daily);
            Debug($"We got {history.Count()} items from our history request for {symbol}");
        }
    }

    public override void OnData(Slice slice)
    {
        // Get all BrainWikipediaPageViews points in the slice
        var points = slice.Get<BrainWikipediaPageViews>();
        if (points == null || points.Count == 0)
        {
            return;
        }

        var ranked = points.Values.ToDictionary(
            x => x.Symbol.Underlying,
            x =>
            {
                // Example composite signal:
                var number_of_views = x.NumberViews1.HasValue ? x.NumberViews1.Value : 0m;
                var buzz1day = x.Buzz1.HasValue ? x.Buzz1.Value : 0m;
                return buzz1day * (decimal)Math.Sqrt((double)number_of_views);
            })
            // Rank by score (higher score = better)
            .OrderByDescending(x => x.Value).ToList();

        // Convert ranks to weights (same style as your example)
        // best gets highest rank number
        var n = ranked.Count;
        var ranks = Enumerable.Range(1, n).Reverse().ToArray(); // n, n-1, ..., 1
        var denom = ranks.Sum();
        var top = string.Join(", ", ranked.Take(3).Select(x => $"{x.Key.Value}:{x.Value:0.0000}"));
        Debug($"{Time.Date:yyyy-MM-dd} top: {top}");

        // Place orders according to the ML ranking, the better the rank, the higher the estimated return and hence
weight
        for (var i = 0; i < ranked.Count; i++)
        {
            var w = (decimal)ranks[i] / denom;
            SetHoldings(ranked[i].Key, w);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of liquid U.S. equities, ranks them daily using Brain Wikipedia Page Views attention and buzz metrics, and emits weighted bullish insights for the most attention-driven stocks using the Alpha Framework.

C#

```
public class BrainWikipediaPageViewsFrameworkRankingAlgorithm : QCAlgorithm
```

```
{
    public override void Initialize()
    {
        SetStartDate(2025, 1, 1);
        SetEndDate(2025, 11, 23);
        SetCash(100000);

        UniverseSettings.Resolution = Resolution.Daily;

        AddUniverse(f => f
            .Where(c => c.HasFundamentalData && c.Price > 10)
            .OrderByDescending(c => c.DollarVolume)
            .Take(50)
            .Select(c => c.Symbol));

        var alpha = new BrainWikipediaPageViewsRankingAlpha();
        AddAlpha(alpha);

        Schedule.On(
            DateRules.EveryDay(),
            TimeRules.At(9, 0),
            alpha.EmitInsights
        );

        SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel());
        AddRiskManagement(new NullRiskManagementModel());
        SetExecution(new ImmediateExecutionModel());

        SetWarmUp(30, Resolution.Daily);
    }
}

public class BrainWikipediaPageViewsRankingAlpha : AlphaModel
{
    private readonly Dictionary<Symbol, SymbolData> _symbolDataBySymbol = new();
    private readonly Dictionary<Symbol, Symbol> _symbolByDatasetSymbol = new();

    private readonly Dictionary<Symbol, double> _latestScores = new();

    }

    public void Dispose()
    {
        _algorithm.RemoveSecurity(DatasetSymbol);
    }
}
```

Research Example

The following example retrieves historical Brain Wikipedia Page Views data for Apple and prints the daily number of Wikipedia page views over the past six months.

C#

```
#r "../QuantConnect.DataSource.BrainSentiment.dll"
var qb = new QuantBook();
// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<BrainWikipediaPageViews>(aapl).Symbol;

// Historical data
var history = qb.History<BrainWikipediaPageViews>(symbol, 180, Resolution.Daily);
foreach (BrainWikipediaPageViews PageMetrics in history)
{
    Console.WriteLine($"{PageMetrics} at {PageMetrics.EndTime}");
}
```

Data Point Attributes

The Brain Wikipedia Page Views dataset provides `BrainWikipediaPageViews` objects.

`BrainWikipediaPageViews` objects have the following attributes:

Datasets

CoinGecko

CoinGecko was founded in 2014 by TM Lee (CEO) and Bobby Ong (COO) with the mission to democratize the access of crypto data and empower users with actionable insights. We also deep dive into the crypto space to deliver valuable insights to our users through our cryptocurrency reports, as well as our publications, newsletter, and more.

Crypto Market Cap

CoinGecko

Crypto Market Cap

Introduction

The Crypto Market Cap dataset by CoinGecko tracks the market cap of cryptocurrencies. The data covers 620 cryptocurrencies that are supported by QuantConnect, starts in 28 April 2013, and is delivered on a daily frequency. This dataset is created by scraping CoinGecko's Market Chart.

For more information about the Crypto Market Cap dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

CoinGecko was founded in 2014 by TM Lee (CEO) and Bobby Ong (COO) with the mission to democratize the access of crypto data and empower users with actionable insights. We also deep dive into the crypto space to deliver valuable insights to our users through our cryptocurrency reports, as well as our publications, newsletter, and more.

Getting Started

The following snippet demonstrates how to request data from the CoinGecko Crypto Market Cap dataset:

```C#
_symbol = AddData<CoinGecko>("BTC").Symbol;
_universe = AddUniverse(CoinGeckoUniverse, UniverseSelection)
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	28 April 2013
Asset Coverage	620 cryptocurrencies
Resolution	Daily
Timezone	UTC

Requesting Data

To add CoinGecko Crypto Market Cap data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class CoinGeckoMarketCapDataAlgorithm: QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _symbol = AddCrypto("BTCUSD", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<CoinGecko>("BTC").Symbol;
    }
}
```

Accessing Data

To get the current Crypto Market Cap data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} market cap::volume at {slice.Time}: {dataPoint.MarketCap}::{dataPoint.Volume}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<CoinGecko>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} market cap::volume at {slice.Time}: {dataPoint.MarketCap}::{dataPoint.Volume}");
    }
}
```

Historical Data

To get historical CoinGecko Crypto Market Cap data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<CoinGecko>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of Cryptos based on CoinGecko Crypto Market Cap data, call the `AddUniverse` method with the `CoinGeckoUniverse` class and a selection function. Note that the filtered output is a list of names of the coins. If corresponding tradable crypto pairs are preferred, call `CreateSymbol(market, quoteCurrency)` method for each output item.

```C#
public class CryptoMarketCapUniverseAlgorithm : QCAlgorithm
{
    private Universe _universe;
    public override void Initialize()
    {
        SetAccountCurrency("USD");
        var market = Market.Coinbase;
        var marketPairs = SymbolPropertiesDatabase.GetSymbolPropertiesList(market)
            .Where(x => x.Value.QuoteCurrency == AccountCurrency)
            .Select(x => x.Key.Symbol)
            .ToList();
        _universe = AddUniverse<CoinGecko>(data =>
        {
            foreach (var datum in data.OfType<CoinGecko>())
            {
                Debug($"{datum.Coin},{datum.MarketCap},{datum.Price}");
            }
            return data
                .Select(c => c as CoinGecko)
                // Select the coins that the brokerage supports and have a quote currency that
                // matches our account currency.
                .Where(c => marketPairs.Contains(c.Coin + AccountCurrency))
                // Select the 10 largest coins.
                .OrderByDescending(c => c.MarketCap)
                .Take(10)
                // Create the Symbol objects of the selected coins.
                .Select(c => c.CreateSymbol(market, AccountCurrency));
        });
    }
}
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = History(_universe, 30, Resolution.Daily);
foreach (var coins in universeHistory)
{
    foreach (CoinGecko coin in coins)
    {
        Log($"{coin.Symbol.Value} market cap at {coin.EndTime}: {coin.MarketCap}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var coins in universeHistory)
{
    foreach (CoinGecko coin in coins)
    {
        Console.WriteLine($"{coin.Symbol.Value} market cap at {coin.EndTime}: {coin.MarketCap}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove your subscription to CoinGecko Crypto Market Cap data, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Supported Assets

Example Applications

The CoinGecko Crypto Market Cap dataset provides information on the size of the crypto coin and can be used to compare the size of one coin to another. Examples include the following strategies:

- Construct a major crypto index fund.
- Invest in the cryptos with the fastest growth in market size.
- Red flag stop when there might be a crypto bank run.

Classic Algorithm Example

The following example algorithm buy BTCUSD when the market cap of BTC is rising, while sell it when the market cap of BTC is dropping.

```C#
public class CoinGeckoAlgorithm : QCAlgorithm
{
    private Symbol _cryptoSymbol, _customDataSymbol;
    private RollingWindow<CoinGecko> _window;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request BTCUSD crypto data for trading
        _cryptoSymbol = AddCrypto("BTCUSD").Symbol;
        // Request CoinGecko Market Cap data of BTC for trade signal generation
        _customDataSymbol = AddData<CoinGecko>("BTC").Symbol;
        // Use RollingWindow to save the last 2 market cap data for capital flow analysis
        _window = new RollingWindow<CoinGecko>(2);
    }

    public override void OnData(Slice slice)
    {
        // Trade based on updated market cap data
        var data = slice.Get<CoinGecko>();
        if (!data.IsNullOrEmpty() && data.ContainsKey(_customDataSymbol))
        {
            // Update RollingWindow for updated comparison
            _window.Add(data[_customDataSymbol]);
            if (!_window.IsReady)
            {
                return;
            }

            // Buy BTCUSD if the market cap of BTC is increasing, which suggests the capital flow towards BTC market
and drive up the demand
            if (_window[0].MarketCap > _window[1].MarketCap)
            {
                SetHoldings(_cryptoSymbol, 1);
            }
            // Sell otherwise, since the capital is flowing out and the demand of BTC lowered
            else
            {
                SetHoldings(_cryptoSymbol, -0.5m);
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status.IsFill())
        {
            Debug($"Purchased Crypto: {orderEvent.Symbol}");
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buy BTCUSD when the market cap of BTC is rising, while sell it when the market cap of BTC is

dropping with framework implementation.

```C#
public class CoinGeckoAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request CoinGecko Market Cap data of BTC for trade signal generation
        var symbol = AddData<CoinGecko>("BTC").Symbol;
        // Request BTCUSD crypto data for trading
        var crypto = AddCrypto("BTCUSD", market: Market.Coinbase).Symbol;
        var symbolDict = new Dictionary<Symbol, Symbol> { {symbol, crypto} };
        // Use RollingWindow to save the last 2 market cap data for capital flow analysis
        var window = new Dictionary<Symbol, RollingWindow<CoinGecko>>{ {symbol, new RollingWindow<CoinGecko>(2)} };

        // Custom alpha model that emit insights based on updated market cap data
        AddAlpha(new CoinGeckoAlphaModel(symbolDict, window));
        // Equal invest to evenly dissipate capital concentration risk from non-systematic individual risky event
        SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel());
    }
}

public class CoinGeckoAlphaModel : AlphaModel
{
    private Dictionary<Symbol, Symbol> _symbolDict = new();
    private Dictionary<Symbol, RollingWindow<CoinGecko>> _window = new();

    public CoinGeckoAlphaModel(Dictionary<Symbol, Symbol> symbolDict, Dictionary<Symbol, RollingWindow<CoinGecko>>
window)
    {
        _symbolDict = symbolDict;
        _window = window;
    }

    public override List<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        // Trade based on updated market cap data
        var data = slice.Get<CoinGecko>();

        foreach (var kvp in _symbolDict)
        {
            var datasetSymbol = kvp.Key;
            var cryptoSymbol = kvp.Value;

            if (!data.ContainsKey(kvp.Key)) continue;
            // Update RollingWindow for updated comparison
            _window[datasetSymbol].Add(data[datasetSymbol]);

            // Can only compare market cap if the RollingWindow is ready
            var window = _window[datasetSymbol];
            if (!window.IsReady) continue;

            // Buy BTCUSD if the market cap of BTC is increasing, which suggests the capital flow towards BTC market
and drive up the demand
            if (window[0].MarketCap > window[1].MarketCap)
            {
                var insight = Insight.Price(cryptoSymbol, TimeSpan.FromDays(1), InsightDirection.Up, weight: 1d);
                insights.Add(insight);
            }
            // Sell otherwise, since the capital is flowing out and the demand of BTC lowered
            else
            {
                var insight = Insight.Price(cryptoSymbol, TimeSpan.FromDays(1), InsightDirection.Down, weight:
0.25d);
                insights.Add(insight);
            }
        }

        return insights;
    }
}
```

Research Example

The following example lists US Equities having the highest 7-day sentiment.

```C#
#r "../QuantConnect.DataSource.CoinGecko.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting Data
var symbol = qb.AddData<CoinGecko>("BTC").Symbol;

// Historical data
var history = qb.History<CoinGecko>(symbol, 30, Resolution.Daily);
foreach (CoinGecko coin in history)
{
    Console.WriteLine($"{coin} at {coin.EndTime}");
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return (from d in altCoarse.OfType<CoinGecko>()
        orderby d.MarketCap descending select d.Symbol).Take(10);
}
var universe = qb.AddUniverse<CoinGeckoUniverse<(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-5), qb.Time);
foreach (var coins in universeHistory)
{
    foreach (CoinGecko coin in coins)
    {
        Console.WriteLine($"{coin.Symbol.Value} market cap at {coin.EndTime}: {coin.MarketCap}");
    }
}
```

Data Point Attributes

The Crypto Market Cap dataset provides `CoinGecko` and `CoinGeckoUniverse` objects.

CoinGecko Attributes

`CoinGecko` objects have the following attributes:

CoinGeckoUniverse Attributes

`CoinGeckoUniverse` objects have the following attributes:

Datasets

EOD Historical Data

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Economic Events

Macroeconomics Indicators

Upcoming Dividends

Upcoming Earnings

Upcoming IPOs

Upcoming Splits

EOD Historical Data

Economic Events

Introduction

The Economic Events dataset, provided by EODHD, offers daily alerts for major economic events or announcements of global markets within the upcoming 7 days, with estimation and previous record if available. The data starts in January 2019, and is delivered on a daily frequency.

For more information about the Economic Events dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Getting Started

The following snippet demonstrates how to request data from the Economic Events dataset:

```C#
AddData<EODHDEconomicEvents>(Country.UnitedStates);
AddData<EODHDEconomicEvents>(EODHD.Events.UnitedStates.Cpi);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2019
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Economic Events data to your algorithm, call the `AddData<EODHDUpcomingIPOs>` method.

```
C#
public class EconomicEventsDataAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        var ticker = EODHD.Events.UnitedStates.Cpi;
        // var ticker = Country.UnitedStates;
        _datasetSymbol = AddData<EODHDEconomicEvents>(ticker).Symbol;
    }
}
```

Accessing Data

To get the current Economic Events data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.Get<EODHDEconomicEvents>().TryGetValue(_datasetSymbol, out var economicEvents))
    {
        foreach (EODHDEconomicEvent economicEvent in economicEvents)
        {
           Log($"{economicEvent.EventType} of {economicEvent.Country} over {economicEvent.EventPeriod} with be held
at {economicEvent.EventTime} with estimated value {economicEvent.Estimate}");
        }
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var (symbol, economicEvents) in slice.Get<EODHDEconomicEvents>())
    {
        foreach (EODHDEconomicEvent economicEvent in economicEvents)
        {
           Log($"{economicEvent.EventType} of {economicEvent.Country} over {economicEvent.EventPeriod} with be held
at {economicEvent.EventTime} with estimated value {economicEvent.Estimate}");
        }
    }
}
```

Historical Data

To get historical Economic Events data, call the `History` method with the type `EODHDEconomicEvents` cast and the underlying `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<EODHDEconomicEvents>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Economic Events dataset provides timely notifications about upcoming economic events, allowing traders to trade on that volatility. Examples include the following strategies:

- Long straddle to trade the volatility of the economic events.
- Trade market representative ETFs based on estimated figures for the upcoming events.
- Statistical arbitrage on two or more correlated global markets based on economic events of different locations.

Classic Algorithm Example

The following example algorithm trade Industrial sector ETF based on US PMI estimated change direction. If the estimated PMI of the upcoming announcement is above the previous PMI, buy the Industrial ETF, and sell it otherwise.

```
public class EODHDEconomicEventsAlgorithm : QCAlgorithm
{
    private Symbol _equitySymbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Use industrial sector ETF as a vehicle to trade.
        _equitySymbol = AddEquity("XLI").Symbol;
        // Request US PMI economic event data to generate trade signals.
        var ticker = EODHD.Events.UnitedStates.MarkitManufacturingPurchasingManagersIndex;
        _datasetSymbol = AddData<EODHDEconomicEvents>(ticker).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Trade based on the updated economic events.
        if (slice.Get<EODHDEconomicEvents>().TryGetValue(_datasetSymbol, out var economicEvents))
        {
            var economicEvent = economicEvents.FirstOrDefault() as EODHDEconomicEvent;
            // Use the Manufacturing Index to generate trade signals on manufacturing industry vehicles.
            // Make sure previous and estimate are available to estimate the direction of the industry.
            if (economicEvent.Previous.HasValue && economicEvent.Estimate.HasValue)
            {
                //If the estimated PMI is higher than the previous PMI, the manufacturing ETF price is expected to
rise.
                if (economicEvent.Previous.Value > economicEvent.Estimate.Value)
                {
                    SetHoldings(_equitySymbol, 1);
                }
                // Otherwise, it is expected manufacturing ETF price will drop.
                else
                {
                    SetHoldings(_equitySymbol, -1);
                }
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm trade Industrial sector ETF based on US PMI estimated change direction using algorithm framework. If the estimated PMI of the upcoming announcement is above the previous PMI, buy the Industrial ETF, sell it otherwise.

```C#
public class EODHDEconomicEventsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Use industrial sector ETF as a vehicle to trade.
        var symbol = QuantConnect.Symbol.Create("XLI", SecurityType.Equity, Market.USA);
        AddUniverseSelection(new ManualUniverseSelectionModel(new[] {symbol}));
        // Custom alpha model to emit insights according to economic events.
        AddAlpha(new EconomicEventAlphaModel(this));
        // Equal weighting position sizing to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Expiry.EndOfMonth));
    }
}

public class EconomicEventAlphaModel : AlphaModel
{
    private Symbol _symbol, _datasetSymbol;

    public EconomicEventAlphaModel(QCAlgorithm algorithm)
    {
        // Request US PMI economic event data to generate trade signals.
        var ticker = EODHD.Events.UnitedStates.MarkitManufacturingPurchasingManagersIndex;
        _datasetSymbol = algorithm.AddData<EODHDEconomicEvents>(ticker).Symbol;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Trade based on the updated economic events.
        if (slice.Get<EODHDEconomicEvents>().TryGetValue(_datasetSymbol, out var economicEvents))
        {
            // Use the US Manufacturing Index to generate trade signals on manufacturing industry vehicles.
            // Make sure previous and estimate are available to estimate the direction of the industry.
            var economicEvent = economicEvents.FirstOrDefault() as EODHDEconomicEvent;
            if (economicEvent.Previous.HasValue && economicEvent.Estimate.HasValue)
            {
                // If the estimated PMI is higher than the previous PMI, the manufacturing ETF price is expected to
rise.
                // Otherwise, it is expected manufacturing ETF prices will drop.
                var direction = economicEvent.Previous.Value > economicEvent.Estimate.Value
                    ? InsightDirection.Up
                    : InsightDirection.Down;
                yield return Insight.Price(_symbol, TimeSpan.FromDays(5), direction);
            }
        }
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var added in changes.AddedSecurities)
        {
            _symbol = added.Symbol;
        }
    }
}
```

Data Point Attributes

The EODHD Economic Events dataset provides `EODHDEconomicEvent` objects, which have the following attributes:

The `EODHDEconomicEvents` objects represent a collection of `EODHDEconomicEvent` object

Country Enumeration

To filter the countries of the economic events, you can make use of the `Country` enumeration. The `Country` enumeration has the following members:

Events Enumeration

To filter the event types of the economic events, you can make use of the `Events` enumeration. The `Events` enumeration has the

following members:

EOD Historical Data

Macroeconomics Indicators

Introduction

The Macroeconomic Indicators dataset, provided by EODHD, provides data on 39 major macroeconomic indicators of 249 countries and regions. The data starts in January 1998, and is delivered on indicators update.

For more information about the Macroeconomics Indicators dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Getting Started

The following snippet demonstrates how to request data from the Macroeconomic Indicators dataset:

```C#
AddData<EODHDMacroIndicators>(Country.UnitedStates);
AddData<EODHDMacroIndicators>(EODHD.MacroIndicators.UnitedStates.GdpCurrentUsd);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Macroeconomic Indicators data to your algorithm, call the `AddData<EODHDMacroIndicators>` method.

```C#
public class EODHDMacroIndicatorsAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _datasetSymbol = AddData<EODHDMacroIndicators>(
            EODHD.MacroIndicators.UnitedStates.GdpCurrentUsd
        ).Symbol;
        // _datasetSymbol = AddData<EODHDMacroIndicators>(Country.UnitedStates).Symbol;
    }
}
```

Accessing Data

To get the current Macroeconomic Indicators data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{dataPoint.Frequency} {dataPoint.Indicator} of {dataPoint.Country} at {dataPoint.Time} with value
{dataPoint.Value}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<EODHDMacroIndicators>())
    {
        var eventDataPoint = kvp.Value;
        Log($"{dataPoint.Frequency} {dataPoint.Indicator} of {dataPoint.Country} at {dataPoint.Time} with value
{dataPoint.Value}");
    }
}
```

Historical Data

To get historical Macroeconomic Indicators data, call the `History` method with the type `EODHDMacroIndicators` cast and the underlying `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
var history = History<EODHDMacroIndicators>(_datasetSymbol, 100);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Macroeconomic Indicators dataset provides data on global macro indicators, allowing traders to react to market sentiment. Examples include the following strategies:

- Long straddle to trade the market shock brought by the macro indicators.
- Hold long or short position of the market representative ETF based on the expected market direction.
- Statistical arbitrage on 2 or more correlated global markets based on market strength indicated by macro indicators.

Classic Algorithm Example

The following example algorithm holds long position of SPY if the US GDP is in positive growth, while holds short position if it is the opposite case.

```
public class EODHDMacroIndicatorsAlgorithm : QCAlgorithm
{
    private Symbol _equitySymbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _equitySymbol = AddEquity("SPY", Resolution.Daily).Symbol;
        var ticker = EODHD.MacroIndicators.UnitedStates.GdpGrowthAnnual;
        _datasetSymbol = AddData<EODHDMacroIndicators>(ticker).Symbol;
    }

    public override void OnData(Slice slice)
    {
        if (slice.Get<EODHDMacroIndicators>().TryGetValue(_datasetSymbol, out var indicators))
        {
            var gdp = indicators.FirstOrDefault() as EODHDMacroIndicator;
            SetHoldings(_equitySymbol, gdp.Value > 0m ? 1 : -1);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm holds the long position of SPY if the US GDP is in positive growth while holding a short position if it is the opposite case. It is implemented in the framework algorithm.

```C#
public class EODHDMacroIndicatorsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Use market ETF as a vehicle to trade.
        var symbol = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        AddUniverseSelection(new ManualUniverseSelectionModel(symbol));
        // Custom alpha model to emit insights according to macroeconomic indicators.
        AddAlpha(new MacroIndicatorAlphaModel(this));
        // Equal weighting position sizing to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Expiry.EndOfMonth));
    }
}

public class MacroIndicatorAlphaModel : AlphaModel
{
    private Symbol _symbol, _datasetSymbol;

    public MacroIndicatorAlphaModel(QCAlgorithm algorithm)
    {
        // Request US GDP growth indicator data to generate trade signals.
        var ticker = EODHD.MacroIndicators.UnitedStates.GdpGrowthAnnual;
        _datasetSymbol = algorithm.AddData<EODHDMacroIndicators>(ticker).Symbol;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Trade based on the updated macroeconomic indicator.
        if (slice.Get<EODHDMacroIndicators>().TryGetValue(_datasetSymbol, out var indicators))
        {
            var gdp = indicators.FirstOrDefault() as EODHDMacroIndicator;
            // If the GDP growth is positive, the market ETF is expected to rise.
            // Otherwise, it is expected the market ETF will drop.
            var direction = gdp.Value > 0m ? InsightDirection.Up : InsightDirection.Down;
            yield return Insight.Price(_symbol, TimeSpan.FromDays(5), direction);
        }
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var added in changes.AddedSecurities)
        {
            _symbol = added.Symbol;
        }
    }
}
```

Data Point Attributes

The EODHD Macro Indicators dataset provides `EODHDMacroIndicators` objects, which have the following attributes:

MacroIndicators Enumeration

To filter the specific indicator, you can make use of the `MacroIndicators` enumeration. The `MacroIndicators` enumeration has the following members:

Country Enumeration

To filter the country of the macro indicators, you can make use of the `Country` enumeration. The `Country` enumeration has the following members:

Frequency Enumeration

To filter the indicator frequency of the macro indicators, you can make use of the `Frequency` enumeration. The `Frequency` enumeration has the following members:

EOD Historical Data

Upcoming Dividends

Introduction

The Upcoming Dividends dataset, provided by EODHD, offers daily alerts for US Equities that will have a dividend event within the upcoming 7 days. The data starts in January 2015 and is delivered on a daily frequency.

Compared to US Equity Security Master as a benchmark, the Upcoming Dividends dataset has a 98.56% coverage of all dividend events, while having a 99.71% precision on the exact dividend dates of the covered ones and a 99.90% precision within +/- 3 days.

For more information about the Upcoming Dividends dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EOD Historical Data (EODHD) is a financial data provider based in France, and founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomic indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly. For more information about EODHD, visit https://eodhd.com/ .

Getting Started

The following snippet demonstrates how to request data from the Upcoming Dividends dataset:

```C#
using QuantConnect.DataSource;
AddUniverse<EODHDUpcomingDividends>(SelectionFunction);
AddData<EODHDUpcomingDividends>("dividends");
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2015
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming Dividends dataset, call the `AddUniverse` method with a `EODHDUpcomingDividends` cast.

```
C#
public override void Initialize()
{
    _universe = AddUniverse<EODHDUpcomingDividends>(UniverseSelectionFilter);
}

private IEnumerable<Symol> UniverseSelectionFilter(IEnumerable<BaseData> dividends)
{
    return from EODHDUpcomingDividends d in dividends
           where d.DividendsDate <= Time.AddDays(1) && d.Dividends > 0.05m
           select d.Symbol;
}
```

For more information about universe settings, see Settings .

Requesting Data

To add Upcoming Dividends data to your algorithm, call the `AddData<EODHDUpcomingDividends>` method.

```
C#
public class UpcomingDividendsDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<EODHDUpcomingDividends>("dividends").Symbol;
    }
}
```

Accessing Data

To get the current Upcoming Dividends data, call the `Get<EODHDUpcomingDividends>` method from the current `Slice` and index the result with the security `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    var upcomingDividends = slice.Get<EODHDUpcomingDividends>();
    if (upcomingDividends.TryGetValue(_symbol, out var upcomingDividendsDataPoint))
    {
        Log($"{_symbol} will pay dividend at {upcomingDividendsDataPoint.DividendDate} with dividend per share of
${upcomingDividendsDataPoint.Dividend}");
    }
}
```

You can also iterate through all of the dataset objects in the current `Slice`

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<EODHDUpcomingDividends>())
    {
        var equitySymbol = kvp.Key;
        var upcomingDividendsDataPoint = kvp.Value;
        Log($"{equitySymbol} will pay dividend at {upcomingDividendsDataPoint.DividendDate} with dividend per share
of ${upcomingDividendsDataPoint.Dividend}");
    }
}
```

Historical Data

To get historical Upcoming Dividends data, call the `History` method with the type `EODHDUpcomingDividends` cast and the period of request. If there is no data in the period you request, the history result is empty.

```C#
var history = History<EODHDUpcomingDividends>(TimeSpan.FromDays(100), Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Upcoming Dividends dataset allows traders to trade the price change due to dividends. Examples include the following strategies:

- Short the stocks on dividend report day to earn the dividend discount on pricing.
- Avoid volatility on securities with upcoming dividends

Classic Algorithm Example

The following example algorithm shorts each equity in equal size with an upcoming dividend by the next day. It selects stocks with dividend recording over $0.5 per share to capitalize on the price shock momentum due to dividend payment.

```C#
public class UpcomingDividendsExampleAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Universe consists of equities with upcoming dividend events.
        _universe = AddUniverse<EODHDUpcomingDividends>((dividends) => {
            // Select the stocks with upcoming dividend record date, with a sufficient dividend size.
            return from EODHDUpcomingDividends d in dividends
                    where d.DividendDate < Time.AddDays(1) && d.Dividend > 0.5m
                    select d.Symbol;
        });
       // Add a Scheduled Event to rebalance the portfolio every morning
        // based on upcoming dividend signals.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(DateRules.EveryDay(spy), TimeRules.AfterMarketOpen(spy, 1), Rebalance);
    }

    public void Rebalance()
    {
        // Equally invest in each member of the universe to evenly dissipate the capital risk.
        var symbols = _universe.Selected.Where(s => Securities[s].Price != 0);
        var totalCount = symbols.Count();
        var targets = symbols
            .Select(symbol => new PortfolioTarget(symbol, -1m / totalCount))
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}
```

Framework Algorithm Example

The following example implements a strategy of shorting each equity in equal size with an upcoming dividend by the next day using the framework. It selects stocks with dividend recording over $0.5 per share to capitalize on the price shock momentum due to dividend payment.

```C#
public class UpcomingDividendsExampleAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Trade on a daily basis based on upcoming dividend signals daily.
        UniverseSettings.Resolution = Resolution.Daily;
        // Universe consists of equities with upcoming dividend events.
        _universe = AddUniverse<EODHDUpcomingDividends>((dividends) => {
            // Select the stocks with upcoming dividend record dates with a sufficient dividend size.
            return from EODHDUpcomingDividends d in dividends
                    where d.DividendDate < Time.AddDays(1) && d.Dividend > 0.5m
                    select d.Symbol;
        });

        // A constant alpha model will emit insights for the stocks with dividend events in the upcoming day.
        // It is expecting a price shock due to pricing after the dividend, which might affect some momentum traders.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Down, TimeSpan.FromDays(1)));

        // Equal weighting for each signal to dissipate the capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Expiry.EndOfDay));
    }
}
```

Data Point Attributes

The EODHD Upcoming Dividends dataset provides `EODHDUpcomingDividends` objects, which have the following attributes:

EOD Historical Data

Upcoming Earnings

Introduction

The Upcoming Earnings dataset, provided by EOD Historical Data (EODHD), is a daily universe of US Equities with an earnings report publication in the upcoming 7 days. The data starts in January 1998 and is delivered on a daily frequency.

Compared to Nasdaq's Earning Reports as a benchmark, the Upcoming Earnings dataset has captured 96.79% of the scheduled earnings report, with a 97.25% exact-date precision of the captured events, while having a 99.28% precision within +/- 3 days. Note that the Upcoming Earnings dataset also contains unscheduled special earning reports.

For more information about the Upcoming Earnings dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EOD Historical Data (EODHD) is a financial data provider based in France, and founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomic indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly. For more information about EODHD, visit https://eodhd.com/ .

Getting Started

The following snippet demonstrates how to request data from the Upcoming Earnings dataset:

```C#
AddUniverse<EODHDUpcomingEarnings>(SelectionFunction);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming Earnings dataset, call the `AddUniverse` method with a `EODHDUpcomingEarnings` cast.

```
C#
public override void Initialize()
{
    _universe = AddUniverse<EODHDUpcomingEarnings>(UniverseSelectionFilter);
}

private IEnumerable<Symbol> UniverseSelectionFilter(IEnumerable<EODHDUpcomingEarnings> earnings)
{
    return from d in earnings
           where d.ReportDate <= Time.AddDays(3) && d.Estimate > 0m
           select d.Symbol;
}
```

For more information about universe settings, see Settings .

Requesting Data

This dataset is designed for universe selection. However, you can add Upcoming Earnings data to your algorithm using the `AddData<EODHDUpcomingEarnings>` method.

```
C#
public class UpcomingEarningsDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<EODHDUpcomingEarnings>("earnings").Symbol;
    }
}
```

Accessing Data

To get the current Upcoming Earnings data, call the `Get<EODHDUpcomingEarnings>` method from the current `Slice` and index the result with the security `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    var upcomingEarnings = slice.Get<EODHDUpcomingEarnings>();
    if (upcomingEarnings.TryGetValue(_symbol, out var upcomingEarningsDataPoint))
    {
        Log($"{_symbol} will report earnings at {upcomingEarningsDataPoint.ReportDate}
{upcomingEarningsDataPoint.ReportTime} with estimated EPS {upcomingEarningsDataPoint.Estimate}");
    }
}
```

You can also iterate through all of the dataset objects in the current `Slice`

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<EODHDUpcomingEarnings>())
    {
        var equitySymbol = kvp.Key;
        var upcomingEarningsDataPoint = kvp.Value;
        Log($"{equitySymbol} will report earnings at {upcomingEarningsDataPoint.ReportDate}
{upcomingEarningsDataPoint.ReportTime} with estimated EPS {upcomingEarningsDataPoint.Estimate}");
    }
}
```

Historical Data

To get historical Upcoming Earnings for the universe, call the `History` method with the type `EODHDUpcomingEarning` .

```C#
var history = History<EODHDUpcomingEarnings>(TimeSpan.FromDays(100), Resolution.Daily);
```

To get historical Upcoming Earnings data for a known security, call the `History` method with the type `EODHDUpcomingEarning` cast and the security `Symbol` .

```C#
var history = History<EODHDUpcomingEarnings>(TimeSpan.FromDays(100), Resolution.Daily)
    .Select(x => x[_symbol])
    .ToList();
```

If there is no data in the period you request, the history result is empty. For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Upcoming Earnings dataset provides timely notifications about earnings announcements, allowing traders to make capitalize on potential price movements and manage risks effectively. Examples include the following strategies:

- Short Straddle to trade on heightened volatility during earnings report.
- Filter universe for the stocks with or without upcoming earnings report to trade or avoid volatility.
- Hold the stocks with upcoming earnings estimated to be positive.

Classic Algorithm Example

The following example algorithm long a straddle on the stocks with upcoming earnings report within 5 days to trade the volatility. It allows 5 days to build up the volatility and capitalize the positions 1 day after the earnings announcement.

```C#
public class UpcomingEarningsExampleAlgorithm : QCAlgorithm
{
    // A dictionary to save the underlying-call,put pair for position open/close management.
    private Dictionary<Symbol, (Symbol Call, Symbol Put)> _optionsBySymbol = [];

    public override void Initialize()
    {
```

```
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Seed the last price as price since we need to use the underlying price for option contract filtering when
it join the universe.
        Settings.SeedInitialPrices = true;

        // Trade on daily basis based on daily upcoming earnings signals.
        UniverseSettings.Resolution = Resolution.Daily;
        // Option trading requires raw price for strike price comparison.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        // Universe consists of equities with upcoming earnings events.
        AddUniverse<EODHDUpcomingEarnings>((earnings) => {
            foreach(var i in Enumerable.Range(1,5).Reverse())
            {
                var targetDate = Time.AddDays(i);
                var symbols = earnings
                    // We do not want to lock our fund too early, so filter for stocks is in lower volatility but
will go up.
                    // Assuming 5 days before the earnings report publish is less volatile.
                    // We do not want depository due to their low liquidity.
                    .Where(datum => (datum as EODHDUpcomingEarnings).ReportDate == targetDate)
                    .ToHashSet(datum => datum.Symbol);
                if (symbols.IsNullOrEmpty()) continue;
                Plot("Universe", "Count", symbols.Count);
                return symbols;
            }
            return [];
        });
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Actions only based on the equity universe changes.
        foreach (var removed in changes.RemovedSecurities.Where(x=> x.Type == SecurityType.Equity))
        {
            // Liquidate any assigned position.
            Liquidate(removed.Symbol);
            // Liquidate the option positions and capitalize the volatility 1-day after the earnings announcement.
            if (_optionsBySymbol.Remove(removed.Symbol, out var options))
            {
                RemoveOptionContract(options.Call);
                RemoveOptionContract(options.Put);
            }
        }

        // Actions only based on the equity universe changes.
        foreach (var added in changes.AddedSecurities.Where(x=> x.Type == SecurityType.Equity))
        {
            // Select the option contracts to construct a straddle to trade the volatility.
            var (call, put) = SelectOptionContracts(added.Symbol);
            if (call == null || put == null)
            {
                continue;
            }
                _optionsBySymbol[added.Symbol] = (call, put);
            // Request the option contract data for trading.
            call = AddOptionContract(call).Symbol;
            put = AddOptionContract(put).Symbol;
            // Long a straddle by shorting the selected ATM call and put.
            ComboMarketOrder(
                new List<Leg> {
                    Leg.Create(call, 1),
                    Leg.Create(put, 1)
                },
                1
            );
        }
    }

    private (Symbol, Symbol) SelectOptionContracts(Symbol underlying)
    {
        // Get all tradable option contracts for filtering.
        var optionContractList = OptionChain(underlying);

        // Expiry at least 30 days later to have a smaller theta to reduce time decay loss.
        // Yet also be ensure liquidity over the volatility fluctuation hence we take the closet expiry after that.
        var longExpiries = optionContractList.Where(x => x.ID.Date >= Time.AddDays(30)).ToList();
        if (longExpiries.Count < 2)
        {
```

```
            return (null, null);
        }
        var expiry = longExpiries.Min(x => x.ID.Date);
        var filteredContracts = optionContractList.Where(x => x.ID.Date == expiry).ToList();

        // Select ATM call and put to form a straddle for trading the volatility.
        var strike = filteredContracts.MinBy(x => Math.Abs(x.ID.StrikePrice - Securities[underlying].Price))
            .ID.StrikePrice;
        var atmContracts = filteredContracts.Where(x => x.ID.StrikePrice == strike).ToList();
        if (atmContracts.Count < 2)
        {
            return (null, null);
        }

        var atmCall = atmContracts.Single(x => x.ID.OptionRight == OptionRight.Call);
        var atmPut = atmContracts.Single(x => x.ID.OptionRight == OptionRight.Put);
        return (atmCall, atmPut);
    }
}
```

Framework Algorithm Example

The following example algorithm long a straddle on the stocks with upcoming earnings report within 5 days to trade the volatility implemented in framework algorithm. It allows 5 days to build up the volatility and capitalize the positions 1 day after the earnings announcement.

C#

```
public class UpcomingEarningsExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Seed the last price as price since we need to use the underlying price for option contract filtering when
it join the universe.
        Settings.SeedInitialPrices = true;

        // Trade on daily basis based on daily upcoming earnings signals.
        UniverseSettings.Resolution = Resolution.Daily;
        // Option trading requires raw price for strike price comparison.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        // Universe consists of equities with upcoming earnings events.
        AddUniverse<EODHDUpcomingEarnings>((earnings) => {
            foreach(var i in Enumerable.Range(1,5).Reverse())
            {
                var targetDate = Time.AddDays(i);
                var symbols = earnings
                    // We do not want to lock our fund too early, so filter for stocks is in lower volatility but
will go up.
                    // Assuming 5 days before the earnings report publish is less volatile.
                    // We do not want depository due to their low liquidity.
                    .Where(datum => (datum as EODHDUpcomingEarnings).ReportDate == targetDate)
                    .ToHashSet(datum => datum.Symbol);
                if (symbols.IsNullOrEmpty()) continue;
                Plot("Universe", "Count", symbols.Count);
                return symbols;
            }
            return [];
        });

        // A custom alpha model that emit signal based on upcoming earnings events.
        AddAlpha(new UpcomingEarningsAlphaModel());

        // To trade 1 contract per signal to ensure equal size per leg of the short straddle.
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }
}

                continue;
            }
            // Request the option contract data for trading.
            call = algorithm.AddOptionContract(call).Symbol;
            put = algorithm.AddOptionContract(put).Symbol;
            _optionsBySymbol[added.Symbol] = (call, put);
        }
    }

    private (Symbol, Symbol) SelectOptionContracts(QCAlgorithm algorithm, Symbol underlying, DateTime time)
    {
        // Get all tradable option contracts for filtering.
        var optionContractList = algorithm.OptionChain(underlying);

        // Expiry at least 30 days later to have a smaller theta to reduce time decay loss.
        // Yet also be ensure liquidity over the volatility fluctuation hence we take the closet expiry after that.
        var longExpiries = optionContractList.Where(x => x.ID.Date >= time.AddDays(30)).ToList();
        if (longExpiries.Count < 2)
        {
            return (null, null);
        }
        var expiry = longExpiries.Min(x => x.ID.Date);
        var filteredContracts = optionContractList.Where(x => x.ID.Date == expiry).ToList();

        // Select ATM call and put to form a straddle for trading the volatility.
        var strike = filteredContracts.MinBy(x => Math.Abs(x.ID.StrikePrice -
algorithm.Securities[underlying].Price))
            .ID.StrikePrice;
        var atmContracts = filteredContracts.Where(x => x.ID.StrikePrice == strike).ToList();
        if (atmContracts.Count < 2)
        {
            return (null, null);
        }

        var atmCall = atmContracts.Single(x => x.ID.OptionRight == OptionRight.Call);
        var atmPut = atmContracts.Single(x => x.ID.OptionRight == OptionRight.Put);
        return (atmCall, atmPut);
    }
}

public class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
```

```
{
    public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
    {
        if (insights.Length == 0)
        {
            return [];
        }
        // Only a single contract to ensure both legs size is equal.
        var quantity = insights.Min(i => Math.Abs(algorithm.CalculateOrderQuantity(i.Symbol, (decimal)i.Direction)))
/ 100;

        return insights.Select(i => new PortfolioTarget(i.Symbol, quantity * (int)i.Direction));
    }
}
```

Data Point Attributes

The EODHD Upcoming Earnings dataset provides `EODHDUpcomingEarnings` objects, which have the following attributes:

To filter the EODHD Upcoming Earnings data with their reporting timing, use the `EODHD.ReportTime` enum, which have the following attributes:

EOD Historical Data

Upcoming IPOs

Introduction

The Upcoming IPOs dataset, provided by EODHD, offers daily alerts for US Equities that will start their IPOs or have any updates on their IPO registrations within the upcoming 7 days. The data started in February 2013 and is delivered on a daily basis.

`Notice that this dataset might have a +/-2 days accuracy due to the data provider.`

For more information about the Upcoming IPOs dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EODHD was a France financial data provider founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomy indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly.

Getting Started

The following snippet demonstrates how to request data from the Upcoming IPOs dataset:

```C#
AddData<EODHDUpcomingIPOs>("ipos");
AddUniverse<EODHDUpcomingIPOs>(SelectionFunction);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	February 2013
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming IPOs dataset, call the `AddUniverse` method with a `EODHDUpcomingIPOs` cast.

```C#
private static readonly List<DealType> _dealTypesWanted = new { DealType.Expected, DealType.Priced };

public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    _universe = AddUniverse<EODHDUpcomingIPOs>(UniverseSelectionFilter);
}

private IEnumerable<Symol> UniverseSelectionFilter(IEnumerable<EODHDUpcomingIPOs> ipos)
{
    // confirmed non-penny stock IPO that launches within 7 days.
    return from d in ipos
           where _dealTypesWanted.Contains(d.DealType) &&
               d.IpoDate.HasValue &&
               new[] { d.LowestPrice, d.HighestPrice, d.OfferPrice }.Where(x => x.HasValue).Min().Value > 1
           select d.Symbol;
}
```

For more information about universe settings, see Settings .

Requesting Data

To add Upcoming IPOs data to your algorithm, call the `AddData<EODHDUpcomingIPOs>` method.

```C#
public class UpcomingIPOsDataAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _datasetSymbol = AddData<EODHDUpcomingIPOs>("ipos").Symbol;
    }
}
```

Accessing Data

To get the current Upcoming IPOs data, call the `Get<EODHDUpcomingIPOs>` method from the current `Slice` . Then, iterate through all of the dataset objects in the current `Slice`

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<EODHDUpcomingIPOs>())
    {
        var equitySymbol = kvp.Key;
        var upcomingIPOsDataPoint = kvp.Value;
        Log($"{equitySymbol} will start IPO at {upcomingIPOsDataPoint.IPODate} with price
{upcomingIPOsDataPoint.OfferPrice} and {upcomingIPOsDataPoint.Shares} shares");
    }
}
```

Historical Data

To get historical Upcoming IPOs data, call the `History` method with the type `EODHDUpcomingIPOs` cast and the period of request. If there is no data in the period you request, the history result is empty.

```C#
var history = History<EODHDUpcomingSplits>(TimeSpan.FromDays(100), Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Upcoming IPOs dataset provides timely notifications about upcoming IPOs start, allowing traders to capitalize on the high volatility of new stocks. Examples include the following strategies:

- Long straddle to trade the volatility of the new IPO stock.
- Arbitration on fair price versus IPO price.
- Use SMA of IPO number to estimate the IPO trend and market popularity.

Classic Algorithm Example

Example 1: New Stock

The following example algorithm holds new stocks for its IPO day to capitalize its hype.

```
C#
public class UpcomingIPOsExampleAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Filter for new stocks to trade their hype using EODHDUpcomingIPOs.
        _universe = AddUniverse<EODHDUpcomingIPOs>(ipos =>
            ipos.Select(x => x as EODHDUpcomingIPOs)
                .Where(x => x.IpoDate <= Time.AddDays(1) && x.Exchange == Exchange.NASDAQ)
                .Select(x => x.Symbol)
        );
    }

    public override void OnData(Slice slice)
    {
        // Invest in new stocks and trade on their first day for their hype.
        // Equally invest in each new stocks to evenly dissipate the capital risk.
        foreach (var symbol in _universe.Selected)
        {
            var security = Securities[symbol];
            if (!security.Holdings.Invested && security.Price != 0)
            {
                SetHoldings(symbol, 0.1m/_universe.Selected.Count);
            }
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Liquidate the new stocks traded today/yesterday to capitalize the first-day hype.
        foreach (var removed in changes.RemovedSecurities)
        {
            Liquidate(removed.Symbol);
        }
    }
}
```

Example 2: Market Popularity

The following example algorithm buy QQQ if the number of IPO in Nasdaq is in increasing trend, sell otherwise.

```C#
public class IndexOptionHandlingDataAlgorithm : QCAlgorithm
{
    // Create a EMA indicator to estimate the trend of IPO number to reflect the market popularity.
    private ExponentialMovingAverage _ema = new(50);
    private Symbol _qqq;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        UniverseSettings.Resolution = Resolution.Daily;
        // Filter for new stocks to trade their hype using EODHDUpcomingIPOs.
        AddUniverse<EODHDUpcomingIPOs>(Selection);
        // Request QQQ data to trade.
        _qqq = AddEquity("QQQ", Resolution.Daily).Symbol;

        SetWarmUp(50, Resolution.Daily);
    }

    private IEnumerable<Symbol> Selection(IEnumerable<BaseData> ipos)
    {
        // Filter for the stocks that IPO starts today and traded in Nasdaq.
        var universeCount = ipos.Select(x => x as EODHDUpcomingIPOs)
            .Where(x => x.IpoDate.HasValue && x.IpoDate.Value <= Time.AddDays(1) && x.Exchange == Exchange.NASDAQ)
            .Count();
        _ema.Update(Time, Convert.ToDecimal(universeCount));
        return Universe.Unchanged;
    }

    public override void OnData(Slice slice)
    {
        if (!IsWarmingUp && _ema.IsReady)
        {
            // If the EMA is decreasing, we estimate the market popularity is decreasing, so we sell QQQ.
            if (_ema.Previous > _ema)
            {
                SetHoldings(_qqq, -1m);
            }
            // Otherwise, we estimate the market popularity is increasing, so we buy QQQ.
            else
            {
                SetHoldings(_qqq, 1m);
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm holds new stocks for its IPO day to capitalize its hype using framework algorithm.

```C#
public class UpcomingIPOsExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Filter for new stocks to trade their hype using EODHDUpcomingIPOs.
        AddUniverse<EODHDUpcomingIPOs>(ipos =>
            ipos.Select(x => x as EODHDUpcomingIPOs)
                .Where(x => x.IpoDate <= Time.AddDays(1) && x.Exchange == Exchange.NASDAQ)
                .Select(x => x.Symbol)
        );

        // Invest in new stocks and trade on their first day for their hype.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1), null, null,
0.01d));

        // Equally invest in each new stocks to evenly dissipate the capital risk.
        SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel(Expiry.EndOfDay));
    }
}
```

Data Point Attributes

The EODHD Upcoming IPOs dataset provides `EODHDUpcomingIPOs` objects, which have the following attributes:

EOD Historical Data

Upcoming Splits

Introduction

The Upcoming Splits dataset, provided by EODHD, offers daily alerts for US Equities that will have a split event within the upcoming 7 days. The data starts in January 2010, and is delivered on a daily frequency.

Compared to US Equity Security Master as a benchmark, the Upcoming Splits dataset has an 85.18% coverage of all splits since 2015, while having a 92.74% precision on the exact split dates of the covered ones and a 97.18% precision within +/- 3 days.

For more information about the Upcoming Splits dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

EOD Historical Data (EODHD) is a financial data provider based in France, and founded in April 2015. They focus on providing clean financial data, including stock prices, splits, dividends, fundamentals, macroeconomic indicators, technical indicators, and alternative data sources, through 24/7 API seamlessly. For more information about EODHD, visit https://eodhd.com/ .

Getting Started

The following snippet demonstrates how to request data from the Upcoming Splits dataset:

```C#
AddUniverse<EODHDUpcomingSplits>(SelectionFunction);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2010
Data Density	Sparse
Resolution	Daily
Timezone	New York

Universe Selection

To select a dynamic universe of US Equities based on the Upcoming Splits dataset, call the `AddUniverse` method with a `EODHDUpcomingSplits` cast.

```
C#
public override void Initialize()
{
    _universe = AddUniverse<EODHDUpcomingSplits>(UniverseSelectionFilter);
}

private IEnumerable<Symol> UniverseSelectionFilter(IEnumerable<EODHDUpcomingSplits> splits)
{
    return from d in splits
           where d.SplitDate <= Time.AddDays(3) && d.SplitFactor > 1m
           select d.Symbol;
}
```

For more information about universe settings, see Settings .

Requesting Data

To add Upcoming Splits data to your algorithm, call the `AddData<EODHDUpcomingSplits>` method.

```
C#
public class UpcomingSplitsDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<EODHDUpcomingSplits>("splits").Symbol;
    }
}
```

Accessing Data

To get the current Upcoming Splits data, call the `Get<EODHDUpcomingSplits>` method from the current `Slice` and index the result with the security `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your security at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    var upcomingSplits = slice.Get<EODHDUpcomingSplits>();
    if (upcomingSplits.TryGetValue(_symbol, out var upcomingSplitsDataPoint))
    {
        Log($"{_symbol} will split at {upcomingSplitsDataPoint.SplitDate} with split factor
{upcomingSplitsDataPoint.SplitFactor}");
    }
}
```

You can also iterate through all of the dataset objects in the current `Slice`

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<EODHDUpcomingSplits>())
    {
        var equitySymbol = kvp.Key;
        var upcomingSplitsDataPoint = kvp.Value;
        Log($"{equitySymbol} will splits at {upcomingSplitsDataPoint.SplitDdate} with split factor
{upcomingSplitsDataPoint.SplitFactor}");
    }
}
```

Historical Data

To get historical Upcoming Splits data, call the `History` method with the type `EODHDUpcomingSplits` cast and the period of request. If there is no data in the period you request, the history result is empty.

```C#
var history = History<EODHDUpcomingSplits>(TimeSpan.FromDays(100), Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The Upcoming Splits dataset provides timely notifications about upcoming share split or reverse split events, allowing traders to capitalize on potential price movements and manage risks effectively. Examples include the following strategies:

- Splits into shares with lower price will provide higher liquidity for market making algorithms.
- Select a universe of stocks with upcoming splits event and trade their volatility using options.
- Buy stocks with split factor higher than 1, sell vice versa for self-defeating ones.

Classic Algorithm Example

The following example algorithm holds each equity in equal size with upcoming splits within 7 days. It selects stocks that split up to more shares with lower price and tries to capitalize the higher demand of the more afforable stocks.

C#

```
public class UpcomingSplitsExampleAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Universe consists of equities with upcoming earnings events.
        _universe = AddUniverse<EODHDUpcomingSplits>((splits) => {
            return splits
                // Split (more shares with lower price) will make the stock more affordable and drive up the demand.
                // Hence, include all stocks that will have a split within the next 7 days.
                // Note that spliting up the stock means the split factor > 1.
                .Where(datum => (datum as EODHDUpcomingSplits).SplitFactor > 1)
                .Select(datum => datum.Symbol);
        });
        // Add a Scheduled Event to rebalance the portfolio every morning
        // based on upcoming splits signals.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(DateRules.EveryDay(spy), TimeRules.AfterMarketOpen(spy, 1), Rebalance);
    }

    public void Rebalance()
    {
        // Equally invest in each member of the universe to evenly dissipate the capital risk.
        var symbols = _universe.Selected.Where(s => Securities[s].Price != 0);
        var totalCount = symbols.Count();
        var targets = symbols
            .Select(symbol => new PortfolioTarget(symbol, 1m / totalCount))
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}
```

Framework Algorithm Example

The following example algorithm holds each equity in equal size with upcoming splits within 7 days using algorithm framework. It selects stocks that split up to more shares with lower price and tries to capitalize the higher demand of the more afforable stocks.

```C#
public class UpcomingSplitsExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        Settings.FreePortfolioValuePercentage = 0.1m;

        // Trade on daily basis based on daily upcoming splits signals.
        UniverseSettings.Resolution = Resolution.Daily;
        // Universe consists of equities with upcoming splits events.
        AddUniverse<EODHDUpcomingSplits>((splits) => {
            return splits.OfType<EODHDUpcomingSplits>()
                // Split (more shares with lower price) will make the stock more affordable and drive up the demand.
                // Hence, include all stocks that will have a split within the next 7 days.
                // Note that spliting up the stock means the split factor > 1.
                .Where(datum => datum.SplitFactor > 1)
                .OrderBy(datum => datum.SplitFactor)
                .Take(5).Select(datum => datum.Symbol);
        });

        // Constant alpha model to emit insights for the stocks with split up event within a week, estimating their
demand and price will go up.
        // Signal stays for 2 days to fully digest the driven up demands.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(2)));

        // Equal weighting for each signal to evenly dissipate the capital risk.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Expiry.EndOfDay));
    }
}
```

Data Point Attributes

The EODHD Upcoming Splits dataset provides `EODHDUpcomingSplits` objects, which have the following attributes:

Datasets

Energy Information Administration

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

US Energy Information Administration (EIA)

Energy Information Administration

US Energy Information Administration (EIA)

Introduction

The US Energy Information Administration (EIA) datasets by the Department of the Treasury tracks national and international oil production and consumption. The data covers 190 datasets, starts in January 1991, and is delivered on a daily frequency. This dataset is created by QuantConnect processing and caching the EIA archives.

For more information about the US Energy Information Administration (EIA) dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

Getting Started

The following snippet demonstrates how to request data from the EIA dataset:

```C#
_datasetSymbol = AddData<USEnergy>(USEnergy.Petroleum.UnitedStates.WeeklyNetImportsOfTotalPetroleumProducts).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1991
Asset Coverage	190 Datasets
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add EIA data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class USEnergyDataAlgorithm: QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        _datasetSymbol = AddData<USEnergy>
(USEnergy.Petroleum.UnitedStates.WeeklyNetImportsOfTotalPetroleumProducts).Symbol;
    }
}
```

Accessing Data

To get the current EIA data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} value at {slice.Time}: {dataPoint.Value}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<USEnergy>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} value at {slice.Time}: {dataPoint.Value}");
    }
}
```

Historical Data

To get historical EIA data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<USEnergy>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to EIA data, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

Supported Datasets

The following table shows the accessor code you need to add each EIA dataset to your algorithm:

Symbol	Accessor Code	Description
UnitedStates		
PET.WGFRPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyRefinerAndBlenderAdjustedNetProductionOfFinishedMotorGasoline	U.S. Refiner and Blender Adjusted Net Production of Finished Motor Gasoline in Thousand Barrels per Day (Mbbl/d)
PET.WGFSTUS1.W	USEnergy.Petroleum.UnitedStates.WeeklyEndingStocksOfFinishedMotorGasoline	U.S. Ending Stocks of Finished Motor Gasoline in Thousand Barrels (Mbbl)
PET.WGFUPUS2.W	USEnergy.Petroleum.UnitedStates.WeeklyProductSuppliedOfFinishedMotorGasoline	U.S. Product Supplied of Finished Motor Gasoline in Thousand Barrels per Day (Mbbl/d)
