        var aroonUp = indicatorHistory.Select(x => ((dynamic)x).AroonUp).ToList();
        var aroonDown = indicatorHistory.Select(x => ((dynamic)x).AroonDown).ToList();
    }
}
```

Supported Indicators

Augen Price Spike

Introduction

The Augen Price Spike indicator is an indicator that measures price changes in terms of standard deviations. In the book, The Volatility Edge in Options Trading, Jeff Augen describes a method for tracking absolute price changes in terms of recent volatility, using the standard deviation. length = x closes = closeArray closes1 = closeArray shifted right by 1 closes2 = closeArray shifted right by 2 closeLog = np.log(np.divide(closes1, closes2)) SDev = np.std(closeLog) m = SDev * closes1[-1] spike = (closes[-1]-closes1[-1])/m return spike Augen Price Spike from TradingView https://www.tradingview.com/script/fC7Pn2X2-Price-Spike-Jeff-Augen/

To view the implementation of this indicator, see the LEAN GitHub repository .

Using APS Indicator

To create an automatic indicator for `AugenPriceSpike` , call the `APS` helper method from the `QCAlgorithm` class. The `APS` method creates a `AugenPriceSpike` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AugenPriceSpikeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AugenPriceSpike _aps;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _aps = APS(_symbol, 3);
    }

    public override void OnData(Slice data)
    {

        if (_aps.IsReady)
        {
            // The current value of _aps is represented by itself (_aps)
            // or _aps.Current.Value
            Plot("AugenPriceSpike", "aps", _aps);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AugenPriceSpike` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AugenPriceSpikeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AugenPriceSpike _augenpricespike;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _augenpricespike = new AugenPriceSpike(3);
    }

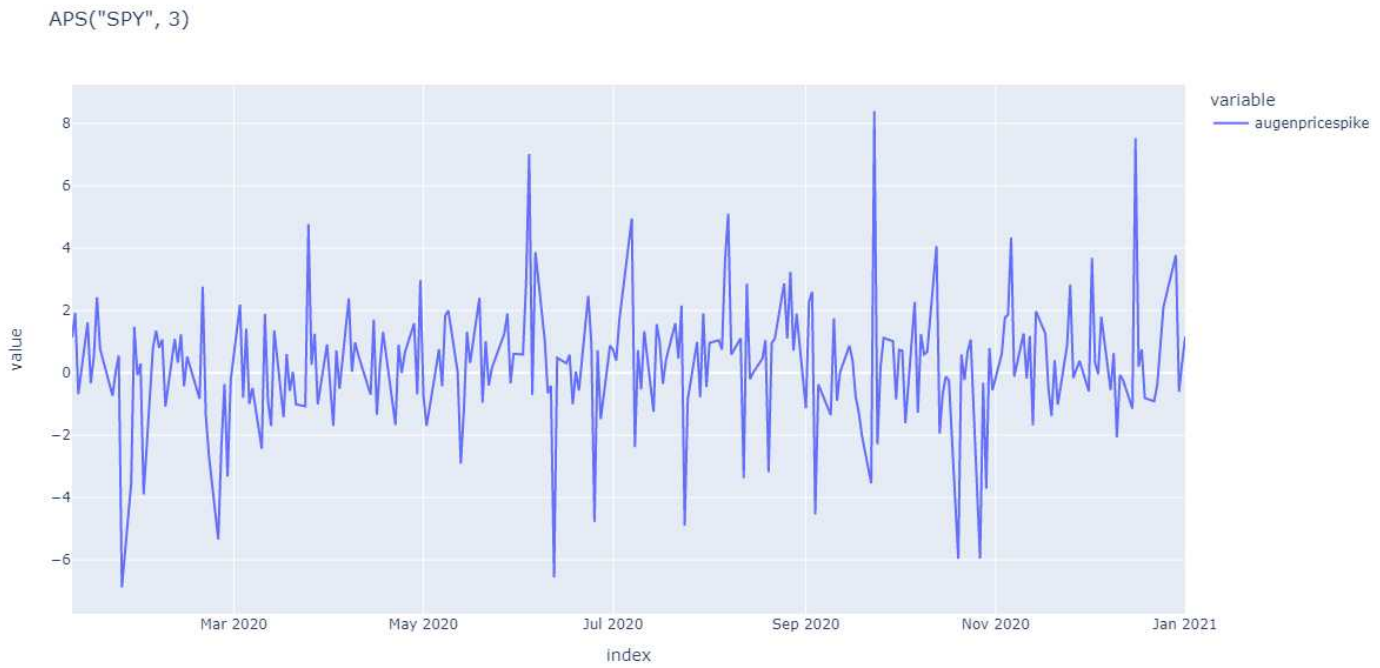
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _augenpricespike.Update(bar.EndTime, bar.Close);

        if (_augenpricespike.IsReady)
        {
            // The current value of _augenpricespike is represented by itself (_augenpricespike)
            // or _augenpricespike.Current.Value
            Plot("AugenPriceSpike", "augenpricespike", _augenpricespike);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AugenPriceSpike` indicator properties:



Indicator History

To get the historical data of the `AugenPriceSpike` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AugenPriceSpikeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AugenPriceSpike _aps;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _aps = APS(_symbol, 3);

        var indicatorHistory = IndicatorHistory(_aps, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_aps, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_aps, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Auto Regressive Integrated Moving Average

Introduction

An Autoregressive Intergrated Moving Average (ARIMA) is a time series model which can be used to describe a set of data. In particular,with X_t representing the series, the model assumes the data are of form (after differencing times): $X_t = c + \varepsilon_t + \Sigma_i \varphi_i X_{t-i} + \Sigma_i \theta_i \varepsilon_{t-i}$ where the first sum has an upper limit of and the second .

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ARIMA Indicator

To create an automatic indicator for `AutoRegressiveIntegratedMovingAverage` , call the `ARIMA` helper method from the `QCAlgorithm` class. The `ARIMA` method creates a `AutoRegressiveIntegratedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class AutoRegressiveIntegratedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AutoRegressiveIntegratedMovingAverage _arima;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _arima = ARIMA(_symbol, 1, 1, 1, 20);
    }

    public override void OnData(Slice data)
    {

        if (_arima.IsReady)
        {
            // The current value of _arima is represented by itself (_arima)
            // or _arima.Current.Value
            Plot("AutoRegressiveIntegratedMovingAverage", "arima", _arima);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AutoRegressiveIntegratedMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class AutoRegressiveIntegratedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AutoRegressiveIntegratedMovingAverage _autoregressiveintegratedmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _autoregressiveintegratedmovingaverage = new AutoRegressiveIntegratedMovingAverage(1, 1, 1, 20, true);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _autoregressiveintegratedmovingaverage.Update(bar.EndTime, bar.Close);

        if (_autoregressiveintegratedmovingaverage.IsReady)
        {
            // The current value of _autoregressiveintegratedmovingaverage is represented by itself
(_autoregressiveintegratedmovingaverage)
            // or _autoregressiveintegratedmovingaverage.Current.Value
            Plot("AutoRegressiveIntegratedMovingAverage", "autoregressiveintegratedmovingaverage",
_autoregressiveintegratedmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Indicator History

To get the historical data of the `AutoRegressiveIntegratedMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AutoRegressiveIntegratedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AutoRegressiveIntegratedMovingAverage _arima;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _arima = ARIMA(_symbol, 1, 1, 1, 20);

        var indicatorHistory = IndicatorHistory(_arima, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_arima, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_arima, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Average Directional Index

Introduction

This indicator computes Average Directional Index which measures trend strength without regard to trend direction. Firstly, it calculates the Directional Movement and the True Range value, and then the values are accumulated and smoothed using a custom smoothing method proposed by Wilder. For an n period smoothing, 1/n of each period's value is added to the total period. From these accumulated values we are therefore able to derived the 'Positive Directional Index' (+DI) and 'Negative Directional Index' (-DI) which is used to calculate the Average Directional Index. Computation source: https://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:average_directional_index_adx

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADX Indicator

To create an automatic indicator for `AverageDirectionalIndex` , call the `ADX` helper method from the `QCAlgorithm` class. The `ADX` method creates a `AverageDirectionalIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class AverageDirectionalIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageDirectionalIndex _adx;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _adx = ADX(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_adx.IsReady)
        {
            // The current value of _adx is represented by itself (_adx)
            // or _adx.Current.Value
            Plot("AverageDirectionalIndex", "adx", _adx);
            // Plot all properties of abands
            Plot("AverageDirectionalIndex", "positivedirectionalindex", _adx.PositiveDirectionalIndex);
            Plot("AverageDirectionalIndex", "negativedirectionalindex", _adx.NegativeDirectionalIndex);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageDirectionalIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class AverageDirectionalIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageDirectionalIndex _averagedirectionalindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _averagedirectionalindex = new AverageDirectionalIndex(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _averagedirectionalindex.Update(bar);

        if (_averagedirectionalindex.IsReady)
        {
            // The current value of _averagedirectionalindex is represented by itself (_averagedirectionalindex)
            // or _averagedirectionalindex.Current.Value
            Plot("AverageDirectionalIndex", "averagedirectionalindex", _averagedirectionalindex);
            // Plot all properties of abands
            Plot("AverageDirectionalIndex", "positivedirectionalindex",
_averagedirectionalindex.PositiveDirectionalIndex);
            Plot("AverageDirectionalIndex", "negativedirectionalindex",
_averagedirectionalindex.NegativeDirectionalIndex);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AverageDirectionalIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security

subscription.

```C#
public class AverageDirectionalIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageDirectionalIndex _adx;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _adx = ADX(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_adx, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_adx, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_adx, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var positiveDirectionalIndex = indicatorHistory.Select(x => ((dynamic)x).PositiveDirectionalIndex).ToList();
        var negativeDirectionalIndex = indicatorHistory.Select(x => ((dynamic)x).NegativeDirectionalIndex).ToList();
    }
}
```

Supported Indicators

Average Directional Movement Index Rating

Introduction

This indicator computes the Average Directional Movement Index Rating (ADXR). The Average Directional Movement Index Rating is calculated with the following formula: ADXR[i] = (ADX[i] + ADX[i - period + 1]) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADXR Indicator

To create an automatic indicator for `AverageDirectionalMovementIndexRating` , call the `ADXR` helper method from the `QCAlgorithm` class. The `ADXR` method creates a `AverageDirectionalMovementIndexRating` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AverageDirectionalMovementIndexRatingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageDirectionalMovementIndexRating _adxr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _adxr = ADXR(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_adxr.IsReady)
        {
            // The current value of _adxr is represented by itself (_adxr)
            // or _adxr.Current.Value
            Plot("AverageDirectionalMovementIndexRating", "adxr", _adxr);
            // Plot all properties of abands
            Plot("AverageDirectionalMovementIndexRating", "adx", _adxr.ADX);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageDirectionalMovementIndexRating` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AverageDirectionalMovementIndexRatingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageDirectionalMovementIndexRating _averagedirectionalmovementindexrating;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _averagedirectionalmovementindexrating = new AverageDirectionalMovementIndexRating(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _averagedirectionalmovementindexrating.Update(bar);

        if (_averagedirectionalmovementindexrating.IsReady)
        {
            // The current value of _averagedirectionalmovementindexrating is represented by itself
(_averagedirectionalmovementindexrating)
            // or _averagedirectionalmovementindexrating.Current.Value
            Plot("AverageDirectionalMovementIndexRating", "averagedirectionalmovementindexrating",
_averagedirectionalmovementindexrating);
            // Plot all properties of abands
            Plot("AverageDirectionalMovementIndexRating", "adx", _averagedirectionalmovementindexrating.ADX);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AverageDirectionalMovementIndexRating` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security

subscription.

```C#
public class AverageDirectionalMovementIndexRatingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageDirectionalMovementIndexRating _adxr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _adxr = ADXR(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_adxr, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_adxr, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_adxr, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var adx = indicatorHistory.Select(x => ((dynamic)x).ADX).ToList();
    }
}
```

Supported Indicators

Average Range

Introduction

This indicator represents the Average Range (AR) indicator, which calculates the average price range

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AR Indicator

To create an automatic indicator for `AverageRange` , call the `AR` helper method from the `QCAlgorithm` class. The `AR` method creates a `AverageRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AverageRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageRange _ar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ar = AR(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_ar.IsReady)
        {
            // The current value of _ar is represented by itself (_ar)
            // or _ar.Current.Value
            Plot("AverageRange", "ar", _ar);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AverageRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageRange _averagerange;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _averagerange = new AverageRange(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _averagerange.Update(bar);

        if (_averagerange.IsReady)
        {
            // The current value of _averagerange is represented by itself (_averagerange)
            // or _averagerange.Current.Value
            Plot("AverageRange", "averagerange", _averagerange);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AverageRange` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AverageRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageRange _ar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ar = AR(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_ar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_ar, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_ar, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Average True Range

Introduction

The AverageTrueRange indicator is a measure of volatility introduced by Welles Wilder in his book: New Concepts in Technical Trading Systems. This indicator computes the TrueRange and then smoothes the TrueRange over a given period. TrueRange is defined as the maximum of the following: High - Low ABS(High - PreviousClose) ABS(Low - PreviousClose)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ATR Indicator

To create an automatic indicator for `AverageTrueRange` , call the `ATR` helper method from the `QCAlgorithm` class. The `ATR` method creates a `AverageTrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AverageTrueRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageTrueRange _atr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _atr = ATR(_symbol, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_atr.IsReady)
        {
            // The current value of _atr is represented by itself (_atr)
            // or _atr.Current.Value
            Plot("AverageTrueRange", "atr", _atr);
            // Plot all properties of abands
            Plot("AverageTrueRange", "truerange", _atr.TrueRange);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AverageTrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AverageTrueRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageTrueRange _averagetruerange;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _averagetruerange = new AverageTrueRange(20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _averagetruerange.Update(bar);

        if (_averagetruerange.IsReady)
        {
            // The current value of _averagetruerange is represented by itself (_averagetruerange)
            // or _averagetruerange.Current.Value
            Plot("AverageTrueRange", "averagetruerange", _averagetruerange);
            // Plot all properties of abands
            Plot("AverageTrueRange", "truerange", _averagetruerange.TrueRange);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AverageTrueRange` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AverageTrueRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AverageTrueRange _atr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _atr = ATR(_symbol, 20, MovingAverageType.Simple);

        var indicatorHistory = IndicatorHistory(_atr, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_atr, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_atr, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var trueRange = indicatorHistory.Select(x => ((dynamic)x).TrueRange).ToList();
    }
}
```

Supported Indicators

Awesome Oscillator

Introduction

The Awesome Oscillator Indicator tracks the price midpoint-movement of a security. Specifically, AO = MAfast[(H+L)/2] - MAslow[(H+L)/2] where MAfast and MAslow denote simple moving averages wherein fast has a shorter period. https://www.barchart.com/education/technical-indicators/awesome_oscillator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AO Indicator

To create an automatic indicator for `AwesomeOscillator` , call the `AO` helper method from the `QCAlgorithm` class. The `AO` method creates a `AwesomeOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AwesomeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AwesomeOscillator _ao;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ao = AO(_symbol, 10, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_ao.IsReady)
        {
            // The current value of _ao is represented by itself (_ao)
            // or _ao.Current.Value
            Plot("AwesomeOscillator", "ao", _ao);
            // Plot all properties of abands
            Plot("AwesomeOscillator", "slowao", _ao.SlowAo);
            Plot("AwesomeOscillator", "fastao", _ao.FastAo);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AwesomeOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class AwesomeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AwesomeOscillator _awesomeoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _awesomeoscillator = new AwesomeOscillator(10, 20, MovingAverageType.Simple);
    }

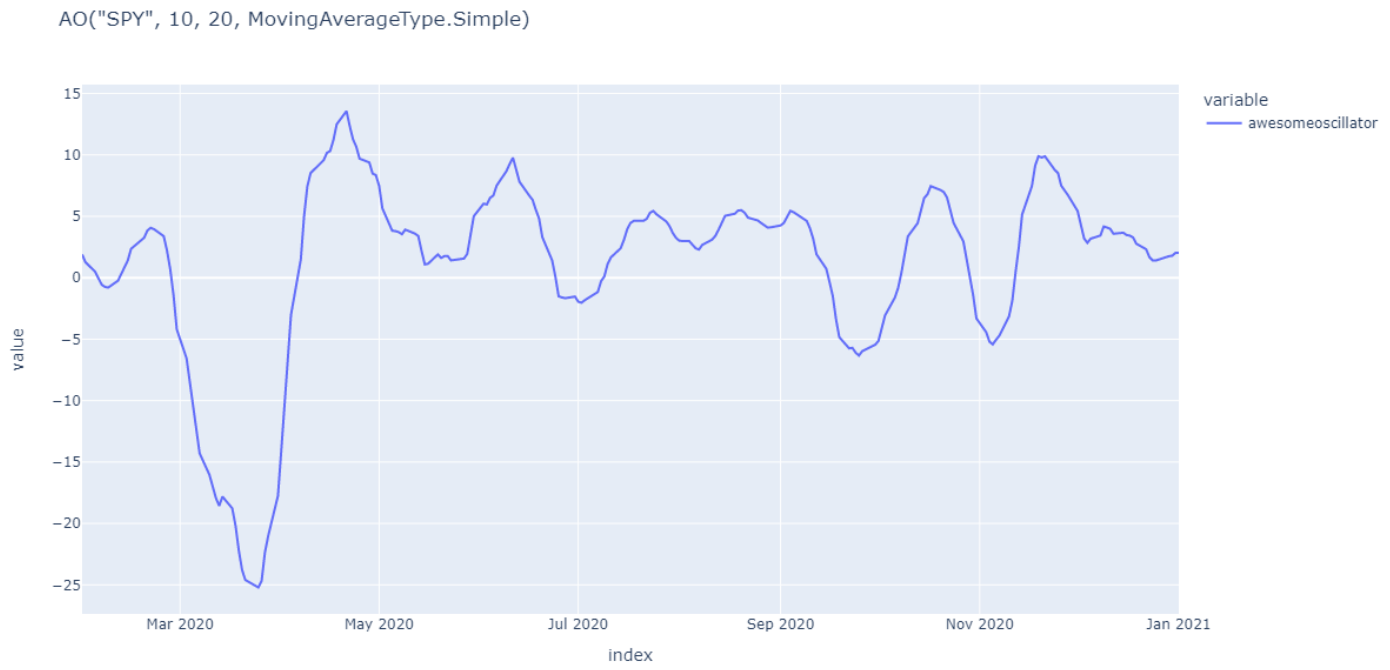
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _awesomeoscillator.Update(bar);

        if (_awesomeoscillator.IsReady)
        {
            // The current value of _awesomeoscillator is represented by itself (_awesomeoscillator)
            // or _awesomeoscillator.Current.Value
            Plot("AwesomeOscillator", "awesomeoscillator", _awesomeoscillator);
            // Plot all properties of abands
            Plot("AwesomeOscillator", "slowao", _awesomeoscillator.SlowAo);
            Plot("AwesomeOscillator", "fastao", _awesomeoscillator.FastAo);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AwesomeOscillator` indicator properties:



Indicator History

To get the historical data of the `AwesomeOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AwesomeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AwesomeOscillator _ao;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ao = AO(_symbol, 10, 20, MovingAverageType.Simple);

        var indicatorHistory = IndicatorHistory(_ao, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_ao, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_ao, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var slowAo = indicatorHistory.Select(x => ((dynamic)x).SlowAo).ToList();
        var fastAo = indicatorHistory.Select(x => ((dynamic)x).FastAo).ToList();
    }
}
```

Supported Indicators

Balance Of Power

Introduction

This indicator computes the Balance Of Power (BOP). The Balance Of Power is calculated with the following formula: BOP = (Close - Open) / (High - Low)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using BOP Indicator

To create an automatic indicator for `BalanceOfPower` , call the `BOP` helper method from the `QCAlgorithm` class. The `BOP` method creates a `BalanceOfPower` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class BalanceOfPowerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BalanceOfPower _bop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _bop = BOP(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_bop.IsReady)
        {
            // The current value of _bop is represented by itself (_bop)
            // or _bop.Current.Value
            Plot("BalanceOfPower", "bop", _bop);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `BalanceOfPower` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class BalanceOfPowerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BalanceOfPower _balanceofpower;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _balanceofpower = new BalanceOfPower();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _balanceofpower.Update(bar);

        if (_balanceofpower.IsReady)
        {
            // The current value of _balanceofpower is represented by itself (_balanceofpower)
            // or _balanceofpower.Current.Value
            Plot("BalanceOfPower", "balanceofpower", _balanceofpower);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Indicator History

To get the historical data of the `BalanceOfPower` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class BalanceOfPowerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BalanceOfPower _bop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _bop = BOP(_symbol);

        var indicatorHistory = IndicatorHistory(_bop, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_bop, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_bop, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Beta

Introduction

In technical analysis Beta indicator is used to measure volatility or risk of a target (ETF) relative to the overall risk (volatility) of the reference (market indexes). The Beta indicators compares target's price movement to the movements of the indexes over the same period of time. It is common practice to use the SPX index as a benchmark of the overall reference market when it comes to Beta calculations. The indicator only updates when both assets have a price for a time step. When a bar is missing for one of the assets, the indicator value fills forward to improve the accuracy of the indicator.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using B Indicator

To create an automatic indicator for `Beta` , call the `B` helper method from the `QCAlgorithm` class. The `B` method creates a `Beta` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class BetaAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Beta _b;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _b = B(_symbol, _reference, 20);
    }

    public override void OnData(Slice data)
    {

        if (_b.IsReady)
        {
            // The current value of _b is represented by itself (_b)
            // or _b.Current.Value
            Plot("Beta", "b", _b);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Beta` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class BetaAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Beta _beta;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _beta = new Beta(_symbol, _reference, 20);
    }

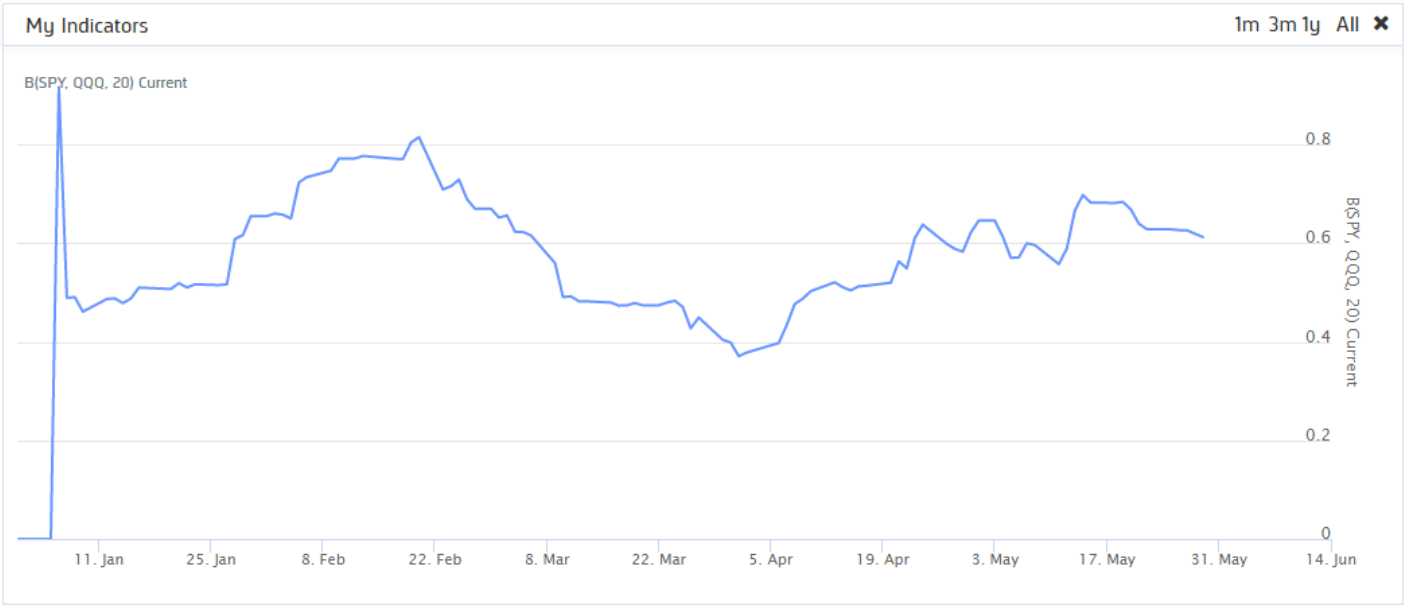
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _beta.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _beta.Update(bar);

        if (_beta.IsReady)
        {
            // The current value of _beta is represented by itself (_beta)
            // or _beta.Current.Value
            Plot("Beta", "beta", _beta);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Beta` indicator properties:



Indicator History

To get the historical data of the `Beta` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class BetaAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Beta _b;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _b = B(_symbol, _reference, 20);

        var indicatorHistory = IndicatorHistory(_b, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_b, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_b, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Bollinger Bands

Introduction

This indicator creates a moving average (middle band) with an upper band and lower band fixed at k standard deviations above and below the moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using BB Indicator

To create an automatic indicator for `BollingerBands` , call the `BB` helper method from the `QCAlgorithm` class. The `BB` method creates a `BollingerBands` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class BollingerBandsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BollingerBands _bb;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _bb = BB(_symbol, 30, 2m);
    }

    public override void OnData(Slice data)
    {

        if (_bb.IsReady)
        {
            // The current value of _bb is represented by itself (_bb)
            // or _bb.Current.Value
            Plot("BollingerBands", "bb", _bb);
            // Plot all properties of abands
            Plot("BollingerBands", "standarddeviation", _bb.StandardDeviation);
            Plot("BollingerBands", "middleband", _bb.MiddleBand);
            Plot("BollingerBands", "upperband", _bb.UpperBand);
            Plot("BollingerBands", "lowerband", _bb.LowerBand);
            Plot("BollingerBands", "bandwidth", _bb.BandWidth);
            Plot("BollingerBands", "percentb", _bb.PercentB);
            Plot("BollingerBands", "price", _bb.Price);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `BollingerBands` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class BollingerBandsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BollingerBands _bollingerbands;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _bollingerbands = new BollingerBands(30, 2m);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _bollingerbands.Update(bar.EndTime, bar.Close);

        if (_bollingerbands.IsReady)
        {
            // The current value of _bollingerbands is represented by itself (_bollingerbands)
            // or _bollingerbands.Current.Value
            Plot("BollingerBands", "bollingerbands", _bollingerbands);
            // Plot all properties of abands
            Plot("BollingerBands", "standarddeviation", _bollingerbands.StandardDeviation);
            Plot("BollingerBands", "middleband", _bollingerbands.MiddleBand);
            Plot("BollingerBands", "upperband", _bollingerbands.UpperBand);
            Plot("BollingerBands", "lowerband", _bollingerbands.LowerBand);
            Plot("BollingerBands", "bandwidth", _bollingerbands.BandWidth);
            Plot("BollingerBands", "percentb", _bollingerbands.PercentB);
            Plot("BollingerBands", "price", _bollingerbands.Price);
        }
    }
}
```

For more information about this indicator, see its reference .

Chaikin Money Flow

Introduction

The Chaikin Money Flow Index (CMF) is a volume-weighted average of accumulation and distribution over a specified period. CMF = n-day Sum of [(((C - L) - (H - C)) / (H - L)) x Vol] / n-day Sum of Vol Where: n = number of periods, typically 21 H = high L = low C = close Vol = volume https://www.fidelity.com/learning-center/trading-investing/technical-analysis/technical-indicator-guide/cmf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CMF Indicator

To create an automatic indicator for `ChaikinMoneyFlow` , call the `CMF` helper method from the `QCAlgorithm` class. The `CMF` method creates a `ChaikinMoneyFlow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ChaikinMoneyFlowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChaikinMoneyFlow _cmf;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cmf = CMF(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_cmf.IsReady)
        {
            // The current value of _cmf is represented by itself (_cmf)
            // or _cmf.Current.Value
            Plot("ChaikinMoneyFlow", "cmf", _cmf);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChaikinMoneyFlow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ChaikinMoneyFlowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChaikinMoneyFlow _chaikinmoneyflow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _chaikinmoneyflow = new ChaikinMoneyFlow(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _chaikinmoneyflow.Update(bar);

        if (_chaikinmoneyflow.IsReady)
        {
            // The current value of _chaikinmoneyflow is represented by itself (_chaikinmoneyflow)
            // or _chaikinmoneyflow.Current.Value
            Plot("ChaikinMoneyFlow", "chaikinmoneyflow", _chaikinmoneyflow);
        }
    }
}
```

For more information about this indicator, see its reference .

Chaikin Oscillator

Introduction

This class is an alias for AccumulationDistributionOscillator (also known as Chaikin Oscillator).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CO Indicator

To create an automatic indicator for `ChaikinOscillator` , call the `CO` helper method from the `QCAlgorithm` class. The `CO` method creates a `ChaikinOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ChaikinOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChaikinOscillator _co;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _co = CO(_symbol, 3, 10);
    }

    public override void OnData(Slice data)
    {

        if (_co.IsReady)
        {
            // The current value of _co is represented by itself (_co)
            // or _co.Current.Value
            Plot("ChaikinOscillator", "co", _co);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChaikinOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ChaikinOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChaikinOscillator _chaikinoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _chaikinoscillator = new ChaikinOscillator(3, 10);
    }

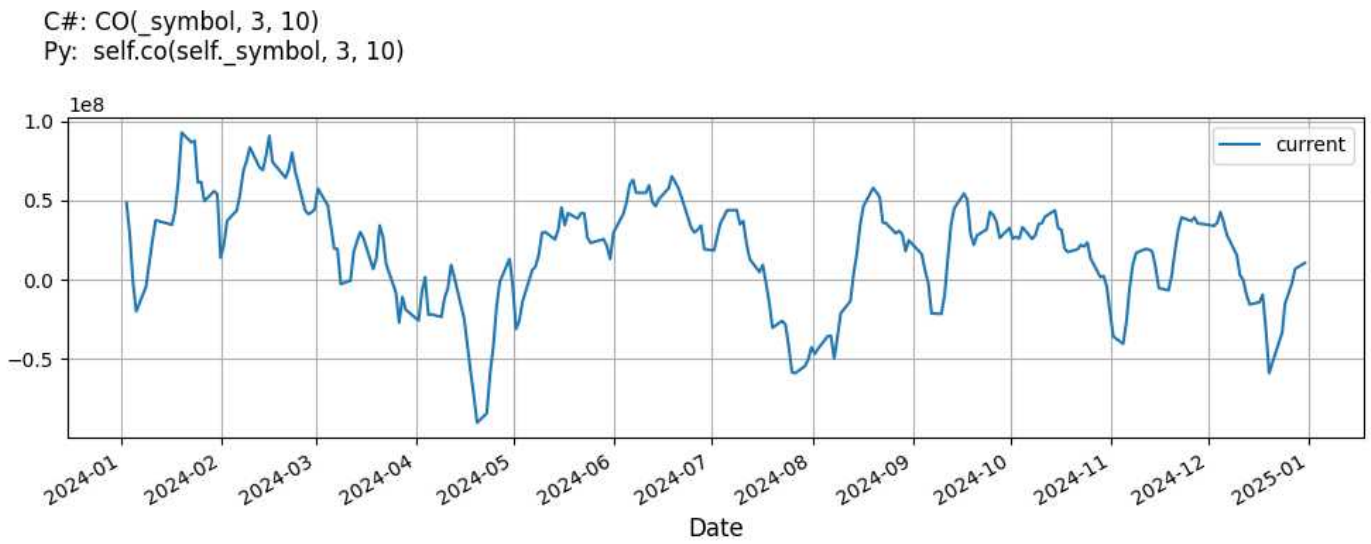
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _chaikinoscillator.Update(bar);

        if (_chaikinoscillator.IsReady)
        {
            // The current value of _chaikinoscillator is represented by itself (_chaikinoscillator)
            // or _chaikinoscillator.Current.Value
            Plot("ChaikinOscillator", "chaikinoscillator", _chaikinoscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ChaikinOscillator` indicator properties:



Indicator History

To get the historical data of the `ChaikinOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class ChaikinOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChaikinOscillator _co;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _co = CO(_symbol, 3, 10);

        var indicatorHistory = IndicatorHistory(_co, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_co, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_co, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Chande Kroll Stop

Introduction

This indicator computes the short stop and lower stop values of the Chande Kroll Stop Indicator. It is used to determine the optimal placement of a stop-loss order.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CKS Indicator

To create an automatic indicator for `ChandeKrollStop` , call the `CKS` helper method from the `QCAlgorithm` class. The `CKS` method creates a `ChandeKrollStop` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ChandeKrollStopAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChandeKrollStop _cks;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cks = CKS(_symbol, 10, 1, 9);
    }

    public override void OnData(Slice data)
    {

        if (_cks.IsReady)
        {
            // The current value of _cks is represented by itself (_cks)
            // or _cks.Current.Value
            Plot("ChandeKrollStop", "cks", _cks);
            // Plot all properties of abands
            Plot("ChandeKrollStop", "shortstop", _cks.ShortStop);
            Plot("ChandeKrollStop", "longstop", _cks.LongStop);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChandeKrollStop` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class ChandeKrollStopAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChandeKrollStop _chandekrollstop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _chandekrollstop = new ChandeKrollStop(10, 1, 9);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _chandekrollstop.Update(bar);

        if (_chandekrollstop.IsReady)
        {
            // The current value of _chandekrollstop is represented by itself (_chandekrollstop)
            // or _chandekrollstop.Current.Value
            Plot("ChandeKrollStop", "chandekrollstop", _chandekrollstop);
            // Plot all properties of abands
            Plot("ChandeKrollStop", "shortstop", _chandekrollstop.ShortStop);
            Plot("ChandeKrollStop", "longstop", _chandekrollstop.LongStop);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

{
    private Symbol _symbol;
    private ChandeKrollStop _cks;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cks = CKS(_symbol, 10, 1, 9);

        var indicatorHistory = IndicatorHistory(_cks, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_cks, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_cks, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var shortStop = indicatorHistory.Select(x => ((dynamic)x).ShortStop).ToList();
        var longStop = indicatorHistory.Select(x => ((dynamic)x).LongStop).ToList();
    }
}
```

Supported Indicators

Chande Momentum Oscillator

Introduction

This indicator computes the Chande Momentum Oscillator (CMO). CMO calculation is mostly identical to RSI. The only difference is in the last step of calculation: RSI = gain / (gain+loss) CMO = (gain-loss) / (gain+loss)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CMO Indicator

To create an automatic indicator for `ChandeMomentumOscillator` , call the `CMO` helper method from the `QCAlgorithm` class. The `CMO` method creates a `ChandeMomentumOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ChandeMomentumOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChandeMomentumOscillator _cmo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cmo = CMO(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_cmo.IsReady)
        {
            // The current value of _cmo is represented by itself (_cmo)
            // or _cmo.Current.Value
            Plot("ChandeMomentumOscillator", "cmo", _cmo);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChandeMomentumOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class ChandeMomentumOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChandeMomentumOscillator _chandemomentumoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _chandemomentumoscillator = new ChandeMomentumOscillator(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _chandemomentumoscillator.Update(bar.EndTime, bar.Close);

        if (_chandemomentumoscillator.IsReady)
        {
            // The current value of _chandemomentumoscillator is represented by itself (_chandemomentumoscillator)
            // or _chandemomentumoscillator.Current.Value
            Plot("ChandeMomentumOscillator", "chandemomentumoscillator", _chandemomentumoscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

C#

```
public class ChandeMomentumOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChandeMomentumOscillator _cmo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cmo = CMO(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_cmo, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_cmo, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_cmo, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Choppiness Index

Introduction

The ChoppinessIndex indicator is an indicator designed to determine if the market is choppy (trading sideways) or not choppy (trading within a trend in either direction)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CHOP Indicator

To create an automatic indicator for `ChoppinessIndex` , call the `CHOP` helper method from the `QCAlgorithm` class. The `CHOP` method creates a `ChoppinessIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ChoppinessIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChoppinessIndex _chop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _chop = CHOP(_symbol, 14);
    }

    public override void OnData(Slice data)
    {

        if (_chop.IsReady)
        {
            // The current value of _chop is represented by itself (_chop)
            // or _chop.Current.Value
            Plot("ChoppinessIndex", "chop", _chop);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ChoppinessIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ChoppinessIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChoppinessIndex _choppinessindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _choppinessindex = new ChoppinessIndex(14);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _choppinessindex.Update(bar);

        if (_choppinessindex.IsReady)
        {
            // The current value of _choppinessindex is represented by itself (_choppinessindex)
            // or _choppinessindex.Current.Value
            Plot("ChoppinessIndex", "choppinessindex", _choppinessindex);
        }
    }
}
```

For more information about this indicator, see its reference .

If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class ChoppinessIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ChoppinessIndex _chop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _chop = CHOP(_symbol, 14);

        var indicatorHistory = IndicatorHistory(_chop, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_chop, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_chop, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Commodity Channel Index

Introduction

This indicator represents the traditional commodity channel index (CCI) CCI = (Typical Price - 20-period SMA of TP) / (.015 * Mean Deviation) Typical Price (TP) = (High + Low + Close)/3 Constant = 0.015 There are four steps to calculating the Mean Deviation, first, subtract the most recent 20-period average of the typical price from each period's typical price. Second, take the absolute values of these numbers. Third, sum the absolute values. Fourth, divide by the total number of periods (20).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CCI Indicator

To create an automatic indicator for `CommodityChannelIndex` , call the `CCI` helper method from the `QCAlgorithm` class. The `CCI` method creates a `CommodityChannelIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class CommodityChannelIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private CommodityChannelIndex _cci;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cci = CCI(_symbol, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_cci.IsReady)
        {
            // The current value of _cci is represented by itself (_cci)
            // or _cci.Current.Value
            Plot("CommodityChannelIndex", "cci", _cci);
            // Plot all properties of abands
            Plot("CommodityChannelIndex", "typicalpriceaverage", _cci.TypicalPriceAverage);
            Plot("CommodityChannelIndex", "typicalpricemeandeviation", _cci.TypicalPriceMeanDeviation);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `CommodityChannelIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class CommodityChannelIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private CommodityChannelIndex _commoditychannelindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _commoditychannelindex = new CommodityChannelIndex(20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _commoditychannelindex.Update(bar);

        if (_commoditychannelindex.IsReady)
        {
            // The current value of _commoditychannelindex is represented by itself (_commoditychannelindex)
            // or _commoditychannelindex.Current.Value
            Plot("CommodityChannelIndex", "commoditychannelindex", _commoditychannelindex);
            // Plot all properties of abands
            Plot("CommodityChannelIndex", "typicalpriceaverage", _commoditychannelindex.TypicalPriceAverage);
            Plot("CommodityChannelIndex", "typicalpricemeandeviation",
_commoditychannelindex.TypicalPriceMeanDeviation);
        }
    }
}
```

Supported Indicators

Connors Relative Strength Index

Introduction

This indicator represents the Connors Relative Strength Index (CRSI), a combination of the traditional Relative Strength Index (RSI), a Streak RSI (SRSI), and Percent Rank. This index is designed to provide a more robust measure of market strength by combining momentum, streak behavior, and price change.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CRSI Indicator

To create an automatic indicator for `ConnorsRelativeStrengthIndex` , call the `CRSI` helper method from the `QCAlgorithm` class. The `CRSI` method creates a `ConnorsRelativeStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ConnorsRelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ConnorsRelativeStrengthIndex _crsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _crsi = CRSI(_symbol, 3, 2, 100);
    }

    public override void OnData(Slice data)
    {

        if (_crsi.IsReady)
        {
            // The current value of _crsi is represented by itself (_crsi)
            // or _crsi.Current.Value
            Plot("ConnorsRelativeStrengthIndex", "crsi", _crsi);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ConnorsRelativeStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ConnorsRelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ConnorsRelativeStrengthIndex _connorsrelativestrengthindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _connorsrelativestrengthindex = new ConnorsRelativeStrengthIndex(3, 2, 100);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _connorsrelativestrengthindex.Update(bar.EndTime, bar.Close);

        if (_connorsrelativestrengthindex.IsReady)
        {
            // The current value of _connorsrelativestrengthindex is represented by itself
(_connorsrelativestrengthindex)
            // or _connorsrelativestrengthindex.Current.Value
            Plot("ConnorsRelativeStrengthIndex", "connorsrelativestrengthindex", _connorsrelativestrengthindex);
        }
    }
}
```

C#

```
public class ConnorsRelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ConnorsRelativeStrengthIndex _crsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _crsi = CRSI(_symbol, 3, 2, 100);

        var indicatorHistory = IndicatorHistory(_crsi, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_crsi, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_crsi, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Coppock Curve

Introduction

A momentum indicator developed by Edwin “Sedge” Coppock in October 1965. The goal of this indicator is to identify long-term buying opportunities in the S&P500 and Dow Industrials. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using CC Indicator

To create an automatic indicator for `CoppockCurve` , call the `CC` helper method from the `QCAlgorithm` class. The `CC` method creates a `CoppockCurve` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class CoppockCurveAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private CoppockCurve _cc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cc = CC(_symbol, 11, 14, 10);
    }

    public override void OnData(Slice data)
    {

        if (_cc.IsReady)
        {
            // The current value of _cc is represented by itself (_cc)
            // or _cc.Current.Value
            Plot("CoppockCurve", "cc", _cc);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `CoppockCurve` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class CoppockCurveAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private CoppockCurve _coppockcurve;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _coppockcurve = new CoppockCurve(11, 14, 10);
    }

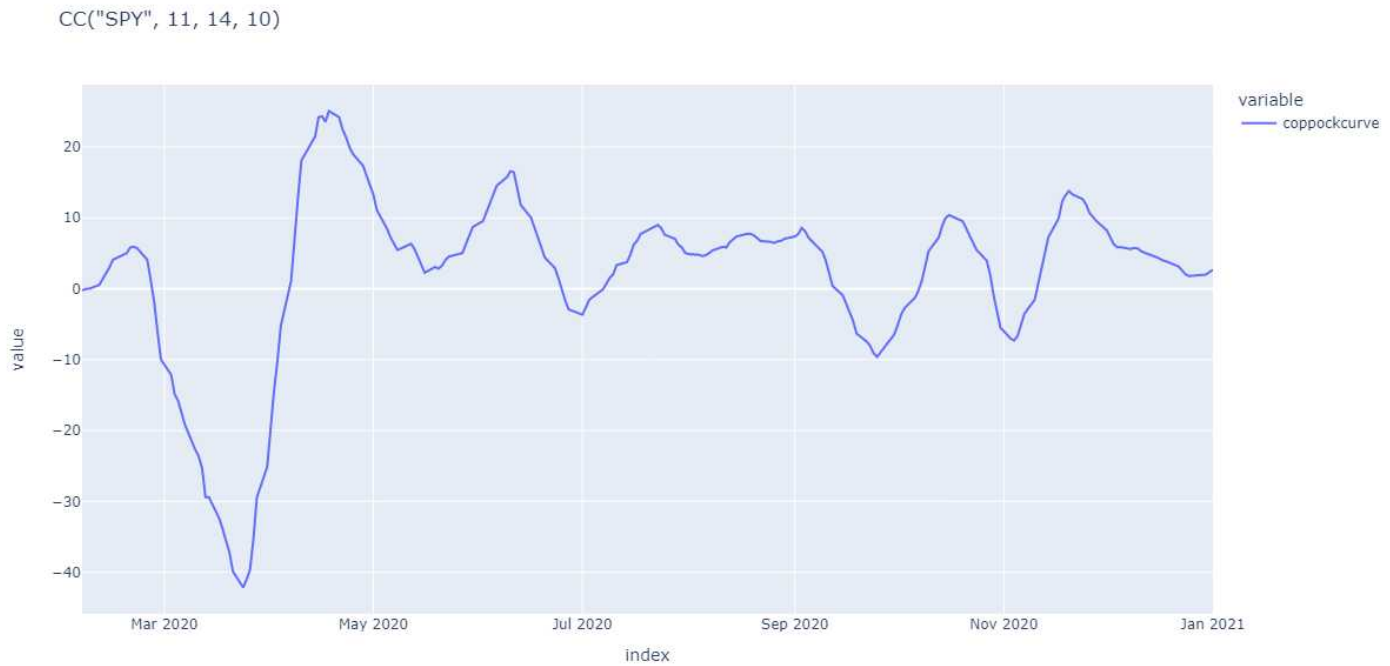
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _coppockcurve.Update(bar.EndTime, bar.Close);

        if (_coppockcurve.IsReady)
        {
            // The current value of _coppockcurve is represented by itself (_coppockcurve)
            // or _coppockcurve.Current.Value
            Plot("CoppockCurve", "coppockcurve", _coppockcurve);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `CoppockCurve` indicator properties:



Indicator History

To get the historical data of the `CoppockCurve` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class CoppockCurveAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private CoppockCurve _cc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _cc = CC(_symbol, 11, 14, 10);

        var indicatorHistory = IndicatorHistory(_cc, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_cc, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_cc, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Correlation

Introduction

The Correlation Indicator is a valuable tool in technical analysis, designed to quantify the degree of relationship between the price movements of a target security (e.g., a stock or ETF) and a reference market index. It measures how closely the target's price changes are aligned with the fluctuations of the index over a specific period of time, providing insights into the target's susceptibility to market movements. A positive correlation indicates that the target tends to move in the same direction as the market index, while a negative correlation suggests an inverse relationship. A correlation close to 0 implies a weak or no linear relationship. Commonly, the SPX index is employed as the benchmark for the overall market when calculating correlation, ensuring a consistent and reliable reference point. This helps traders and investors make informed decisions regarding the risk and behavior of the target security in relation to market trends. The indicator only updates when both assets have a price for a time step. When a bar is missing for one of the assets, the indicator value fills forward to improve the accuracy of the indicator.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using C Indicator

To create an automatic indicator for `Correlation` , call the `C` helper method from the `QCAlgorithm` class. The `C` method creates a `Correlation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class CorrelationAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Correlation _c;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _c = C(_symbol, _reference, 20, CorrelationType.Pearson);
    }

    public override void OnData(Slice data)
    {

        if (_c.IsReady)
        {
            // The current value of _c is represented by itself (_c)
            // or _c.Current.Value
            Plot("Correlation", "c", _c);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Correlation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class CorrelationAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Correlation _correlation;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _correlation = new Correlation(_symbol, _reference, 20, CorrelationType.Pearson);
    }

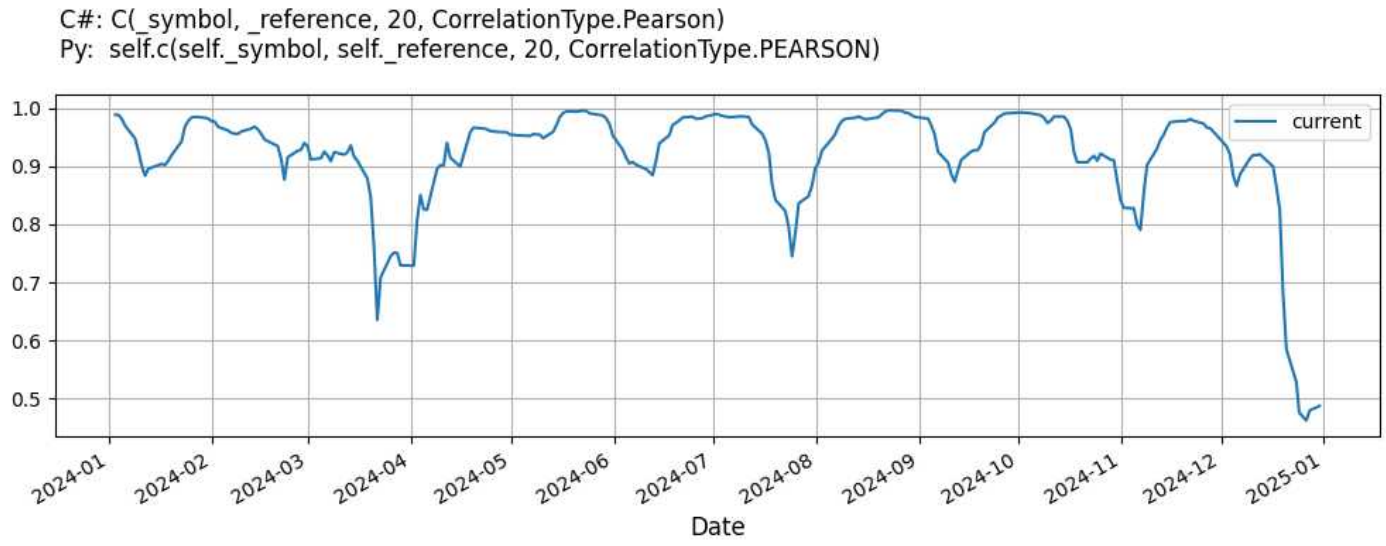
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _correlation.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _correlation.Update(bar);

        if (_correlation.IsReady)
        {
            // The current value of _correlation is represented by itself (_correlation)
            // or _correlation.Current.Value
            Plot("Correlation", "correlation", _correlation);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Correlation` indicator properties:



Indicator History

To get the historical data of the `Correlation` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class CorrelationAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Correlation _c;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _c = C(_symbol, _reference, 20, CorrelationType.Pearson);

        var indicatorHistory = IndicatorHistory(_c, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_c, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_c, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Covariance

Introduction

This indicator computes the Covariance of two assets using the given Look-Back period. The Covariance of two assets is a measure of their co-movement.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using COV Indicator

To create an automatic indicator for `Covariance` , call the `COV` helper method from the `QCAlgorithm` class. The `COV` method creates a `Covariance` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class CovarianceAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Covariance _cov;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _cov = COV([_symbol, _reference]);
    }

    public override void OnData(Slice data)
    {

        if (_cov.IsReady)
        {
            // The current value of _cov is represented by itself (_cov)
            // or _cov.Current.Value
            Plot("Covariance", "cov", _cov);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Covariance` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class CovarianceAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Covariance _covariance;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _covariance = new Covariance(_symbol, _reference, 5);
    }

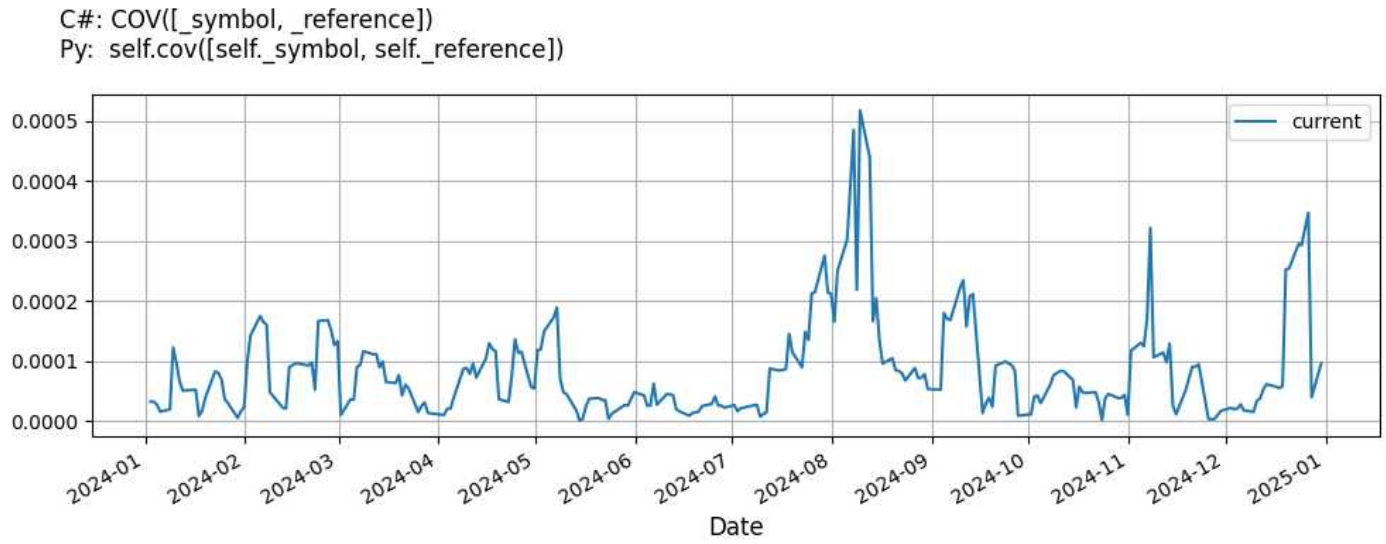
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _covariance.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _covariance.Update(bar);

        if (_covariance.IsReady)
        {
            // The current value of _covariance is represented by itself (_covariance)
            // or _covariance.Current.Value
            Plot("Covariance", "covariance", _covariance);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Covariance` indicator properties:



Indicator History

To get the historical data of the `Covariance` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class CovarianceAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Covariance _cov;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _cov = COV([_symbol, _reference]);

        var indicatorHistory = IndicatorHistory(_cov, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_cov, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_cov, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

DeMarker Indicator

Introduction

In the DeMarker strategy, for some period of size N, set: DeMax = High - Previous High, and DeMin = Previous Low - Low where, in the prior, if either term is less than zero (DeMax or DeMin), set it to zero. We can now define the indicator itself, DEM, as: DEM = MA(DeMax)/(MA(DeMax)+MA(DeMin)) where MA denotes a Moving Average of period N. https://www.investopedia.com/terms/d/demarkerindicator.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DEM Indicator

To create an automatic indicator for `DeMarkerIndicator` , call the `DEM` helper method from the `QCAlgorithm` class. The `DEM` method creates a `DeMarkerIndicator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class DeMarkerIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DeMarkerIndicator _dem;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dem = DEM(_symbol, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_dem.IsReady)
        {
            // The current value of _dem is represented by itself (_dem)
            // or _dem.Current.Value
            Plot("DeMarkerIndicator", "dem", _dem);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DeMarkerIndicator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class DeMarkerIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DeMarkerIndicator _demarkerindicator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _demarkerindicator = new DeMarkerIndicator(20, MovingAverageType.Simple);
    }

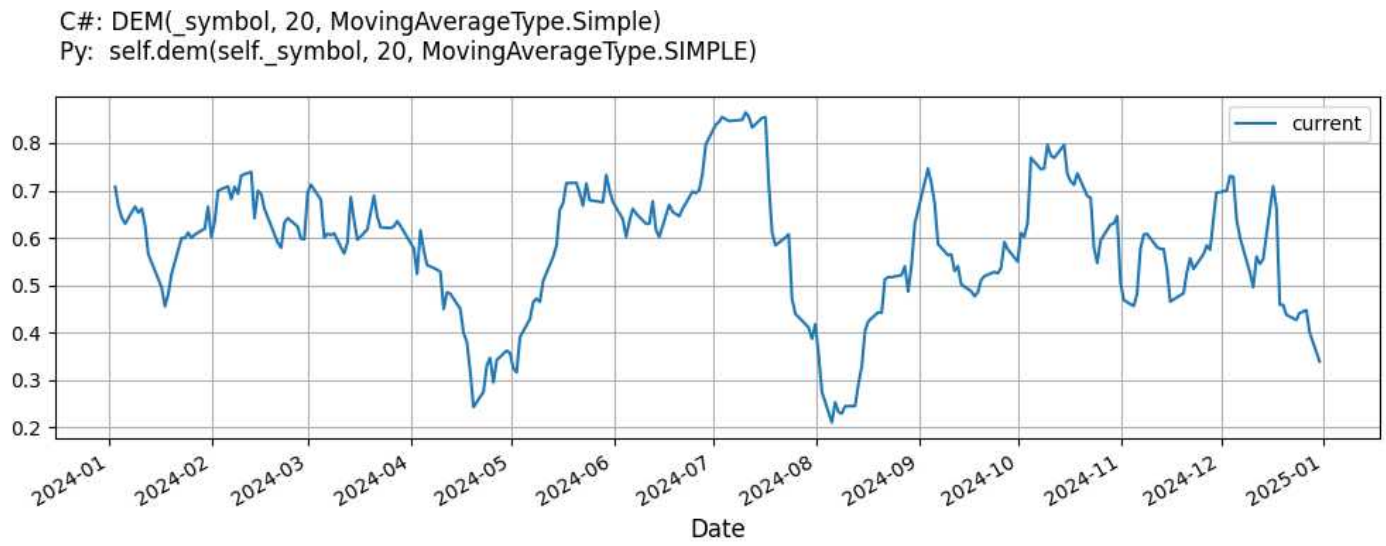
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _demarkerindicator.Update(bar);

        if (_demarkerindicator.IsReady)
        {
            // The current value of _demarkerindicator is represented by itself (_demarkerindicator)
            // or _demarkerindicator.Current.Value
            Plot("DeMarkerIndicator", "demarkerindicator", _demarkerindicator);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `DeMarkerIndicator` indicator properties:



Indicator History

To get the historical data of the `DeMarkerIndicator` indicator, call the `IndicatorHistory` method. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class DeMarkerIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DeMarkerIndicator _dem;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dem = DEM(_symbol, 20, MovingAverageType.Simple);

        var indicatorHistory = IndicatorHistory(_dem, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_dem, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_dem, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Delta

Introduction

Option Delta indicator that calculate the delta of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using D Indicator

To create an automatic indicator for `Delta` , call the `D` helper method from the `QCAlgorithm` class. The `D` method creates a `Delta` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class DeltaAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Delta _d;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _d = D(_option, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (_d.IsReady)
        {
            // The current value of _d is represented by itself (_d)
            // or _d.Current.Value
            Plot("Delta", "d", _d);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Delta` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class DeltaAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Delta _delta;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        var interestRateModel = new InterestRateProvider();
        var dividendYieldModel = new DividendYieldProvider(_symbol);

        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _delta = new Delta(_option, interestRateModel, dividendYieldModel, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _delta.Update(new IndicatorDataPoint(_symbol, bar.EndTime, bar.Close));
        if (data.QuoteBars.TryGetValue(_option, out var quoteBar))
            _delta.Update(new IndicatorDataPoint(_option, quoteBar.EndTime, quoteBar.Close));
        if (data.QuoteBars.TryGetValue(_mirrorOption, out quoteBar))
            _delta.Update(new IndicatorDataPoint(_mirrorOption, quoteBar.EndTime, quoteBar.Close));

        if (_delta.IsReady)
        {
            // The current value of _delta is represented by itself (_delta)
            // or _delta.Current.Value
            Plot("Delta", "delta", _delta);
        }
    }
}
```

Derivative Oscillator

Introduction

This indicator represents the Derivative Oscillator Indicator, utilizing a moving average convergence-divergence (MACD) histogram to a double-smoothed relative strength index (RSI).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DO Indicator

To create an automatic indicator for `DerivativeOscillator` , call the `DO` helper method from the `QCAlgorithm` class. The `DO` method creates a `DerivativeOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class DerivativeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DerivativeOscillator _do;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _do = DO(_symbol, 14, 5, 3, 9);
    }

    public override void OnData(Slice data)
    {

        if (_do.IsReady)
        {
            // The current value of _do is represented by itself (_do)
            // or _do.Current.Value
            Plot("DerivativeOscillator", "do", _do);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DerivativeOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class DerivativeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DerivativeOscillator _derivativeoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _derivativeoscillator = new DerivativeOscillator(14, 5, 3, 9);
    }

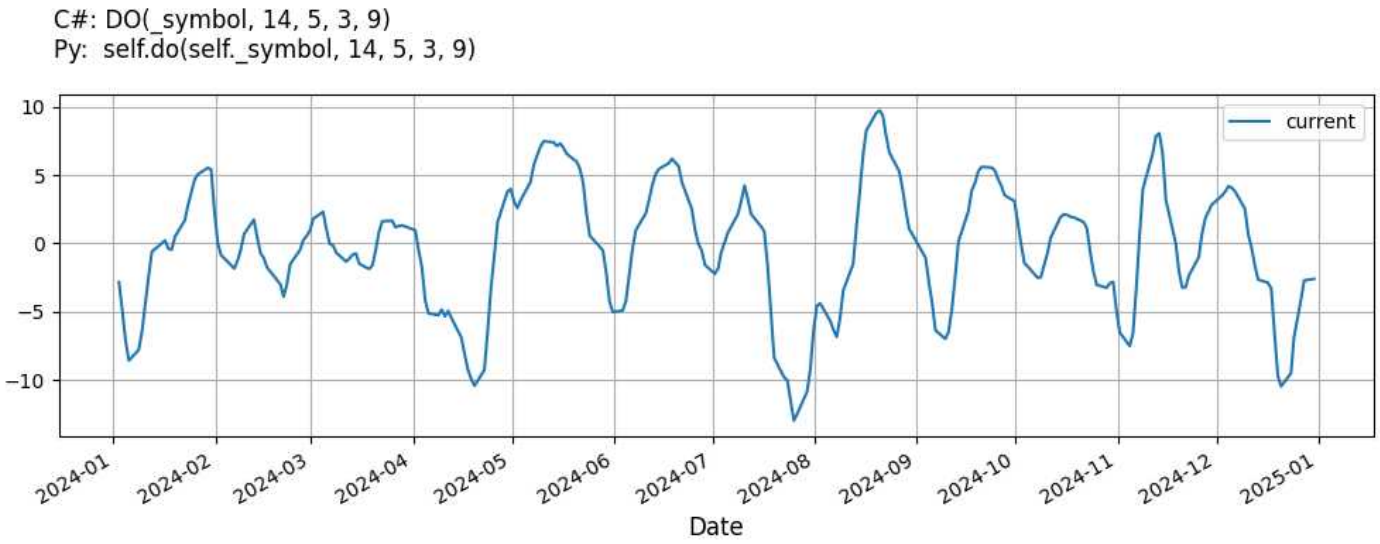
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _derivativeoscillator.Update(bar.EndTime, bar.Close);

        if (_derivativeoscillator.IsReady)
        {
            // The current value of _derivativeoscillator is represented by itself (_derivativeoscillator)
            // or _derivativeoscillator.Current.Value
            Plot("DerivativeOscillator", "derivativeoscillator", _derivativeoscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `DerivativeOscillator` indicator properties:



Indicator History

To get the historical data of the `DerivativeOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class DerivativeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DerivativeOscillator _do;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _do = DO(_symbol, 14, 5, 3, 9);

        var indicatorHistory = IndicatorHistory(_do, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_do, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_do, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Detrended Price Oscillator

Introduction

The Detrended Price Oscillator is an indicator designed to remove trend from price and make it easier to identify cycles. DPO does not extend to the last date because it is based on a displaced moving average. Is estimated as Price {X/2 + 1} periods ago less the X-period simple moving average. E.g.DPO(20) equals price 11 days ago less the 20-day SMA.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DPO Indicator

To create an automatic indicator for `DetrendedPriceOscillator` , call the `DPO` helper method from the `QCAlgorithm` class. The `DPO` method creates a `DetrendedPriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class DetrendedPriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DetrendedPriceOscillator _dpo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dpo = DPO(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_dpo.IsReady)
        {
            // The current value of _dpo is represented by itself (_dpo)
            // or _dpo.Current.Value
            Plot("DetrendedPriceOscillator", "dpo", _dpo);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DetrendedPriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class DetrendedPriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DetrendedPriceOscillator _detrendedpriceoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _detrendedpriceoscillator = new DetrendedPriceOscillator(20);
    }

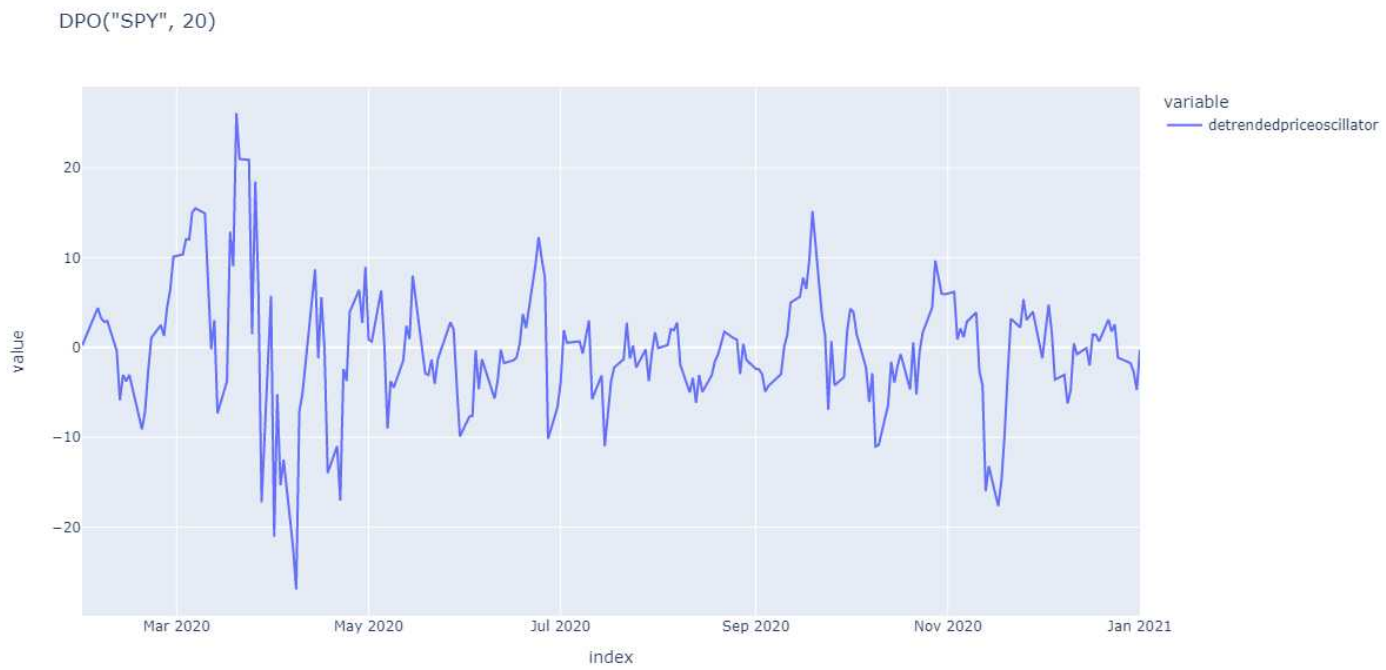
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _detrendedpriceoscillator.Update(bar.EndTime, bar.Close);

        if (_detrendedpriceoscillator.IsReady)
        {
            // The current value of _detrendedpriceoscillator is represented by itself (_detrendedpriceoscillator)
            // or _detrendedpriceoscillator.Current.Value
            Plot("DetrendedPriceOscillator", "detrendedpriceoscillator", _detrendedpriceoscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `DetrendedPriceOscillator` indicator properties:



Indicator History

To get the historical data of the `DetrendedPriceOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class DetrendedPriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DetrendedPriceOscillator _dpo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dpo = DPO(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_dpo, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_dpo, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_dpo, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Donchian Channel

Introduction

This indicator computes the upper and lower band of the Donchian Channel. The upper band is computed by finding the highest high over the given period. The lower band is computed by finding the lowest low over the given period. The primary output value of the indicator is the mean of the upper and lower band for the given timeframe.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DCH Indicator

To create an automatic indicator for `DonchianChannel` , call the `DCH` helper method from the `QCAlgorithm` class. The `DCH` method creates a `DonchianChannel` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class DonchianChannelAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DonchianChannel _dch;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dch = DCH(_symbol, 20, 20);
    }

    public override void OnData(Slice data)
    {

        if (_dch.IsReady)
        {
            // The current value of _dch is represented by itself (_dch)
            // or _dch.Current.Value
            Plot("DonchianChannel", "dch", _dch);
            // Plot all properties of abands
            Plot("DonchianChannel", "upperband", _dch.UpperBand);
            Plot("DonchianChannel", "lowerband", _dch.LowerBand);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DonchianChannel` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class DonchianChannelAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DonchianChannel _donchianchannel;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _donchianchannel = new DonchianChannel(20, 20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _donchianchannel.Update(bar);

        if (_donchianchannel.IsReady)
        {
            // The current value of _donchianchannel is represented by itself (_donchianchannel)
            // or _donchianchannel.Current.Value
            Plot("DonchianChannel", "donchianchannel", _donchianchannel);
            // Plot all properties of abands
            Plot("DonchianChannel", "upperband", _donchianchannel.UpperBand);
            Plot("DonchianChannel", "lowerband", _donchianchannel.LowerBand);
        }
    }
}
```

For more information about this indicator, see its reference .

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dch = DCH(_symbol, 20, 20);

        var indicatorHistory = IndicatorHistory(_dch, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_dch, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_dch, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var upperBand = indicatorHistory.Select(x => ((dynamic)x).UpperBand).ToList();
        var lowerBand = indicatorHistory.Select(x => ((dynamic)x).LowerBand).ToList();
    }
}
```

Supported Indicators

Double Exponential Moving Average

Introduction

This indicator computes the Double Exponential Moving Average (DEMA). The Double Exponential Moving Average is calculated with the following formula: EMA2 = EMA(EMA(t,period),period) DEMA = 2 * EMA(t,period) - EMA2 The Generalized DEMA (GD) is calculated with the following formula: GD = (volumeFactor+1) * EMA(t,period) - volumeFactor * EMA2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using DEMA Indicator

To create an automatic indicator for `DoubleExponentialMovingAverage` , call the `DEMA` helper method from the `QCAlgorithm` class. The `DEMA` method creates a `DoubleExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class DoubleExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DoubleExponentialMovingAverage _dema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dema = DEMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_dema.IsReady)
        {
            // The current value of _dema is represented by itself (_dema)
            // or _dema.Current.Value
            Plot("DoubleExponentialMovingAverage", "dema", _dema);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `DoubleExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class DoubleExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DoubleExponentialMovingAverage _doubleexponentialmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _doubleexponentialmovingaverage = new DoubleExponentialMovingAverage(20);
    }

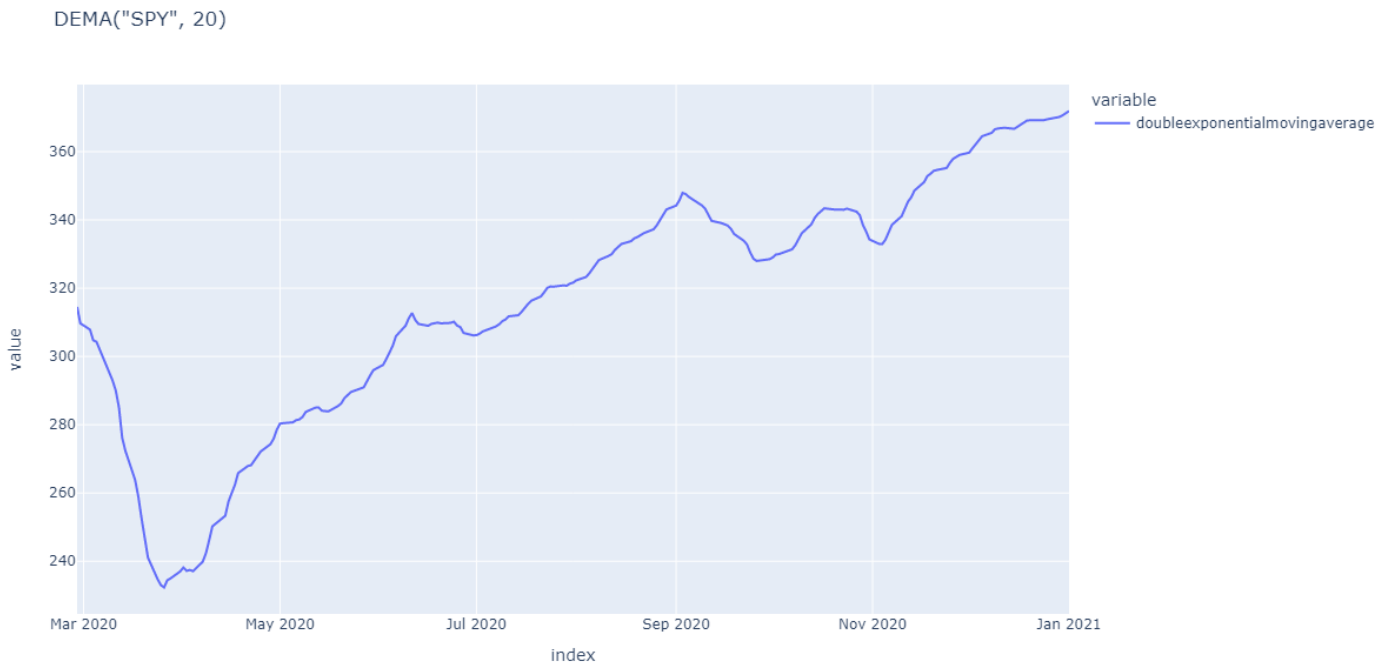
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _doubleexponentialmovingaverage.Update(bar.EndTime, bar.Close);

        if (_doubleexponentialmovingaverage.IsReady)
        {
            // The current value of _doubleexponentialmovingaverage is represented by itself
(_doubleexponentialmovingaverage)
            // or _doubleexponentialmovingaverage.Current.Value
            Plot("DoubleExponentialMovingAverage", "doubleexponentialmovingaverage",
_doubleexponentialmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `DoubleExponentialMovingAverage` indicator properties:



Indicator History

To get the historical data of the `DoubleExponentialMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class DoubleExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DoubleExponentialMovingAverage _dema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dema = DEMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_dema, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_dema, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_dema, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Ease Of Movement Value

Introduction

This indicator computes the n-period Ease of Movement Value using the following: MID = (high_1 + low_1)/2 - (high_0 + low_0)/2 RATIO = (currentVolume/10000) / (high_1 - low_1) EMV = MID/RATIO _SMA = n-period of EMV Returns _SMA source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using EMV Indicator

To create an automatic indicator for `EaseOfMovementValue` , call the `EMV` helper method from the `QCAlgorithm` class. The `EMV` method creates a `EaseOfMovementValue` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class EaseOfMovementValueAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EaseOfMovementValue _emv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _emv = EMV(_symbol, 1, 10000);
    }

    public override void OnData(Slice data)
    {

        if (_emv.IsReady)
        {
            // The current value of _emv is represented by itself (_emv)
            // or _emv.Current.Value
            Plot("EaseOfMovementValue", "emv", _emv);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `EaseOfMovementValue` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class EaseOfMovementValueAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EaseOfMovementValue _easeofmovementvalue;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _easeofmovementvalue = new EaseOfMovementValue(1, 10000);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _easeofmovementvalue.Update(bar);

        if (_easeofmovementvalue.IsReady)
        {
            // The current value of _easeofmovementvalue is represented by itself (_easeofmovementvalue)
            // or _easeofmovementvalue.Current.Value
            Plot("EaseOfMovementValue", "easeofmovementvalue", _easeofmovementvalue);
        }
    }
}
```

For more information about this indicator, see its reference .

C#

```
public class EaseOfMovementValueAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EaseOfMovementValue _emv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _emv = EMV(_symbol, 1, 10000);

        var indicatorHistory = IndicatorHistory(_emv, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_emv, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_emv, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Exponential Moving Average

Introduction

This indicator represents the traditional exponential moving average indicator (EMA). When the indicator is ready, the first value of the EMA is equivalent to the simple moving average. After the first EMA value, the EMA value is a function of the previous EMA value. Therefore, depending on the number of samples you feed into the indicator, it can provide different EMA values for a single security and lookback period. To make the indicator values consistent across time, warm up the indicator with all the trailing security price history.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using EMA Indicator

To create an automatic indicator for `ExponentialMovingAverage` , call the `EMA` helper method from the `QCAlgorithm` class. The `EMA` method creates a `ExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class ExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ema = EMA(_symbol, 20, 0.5m);
    }

    public override void OnData(Slice data)
    {

        if (_ema.IsReady)
        {
            // The current value of _ema is represented by itself (_ema)
            // or _ema.Current.Value
            Plot("ExponentialMovingAverage", "ema", _ema);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ExponentialMovingAverage _exponentialmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _exponentialmovingaverage = new ExponentialMovingAverage(20, 0.5m);
    }

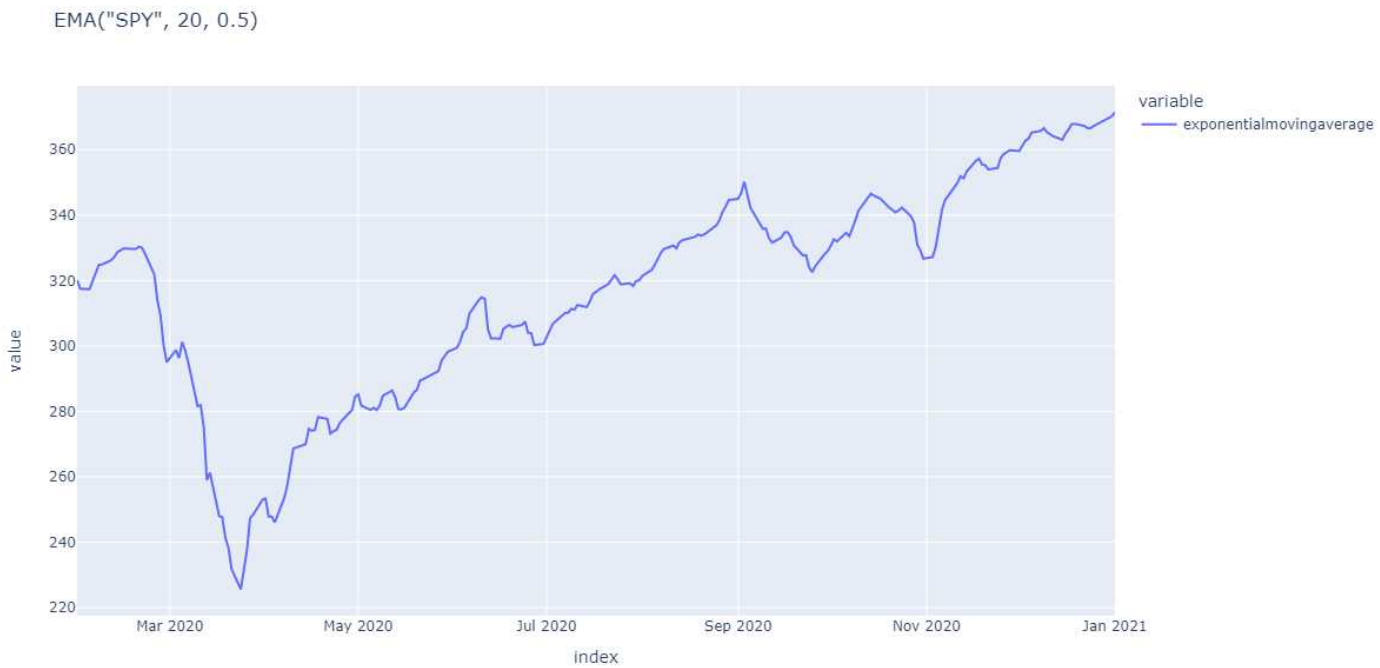
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _exponentialmovingaverage.Update(bar.EndTime, bar.Close);

        if (_exponentialmovingaverage.IsReady)
        {
            // The current value of _exponentialmovingaverage is represented by itself (_exponentialmovingaverage)
            // or _exponentialmovingaverage.Current.Value
            Plot("ExponentialMovingAverage", "exponentialmovingaverage", _exponentialmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ExponentialMovingAverage` indicator properties:



Indicator History

To get the historical data of the `ExponentialMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class ExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ema = EMA(_symbol, 20, 0.5m);

        var indicatorHistory = IndicatorHistory(_ema, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_ema, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_ema, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Filtered Identity

Introduction

This indicator represents an indicator that is a ready after ingesting a single sample and always returns the same value as it is given if it passes a filter condition

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FilteredIdentity Indicator

To create an automatic indicator for `FilteredIdentity` , call the `FilteredIdentity` helper method from the `QCAlgorithm` class. The `FilteredIdentity` method creates a `FilteredIdentity` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class FilteredIdentityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FilteredIdentity _filteredidentity;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _filteredidentity = FilteredIdentity(_symbol, filter: x =>  (x as TradeBar).Close > (x as TradeBar).Open);
    }

    public override void OnData(Slice data)
    {

        if (_filteredidentity.IsReady)
        {
            // The current value of _filteredidentity is represented by itself (_filteredidentity)
            // or _filteredidentity.Current.Value
            Plot("FilteredIdentity", "filteredidentity", _filteredidentity);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `FilteredIdentity` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class FilteredIdentityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FilteredIdentity _filteredidentity;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _filteredidentity = new FilteredIdentity(filter: x =>  (x as TradeBar).Close > (x as TradeBar).Open);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _filteredidentity.Update(bar);

        if (_filteredidentity.IsReady)
        {
            // The current value of _filteredidentity is represented by itself (_filteredidentity)
            // or _filteredidentity.Current.Value
            Plot("FilteredIdentity", "filteredidentity", _filteredidentity);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `FilteredIdentity` indicator properties:

Indicator History

To get the historical data of the `FilteredIdentity` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class FilteredIdentityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FilteredIdentity _filteredidentity;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _filteredidentity = FilteredIdentity(_symbol, filter: x =>  (x as TradeBar).Close > (x as TradeBar).Open);

        var indicatorHistory = IndicatorHistory(_filteredidentity, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_filteredidentity, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_filteredidentity, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Fisher Transform

Introduction

The Fisher transform is a mathematical process which is used to convert any data set to a modified data set whose Probability Distribution Function is approximately Gaussian. Once the Fisher transform is computed, the transformed data can then be analyzed in terms of it's deviation from the mean. The equation is y = .5 * ln [1 + x / 1 - x] where x is the input y is the output ln is the natural logarithm The Fisher transform has much sharper turning points than other indicators such as MACD For more info, read chapter 1 of Cybernetic Analysis for Stocks and Futures by John F. Ehlers We are implementing the latest version of this indicator found at Fig. 4 of http://www.mesasoftware.com/papers/UsingTheFisherTransform.pdf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FISH Indicator

To create an automatic indicator for `FisherTransform` , call the `FISH` helper method from the `QCAlgorithm` class. The `FISH` method creates a `FisherTransform` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class FisherTransformAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FisherTransform _fish;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _fish = FISH(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_fish.IsReady)
        {
            // The current value of _fish is represented by itself (_fish)
            // or _fish.Current.Value
            Plot("FisherTransform", "fish", _fish);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `FisherTransform` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class FisherTransformAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FisherTransform _fishertransform;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _fishertransform = new FisherTransform(20);
    }

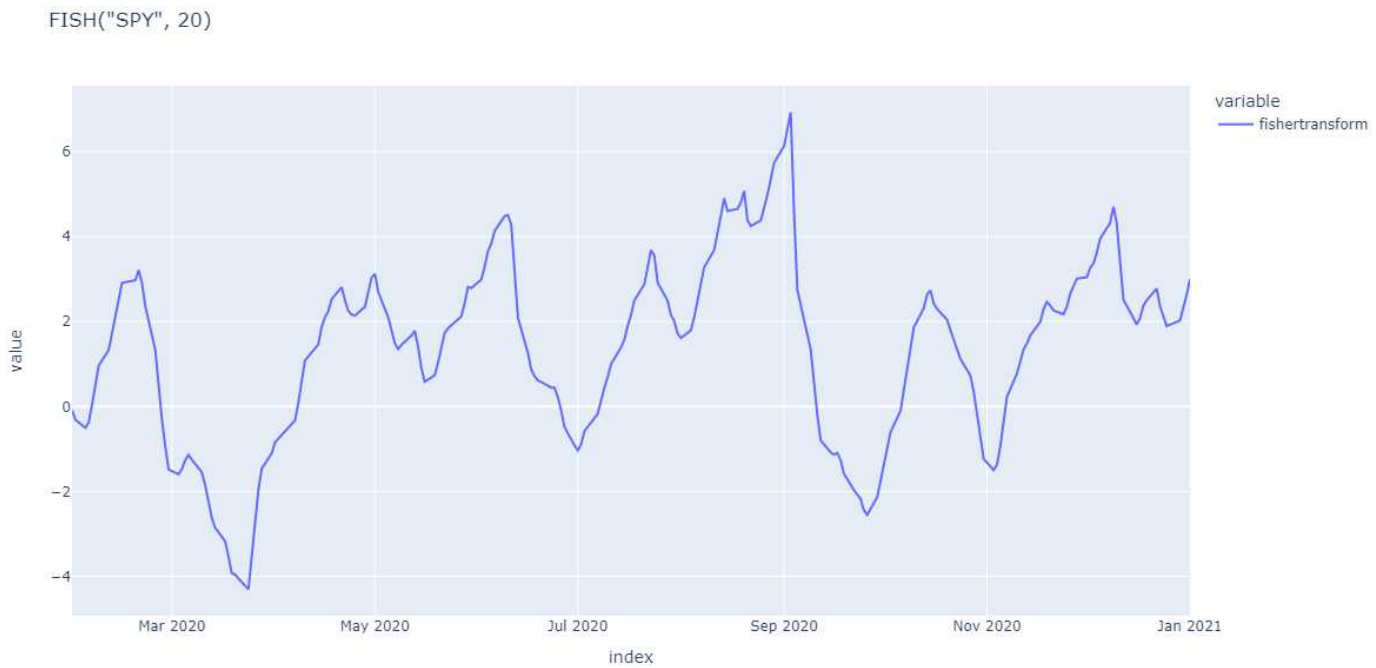
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _fishertransform.Update(bar);

        if (_fishertransform.IsReady)
        {
            // The current value of _fishertransform is represented by itself (_fishertransform)
            // or _fishertransform.Current.Value
            Plot("FisherTransform", "fishertransform", _fishertransform);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `FisherTransform` indicator properties:



Indicator History

To get the historical data of the `FisherTransform` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class FisherTransformAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FisherTransform _fish;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _fish = FISH(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_fish, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_fish, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_fish, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Force Index

Introduction

The Force Index is calculated by comparing the current market price with the previous market price and multiplying its difference with the traded volume during a specific time period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FI Indicator

To create an automatic indicator for `ForceIndex` , call the `FI` helper method from the `QCAlgorithm` class. The `FI` method creates a `ForceIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ForceIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ForceIndex _fi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _fi = FI(_symbol, 13);
    }

    public override void OnData(Slice data)
    {

        if (_fi.IsReady)
        {
            // The current value of _fi is represented by itself (_fi)
            // or _fi.Current.Value
            Plot("ForceIndex", "fi", _fi);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ForceIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

public class ForceIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ForceIndex _forceindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _forceindex = new ForceIndex(13);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _forceindex.Update(bar);

        if (_forceindex.IsReady)
        {
            // The current value of _forceindex is represented by itself (_forceindex)
            // or _forceindex.Current.Value
            Plot("ForceIndex", "forceindex", _forceindex);
        }
    }
}
```

For more information about this indicator, see its reference .

Fractal Adaptive Moving Average

Introduction

The Fractal Adaptive Moving Average (FRAMA) by John Ehlers

To view the implementation of this indicator, see the LEAN GitHub repository .

Using FRAMA Indicator

To create an automatic indicator for `FractalAdaptiveMovingAverage` , call the `FRAMA` helper method from the `QCAlgorithm` class. The `FRAMA` method creates a `FractalAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class FractalAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FractalAdaptiveMovingAverage _frama;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _frama = FRAMA(_symbol, 20, 198);
    }

    public override void OnData(Slice data)
    {

        if (_frama.IsReady)
        {
            // The current value of _frama is represented by itself (_frama)
            // or _frama.Current.Value
            Plot("FractalAdaptiveMovingAverage", "frama", _frama);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `FractalAdaptiveMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class FractalAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FractalAdaptiveMovingAverage _fractaladaptivemovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _fractaladaptivemovingaverage = new FractalAdaptiveMovingAverage(20, 198);
    }

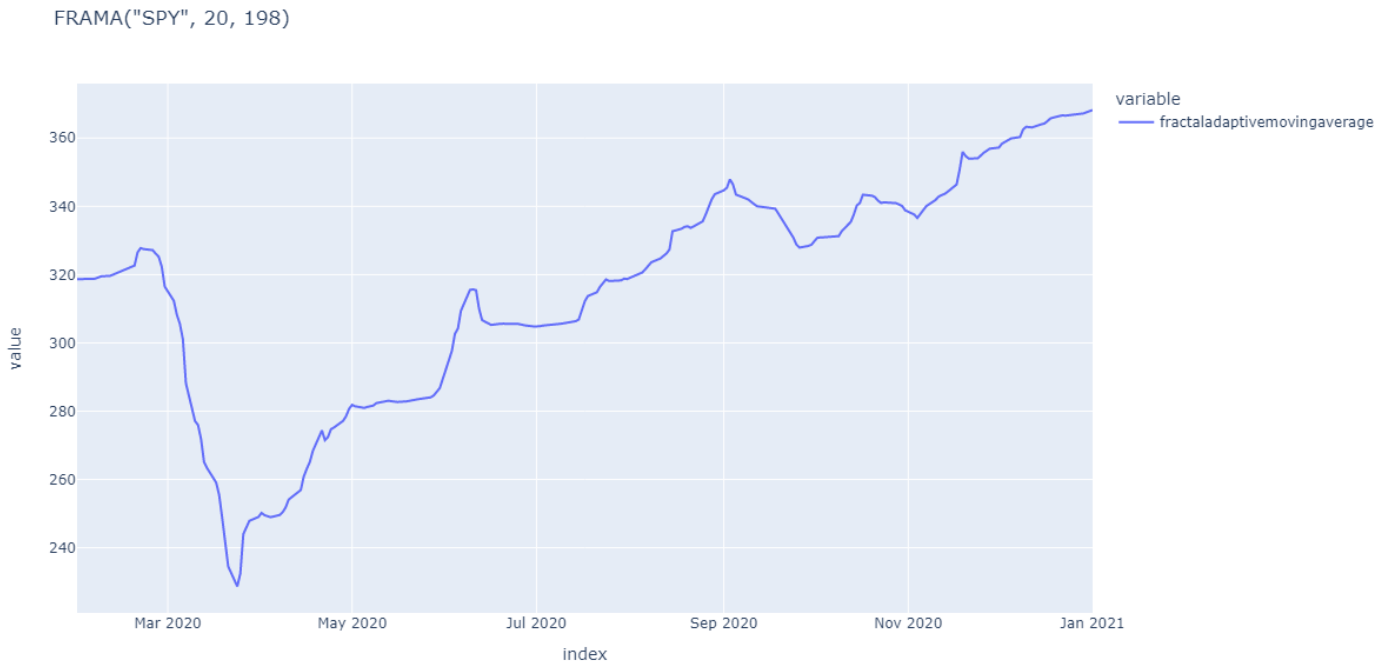
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _fractaladaptivemovingaverage.Update(bar);

        if (_fractaladaptivemovingaverage.IsReady)
        {
            // The current value of _fractaladaptivemovingaverage is represented by itself
(_fractaladaptivemovingaverage)
            // or _fractaladaptivemovingaverage.Current.Value
            Plot("FractalAdaptiveMovingAverage", "fractaladaptivemovingaverage", _fractaladaptivemovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `FractalAdaptiveMovingAverage` indicator properties:



Indicator History

To get the historical data of the `FractalAdaptiveMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class FractalAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private FractalAdaptiveMovingAverage _frama;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _frama = FRAMA(_symbol, 20, 198);

        var indicatorHistory = IndicatorHistory(_frama, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_frama, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_frama, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Gamma

Introduction

Option Gamma indicator that calculate the gamma of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using G Indicator

To create an automatic indicator for `Gamma` , call the `G` helper method from the `QCAlgorithm` class. The `G` method creates a `Gamma` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class GammaAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Gamma _g;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _g = G(_option, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (_g.IsReady)
        {
            // The current value of _g is represented by itself (_g)
            // or _g.Current.Value
            Plot("Gamma", "g", _g);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Gamma` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class GammaAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Gamma _gamma;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        var interestRateModel = new InterestRateProvider();
        var dividendYieldModel = new DividendYieldProvider(_symbol);

        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _gamma = new Gamma(_option, interestRateModel, dividendYieldModel, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _gamma.Update(new IndicatorDataPoint(_symbol, bar.EndTime, bar.Close));
        if (data.QuoteBars.TryGetValue(_option, out var quoteBar))
            _gamma.Update(new IndicatorDataPoint(_option, quoteBar.EndTime, quoteBar.Close));
        if (data.QuoteBars.TryGetValue(_mirrorOption, out quoteBar))
            _gamma.Update(new IndicatorDataPoint(_mirrorOption, quoteBar.EndTime, quoteBar.Close));

        if (_gamma.IsReady)
        {
            // The current value of _gamma is represented by itself (_gamma)
            // or _gamma.Current.Value
            Plot("Gamma", "gamma", _gamma);
        }
    }
}
```

For more information about this indicator, see its reference .

Heikin Ashi

Introduction

This indicator computes the Heikin-Ashi bar (HA) The Heikin-Ashi bar is calculated using the following formulas: HA_Close[0] = (Open[0] + High[0] + Low[0] + Close[0]) / 4 HA_Open[0] = (HA_Open[1] + HA_Close[1]) / 2 HA_High[0] = MAX(High[0], HA_Open[0], HA_Close[0]) HA_Low[0] = MIN(Low[0], HA_Open[0], HA_Close[0])

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HeikinAshi Indicator

To create an automatic indicator for `HeikinAshi` , call the `HeikinAshi` helper method from the `QCAlgorithm` class. The `HeikinAshi` method creates a `HeikinAshi` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class HeikinAshiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HeikinAshi _heikinashi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _heikinashi = HeikinAshi(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_heikinashi.IsReady)
        {
            // The current value of _heikinashi is represented by itself (_heikinashi)
            // or _heikinashi.Current.Value
            Plot("HeikinAshi", "heikinashi", _heikinashi);
            // Plot all properties of abands
            Plot("HeikinAshi", "open", _heikinashi.Open);
            Plot("HeikinAshi", "high", _heikinashi.High);
            Plot("HeikinAshi", "low", _heikinashi.Low);
            Plot("HeikinAshi", "close", _heikinashi.Close);
            Plot("HeikinAshi", "volume", _heikinashi.Volume);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HeikinAshi` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
```

```
public class HeikinAshiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HeikinAshi _heikinashi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _heikinashi = new HeikinAshi();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _heikinashi.Update(bar);

        if (_heikinashi.IsReady)
        {
            // The current value of _heikinashi is represented by itself (_heikinashi)
            // or _heikinashi.Current.Value
            Plot("HeikinAshi", "heikinashi", _heikinashi);
            // Plot all properties of abands
            Plot("HeikinAshi", "open", _heikinashi.Open);
            Plot("HeikinAshi", "high", _heikinashi.High);
            Plot("HeikinAshi", "low", _heikinashi.Low);
            Plot("HeikinAshi", "close", _heikinashi.Close);
            Plot("HeikinAshi", "volume", _heikinashi.Volume);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `HeikinAshi` indicator properties:

Indicator History

To get the historical data of the `HeikinAshi` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period

of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class HeikinAshiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HeikinAshi _heikinashi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _heikinashi = HeikinAshi(_symbol);

        var indicatorHistory = IndicatorHistory(_heikinashi, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_heikinashi, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_heikinashi, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var open = indicatorHistory.Select(x => ((dynamic)x).Open).ToList();
        var high = indicatorHistory.Select(x => ((dynamic)x).High).ToList();
        var low = indicatorHistory.Select(x => ((dynamic)x).Low).ToList();
        var close = indicatorHistory.Select(x => ((dynamic)x).Close).ToList();
        var volume = indicatorHistory.Select(x => ((dynamic)x).Volume).ToList();
    }

Supported Indicators

Hilbert Transform

Introduction

This indicator computes the Hilbert Transform Indicator by John Ehlers. By using present and prior price differences, and some feedback, price values are split into their complex number components of real (inPhase) and imaginary (quadrature) parts. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HT Indicator

To create an automatic indicator for `HilbertTransform` , call the `HT` helper method from the `QCAlgorithm` class. The `HT` method creates a `HilbertTransform` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class HilbertTransformAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HilbertTransform _ht;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ht = HT(_symbol, 7, 0.635m, 0.338m);
    }

    public override void OnData(Slice data)
    {

        if (_ht.IsReady)
        {
            // The current value of _ht is represented by itself (_ht)
            // or _ht.Current.Value
            Plot("HilbertTransform", "ht", _ht);
            // Plot all properties of abands
            Plot("HilbertTransform", "inphase", _ht.InPhase);
            Plot("HilbertTransform", "quadrature", _ht.Quadrature);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HilbertTransform` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class HilbertTransformAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HilbertTransform _hilberttransform;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hilberttransform = new HilbertTransform(7, 0.635m, 0.338m);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _hilberttransform.Update(bar.EndTime, bar.Close);

        if (_hilberttransform.IsReady)
        {
            // The current value of _hilberttransform is represented by itself (_hilberttransform)
            // or _hilberttransform.Current.Value
            Plot("HilbertTransform", "hilberttransform", _hilberttransform);
            // Plot all properties of abands
            Plot("HilbertTransform", "inphase", _hilberttransform.InPhase);
            Plot("HilbertTransform", "quadrature", _hilberttransform.Quadrature);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `HilbertTransform` indicator properties:

Indicator History

To get the historical data of the `HilbertTransform` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class HilbertTransformAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HilbertTransform _ht;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ht = HT(_symbol, 7, 0.635m, 0.338m);

        var indicatorHistory = IndicatorHistory(_ht, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_ht, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_ht, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var inPhase = indicatorHistory.Select(x => ((dynamic)x).InPhase).ToList();
        var quadrature = indicatorHistory.Select(x => ((dynamic)x).Quadrature).ToList();
    }
}
```

Supported Indicators

Hull Moving Average

Introduction

Produces a Hull Moving Average as explained at http://www.alanhull.com/hull-moving-average/ and derived from the instructions for the Excel VBA code at http://finance4traders.blogspot.com/2009/06/how-to-calculate-hull-moving-average.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HMA Indicator

To create an automatic indicator for `HullMovingAverage` , call the `HMA` helper method from the `QCAlgorithm` class. The `HMA` method creates a `HullMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class HullMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HullMovingAverage _hma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hma = HMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_hma.IsReady)
        {
            // The current value of _hma is represented by itself (_hma)
            // or _hma.Current.Value
            Plot("HullMovingAverage", "hma", _hma);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HullMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class HullMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HullMovingAverage _hullmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hullmovingaverage = new HullMovingAverage(20);
    }

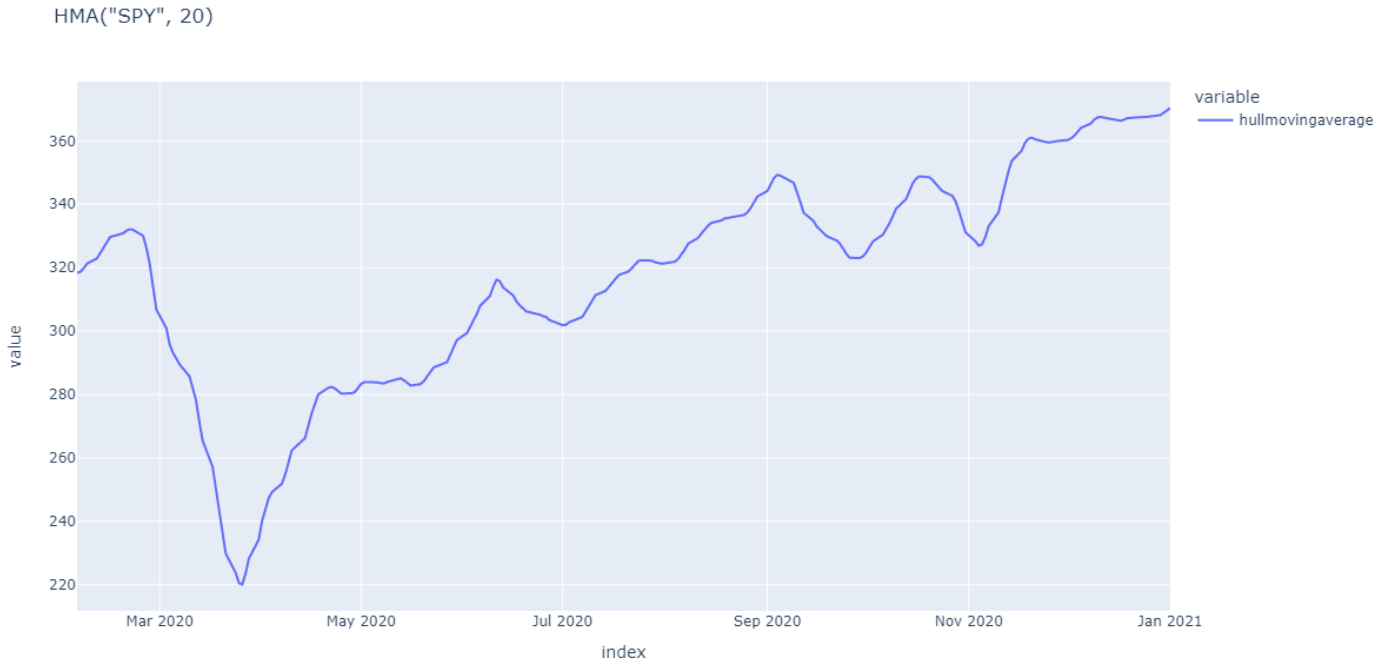
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _hullmovingaverage.Update(bar.EndTime, bar.Close);

        if (_hullmovingaverage.IsReady)
        {
            // The current value of _hullmovingaverage is represented by itself (_hullmovingaverage)
            // or _hullmovingaverage.Current.Value
            Plot("HullMovingAverage", "hullmovingaverage", _hullmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `HullMovingAverage` indicator properties:



Indicator History

To get the historical data of the `HullMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class HullMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HullMovingAverage _hma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hma = HMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_hma, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_hma, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_hma, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Hurst Exponent

Introduction

This indicator represents the Hurst Exponent indicator, which is used to measure the long-term memory of a time series. - H less than 0.5: Mean-reverting; high values followed by low ones, stronger as H approaches 0. - H equal to 0.5: Random walk (geometric). - H greater than 0.5: Trending; high values followed by higher ones, stronger as H approaches 1.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using HE Indicator

To create an automatic indicator for `HurstExponent` , call the `HE` helper method from the `QCAlgorithm` class. The `HE` method creates a `HurstExponent` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class HurstExponentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HurstExponent _he;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _he = HE(_symbol, 32);
    }

    public override void OnData(Slice data)
    {

        if (_he.IsReady)
        {
            // The current value of _he is represented by itself (_he)
            // or _he.Current.Value
            Plot("HurstExponent", "he", _he);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `HurstExponent` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class HurstExponentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HurstExponent _hurstexponent;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hurstexponent = new HurstExponent(32);
    }

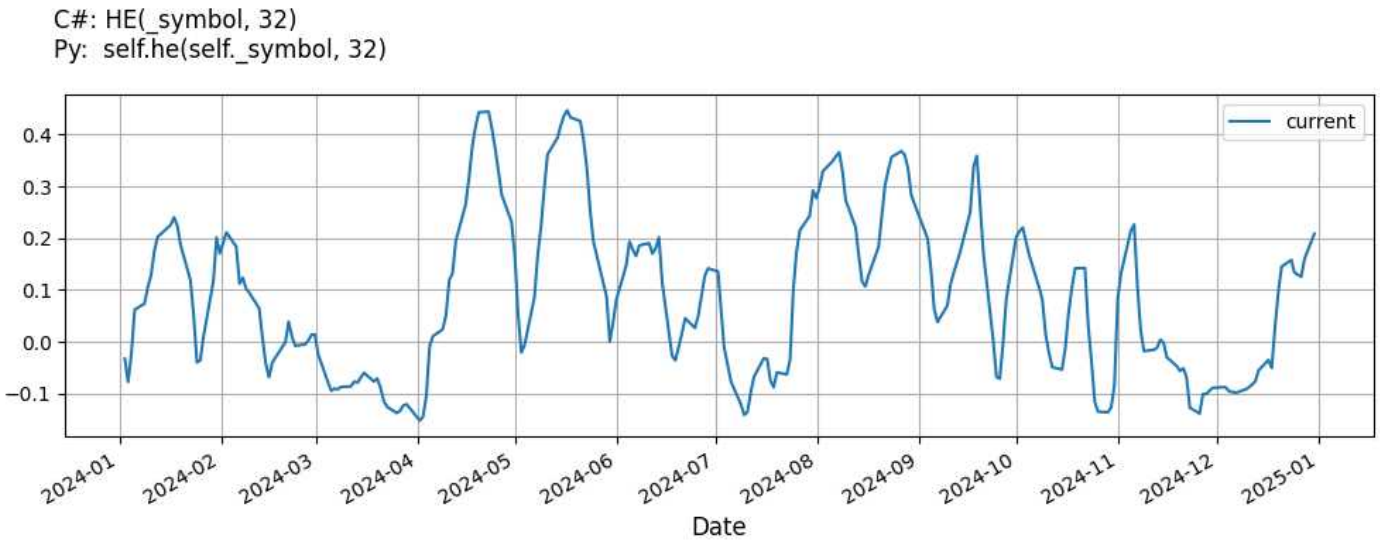
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _hurstexponent.Update(bar.EndTime, bar.Close);

        if (_hurstexponent.IsReady)
        {
            // The current value of _hurstexponent is represented by itself (_hurstexponent)
            // or _hurstexponent.Current.Value
            Plot("HurstExponent", "hurstexponent", _hurstexponent);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `HurstExponent` indicator properties:



Indicator History

To get the historical data of the `HurstExponent` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class HurstExponentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HurstExponent _he;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _he = HE(_symbol, 32);

        var indicatorHistory = IndicatorHistory(_he, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_he, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_he, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Ichimoku Kinko Hyo

Introduction

This indicator computes the Ichimoku Kinko Hyo indicator. It consists of the following main indicators: Tenkan-sen: (Highest High + Lowest Low) / 2 for the specific period (normally 9) Kijun-sen: (Highest High + Lowest Low) / 2 for the specific period (normally 26) Senkou A Span: (Tenkan-sen + Kijun-sen)/ 2 from a specific number of periods ago (normally 26) Senkou B Span: (Highest High + Lowest Low) / 2 for the specific period (normally 52), from a specific number of periods ago (normally 26)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ICHIMOKU Indicator

To create an automatic indicator for `IchimokuKinkoHyo` , call the `ICHIMOKU` helper method from the `QCAlgorithm` class. The `ICHIMOKU` method creates a `IchimokuKinkoHyo` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class IchimokuKinkoHyoAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private IchimokuKinkoHyo _ichimoku;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ichimoku = ICHIMOKU(_symbol, 9, 26, 17, 52, 26, 26);
    }

    public override void OnData(Slice data)
    {

        if (_ichimoku.IsReady)
        {
            // The current value of _ichimoku is represented by itself (_ichimoku)
            // or _ichimoku.Current.Value
            Plot("IchimokuKinkoHyo", "ichimoku", _ichimoku);
            // Plot all properties of abands
            Plot("IchimokuKinkoHyo", "tenkan", _ichimoku.Tenkan);
            Plot("IchimokuKinkoHyo", "kijun", _ichimoku.Kijun);
            Plot("IchimokuKinkoHyo", "senkoua", _ichimoku.SenkouA);
            Plot("IchimokuKinkoHyo", "senkoub", _ichimoku.SenkouB);
            Plot("IchimokuKinkoHyo", "chikou", _ichimoku.Chikou);
            Plot("IchimokuKinkoHyo", "tenkanmaximum", _ichimoku.TenkanMaximum);
            Plot("IchimokuKinkoHyo", "tenkanminimum", _ichimoku.TenkanMinimum);
            Plot("IchimokuKinkoHyo", "kijunmaximum", _ichimoku.KijunMaximum);
            Plot("IchimokuKinkoHyo", "kijunminimum", _ichimoku.KijunMinimum);
            Plot("IchimokuKinkoHyo", "senkoubmaximum", _ichimoku.SenkouBMaximum);
            Plot("IchimokuKinkoHyo", "senkoubminimum", _ichimoku.SenkouBMinimum);
            Plot("IchimokuKinkoHyo", "delayedtenkansenkoua", _ichimoku.DelayedTenkanSenkouA);
            Plot("IchimokuKinkoHyo", "delayedkijunsenkoua", _ichimoku.DelayedKijunSenkouA);
            Plot("IchimokuKinkoHyo", "delayedmaximumsenkoub", _ichimoku.DelayedMaximumSenkouB);
            Plot("IchimokuKinkoHyo", "delayedminimumsenkoub", _ichimoku.DelayedMinimumSenkouB);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `IchimokuKinkoHyo` indicator, so it doesn't automatically update. Manual indicators let you update

their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class IchimokuKinkoHyoAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private IchimokuKinkoHyo _ichimokukinkohyo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ichimokukinkohyo = new IchimokuKinkoHyo(9, 26, 17, 52, 26, 26);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _ichimokukinkohyo.Update(bar);

        if (_ichimokukinkohyo.IsReady)
        {
            // The current value of _ichimokukinkohyo is represented by itself (_ichimokukinkohyo)
            // or _ichimokukinkohyo.Current.Value
            Plot("IchimokuKinkoHyo", "ichimokukinkohyo", _ichimokukinkohyo);
            // Plot all properties of abands
            Plot("IchimokuKinkoHyo", "tenkan", _ichimokukinkohyo.Tenkan);
            Plot("IchimokuKinkoHyo", "kijun", _ichimokukinkohyo.Kijun);
            Plot("IchimokuKinkoHyo", "senkoua", _ichimokukinkohyo.SenkouA);
            Plot("IchimokuKinkoHyo", "senkoub", _ichimokukinkohyo.SenkouB);
            Plot("IchimokuKinkoHyo", "chikou", _ichimokukinkohyo.Chikou);
            Plot("IchimokuKinkoHyo", "tenkanmaximum", _ichimokukinkohyo.TenkanMaximum);
            Plot("IchimokuKinkoHyo", "tenkanminimum", _ichimokukinkohyo.TenkanMinimum);
            Plot("IchimokuKinkoHyo", "kijunmaximum", _ichimokukinkohyo.KijunMaximum);
            Plot("IchimokuKinkoHyo", "kijunminimum", _ichimokukinkohyo.KijunMinimum);
            Plot("IchimokuKinkoHyo", "senkoubmaximum", _ichimokukinkohyo.SenkouBMaximum);
            Plot("IchimokuKinkoHyo", "senkoubminimum", _ichimokukinkohyo.SenkouBMinimum);
            Plot("IchimokuKinkoHyo", "delayedtenkansenkoua", _ichimokukinkohyo.DelayedTenkanSenkouA);
            Plot("IchimokuKinkoHyo", "delayedkijunsenkoua", _ichimokukinkohyo.DelayedKijunSenkouA);
            Plot("IchimokuKinkoHyo", "delayedmaximumsenkoub", _ichimokukinkohyo.DelayedMaximumSenkouB);
            Plot("IchimokuKinkoHyo", "delayedminimumsenkoub", _ichimokukinkohyo.DelayedMinimumSenkouB);
        }
    }
}
```

        var delayedMaximumSenkouB = indicatorHistory.Select(x => ((dynamic)x).DelayedMaximumSenkouB).ToList();
        var delayedMinimumSenkouB = indicatorHistory.Select(x => ((dynamic)x).DelayedMinimumSenkouB).ToList();
    }
}
```

Supported Indicators

Identity

Introduction

This indicator represents an indicator that is a ready after ingesting a single sample and always returns the same value as it is given.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using Identity Indicator

To create an automatic indicator for `Identity` , call the `Identity` helper method from the `QCAlgorithm` class. The `Identity` method creates a `Identity` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class IdentityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Identity _identity;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _identity = Identity(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_identity.IsReady)
        {
            // The current value of _identity is represented by itself (_identity)
            // or _identity.Current.Value
            Plot("Identity", "identity", _identity);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Identity` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class IdentityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Identity _identity;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _identity = new Identity();
    }

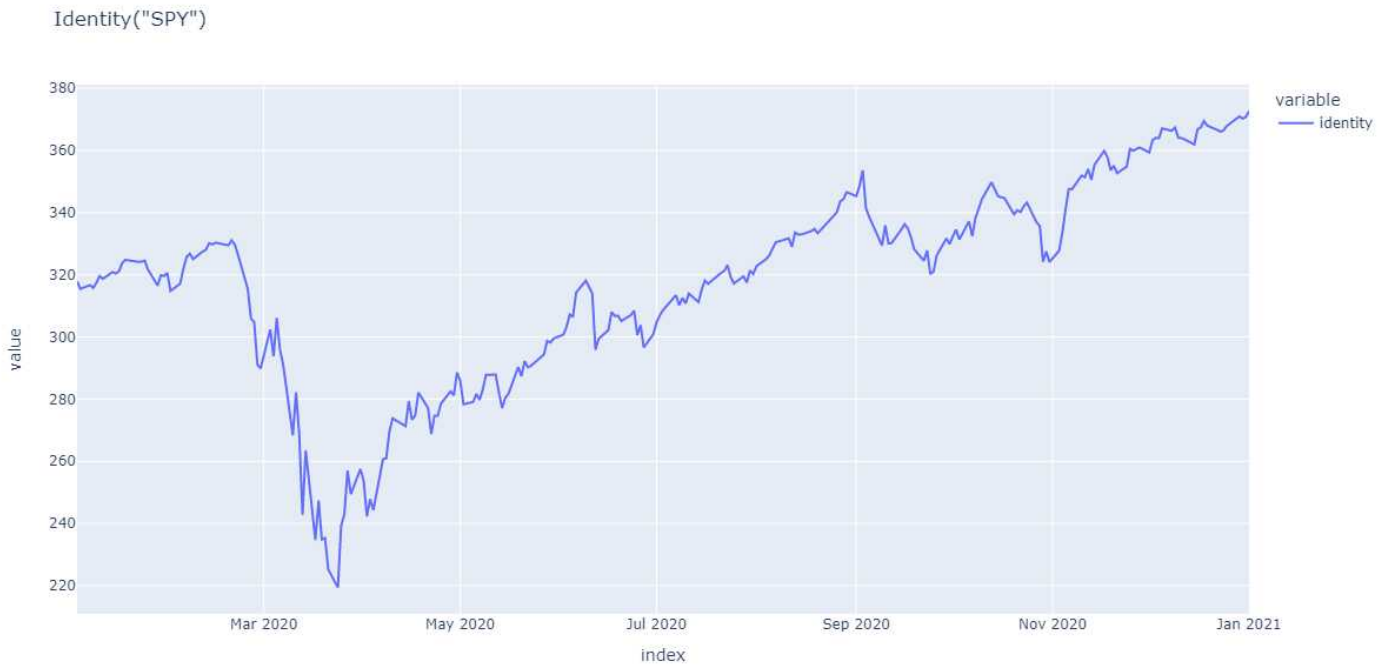
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _identity.Update(bar.EndTime, bar.Close);

        if (_identity.IsReady)
        {
            // The current value of _identity is represented by itself (_identity)
            // or _identity.Current.Value
            Plot("Identity", "identity", _identity);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Identity` indicator properties:



Indicator History

To get the historical data of the `Identity` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class IdentityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Identity _identity;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _identity = Identity(_symbol);

        var indicatorHistory = IndicatorHistory(_identity, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_identity, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_identity, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Implied Volatility

Introduction

Implied Volatility indicator that calculate the IV of an option using Black-Scholes Model

To view the implementation of this indicator, see the LEAN GitHub repository .

Using IV Indicator

To create an automatic indicator for `ImpliedVolatility` , call the `IV` helper method from the `QCAlgorithm` class. The `IV` method creates a `ImpliedVolatility` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ImpliedVolatilityAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private ImpliedVolatility _iv;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _iv = IV(_option, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (_iv.IsReady)
        {
            // The current value of _iv is represented by itself (_iv)
            // or _iv.Current.Value
            Plot("ImpliedVolatility", "iv", _iv);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ImpliedVolatility` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ImpliedVolatilityAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private ImpliedVolatility _impliedvolatility;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        var interestRateModel = new InterestRateProvider();
        var dividendYieldModel = new DividendYieldProvider(_symbol);

        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _impliedvolatility = new ImpliedVolatility(_option, interestRateModel, dividendYieldModel, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _impliedvolatility.Update(new IndicatorDataPoint(_symbol, bar.EndTime, bar.Close));
        if (data.QuoteBars.TryGetValue(_option, out var quoteBar))
            _impliedvolatility.Update(new IndicatorDataPoint(_option, quoteBar.EndTime, quoteBar.Close));
        if (data.QuoteBars.TryGetValue(_mirrorOption, out quoteBar))
            _impliedvolatility.Update(new IndicatorDataPoint(_mirrorOption, quoteBar.EndTime, quoteBar.Close));

        if (_impliedvolatility.IsReady)
        {
            // The current value of _impliedvolatility is represented by itself (_impliedvolatility)
            // or _impliedvolatility.Current.Value
            Plot("ImpliedVolatility", "impliedvolatility", _impliedvolatility);
        }
    }
}
```

For more information about this indicator, see its reference .

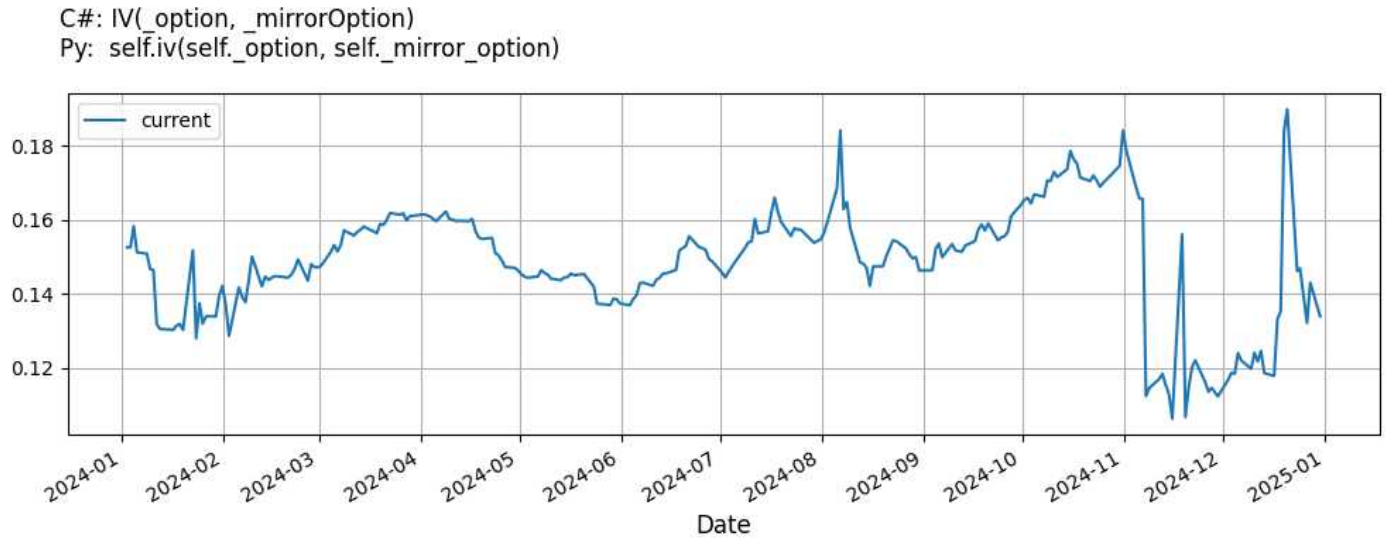
The following plot shows values for some of the `ImpliedVolatility` indicator properties:



Indicator History

To get the historical data of the `ImpliedVolatility` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the

`IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class ImpliedVolatilityAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private ImpliedVolatility _iv;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _iv = IV(_option, _mirrorOption);

        var indicatorHistory = IndicatorHistory(_iv, new[] { _symbol, _option, _mirrorOption }, 100,
Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_iv, new[] { _symbol, _option, _mirrorOption },
TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_iv, new[] { _symbol, _option, _mirrorOption }, new
DateTime(2024, 7, 1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Internal Bar Strength

Introduction

The InternalBarStrenght indicator is a measure of the relative position of a period's closing price to the same period's high and low. The IBS can be interpreted to predict a bullish signal when displaying a low value and a bearish signal when presenting a high value.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using IBS Indicator

To create an automatic indicator for `InternalBarStrength` , call the `IBS` helper method from the `QCAlgorithm` class. The `IBS` method creates a `InternalBarStrength` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class InternalBarStrengthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InternalBarStrength _ibs;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ibs = IBS(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_ibs.IsReady)
        {
            // The current value of _ibs is represented by itself (_ibs)
            // or _ibs.Current.Value
            Plot("InternalBarStrength", "ibs", _ibs);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `InternalBarStrength` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class InternalBarStrengthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InternalBarStrength _internalbarstrength;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _internalbarstrength = new InternalBarStrength();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _internalbarstrength.Update(bar);

        if (_internalbarstrength.IsReady)
        {
            // The current value of _internalbarstrength is represented by itself (_internalbarstrength)
            // or _internalbarstrength.Current.Value
            Plot("InternalBarStrength", "internalbarstrength", _internalbarstrength);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Intraday Vwap

Introduction

Defines the canonical intraday VWAP indicator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWAP Indicator

To create an automatic indicator for `IntradayVwap` , call the `VWAP` helper method from the `QCAlgorithm` class. The `VWAP` method creates a `IntradayVwap` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class IntradayVwapAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private IntradayVwap _vwap;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Minute).Symbol;
        _vwap = VWAP(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_vwap.IsReady)
        {
            // The current value of _vwap is represented by itself (_vwap)
            // or _vwap.Current.Value
            Plot("IntradayVwap", "vwap", _vwap);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `IntradayVwap` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class IntradayVwapAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private IntradayVwap _intradayvwap;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Minute).Symbol;
        _intradayvwap = new IntradayVwap();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _intradayvwap.Update(bar);

        if (_intradayvwap.IsReady)
        {
            // The current value of _intradayvwap is represented by itself (_intradayvwap)
            // or _intradayvwap.Current.Value
            Plot("IntradayVwap", "intradayvwap", _intradayvwap);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `IntradayVwap` indicator properties:

Indicator History

To get the historical data of the `IntradayVwap` indicator, call the `IndicatorHistory` method. Kaufman Adaptive Moving Average

Introduction

This indicator computes the Kaufman Adaptive Moving Average (KAMA). The Kaufman Adaptive Moving Average is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:kaufman_s_adaptive_moving_average

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KAMA Indicator

To create an automatic indicator for `KaufmanAdaptiveMovingAverage` , call the `KAMA` helper method from the `QCAlgorithm` class. The `KAMA` method creates a `KaufmanAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class KaufmanAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KaufmanAdaptiveMovingAverage _kama;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kama = KAMA(_symbol, 20, 10, 20);
    }

    public override void OnData(Slice data)
    {

        if (_kama.IsReady)
        {
            // The current value of _kama is represented by itself (_kama)
            // or _kama.Current.Value
            Plot("KaufmanAdaptiveMovingAverage", "kama", _kama);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KaufmanAdaptiveMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class KaufmanAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KaufmanAdaptiveMovingAverage _kaufmanadaptivemovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kaufmanadaptivemovingaverage = new KaufmanAdaptiveMovingAverage(20, 10, 20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _kaufmanadaptivemovingaverage.Update(bar.EndTime, bar.Close);

        if (_kaufmanadaptivemovingaverage.IsReady)
        {
            // The current value of _kaufmanadaptivemovingaverage is represented by itself
(_kaufmanadaptivemovingaverage)
            // or _kaufmanadaptivemovingaverage.Current.Value
            Plot("KaufmanAdaptiveMovingAverage", "kaufmanadaptivemovingaverage", _kaufmanadaptivemovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Kaufman Efficiency Ratio

Introduction

This indicator computes the Kaufman Efficiency Ratio (KER). The Kaufman Efficiency Ratio is calculated as explained here: https://www.marketvolume.com/technicalanalysis/efficiencyratio.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KER Indicator

To create an automatic indicator for `KaufmanEfficiencyRatio` , call the `KER` helper method from the `QCAlgorithm` class. The `KER` method creates a `KaufmanEfficiencyRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class KaufmanEfficiencyRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KaufmanEfficiencyRatio _ker;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ker = KER(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_ker.IsReady)
        {
            // The current value of _ker is represented by itself (_ker)
            // or _ker.Current.Value
            Plot("KaufmanEfficiencyRatio", "ker", _ker);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KaufmanEfficiencyRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class KaufmanEfficiencyRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KaufmanEfficiencyRatio _kaufmanefficiencyratio;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kaufmanefficiencyratio = new KaufmanEfficiencyRatio(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _kaufmanefficiencyratio.Update(bar.EndTime, bar.Close);

        if (_kaufmanefficiencyratio.IsReady)
        {
            // The current value of _kaufmanefficiencyratio is represented by itself (_kaufmanefficiencyratio)
            // or _kaufmanefficiencyratio.Current.Value
            Plot("KaufmanEfficiencyRatio", "kaufmanefficiencyratio", _kaufmanefficiencyratio);
        }
    }
}
```

For more information about this indicator, see its reference .

Keltner Channels

Introduction

This indicator creates a moving average (middle band) with an upper band and lower band fixed at k average True range multiples away from the middle band.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KCH Indicator

To create an automatic indicator for `KeltnerChannels` , call the `KCH` helper method from the `QCAlgorithm` class. The `KCH` method creates a `KeltnerChannels` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class KeltnerChannelsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KeltnerChannels _kch;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kch = KCH(_symbol, 20, 2, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_kch.IsReady)
        {
            // The current value of _kch is represented by itself (_kch)
            // or _kch.Current.Value
            Plot("KeltnerChannels", "kch", _kch);
            // Plot all properties of abands
            Plot("KeltnerChannels", "middleband", _kch.MiddleBand);
            Plot("KeltnerChannels", "upperband", _kch.UpperBand);
            Plot("KeltnerChannels", "lowerband", _kch.LowerBand);
            Plot("KeltnerChannels", "averagetruerange", _kch.AverageTrueRange);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KeltnerChannels` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class KeltnerChannelsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KeltnerChannels _keltnerchannels;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _keltnerchannels = new KeltnerChannels(20, 2, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _keltnerchannels.Update(bar);

        if (_keltnerchannels.IsReady)
        {
            // The current value of _keltnerchannels is represented by itself (_keltnerchannels)
            // or _keltnerchannels.Current.Value
            Plot("KeltnerChannels", "keltnerchannels", _keltnerchannels);
            // Plot all properties of abands
            Plot("KeltnerChannels", "middleband", _keltnerchannels.MiddleBand);
            Plot("KeltnerChannels", "upperband", _keltnerchannels.UpperBand);
            Plot("KeltnerChannels", "lowerband", _keltnerchannels.LowerBand);
            Plot("KeltnerChannels", "averagetruerange", _keltnerchannels.AverageTrueRange);
        }
    }
}
```

For more information about this indicator, see its reference .

```
public class KeltnerChannelsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KeltnerChannels _kch;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kch = KCH(_symbol, 20, 2, MovingAverageType.Simple);

        var indicatorHistory = IndicatorHistory(_kch, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_kch, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_kch, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var middleBand = indicatorHistory.Select(x => ((dynamic)x).MiddleBand).ToList();
        var upperBand = indicatorHistory.Select(x => ((dynamic)x).UpperBand).ToList();
        var lowerBand = indicatorHistory.Select(x => ((dynamic)x).LowerBand).ToList();
        var averageTrueRange = indicatorHistory.Select(x => ((dynamic)x).AverageTrueRange).ToList();
    }
}
```

Supported Indicators

Klinger Volume Oscillator

Introduction

The Klinger Volume Oscillator (KVO) is a technical indicator that analyzes the relationship between price movement and trading volume to assess the strength of market trends and identify potential trend reversals. As a volume-based oscillator, it measures the force behind price movements by incorporating volume data adjusted for price trends and specific conditions. Traders use the KVO to analyze its behavior relative to price action, looking for patterns such as divergences or crossovers that can provide insights into market trends and potential turning points.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KVO Indicator

To create an automatic indicator for `KlingerVolumeOscillator` , call the `KVO` helper method from the `QCAlgorithm` class. The `KVO` method creates a `KlingerVolumeOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class KlingerVolumeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KlingerVolumeOscillator _kvo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kvo = KVO(_symbol, 5, 10, 13);
    }

    public override void OnData(Slice data)
    {

        if (_kvo.IsReady)
        {
            // The current value of _kvo is represented by itself (_kvo)
            // or _kvo.Current.Value
            Plot("KlingerVolumeOscillator", "kvo", _kvo);
            // Plot all properties of abands
            Plot("KlingerVolumeOscillator", "signal", _kvo.Signal);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KlingerVolumeOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class KlingerVolumeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KlingerVolumeOscillator _klingervolumeoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _klingervolumeoscillator = new KlingerVolumeOscillator(5, 10, 13);
    }

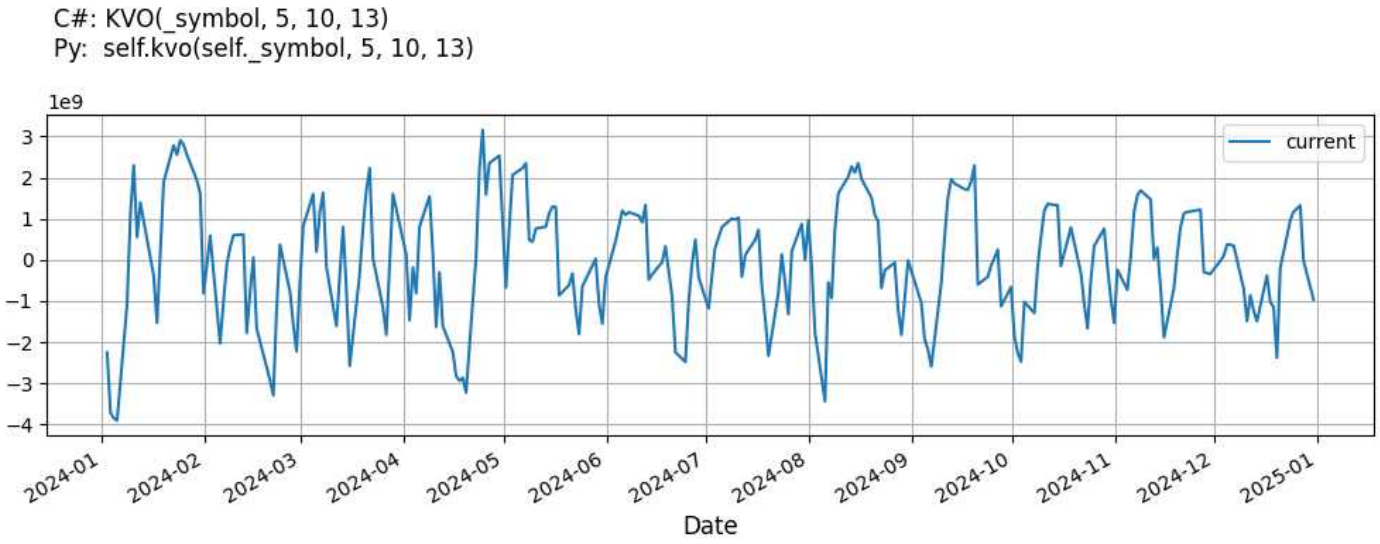
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _klingervolumeoscillator.Update(bar);

        if (_klingervolumeoscillator.IsReady)
        {
            // The current value of _klingervolumeoscillator is represented by itself (_klingervolumeoscillator)
            // or _klingervolumeoscillator.Current.Value
            Plot("KlingerVolumeOscillator", "klingervolumeoscillator", _klingervolumeoscillator);
            // Plot all properties of abands
            Plot("KlingerVolumeOscillator", "signal", _klingervolumeoscillator.Signal);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `KlingerVolumeOscillator` indicator properties:



Indicator History

To get the historical data of the `KlingerVolumeOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class KlingerVolumeOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KlingerVolumeOscillator _kvo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kvo = KVO(_symbol, 5, 10, 13);

        var indicatorHistory = IndicatorHistory(_kvo, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_kvo, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_kvo, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var signal = indicatorHistory.Select(x => ((dynamic)x).Signal).ToList();
    }
}
```

Supported Indicators

Know Sure Thing

Introduction

This indicator creates a moving average (middle band) with an upper band and lower band fixed at k standard deviations above and below the moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using KST Indicator

To create an automatic indicator for `KnowSureThing` , call the `KST` helper method from the `QCAlgorithm` class. The `KST` method creates a `KnowSureThing` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class KnowSureThingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KnowSureThing _kst;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kst = KST(_symbol, 5, 5, 10, 5, 15, 5, 25, 10, 9, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_kst.IsReady)
        {
            // The current value of _kst is represented by itself (_kst)
            // or _kst.Current.Value
            Plot("KnowSureThing", "kst", _kst);
            // Plot all properties of abands
            Plot("KnowSureThing", "roc1", _kst.ROC1);
            Plot("KnowSureThing", "roc2", _kst.ROC2);
            Plot("KnowSureThing", "roc3", _kst.ROC3);
            Plot("KnowSureThing", "roc4", _kst.ROC4);
            Plot("KnowSureThing", "roc1ma", _kst.ROC1MA);
            Plot("KnowSureThing", "roc2ma", _kst.ROC2MA);
            Plot("KnowSureThing", "roc3ma", _kst.ROC3MA);
            Plot("KnowSureThing", "roc4ma", _kst.ROC4MA);
            Plot("KnowSureThing", "signalline", _kst.SignalLine);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `KnowSureThing` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class KnowSureThingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KnowSureThing _knowsurething;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _knowsurething = new KnowSureThing(5, 5, 10, 5, 15, 5, 25, 10, 9, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _knowsurething.Update(bar.EndTime, bar.Close);

        if (_knowsurething.IsReady)
        {
            // The current value of _knowsurething is represented by itself (_knowsurething)
            // or _knowsurething.Current.Value
            Plot("KnowSureThing", "knowsurething", _knowsurething);
            // Plot all properties of abands
            Plot("KnowSureThing", "roc1", _knowsurething.ROC1);
            Plot("KnowSureThing", "roc2", _knowsurething.ROC2);
            Plot("KnowSureThing", "roc3", _knowsurething.ROC3);
            Plot("KnowSureThing", "roc4", _knowsurething.ROC4);
            Plot("KnowSureThing", "roc1ma", _knowsurething.ROC1MA);
            Plot("KnowSureThing", "roc2ma", _knowsurething.ROC2MA);
            Plot("KnowSureThing", "roc3ma", _knowsurething.ROC3MA);
            Plot("KnowSureThing", "roc4ma", _knowsurething.ROC4MA);
            Plot("KnowSureThing", "signalline", _knowsurething.SignalLine);
        }
    }
}
```

For more information about this indicator, see its reference .

7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var roc1 = indicatorHistory.Select(x => ((dynamic)x).ROC1).ToList();
        var roc2 = indicatorHistory.Select(x => ((dynamic)x).ROC2).ToList();
        var roc3 = indicatorHistory.Select(x => ((dynamic)x).ROC3).ToList();
        var roc4 = indicatorHistory.Select(x => ((dynamic)x).ROC4).ToList();
        var roc1ma = indicatorHistory.Select(x => ((dynamic)x).ROC1MA).ToList();
        var roc2ma = indicatorHistory.Select(x => ((dynamic)x).ROC2MA).ToList();
        var roc3ma = indicatorHistory.Select(x => ((dynamic)x).ROC3MA).ToList();
        var roc4ma = indicatorHistory.Select(x => ((dynamic)x).ROC4MA).ToList();
        var signalLine = indicatorHistory.Select(x => ((dynamic)x).SignalLine).ToList();
    }
}
```

Supported Indicators

Least Squares Moving Average

Introduction

The Least Squares Moving Average (LSMA) first calculates a least squares regression line over the preceding time periods, and then projects it forward to the current period. In essence, it calculates what the value would be if the regression line continued. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LSMA Indicator

To create an automatic indicator for `LeastSquaresMovingAverage` , call the `LSMA` helper method from the `QCAlgorithm` class. The `LSMA` method creates a `LeastSquaresMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class LeastSquaresMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LeastSquaresMovingAverage _lsma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _lsma = LSMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_lsma.IsReady)
        {
            // The current value of _lsma is represented by itself (_lsma)
            // or _lsma.Current.Value
            Plot("LeastSquaresMovingAverage", "lsma", _lsma);
            // Plot all properties of abands
            Plot("LeastSquaresMovingAverage", "intercept", _lsma.Intercept);
            Plot("LeastSquaresMovingAverage", "slope", _lsma.Slope);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `LeastSquaresMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class LeastSquaresMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LeastSquaresMovingAverage _leastsquaresmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _leastsquaresmovingaverage = new LeastSquaresMovingAverage(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _leastsquaresmovingaverage.Update(bar.EndTime, bar.Close);

        if (_leastsquaresmovingaverage.IsReady)
        {
            // The current value of _leastsquaresmovingaverage is represented by itself (_leastsquaresmovingaverage)
            // or _leastsquaresmovingaverage.Current.Value
            Plot("LeastSquaresMovingAverage", "leastsquaresmovingaverage", _leastsquaresmovingaverage);
            // Plot all properties of abands
            Plot("LeastSquaresMovingAverage", "intercept", _leastsquaresmovingaverage.Intercept);
            Plot("LeastSquaresMovingAverage", "slope", _leastsquaresmovingaverage.Slope);
        }
    }
}
```

For more information about this indicator, see its reference .

Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class LeastSquaresMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LeastSquaresMovingAverage _lsma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _lsma = LSMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_lsma, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_lsma, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_lsma, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var intercept = indicatorHistory.Select(x => ((dynamic)x).Intercept).ToList();
        var slope = indicatorHistory.Select(x => ((dynamic)x).Slope).ToList();
    }
}
```

Supported Indicators

Linear Weighted Moving Average

Introduction

This indicator represents the traditional Weighted Moving Average indicator. The weight are linearly distributed according to the number of periods in the indicator. For example, a 4 period indicator will have a numerator of (4 * window[0]) + (3 * window[1]) + (2 * window[2]) + window[3] and a denominator of 4 + 3 + 2 + 1 = 10 During the warm up period, IsReady will return False, but the LWMA will still be computed correctly because the denominator will be the minimum of Samples factorial or Size factorial and the computation iterates over that minimum value. The RollingWindow of inputs is created when the indicator is created. A RollingWindow of LWMAs is not saved. That is up to the caller.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LWMA Indicator

To create an automatic indicator for `LinearWeightedMovingAverage` , call the `LWMA` helper method from the `QCAlgorithm` class. The `LWMA` method creates a `LinearWeightedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class LinearWeightedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LinearWeightedMovingAverage _lwma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _lwma = LWMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_lwma.IsReady)
        {
            // The current value of _lwma is represented by itself (_lwma)
            // or _lwma.Current.Value
            Plot("LinearWeightedMovingAverage", "lwma", _lwma);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `LinearWeightedMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class LinearWeightedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LinearWeightedMovingAverage _linearweightedmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _linearweightedmovingaverage = new LinearWeightedMovingAverage(20);
    }

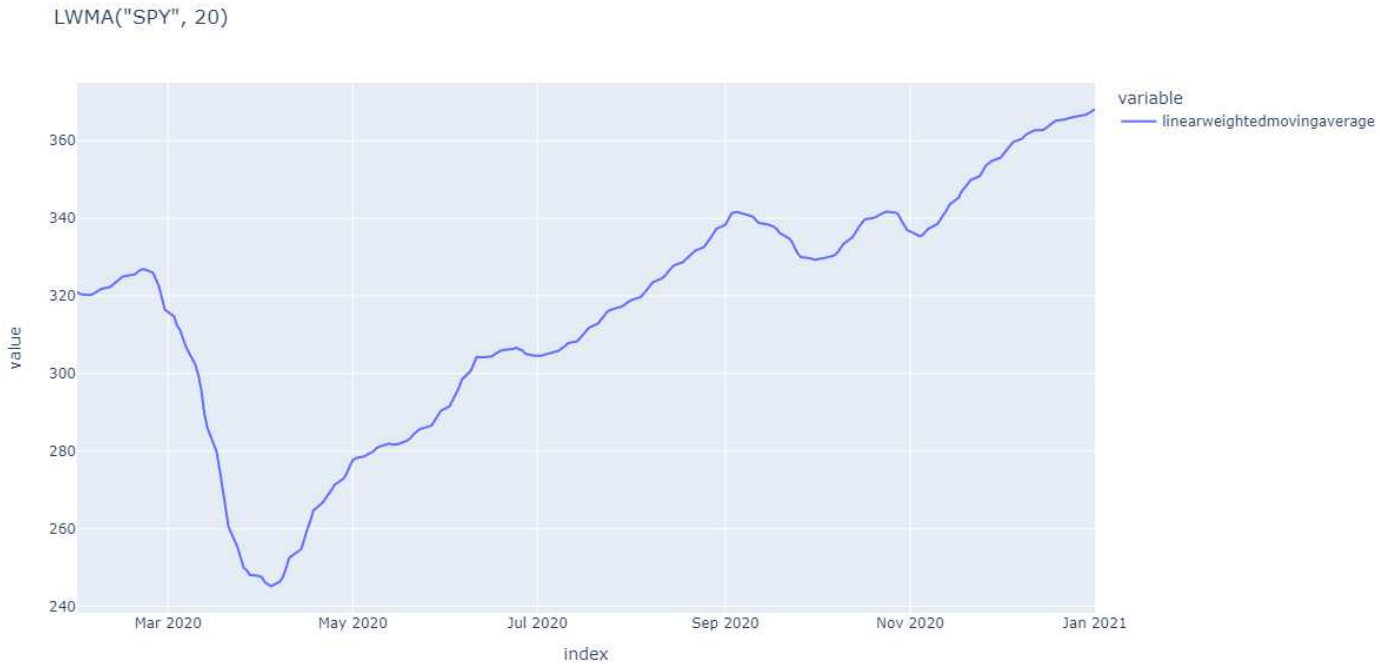
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _linearweightedmovingaverage.Update(bar.EndTime, bar.Close);

        if (_linearweightedmovingaverage.IsReady)
        {
            // The current value of _linearweightedmovingaverage is represented by itself
(_linearweightedmovingaverage)
            // or _linearweightedmovingaverage.Current.Value
            Plot("LinearWeightedMovingAverage", "linearweightedmovingaverage", _linearweightedmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `LinearWeightedMovingAverage` indicator properties:



Indicator History

To get the historical data of the `LinearWeightedMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class LinearWeightedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LinearWeightedMovingAverage _lwma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _lwma = LWMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_lwma, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_lwma, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_lwma, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Log Return

Introduction

This indicator represents the LogReturn indicator (LOGR) - log returns are useful for identifying price convergence/divergence in a given period - logr = log (current price / last price in period)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using LOGR Indicator

To create an automatic indicator for `LogReturn` , call the `LOGR` helper method from the `QCAlgorithm` class. The `LOGR` method creates a `LogReturn` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class LogReturnAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LogReturn _logr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _logr = LOGR(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_logr.IsReady)
        {
            // The current value of _logr is represented by itself (_logr)
            // or _logr.Current.Value
            Plot("LogReturn", "logr", _logr);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `LogReturn` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class LogReturnAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LogReturn _logreturn;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _logreturn = new LogReturn(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _logreturn.Update(bar.EndTime, bar.Close);

        if (_logreturn.IsReady)
        {
            // The current value of _logreturn is represented by itself (_logreturn)
            // or _logreturn.Current.Value
            Plot("LogReturn", "logreturn", _logreturn);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `LogReturn` indicator properties:

Indicator History

To get the historical data of the `LogReturn` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class LogReturnAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LogReturn _logr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _logr = LOGR(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_logr, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_logr, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_logr, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Mass Index

Introduction

The Mass Index uses the high-low range to identify trend reversals based on range expansions. In this sense, the Mass Index is a volatility indicator that does not have a directional bias. Instead, the Mass Index identifies range bulges that can foreshadow a reversal of the current trend. Developed by Donald Dorsey.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MASS Indicator

To create an automatic indicator for `MassIndex` , call the `MASS` helper method from the `QCAlgorithm` class. The `MASS` method creates a `MassIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MassIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MassIndex _mass;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mass = MASS(_symbol, 9, 25);
    }

    public override void OnData(Slice data)
    {

        if (_mass.IsReady)
        {
            // The current value of _mass is represented by itself (_mass)
            // or _mass.Current.Value
            Plot("MassIndex", "mass", _mass);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MassIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MassIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MassIndex _massindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _massindex = new MassIndex(9, 25);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _massindex.Update(bar);

        if (_massindex.IsReady)
        {
            // The current value of _massindex is represented by itself (_massindex)
            // or _massindex.Current.Value
            Plot("MassIndex", "massindex", _massindex);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MassIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MassIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MassIndex _mass;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mass = MASS(_symbol, 9, 25);

        var indicatorHistory = IndicatorHistory(_mass, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_mass, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_mass, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Maximum

Introduction

This indicator represents an indicator capable of tracking the maximum value and how many periods ago it occurred

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MAX Indicator

To create an automatic indicator for `Maximum` , call the `MAX` helper method from the `QCAlgorithm` class. The `MAX` method creates a `Maximum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MaximumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Maximum _max;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _max = MAX(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_max.IsReady)
        {
            // The current value of _max is represented by itself (_max)
            // or _max.Current.Value
            Plot("Maximum", "max", _max);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Maximum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MaximumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Maximum _maximum;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _maximum = new Maximum(20);
    }

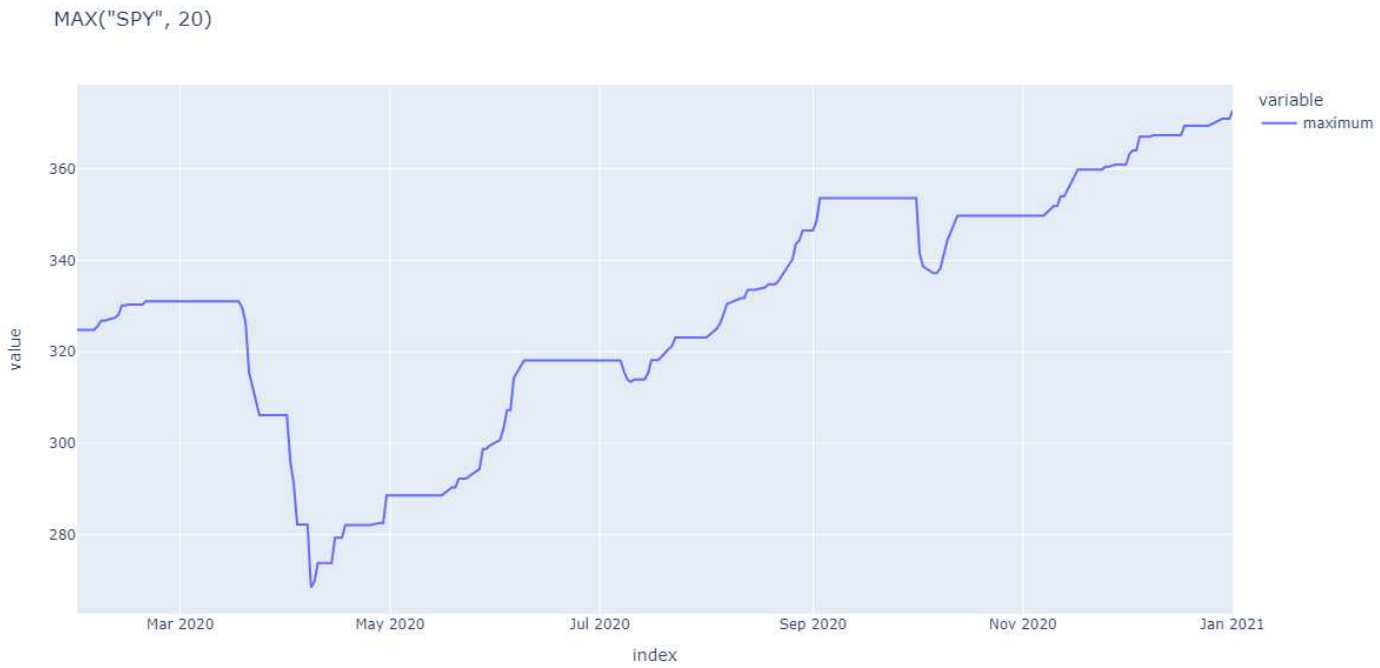
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _maximum.Update(bar.EndTime, bar.Close);

        if (_maximum.IsReady)
        {
            // The current value of _maximum is represented by itself (_maximum)
            // or _maximum.Current.Value
            Plot("Maximum", "maximum", _maximum);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Maximum` indicator properties:



Indicator History

To get the historical data of the `Maximum` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MaximumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Maximum _max;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _max = MAX(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_max, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_max, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_max, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

McClellan Oscillator

Introduction

The McClellan Oscillator is a market breadth indicator which was developed by Sherman and Marian McClellan. It is based on the difference between the number of advancing and declining periods.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOSC Indicator

To create an automatic indicator for `McClellanOscillator` , call the `MOSC` helper method from the `QCAlgorithm` class. The `MOSC` method creates a `McClellanOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class McClellanOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private McClellanOscillator _mosc;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _mosc = MOSC([_symbol, _reference], 19, 39);
    }

    public override void OnData(Slice data)
    {

        if (_mosc.IsReady)
        {
            // The current value of _mosc is represented by itself (_mosc)
            // or _mosc.Current.Value
            Plot("McClellanOscillator", "mosc", _mosc);
            // Plot all properties of abands
            Plot("McClellanOscillator", "emafast", _mosc.EMAFast);
            Plot("McClellanOscillator", "emaslow", _mosc.EMASlow);
            Plot("McClellanOscillator", "addifference", _mosc.ADDifference);
        }
    }
}
```

To create an automatic indicator for `McClellanOscillator` using universe constituents, call the `MOSC` helper method from the `QCAlgorithm` class. The `MOSC` method creates a `McClellanOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class McClellanOscillatorAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private McClellanOscillator _mosc;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _mosc = MOSC(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_mosc.IsReady)
        {
            // The current value of _mosc is represented by itself (_mosc)
            // or _mosc.Current.Value
            Plot("McClellanOscillator", "mosc", _mosc);
            // Plot all properties of abands
            Plot("McClellanOscillator", "emafast", _mosc.EMAFast);
            Plot("McClellanOscillator", "emaslow", _mosc.EMASlow);
            Plot("McClellanOscillator", "addifference", _mosc.ADDifference);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `McClellanOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class McClellanOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private McClellanOscillator _mcclellanoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _mcclellanoscillator = new McClellanOscillator(19, 39);
        _mcclellanoscillator.Add(_symbol);
        _mcclellanoscillator.Add(_reference);
    }

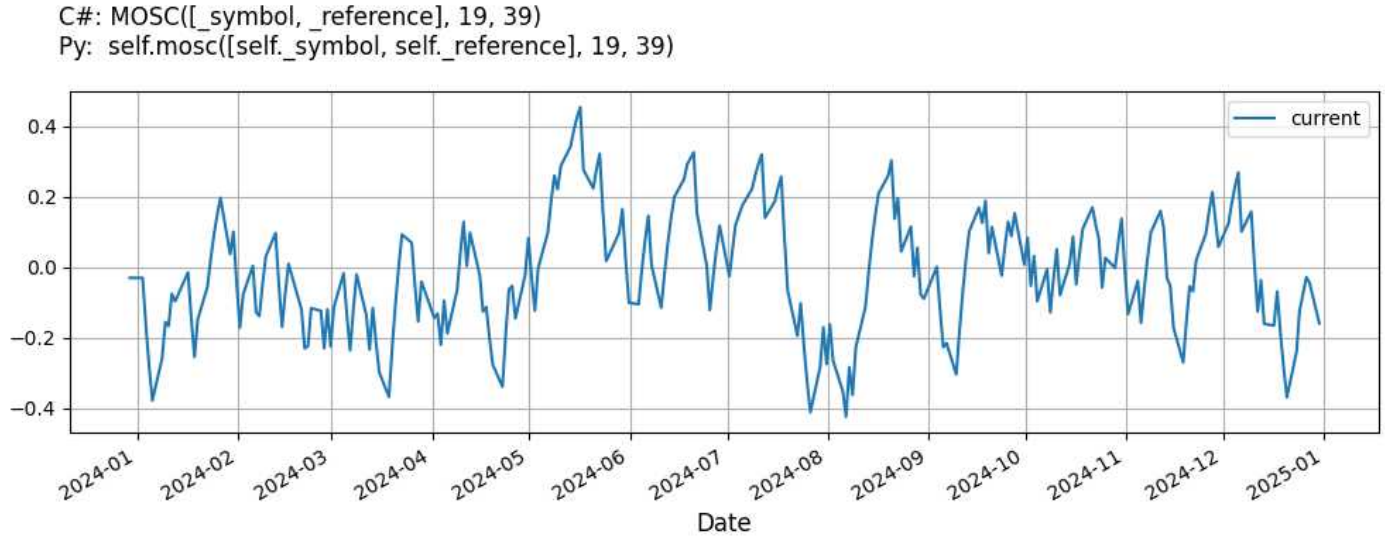
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _mcclellanoscillator.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _mcclellanoscillator.Update(bar);

        if (_mcclellanoscillator.IsReady)
        {
            // The current value of _mcclellanoscillator is represented by itself (_mcclellanoscillator)
            // or _mcclellanoscillator.Current.Value
            Plot("McClellanOscillator", "mcclellanoscillator", _mcclellanoscillator);
            // Plot all properties of abands
            Plot("McClellanOscillator", "emafast", _mcclellanoscillator.EMAFast);
            Plot("McClellanOscillator", "emaslow", _mcclellanoscillator.EMASlow);
            Plot("McClellanOscillator", "addifference", _mcclellanoscillator.ADDifference);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `McClellanOscillator` indicator properties:



Indicator History

To get the historical data of the `McClellanOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class McClellanOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private McClellanOscillator _mosc;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _mosc = MOSC([_symbol, _reference], 19, 39);

        var indicatorHistory = IndicatorHistory(_mosc, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_mosc, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_mosc, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var eMAFast = indicatorHistory.Select(x => ((dynamic)x).EMAFast).ToList();
        var eMASlow = indicatorHistory.Select(x => ((dynamic)x).EMASlow).ToList();
        var aDDifference = indicatorHistory.Select(x => ((dynamic)x).ADDifference).ToList();
    }
}
```

Supported Indicators

McClellan Summation Index

Introduction

The McClellan Summation Index (MSI) is a market breadth indicator that is based on the rolling average of difference between the number of advancing and declining issues on a stock exchange. It is generally considered as is a long-term version of the

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MSI Indicator

To create an automatic indicator for `McClellanSummationIndex` , call the `MSI` helper method from the `QCAlgorithm` class. The `MSI` method creates a `McClellanSummationIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class McClellanSummationIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private McClellanSummationIndex _msi;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _msi = MSI([_symbol, _reference]);
    }

    public override void OnData(Slice data)
    {

        if (_msi.IsReady)
        {
            // The current value of _msi is represented by itself (_msi)
            // or _msi.Current.Value
            Plot("McClellanSummationIndex", "msi", _msi);
            // Plot all properties of abands
            Plot("McClellanSummationIndex", "mcclellanoscillator", _msi.McClellanOscillator);
        }
    }
}
```

To create an automatic indicator for `McClellanSummationIndex` using universe constituents, call the `MSI` helper method from the `QCAlgorithm` class. The `MSI` method creates a `McClellanSummationIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class McClellanSummationIndexAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private McClellanSummationIndex _msi;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _msi = MSI(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_msi.IsReady)
        {
            // The current value of _msi is represented by itself (_msi)
            // or _msi.Current.Value
            Plot("McClellanSummationIndex", "msi", _msi);
            // Plot all properties of abands
            Plot("McClellanSummationIndex", "mcclellanoscillator", _msi.McClellanOscillator);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `McClellanSummationIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class McClellanSummationIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private McClellanSummationIndex _mcclellansummationindex;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _mcclellansummationindex = new McClellanSummationIndex(19, 39);
        _mcclellansummationindex.Add(_symbol);
        _mcclellansummationindex.Add(_reference);
    }

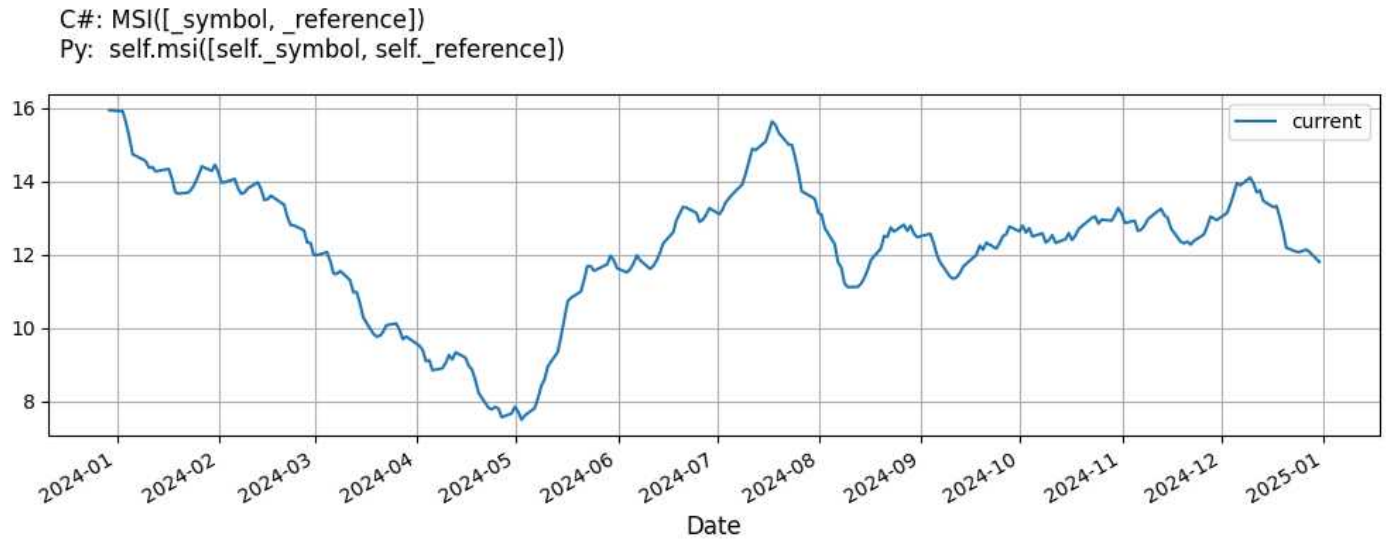
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _mcclellansummationindex.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _mcclellansummationindex.Update(bar);

        if (_mcclellansummationindex.IsReady)
        {
            // The current value of _mcclellansummationindex is represented by itself (_mcclellansummationindex)
            // or _mcclellansummationindex.Current.Value
            Plot("McClellanSummationIndex", "mcclellansummationindex", _mcclellansummationindex);
            // Plot all properties of abands
            Plot("McClellanSummationIndex", "mcclellanoscillator", _mcclellansummationindex.McClellanOscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `McClellanSummationIndex` indicator properties:



Indicator History

To get the historical data of the `McClellanSummationIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time.         var mcClellanOscillator = indicatorHistory.Select(x => ((dynamic)x).McClellanOscillator).ToList();
    }
}
```

Supported Indicators

McGinley Dynamic

Introduction

This indicator represents the McGinley Dynamic (MGD) It is a type of moving average that was designed to track the market better than existing moving average indicators. It is a technical indicator that improves upon moving average lines by adjusting for shifts in market speed.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MGD Indicator

To create an automatic indicator for `McGinleyDynamic` , call the `MGD` helper method from the `QCAlgorithm` class. The `MGD` method creates a `McGinleyDynamic` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class McGinleyDynamicAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private McGinleyDynamic _mgd;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mgd = MGD(_symbol, 10);
    }

    public override void OnData(Slice data)
    {

        if (_mgd.IsReady)
        {
            // The current value of _mgd is represented by itself (_mgd)
            // or _mgd.Current.Value
            Plot("McGinleyDynamic", "mgd", _mgd);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `McGinleyDynamic` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class McGinleyDynamicAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private McGinleyDynamic _mcginleydynamic;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mcginleydynamic = new McGinleyDynamic(10);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _mcginleydynamic.Update(bar.EndTime, bar.Close);

        if (_mcginleydynamic.IsReady)
        {
            // The current value of _mcginleydynamic is represented by itself (_mcginleydynamic)
            // or _mcginleydynamic.Current.Value
            Plot("McGinleyDynamic", "mcginleydynamic", _mcginleydynamic);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Mean Absolute Deviation

Introduction

This indicator computes the n-period mean absolute deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MAD Indicator

To create an automatic indicator for `MeanAbsoluteDeviation` , call the `MAD` helper method from the `QCAlgorithm` class. The `MAD` method creates a `MeanAbsoluteDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MeanAbsoluteDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MeanAbsoluteDeviation _mad;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mad = MAD(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_mad.IsReady)
        {
            // The current value of _mad is represented by itself (_mad)
            // or _mad.Current.Value
            Plot("MeanAbsoluteDeviation", "mad", _mad);
            // Plot all properties of abands
            Plot("MeanAbsoluteDeviation", "mean", _mad.Mean);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MeanAbsoluteDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class MeanAbsoluteDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MeanAbsoluteDeviation _meanabsolutedeviation;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _meanabsolutedeviation = new MeanAbsoluteDeviation(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _meanabsolutedeviation.Update(bar.EndTime, bar.Close);

        if (_meanabsolutedeviation.IsReady)
        {
            // The current value of _meanabsolutedeviation is represented by itself (_meanabsolutedeviation)
            // or _meanabsolutedeviation.Current.Value
            Plot("MeanAbsoluteDeviation", "meanabsolutedeviation", _meanabsolutedeviation);
            // Plot all properties of abands
            Plot("MeanAbsoluteDeviation", "mean", _meanabsolutedeviation.Mean);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Indicator History

To get the historical data of the `MeanAbsoluteDeviation` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MeanAbsoluteDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MeanAbsoluteDeviation _mad;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mad = MAD(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_mad, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_mad, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_mad, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var mean = indicatorHistory.Select(x => ((dynamic)x).Mean).ToList();
    }
}
```

Supported Indicators

Mesa Adaptive Moving Average

Introduction

Implements the Mesa Adaptive Moving Average (MAMA) indicator along with the following FAMA (Following Adaptive Moving Average) as a secondary indicator. The MAMA adjusts its smoothing factor based on the market's volatility, making it more adaptive than a simple moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MAMA Indicator

To create an automatic indicator for `MesaAdaptiveMovingAverage` , call the `MAMA` helper method from the `QCAlgorithm` class. The `MAMA` method creates a `MesaAdaptiveMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MesaAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MesaAdaptiveMovingAverage _mama;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mama = MAMA(_symbol, 0.5m, 0.05m);
    }

    public override void OnData(Slice data)
    {

        if (_mama.IsReady)
        {
            // The current value of _mama is represented by itself (_mama)
            // or _mama.Current.Value
            Plot("MesaAdaptiveMovingAverage", "mama", _mama);
            // Plot all properties of abands
            Plot("MesaAdaptiveMovingAverage", "fama", _mama.Fama);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MesaAdaptiveMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MesaAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MesaAdaptiveMovingAverage _mesaadaptivemovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mesaadaptivemovingaverage = new MesaAdaptiveMovingAverage(0.5m, 0.05m);
    }

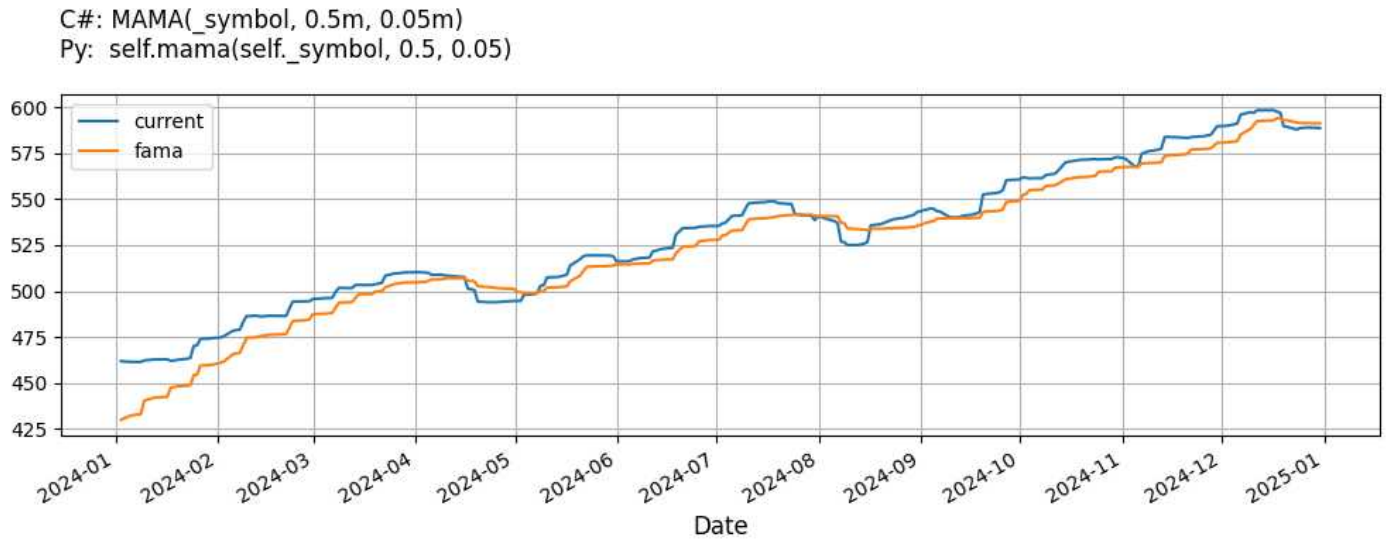
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _mesaadaptivemovingaverage.Update(bar);

        if (_mesaadaptivemovingaverage.IsReady)
        {
            // The current value of _mesaadaptivemovingaverage is represented by itself (_mesaadaptivemovingaverage)
            // or _mesaadaptivemovingaverage.Current.Value
            Plot("MesaAdaptiveMovingAverage", "mesaadaptivemovingaverage", _mesaadaptivemovingaverage);
            // Plot all properties of abands
            Plot("MesaAdaptiveMovingAverage", "fama", _mesaadaptivemovingaverage.Fama);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `MesaAdaptiveMovingAverage` indicator properties:



Indicator History

To get the historical data of the `MesaAdaptiveMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MesaAdaptiveMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MesaAdaptiveMovingAverage _mama;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mama = MAMA(_symbol, 0.5m, 0.05m);

        var indicatorHistory = IndicatorHistory(_mama, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_mama, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_mama, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var fama = indicatorHistory.Select(x => ((dynamic)x).Fama).ToList();
    }
}
```

Mid Point

Introduction

This indicator computes the MidPoint (MIDPOINT) The MidPoint is calculated using the following formula: MIDPOINT = (Highest Value + Lowest Value) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIDPOINT Indicator

To create an automatic indicator for `MidPoint` , call the `MIDPOINT` helper method from the `QCAlgorithm` class. The `MIDPOINT` method creates a `MidPoint` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MidPointAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MidPoint _midpoint;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _midpoint = MIDPOINT(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_midpoint.IsReady)
        {
            // The current value of _midpoint is represented by itself (_midpoint)
            // or _midpoint.Current.Value
            Plot("MidPoint", "midpoint", _midpoint);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MidPoint` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MidPointAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MidPoint _midpoint;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _midpoint = new MidPoint(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _midpoint.Update(bar.EndTime, bar.Close);

        if (_midpoint.IsReady)
        {
            // The current value of _midpoint is represented by itself (_midpoint)
            // or _midpoint.Current.Value
            Plot("MidPoint", "midpoint", _midpoint);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MidPoint` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MidPointAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MidPoint _midpoint;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _midpoint = MIDPOINT(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_midpoint, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_midpoint, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_midpoint, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Mid Price

Introduction

This indicator computes the MidPrice (MIDPRICE). The MidPrice is calculated using the following formula: MIDPRICE = (Highest High + Lowest Low) / 2

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIDPRICE Indicator

To create an automatic indicator for `MidPrice` , call the `MIDPRICE` helper method from the `QCAlgorithm` class. The `MIDPRICE` method creates a `MidPrice` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MidPriceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MidPrice _midprice;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _midprice = MIDPRICE(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_midprice.IsReady)
        {
            // The current value of _midprice is represented by itself (_midprice)
            // or _midprice.Current.Value
            Plot("MidPrice", "midprice", _midprice);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MidPrice` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MidPriceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MidPrice _midprice;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _midprice = new MidPrice(20);
    }

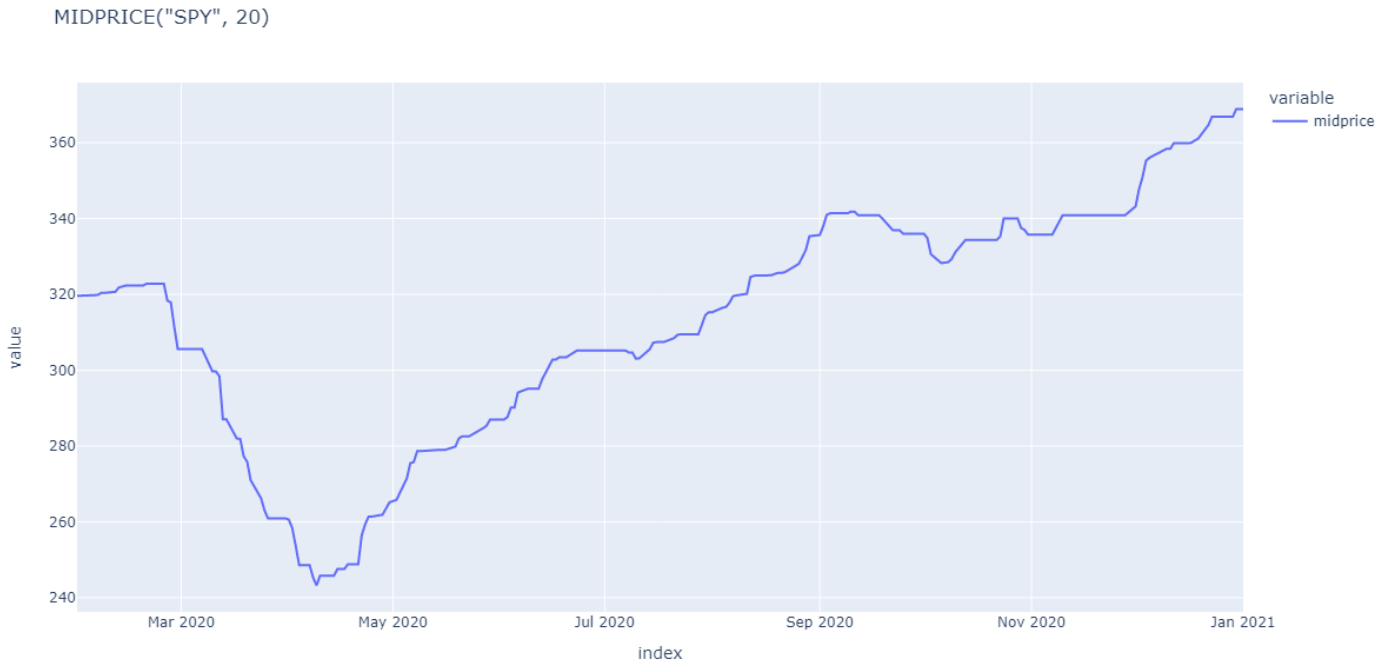
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _midprice.Update(bar);

        if (_midprice.IsReady)
        {
            // The current value of _midprice is represented by itself (_midprice)
            // or _midprice.Current.Value
            Plot("MidPrice", "midprice", _midprice);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `MidPrice` indicator properties:



Indicator History

To get the historical data of the `MidPrice` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MidPriceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MidPrice _midprice;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _midprice = MIDPRICE(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_midprice, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_midprice, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_midprice, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Minimum

Introduction

This indicator represents an indicator capable of tracking the minimum value and how many periods ago it occurred

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MIN Indicator

To create an automatic indicator for `Minimum` , call the `MIN` helper method from the `QCAlgorithm` class. The `MIN` method creates a `Minimum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MinimumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Minimum _min;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _min = MIN(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_min.IsReady)
        {
            // The current value of _min is represented by itself (_min)
            // or _min.Current.Value
            Plot("Minimum", "min", _min);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Minimum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MinimumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Minimum _minimum;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _minimum = new Minimum(20);
    }

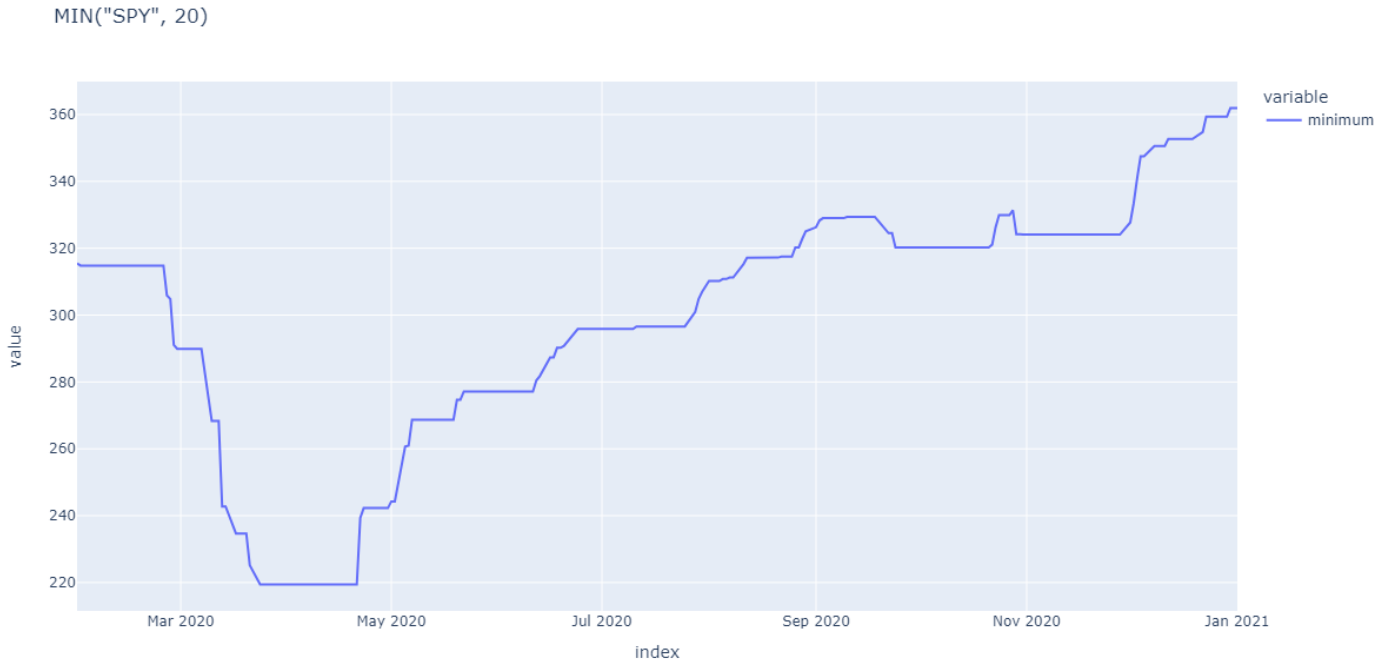
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _minimum.Update(bar.EndTime, bar.Close);

        if (_minimum.IsReady)
        {
            // The current value of _minimum is represented by itself (_minimum)
            // or _minimum.Current.Value
            Plot("Minimum", "minimum", _minimum);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Minimum` indicator properties:



Indicator History

To get the historical data of the `Minimum` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MinimumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Minimum _min;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _min = MIN(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_min, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_min, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_min, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Momentum

Introduction

This indicator computes the n-period change in a value using the following: value_0 - value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOM Indicator

To create an automatic indicator for `Momentum` , call the `MOM` helper method from the `QCAlgorithm` class. The `MOM` method creates a `Momentum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MomentumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Momentum _mom;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mom = MOM(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_mom.IsReady)
        {
            // The current value of _mom is represented by itself (_mom)
            // or _mom.Current.Value
            Plot("Momentum", "mom", _mom);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Momentum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MomentumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Momentum _momentum;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _momentum = new Momentum(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _momentum.Update(bar.EndTime, bar.Close);

        if (_momentum.IsReady)
        {
            // The current value of _momentum is represented by itself (_momentum)
            // or _momentum.Current.Value
            Plot("Momentum", "momentum", _momentum);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Momentum` indicator properties:

Indicator History

To get the historical data of the `Momentum` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MomentumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Momentum _mom;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mom = MOM(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_mom, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_mom, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_mom, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Momentum Percent

Introduction

This indicator computes the n-period percentage rate of change in a value using the following: 100 * (value_0 - value_n) / value_n This indicator yields the same results of RateOfChangePercent

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOMP Indicator

To create an automatic indicator for `MomentumPercent` , call the `MOMP` helper method from the `QCAlgorithm` class. The `MOMP` method creates a `MomentumPercent` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MomentumPercentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MomentumPercent _momp;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _momp = MOMP(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_momp.IsReady)
        {
            // The current value of _momp is represented by itself (_momp)
            // or _momp.Current.Value
            Plot("MomentumPercent", "momp", _momp);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MomentumPercent` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MomentumPercentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MomentumPercent _momentumpercent;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _momentumpercent = new MomentumPercent(20);
    }

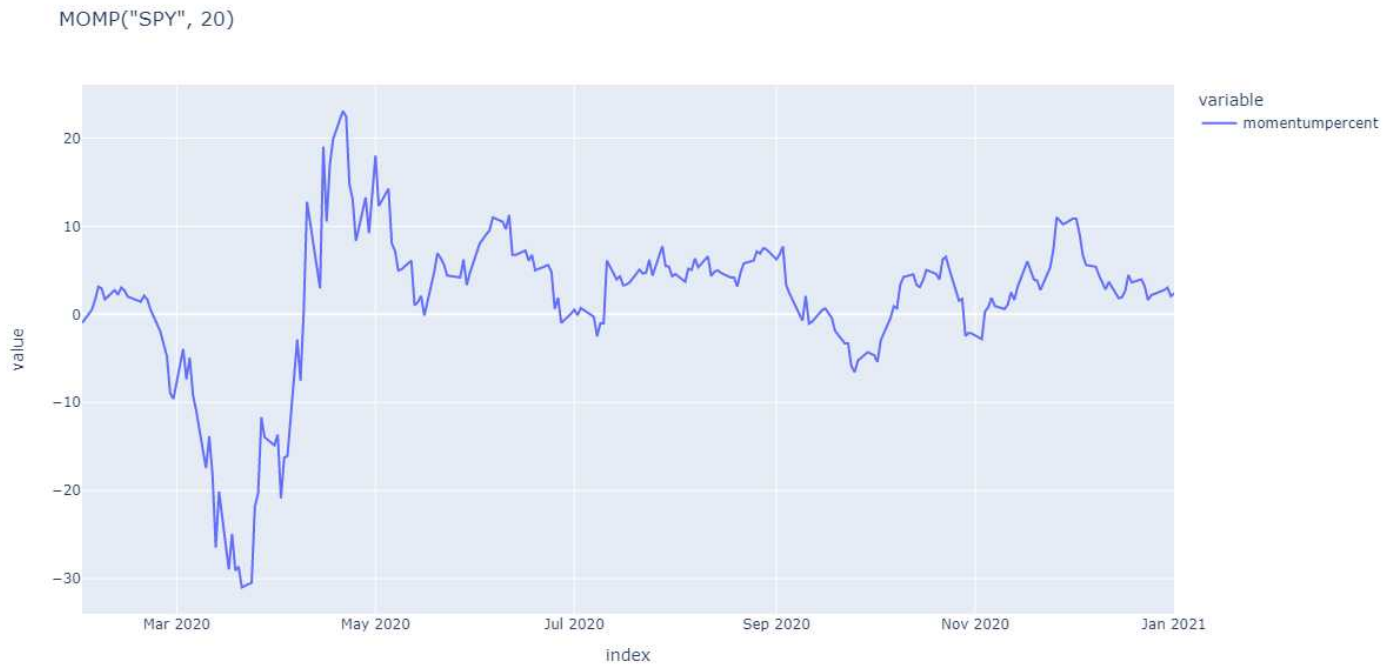
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _momentumpercent.Update(bar.EndTime, bar.Close);

        if (_momentumpercent.IsReady)
        {
            // The current value of _momentumpercent is represented by itself (_momentumpercent)
            // or _momentumpercent.Current.Value
            Plot("MomentumPercent", "momentumpercent", _momentumpercent);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `MomentumPercent` indicator properties:



Indicator History

To get the historical data of the `MomentumPercent` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MomentumPercentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MomentumPercent _momp;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _momp = MOMP(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_momp, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_momp, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_momp, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Momersion

Introduction

Oscillator indicator that measures momentum and mean-reversion over a specified period n. [source] Harris, Michael. "Momersion Indicator." Price Action Lab., 13 Aug. 2015. Web.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MOMERSION Indicator

To create an automatic indicator for `Momersion` , call the `MOMERSION` helper method from the `QCAlgorithm` class. The `MOMERSION` method creates a `Momersion` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MomersionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Momersion _momersion;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _momersion = MOMERSION(_symbol, 10, 20);
    }

    public override void OnData(Slice data)
    {

        if (_momersion.IsReady)
        {
            // The current value of _momersion is represented by itself (_momersion)
            // or _momersion.Current.Value
            Plot("Momersion", "momersion", _momersion);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Momersion` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MomersionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Momersion _momersion;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _momersion = new Momersion(10, 20);
    }

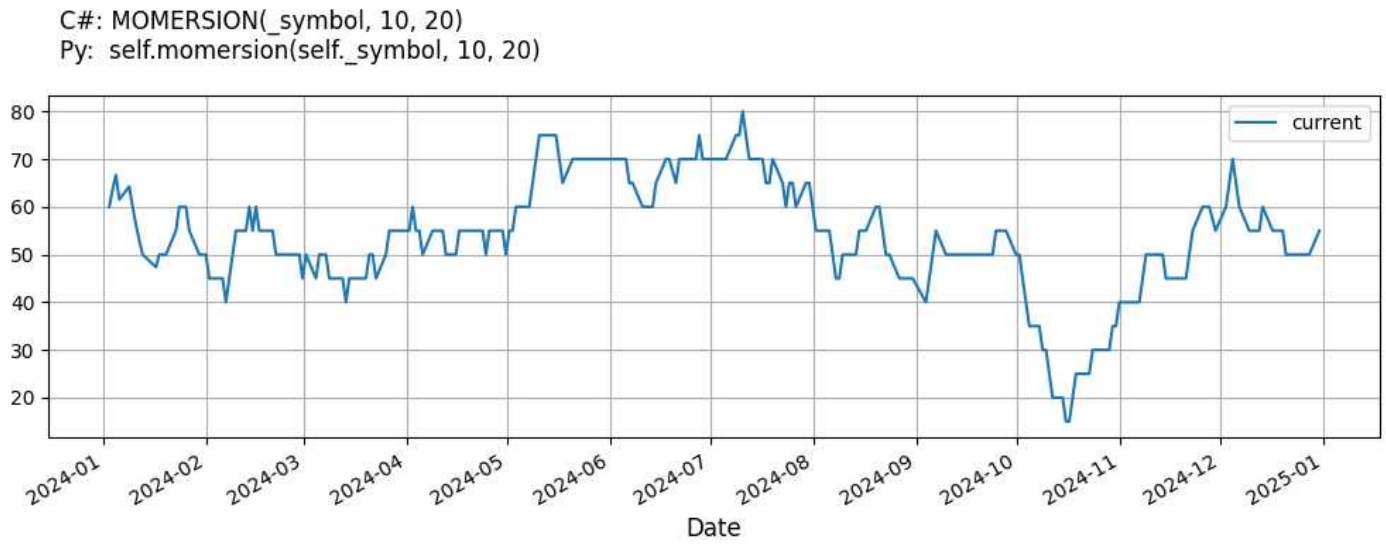
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _momersion.Update(bar.EndTime, bar.Close);

        if (_momersion.IsReady)
        {
            // The current value of _momersion is represented by itself (_momersion)
            // or _momersion.Current.Value
            Plot("Momersion", "momersion", _momersion);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Momersion` indicator properties:



Indicator History

To get the historical data of the `Momersion` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MomersionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Momersion _momersion;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _momersion = MOMERSION(_symbol, 10, 20);

        var indicatorHistory = IndicatorHistory(_momersion, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_momersion, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_momersion, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Money Flow Index

Introduction

The Money Flow Index (MFI) is an oscillator that uses both price and volume to measure buying and selling pressure Typical Price = (High + Low + Close)/3 Money Flow = Typical Price x Volume Positive Money Flow = Sum of the money flows of all days where the typical price is greater than the previous day's typical price Negative Money Flow = Sum of the money flows of all days where the typical price is less than the previous day's typical price Money Flow Ratio = (14-period Positive Money Flow)/(14-period Negative Money Flow) Money Flow Index = 100 x Positive Money Flow / (Positive Money Flow + Negative Money Flow)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MFI Indicator

To create an automatic indicator for `MoneyFlowIndex` , call the `MFI` helper method from the `QCAlgorithm` class. The `MFI` method creates a `MoneyFlowIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class MoneyFlowIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MoneyFlowIndex _mfi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mfi = MFI(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_mfi.IsReady)
        {
            // The current value of _mfi is represented by itself (_mfi)
            // or _mfi.Current.Value
            Plot("MoneyFlowIndex", "mfi", _mfi);
            // Plot all properties of abands
            Plot("MoneyFlowIndex", "positivemoneyflow", _mfi.PositiveMoneyFlow);
            Plot("MoneyFlowIndex", "negativemoneyflow", _mfi.NegativeMoneyFlow);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MoneyFlowIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MoneyFlowIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MoneyFlowIndex _moneyflowindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _moneyflowindex = new MoneyFlowIndex(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _moneyflowindex.Update(bar);

        if (_moneyflowindex.IsReady)
        {
            // The current value of _moneyflowindex is represented by itself (_moneyflowindex)
            // or _moneyflowindex.Current.Value
            Plot("MoneyFlowIndex", "moneyflowindex", _moneyflowindex);
            // Plot all properties of abands
            Plot("MoneyFlowIndex", "positivemoneyflow", _moneyflowindex.PositiveMoneyFlow);
            Plot("MoneyFlowIndex", "negativemoneyflow", _moneyflowindex.NegativeMoneyFlow);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MoneyFlowIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MoneyFlowIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MoneyFlowIndex _mfi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _mfi = MFI(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_mfi, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_mfi, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_mfi, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var positiveMoneyFlow = indicatorHistory.Select(x => ((dynamic)x).PositiveMoneyFlow).ToList();
        var negativeMoneyFlow = indicatorHistory.Select(x => ((dynamic)x).NegativeMoneyFlow).ToList();
    }
}
```

Supported Indicators

Moving Average Convergence Divergence

Introduction

This indicator creates two moving averages defined on a base indicator and produces the difference between the fast and slow averages.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using MACD Indicator

To create an automatic indicator for `MovingAverageConvergenceDivergence` , call the `MACD` helper method from the `QCAlgorithm` class. The `MACD` method creates a `MovingAverageConvergenceDivergence` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MovingAverageConvergenceDivergenceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MovingAverageConvergenceDivergence _macd;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _macd = MACD(_symbol, 12, 26, 9, MovingAverageType.Exponential);
    }

    public override void OnData(Slice data)
    {

        if (_macd.IsReady)
        {
            // The current value of _macd is represented by itself (_macd)
            // or _macd.Current.Value
            Plot("MovingAverageConvergenceDivergence", "macd", _macd);
            // Plot all properties of abands
            Plot("MovingAverageConvergenceDivergence", "fast", _macd.Fast);
            Plot("MovingAverageConvergenceDivergence", "slow", _macd.Slow);
            Plot("MovingAverageConvergenceDivergence", "signal", _macd.Signal);
            Plot("MovingAverageConvergenceDivergence", "histogram", _macd.Histogram);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `MovingAverageConvergenceDivergence` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MovingAverageConvergenceDivergenceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MovingAverageConvergenceDivergence _movingaverageconvergencedivergence;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _movingaverageconvergencedivergence = new MovingAverageConvergenceDivergence(12, 26, 9,
MovingAverageType.Exponential);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _movingaverageconvergencedivergence.Update(bar.EndTime, bar.Close);

        if (_movingaverageconvergencedivergence.IsReady)
        {
            // The current value of _movingaverageconvergencedivergence is represented by itself
(_movingaverageconvergencedivergence)
            // or _movingaverageconvergencedivergence.Current.Value
            Plot("MovingAverageConvergenceDivergence", "movingaverageconvergencedivergence",
_movingaverageconvergencedivergence);
            // Plot all properties of abands
            Plot("MovingAverageConvergenceDivergence", "fast", _movingaverageconvergencedivergence.Fast);
            Plot("MovingAverageConvergenceDivergence", "slow", _movingaverageconvergencedivergence.Slow);
            Plot("MovingAverageConvergenceDivergence", "signal", _movingaverageconvergencedivergence.Signal);
            Plot("MovingAverageConvergenceDivergence", "histogram", _movingaverageconvergencedivergence.Histogram);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Indicator History

To get the historical data of the `MovingAverageConvergenceDivergence` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular

history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class MovingAverageConvergenceDivergenceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MovingAverageConvergenceDivergence _macd;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _macd = MACD(_symbol, 12, 26, 9, MovingAverageType.Exponential);

        var indicatorHistory = IndicatorHistory(_macd, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_macd, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_macd, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var fast = indicatorHistory.Select(x => ((dynamic)x).Fast).ToList();
        var slow = indicatorHistory.Select(x => ((dynamic)x).Slow).ToList();
        var signal = indicatorHistory.Select(x => ((dynamic)x).Signal).ToList();
        var histogram = indicatorHistory.Select(x => ((dynamic)x).Histogram).ToList();
    }
}
```

Supported Indicators

New Highs New Lows

Introduction

The NewHighsNewLows is a New Highs / New Lows indicator that accepts IBaseDataBar data as its input. This type is more of a shim/typedef to reduce the need to refer to things as NewHighsNewLows<IBaseDataBar>

To view the implementation of this indicator, see the LEAN GitHub repository .

Using NHNL Indicator

To create an automatic indicator for `NewHighsNewLows` , call the `NHNL` helper method from the `QCAlgorithm` class. The `NHNL` method creates a `NewHighsNewLows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class NewHighsNewLowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private NewHighsNewLows _nhnl;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _nhnl = NHNL([_symbol, _reference]);
    }

    public override void OnData(Slice data)
    {

        if (_nhnl.IsReady)
        {
            // The current value of _nhnl is represented by itself (_nhnl)
            // or _nhnl.Current.Value
            Plot("NewHighsNewLows", "nhnl", _nhnl);
            // Plot all properties of abands
            Plot("NewHighsNewLows", "difference", _nhnl.Difference);
            Plot("NewHighsNewLows", "ratio", _nhnl.Ratio);
        }
    }
}
```

To create an automatic indicator for `NewHighsNewLows` using universe constituents, call the `NHNL` helper method from the `QCAlgorithm` class. The `NHNL` method creates a `NewHighsNewLows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class NewHighsNewLowsAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private NewHighsNewLows _nhnl;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _nhnl = NHNL(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_nhnl.IsReady)
        {
            // The current value of _nhnl is represented by itself (_nhnl)
            // or _nhnl.Current.Value
            Plot("NewHighsNewLows", "nhnl", _nhnl);
            // Plot all properties of abands
            Plot("NewHighsNewLows", "difference", _nhnl.Difference);
            Plot("NewHighsNewLows", "ratio", _nhnl.Ratio);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `NewHighsNewLows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class NewHighsNewLowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private NewHighsNewLows _newhighsnewlows;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _newhighsnewlows = new NewHighsNewLows(19, 39);
        _newhighsnewlows.Add(_symbol);
        _newhighsnewlows.Add(_reference);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _newhighsnewlows.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _newhighsnewlows.Update(bar);

        if (_newhighsnewlows.IsReady)
        {
            // The current value of _newhighsnewlows is represented by itself (_newhighsnewlows)
            // or _newhighsnewlows.Current.Value
            Plot("NewHighsNewLows", "newhighsnewlows", _newhighsnewlows);
            // Plot all properties of abands
            Plot("NewHighsNewLows", "difference", _newhighsnewlows.Difference);
            Plot("NewHighsNewLows", "ratio", _newhighsnewlows.Ratio);
        }
    }
}
```

For more information about this indicator, see its reference .

The following plot shows values for some of the `NewHighsNewLows` indicator properties:

Indicator History

To get the historical data of the `NewHighsNewLows` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the

`IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class NewHighsNewLowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private NewHighsNewLows _nhnl;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _nhnl = NHNL([_symbol, _reference]);

        var indicatorHistory = IndicatorHistory(_nhnl, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_nhnl, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_nhnl, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var difference = indicatorHistory.Select(x => ((dynamic)x).Difference).ToList();
        var ratio = indicatorHistory.Select(x => ((dynamic)x).Ratio).ToList();
    }
}
```

Supported Indicators

New Highs New Lows Volume

Introduction

The New Highs - New Lows Volume Ratio is a Breadth indicator calculated as ratio of summary volume of stocks reaching new high to summary volume of stocks reaching new low compared to high and low values in defined time period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using NHNLV Indicator

To create an automatic indicator for `NewHighsNewLowsVolume` , call the `NHNLV` helper method from the `QCAlgorithm` class. The `NHNLV` method creates a `NewHighsNewLowsVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class NewHighsNewLowsVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private NewHighsNewLowsVolume _nhnlv;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _nhnlv = NHNLV([_symbol, _reference]);
    }

    public override void OnData(Slice data)
    {

        if (_nhnlv.IsReady)
        {
            // The current value of _nhnlv is represented by itself (_nhnlv)
            // or _nhnlv.Current.Value
            Plot("NewHighsNewLowsVolume", "nhnlv", _nhnlv);
            // Plot all properties of abands
            Plot("NewHighsNewLowsVolume", "volumeratio", _nhnlv.VolumeRatio);
            Plot("NewHighsNewLowsVolume", "difference", _nhnlv.Difference);
            Plot("NewHighsNewLowsVolume", "ratio", _nhnlv.Ratio);
        }
    }
}
```

To create an automatic indicator for `NewHighsNewLowsVolume` using universe constituents, call the `NHNLV` helper method from the `QCAlgorithm` class. The `NHNLV` method creates a `NewHighsNewLowsVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class NewHighsNewLowsVolumeAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private NewHighsNewLowsVolume _nhnlv;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _nhnlv = NHNLV(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_nhnlv.IsReady)
        {
            // The current value of _nhnlv is represented by itself (_nhnlv)
            // or _nhnlv.Current.Value
            Plot("NewHighsNewLowsVolume", "nhnlv", _nhnlv);
            // Plot all properties of abands
            Plot("NewHighsNewLowsVolume", "volumeratio", _nhnlv.VolumeRatio);
            Plot("NewHighsNewLowsVolume", "difference", _nhnlv.Difference);
            Plot("NewHighsNewLowsVolume", "ratio", _nhnlv.Ratio);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `NewHighsNewLowsVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class NewHighsNewLowsVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private NewHighsNewLowsVolume _newhighsnewlowsvolume;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _newhighsnewlowsvolume = new NewHighsNewLowsVolume(19, 39);
        _newhighsnewlowsvolume.Add(_symbol);
        _newhighsnewlowsvolume.Add(_reference);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _newhighsnewlowsvolume.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _newhighsnewlowsvolume.Update(bar);

        if (_newhighsnewlowsvolume.IsReady)
        {
            // The current value of _newhighsnewlowsvolume is represented by itself (_newhighsnewlowsvolume)
            // or _newhighsnewlowsvolume.Current.Value
            Plot("NewHighsNewLowsVolume", "newhighsnewlowsvolume", _newhighsnewlowsvolume);
            // Plot all properties of abands
            Plot("NewHighsNewLowsVolume", "volumeratio", _newhighsnewlowsvolume.VolumeRatio);
            Plot("NewHighsNewLowsVolume", "difference", _newhighsnewlowsvolume.Difference);
            Plot("NewHighsNewLowsVolume", "ratio", _newhighsnewlowsvolume.Ratio);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `NewHighsNewLowsVolume` indicator properties:

Indicator History

To get the historical data of the `NewHighsNewLowsVolume` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the

`IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class NewHighsNewLowsVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private NewHighsNewLowsVolume _nhnlv;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _nhnlv = NHNLV([_symbol, _reference]);

        var indicatorHistory = IndicatorHistory(_nhnlv, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_nhnlv, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_nhnlv, new[] { _symbol, _reference }, new DateTime(2024,
7, 1), new DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var volumeRatio = indicatorHistory.Select(x => ((dynamic)x).VolumeRatio).ToList();
        var difference = indicatorHistory.Select(x => ((dynamic)x).Difference).ToList();
        var ratio = indicatorHistory.Select(x => ((dynamic)x).Ratio).ToList();
    }
}
```

Supported Indicators

Normalized Average True Range

Introduction

This indicator computes the Normalized Average True Range (NATR). The Normalized Average True Range is calculated with the following formula: NATR = (ATR(period) / Close) * 100

To view the implementation of this indicator, see the LEAN GitHub repository .

Using NATR Indicator

To create an automatic indicator for `NormalizedAverageTrueRange` , call the `NATR` helper method from the `QCAlgorithm` class. The `NATR` method creates a `NormalizedAverageTrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class NormalizedAverageTrueRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private NormalizedAverageTrueRange _natr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _natr = NATR(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_natr.IsReady)
        {
            // The current value of _natr is represented by itself (_natr)
            // or _natr.Current.Value
            Plot("NormalizedAverageTrueRange", "natr", _natr);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `NormalizedAverageTrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class NormalizedAverageTrueRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private NormalizedAverageTrueRange _normalizedaveragetruerange;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _normalizedaveragetruerange = new NormalizedAverageTrueRange(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _normalizedaveragetruerange.Update(bar);

        if (_normalizedaveragetruerange.IsReady)
        {
            // The current value of _normalizedaveragetruerange is represented by itself
(_normalizedaveragetruerange)
            // or _normalizedaveragetruerange.Current.Value
            Plot("NormalizedAverageTrueRange", "normalizedaveragetruerange", _normalizedaveragetruerange);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Supported Indicators

On Balance Volume

Introduction

This indicator computes the On Balance Volume (OBV). The On Balance Volume is calculated by determining the price of the current close price and previous close price. If the current close price is equivalent to the previous price the OBV remains the same, If the current close price is higher the volume of that day is added to the OBV, while a lower close price will result in negative value.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using OBV Indicator

To create an automatic indicator for `OnBalanceVolume` , call the `OBV` helper method from the `QCAlgorithm` class. The `OBV` method creates a `OnBalanceVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class OnBalanceVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private OnBalanceVolume _obv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _obv = OBV(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_obv.IsReady)
        {
            // The current value of _obv is represented by itself (_obv)
            // or _obv.Current.Value
            Plot("OnBalanceVolume", "obv", _obv);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `OnBalanceVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class OnBalanceVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private OnBalanceVolume _onbalancevolume;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _onbalancevolume = new OnBalanceVolume();
    }

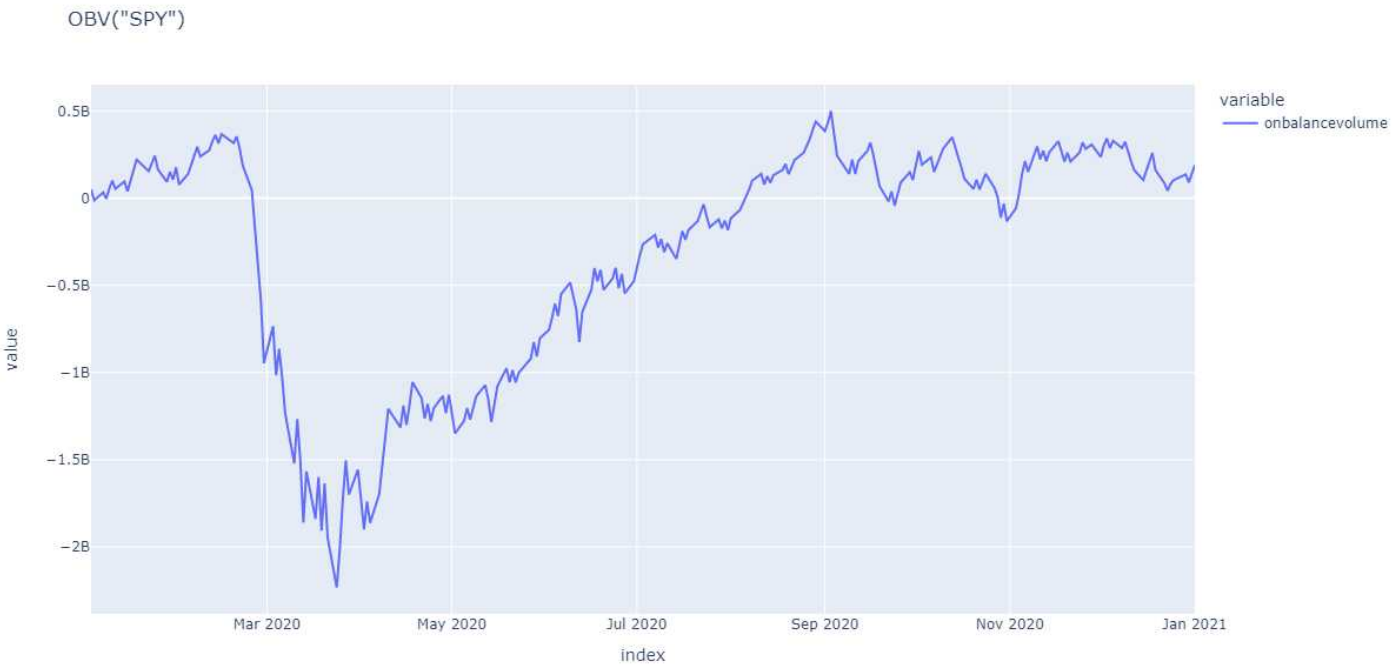
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _onbalancevolume.Update(bar);

        if (_onbalancevolume.IsReady)
        {
            // The current value of _onbalancevolume is represented by itself (_onbalancevolume)
            // or _onbalancevolume.Current.Value
            Plot("OnBalanceVolume", "onbalancevolume", _onbalancevolume);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `OnBalanceVolume` indicator properties:



Indicator History

To get the historical data of the `OnBalanceVolume` indicator, call the `IndicatorHistory` method. Parabolic Stop And Reverse

Introduction

Parabolic SAR Indicator Based on TA-Lib implementation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PSAR Indicator

To create an automatic indicator for `ParabolicStopAndReverse` , call the `PSAR` helper method from the `QCAlgorithm` class. The `PSAR` method creates a `ParabolicStopAndReverse` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ParabolicStopAndReverseAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ParabolicStopAndReverse _psar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _psar = PSAR(_symbol, 0.02m, 0.02m, 0.2m);
    }

    public override void OnData(Slice data)
    {

        if (_psar.IsReady)
        {
            // The current value of _psar is represented by itself (_psar)
            // or _psar.Current.Value
            Plot("ParabolicStopAndReverse", "psar", _psar);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ParabolicStopAndReverse` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ParabolicStopAndReverseAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ParabolicStopAndReverse _parabolicstopandreverse;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _parabolicstopandreverse = new ParabolicStopAndReverse(0.02m, 0.02m, 0.2m);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _parabolicstopandreverse.Update(bar);

        if (_parabolicstopandreverse.IsReady)
        {
            // The current value of _parabolicstopandreverse is represented by itself (_parabolicstopandreverse)
            // or _parabolicstopandreverse.Current.Value
            Plot("ParabolicStopAndReverse", "parabolicstopandreverse", _parabolicstopandreverse);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Parabolic Stop And Reverse Extended

Introduction

Parabolic SAR Extended Indicator Based on TA-Lib implementation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SAREXT Indicator

To create an automatic indicator for `ParabolicStopAndReverseExtended` , call the `SAREXT` helper method from the `QCAlgorithm` class. The `SAREXT` method creates a `ParabolicStopAndReverseExtended` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ParabolicStopAndReverseExtendedAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ParabolicStopAndReverseExtended _sarext;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sarext = SAREXT(_symbol, 0.0m, 0.0m, 0.02m, 0.02m, 0.2m, 0.02m, 0.02m, 0.2m);
    }

    public override void OnData(Slice data)
    {

        if (_sarext.IsReady)
        {
            // The current value of _sarext is represented by itself (_sarext)
            // or _sarext.Current.Value
            Plot("ParabolicStopAndReverseExtended", "sarext", _sarext);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ParabolicStopAndReverseExtended` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class ParabolicStopAndReverseExtendedAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ParabolicStopAndReverseExtended _parabolicstopandreverseextended;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _parabolicstopandreverseextended = new ParabolicStopAndReverseExtended(0.0m, 0.0m, 0.02m, 0.02m, 0.2m, 0.02m,
0.02m, 0.2m);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _parabolicstopandreverseextended.Update(bar);

        if (_parabolicstopandreverseextended.IsReady)
        {
            // The current value of _parabolicstopandreverseextended is represented by itself
(_parabolicstopandreverseextended)
            // or _parabolicstopandreverseextended.Current.Value
            Plot("ParabolicStopAndReverseExtended", "parabolicstopandreverseextended",
_parabolicstopandreverseextended);
        }
    }
}
```

Percentage Price Oscillator

Introduction

This indicator computes the Percentage Price Oscillator (PPO) The Percentage Price Oscillator is calculated using the following formula: PPO[i] = 100 * (FastMA[i] - SlowMA[i]) / SlowMA[i]

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PPO Indicator

To create an automatic indicator for `PercentagePriceOscillator` , call the `PPO` helper method from the `QCAlgorithm` class. The `PPO` method creates a `PercentagePriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class PercentagePriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PercentagePriceOscillator _ppo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ppo = PPO(_symbol, 10, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_ppo.IsReady)
        {
            // The current value of _ppo is represented by itself (_ppo)
            // or _ppo.Current.Value
            Plot("PercentagePriceOscillator", "ppo", _ppo);
            // Plot all properties of abands
            Plot("PercentagePriceOscillator", "fast", _ppo.Fast);
            Plot("PercentagePriceOscillator", "slow", _ppo.Slow);
            Plot("PercentagePriceOscillator", "signal", _ppo.Signal);
            Plot("PercentagePriceOscillator", "histogram", _ppo.Histogram);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `PercentagePriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class PercentagePriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PercentagePriceOscillator _percentagepriceoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _percentagepriceoscillator = new PercentagePriceOscillator(10, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _percentagepriceoscillator.Update(bar.EndTime, bar.Close);

        if (_percentagepriceoscillator.IsReady)
        {
            // The current value of _percentagepriceoscillator is represented by itself (_percentagepriceoscillator)
            // or _percentagepriceoscillator.Current.Value
            Plot("PercentagePriceOscillator", "percentagepriceoscillator", _percentagepriceoscillator);
            // Plot all properties of abands
            Plot("PercentagePriceOscillator", "fast", _percentagepriceoscillator.Fast);
            Plot("PercentagePriceOscillator", "slow", _percentagepriceoscillator.Slow);
            Plot("PercentagePriceOscillator", "signal", _percentagepriceoscillator.Signal);
            Plot("PercentagePriceOscillator", "histogram", _percentagepriceoscillator.Histogram);
        }
    }
}
```

For more information about this indicator, see its reference .

Pivot Points High Low

Introduction

Pivot Points (High/Low), also known as Bar Count Reversals, indicator. https://www.fidelity.com/learning-center/trading-investing/technical-analysis/technical-indicator-guide/pivot-points-high-low

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PPHL Indicator

To create an automatic indicator for `PivotPointsHighLow` , call the `PPHL` helper method from the `QCAlgorithm` class. The `PPHL` method creates a `PivotPointsHighLow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class PivotPointsHighLowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PivotPointsHighLow _pphl;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _pphl = PPHL(_symbol, 10, 10, 100);
    }

    public override void OnData(Slice data)
    {

        if (_pphl.IsReady)
        {
            // The current value of _pphl is represented by itself (_pphl)
            // or _pphl.Current.Value
            Plot("PivotPointsHighLow", "pphl", _pphl);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `PivotPointsHighLow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class PivotPointsHighLowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PivotPointsHighLow _pivotpointshighlow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _pivotpointshighlow = new PivotPointsHighLow(10, 10, 100);
    }

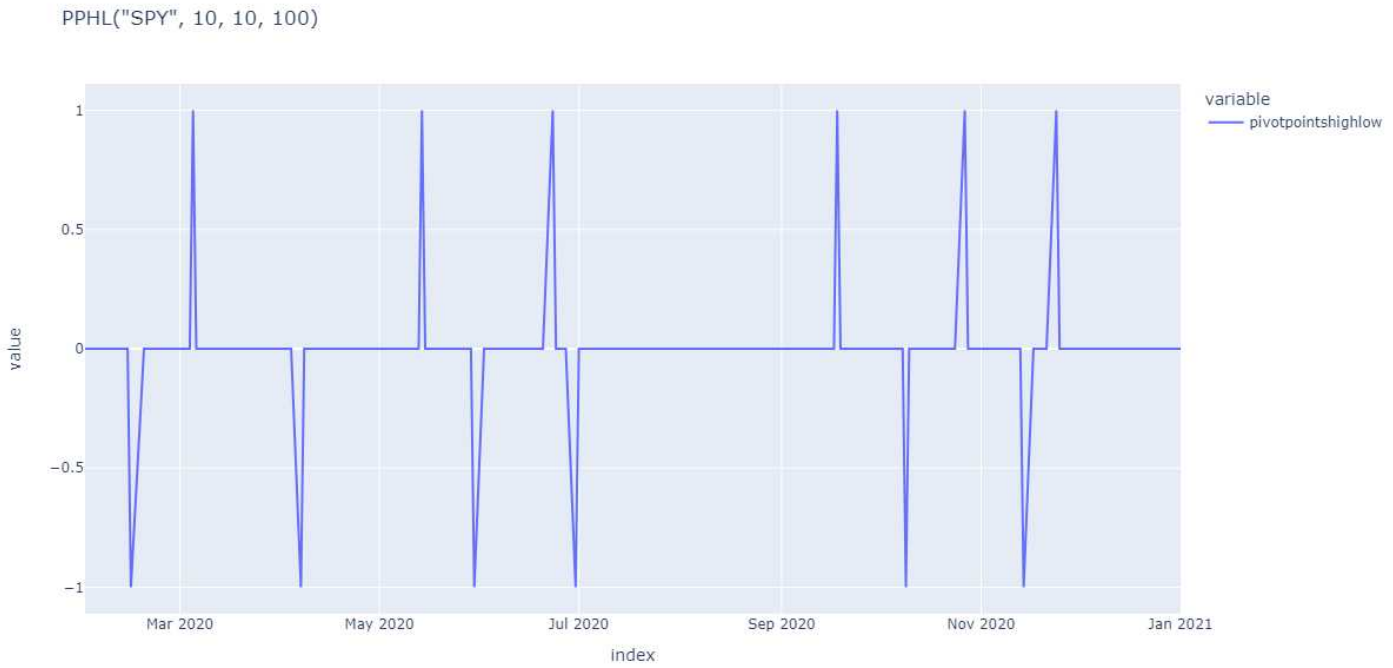
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _pivotpointshighlow.Update(bar);

        if (_pivotpointshighlow.IsReady)
        {
            // The current value of _pivotpointshighlow is represented by itself (_pivotpointshighlow)
            // or _pivotpointshighlow.Current.Value
            Plot("PivotPointsHighLow", "pivotpointshighlow", _pivotpointshighlow);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `PivotPointsHighLow` indicator properties:



Indicator History

To get the historical data of the `PivotPointsHighLow` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class PivotPointsHighLowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PivotPointsHighLow _pphl;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _pphl = PPHL(_symbol, 10, 10, 100);

        var indicatorHistory = IndicatorHistory(_pphl, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_pphl, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_pphl, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Premier Stochastic Oscillator

Introduction

Premier Stochastic Oscillator (PSO) Indicator implementation. This indicator combines a stochastic oscillator with exponential moving averages to provide a normalized output between -1 and 1, which can be useful for identifying trends and potential reversal points in the market.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using PSO Indicator

To create an automatic indicator for `PremierStochasticOscillator` , call the `PSO` helper method from the `QCAlgorithm` class. The `PSO` method creates a `PremierStochasticOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class PremierStochasticOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PremierStochasticOscillator _pso;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _pso = PSO(_symbol, 14, 3);
    }

    public override void OnData(Slice data)
    {

        if (_pso.IsReady)
        {
            // The current value of _pso is represented by itself (_pso)
            // or _pso.Current.Value
            Plot("PremierStochasticOscillator", "pso", _pso);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `PremierStochasticOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class PremierStochasticOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PremierStochasticOscillator _premierstochasticoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _premierstochasticoscillator = new PremierStochasticOscillator(14, 3);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _premierstochasticoscillator.Update(bar);

        if (_premierstochasticoscillator.IsReady)
        {
            // The current value of _premierstochasticoscillator is represented by itself
(_premierstochasticoscillator)
            // or _premierstochasticoscillator.Current.Value
            Plot("PremierStochasticOscillator", "premierstochasticoscillator", _premierstochasticoscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `PremierStochasticOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class PremierStochasticOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private PremierStochasticOscillator _pso;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _pso = PSO(_symbol, 14, 3);

        var indicatorHistory = IndicatorHistory(_pso, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_pso, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_pso, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Rate Of Change

Introduction

This indicator computes the n-period rate of change in a value using the following: (value_0 - value_n) / value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROC Indicator

To create an automatic indicator for `RateOfChange` , call the `ROC` helper method from the `QCAlgorithm` class. The `ROC` method creates a `RateOfChange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class RateOfChangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RateOfChange _roc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _roc = ROC(_symbol, 10);
    }

    public override void OnData(Slice data)
    {

        if (_roc.IsReady)
        {
            // The current value of _roc is represented by itself (_roc)
            // or _roc.Current.Value
            Plot("RateOfChange", "roc", _roc);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RateOfChange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class RateOfChangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RateOfChange _rateofchange;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rateofchange = new RateOfChange(10);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _rateofchange.Update(bar.EndTime, bar.Close);

        if (_rateofchange.IsReady)
        {
            // The current value of _rateofchange is represented by itself (_rateofchange)
            // or _rateofchange.Current.Value
            Plot("RateOfChange", "rateofchange", _rateofchange);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `RateOfChange` indicator properties:

Indicator History

To get the historical data of the `RateOfChange` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class RateOfChangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RateOfChange _roc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _roc = ROC(_symbol, 10);

        var indicatorHistory = IndicatorHistory(_roc, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_roc, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_roc, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Rate Of Change Percent

Introduction

This indicator computes the n-period percentage rate of change in a value using the following: 100 * (value_0 - value_n) / value_n

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROCP Indicator

To create an automatic indicator for `RateOfChangePercent` , call the `ROCP` helper method from the `QCAlgorithm` class. The `ROCP` method creates a `RateOfChangePercent` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class RateOfChangePercentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RateOfChangePercent _rocp;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rocp = ROCP(_symbol, 10);
    }

    public override void OnData(Slice data)
    {

        if (_rocp.IsReady)
        {
            // The current value of _rocp is represented by itself (_rocp)
            // or _rocp.Current.Value
            Plot("RateOfChangePercent", "rocp", _rocp);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RateOfChangePercent` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class RateOfChangePercentAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RateOfChangePercent _rateofchangepercent;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rateofchangepercent = new RateOfChangePercent(10);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _rateofchangepercent.Update(bar.EndTime, bar.Close);

        if (_rateofchangepercent.IsReady)
        {
            // The current value of _rateofchangepercent is represented by itself (_rateofchangepercent)
            // or _rateofchangepercent.Current.Value
            Plot("RateOfChangePercent", "rateofchangepercent", _rateofchangepercent);
        }
    }
}
```

For more information about this indicator, see its reference .

Supported Indicators

Rate Of Change Ratio

Introduction

This indicator computes the Rate Of Change Ratio (ROCR). The Rate Of Change Ratio is calculated with the following formula: ROCR = price / prevPrice

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ROCR Indicator

To create an automatic indicator for `RateOfChangeRatio` , call the `ROCR` helper method from the `QCAlgorithm` class. The `ROCR` method creates a `RateOfChangeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class RateOfChangeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RateOfChangeRatio _rocr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rocr = ROCR(_symbol, 10);
    }

    public override void OnData(Slice data)
    {

        if (_rocr.IsReady)
        {
            // The current value of _rocr is represented by itself (_rocr)
            // or _rocr.Current.Value
            Plot("RateOfChangeRatio", "rocr", _rocr);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RateOfChangeRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class RateOfChangeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RateOfChangeRatio _rateofchangeratio;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rateofchangeratio = new RateOfChangeRatio(10);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _rateofchangeratio.Update(bar.EndTime, bar.Close);

        if (_rateofchangeratio.IsReady)
        {
            // The current value of _rateofchangeratio is represented by itself (_rateofchangeratio)
            // or _rateofchangeratio.Current.Value
            Plot("RateOfChangeRatio", "rateofchangeratio", _rateofchangeratio);
        }
    }
}
```

For more information about this indicator, see its reference .

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rocr = ROCR(_symbol, 10);

        var indicatorHistory = IndicatorHistory(_rocr, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_rocr, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_rocr, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Regression Channel

Introduction

The Regression Channel indicator extends the with the inclusion of two (upper and lower) channel lines that are distanced from the linear regression line by a user defined number of standard deviations. Reference: http://www.onlinetradingconcepts.com/TechnicalAnalysis/LinRegChannel.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RC Indicator

To create an automatic indicator for `RegressionChannel` , call the `RC` helper method from the `QCAlgorithm` class. The `RC` method creates a `RegressionChannel` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class RegressionChannelAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RegressionChannel _rc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rc = RC(_symbol, 20, 2);
    }

    public override void OnData(Slice data)
    {

        if (_rc.IsReady)
        {
            // The current value of _rc is represented by itself (_rc)
            // or _rc.Current.Value
            Plot("RegressionChannel", "rc", _rc);
            // Plot all properties of abands
            Plot("RegressionChannel", "linearregression", _rc.LinearRegression);
            Plot("RegressionChannel", "upperchannel", _rc.UpperChannel);
            Plot("RegressionChannel", "lowerchannel", _rc.LowerChannel);
            Plot("RegressionChannel", "intercept", _rc.Intercept);
            Plot("RegressionChannel", "slope", _rc.Slope);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RegressionChannel` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class RegressionChannelAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RegressionChannel _regressionchannel;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _regressionchannel = new RegressionChannel(20, 2);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _regressionchannel.Update(bar.EndTime, bar.Close);

        if (_regressionchannel.IsReady)
        {
            // The current value of _regressionchannel is represented by itself (_regressionchannel)
            // or _regressionchannel.Current.Value
            Plot("RegressionChannel", "regressionchannel", _regressionchannel);
            // Plot all properties of abands
            Plot("RegressionChannel", "linearregression", _regressionchannel.LinearRegression);
            Plot("RegressionChannel", "upperchannel", _regressionchannel.UpperChannel);
            Plot("RegressionChannel", "lowerchannel", _regressionchannel.LowerChannel);
            Plot("RegressionChannel", "intercept", _regressionchannel.Intercept);
            Plot("RegressionChannel", "slope", _regressionchannel.Slope);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `RegressionChannel` indicator properties:

Indicator History

To get the historical data of the `RegressionChannel` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period

of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class RegressionChannelAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RegressionChannel _rc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rc = RC(_symbol, 20, 2);

        var indicatorHistory = IndicatorHistory(_rc, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_rc, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_rc, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var linearRegression = indicatorHistory.Select(x => ((dynamic)x).LinearRegression).ToList();
        var upperChannel = indicatorHistory.Select(x => ((dynamic)x).UpperChannel).ToList();
        var lowerChannel = indicatorHistory.Select(x => ((dynamic)x).LowerChannel).ToList();
        var intercept = indicatorHistory.Select(x => ((dynamic)x).Intercept).ToList();
        var slope = indicatorHistory.Select(x => ((dynamic)x).Slope).ToList();
    }
}
```

Supported Indicators

Relative Daily Volume

Introduction

The Relative Daily Volume indicator is an indicator that compares current cumulative volume to the cumulative volume for a given time of day, measured as a ratio. Current volume from open to current time of day / Average over the past x days from open to current time of day

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RDV Indicator

To create an automatic indicator for `RelativeDailyVolume` , call the `RDV` helper method from the `QCAlgorithm` class. The `RDV` method creates a `RelativeDailyVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class RelativeDailyVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeDailyVolume _rdv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rdv = RDV(_symbol, 2);
    }

    public override void OnData(Slice data)
    {

        if (_rdv.IsReady)
        {
            // The current value of _rdv is represented by itself (_rdv)
            // or _rdv.Current.Value
            Plot("RelativeDailyVolume", "rdv", _rdv);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeDailyVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class RelativeDailyVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeDailyVolume _relativedailyvolume;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _relativedailyvolume = new RelativeDailyVolume(2);
    }

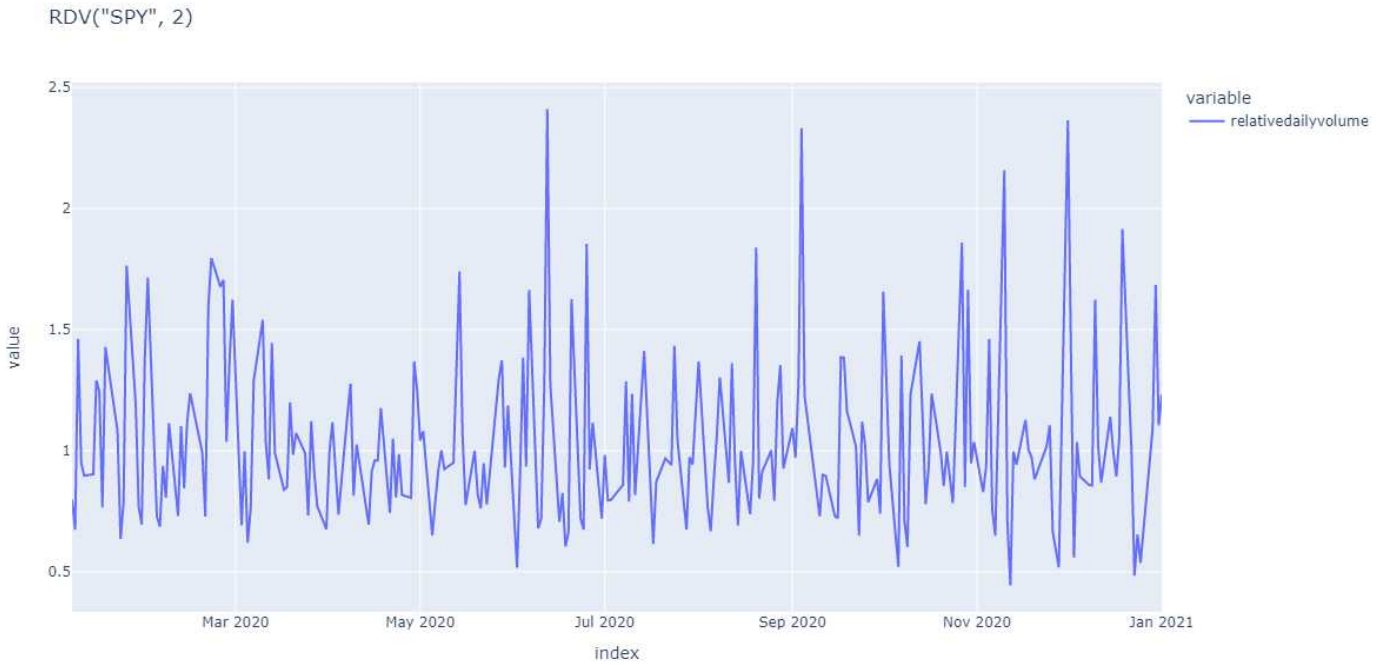
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _relativedailyvolume.Update(bar);

        if (_relativedailyvolume.IsReady)
        {
            // The current value of _relativedailyvolume is represented by itself (_relativedailyvolume)
            // or _relativedailyvolume.Current.Value
            Plot("RelativeDailyVolume", "relativedailyvolume", _relativedailyvolume);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `RelativeDailyVolume` indicator properties:



Indicator History

To get the historical data of the `RelativeDailyVolume` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class RelativeDailyVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeDailyVolume _rdv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rdv = RDV(_symbol, 2);

        var indicatorHistory = IndicatorHistory(_rdv, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_rdv, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_rdv, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Relative Moving Average

Introduction

This indicator represents the relative moving average indicator (RMA). RMA = SMA(3 x Period) - SMA(2 x Period) + SMA(1 x Period) per formula: https://www.hybrid-solutions.com/plugins/client-vtl-plugins/free/rma.html

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RMA Indicator

To create an automatic indicator for `RelativeMovingAverage` , call the `RMA` helper method from the `QCAlgorithm` class. The `RMA` method creates a `RelativeMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class RelativeMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeMovingAverage _rma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rma = RMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_rma.IsReady)
        {
            // The current value of _rma is represented by itself (_rma)
            // or _rma.Current.Value
            Plot("RelativeMovingAverage", "rma", _rma);
            // Plot all properties of abands
            Plot("RelativeMovingAverage", "shortaverage", _rma.ShortAverage);
            Plot("RelativeMovingAverage", "mediumaverage", _rma.MediumAverage);
            Plot("RelativeMovingAverage", "longaverage", _rma.LongAverage);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class RelativeMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeMovingAverage _relativemovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _relativemovingaverage = new RelativeMovingAverage(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _relativemovingaverage.Update(bar.EndTime, bar.Close);

        if (_relativemovingaverage.IsReady)
        {
            // The current value of _relativemovingaverage is represented by itself (_relativemovingaverage)
            // or _relativemovingaverage.Current.Value
            Plot("RelativeMovingAverage", "relativemovingaverage", _relativemovingaverage);
            // Plot all properties of abands
            Plot("RelativeMovingAverage", "shortaverage", _relativemovingaverage.ShortAverage);
            Plot("RelativeMovingAverage", "mediumaverage", _relativemovingaverage.MediumAverage);
            Plot("RelativeMovingAverage", "longaverage", _relativemovingaverage.LongAverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

    private RelativeMovingAverage _rma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rma = RMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_rma, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_rma, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_rma, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var shortAverage = indicatorHistory.Select(x => ((dynamic)x).ShortAverage).ToList();
        var mediumAverage = indicatorHistory.Select(x => ((dynamic)x).MediumAverage).ToList();
        var longAverage = indicatorHistory.Select(x => ((dynamic)x).LongAverage).ToList();
    }
}
```

Supported Indicators

Relative Strength Index

Introduction

This indicator represents the Relative Strength Index (RSI) developed by K. Welles Wilder. You can optionally specified a different moving average type to be used in the computation

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RSI Indicator

To create an automatic indicator for `RelativeStrengthIndex` , call the `RSI` helper method from the `QCAlgorithm` class. The `RSI` method creates a `RelativeStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class RelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeStrengthIndex _rsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rsi = RSI(_symbol, 14);
    }

    public override void OnData(Slice data)
    {

        if (_rsi.IsReady)
        {
            // The current value of _rsi is represented by itself (_rsi)
            // or _rsi.Current.Value
            Plot("RelativeStrengthIndex", "rsi", _rsi);
            // Plot all properties of abands
            Plot("RelativeStrengthIndex", "averageloss", _rsi.AverageLoss);
            Plot("RelativeStrengthIndex", "averagegain", _rsi.AverageGain);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class RelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeStrengthIndex _relativestrengthindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _relativestrengthindex = new RelativeStrengthIndex(14);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _relativestrengthindex.Update(bar.EndTime, bar.Close);

        if (_relativestrengthindex.IsReady)
        {
            // The current value of _relativestrengthindex is represented by itself (_relativestrengthindex)
            // or _relativestrengthindex.Current.Value
            Plot("RelativeStrengthIndex", "relativestrengthindex", _relativestrengthindex);
            // Plot all properties of abands
            Plot("RelativeStrengthIndex", "averageloss", _relativestrengthindex.AverageLoss);
            Plot("RelativeStrengthIndex", "averagegain", _relativestrengthindex.AverageGain);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Indicator History

To get the historical data of the `RelativeStrengthIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class RelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeStrengthIndex _rsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rsi = RSI(_symbol, 14);

        var indicatorHistory = IndicatorHistory(_rsi, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_rsi, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_rsi, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var averageLoss = indicatorHistory.Select(x => ((dynamic)x).AverageLoss).ToList();
        var averageGain = indicatorHistory.Select(x => ((dynamic)x).AverageGain).ToList();
    }
}
```

Supported Indicators

Relative Vigor Index

Introduction

The Relative Vigor Index (RVI) compares the ratio of the closing price of a security to its trading range. For illustration, let: a = Close−Open b = Close−Open of One Bar Prior to a c = Close−Open of One Bar Prior to b d = Close−Open of One Bar Prior to c e = High−Low of Bar a f = High−Low of Bar b g = High−Low of Bar c h = High−Low of Bar d Then let (a+2*(b+c)+d)/6 be NUM and (e+2*(f+g)+h)/6 be DENOM. RVI = SMA(NUM)/SMA(DENOM) for a specified period.
https://www.investopedia.com/terms/r/relative_vigor_index.asp

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RVI Indicator

To create an automatic indicator for `RelativeVigorIndex` , call the `RVI` helper method from the `QCAlgorithm` class. The `RVI` method creates a `RelativeVigorIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class RelativeVigorIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeVigorIndex _rvi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rvi = RVI(_symbol, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_rvi.IsReady)
        {
            // The current value of _rvi is represented by itself (_rvi)
            // or _rvi.Current.Value
            Plot("RelativeVigorIndex", "rvi", _rvi);
            // Plot all properties of abands
            Plot("RelativeVigorIndex", "signal", _rvi.Signal);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RelativeVigorIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class RelativeVigorIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RelativeVigorIndex _relativevigorindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _relativevigorindex = new RelativeVigorIndex(20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _relativevigorindex.Update(bar);

        if (_relativevigorindex.IsReady)
        {
            // The current value of _relativevigorindex is represented by itself (_relativevigorindex)
            // or _relativevigorindex.Current.Value
            Plot("RelativeVigorIndex", "relativevigorindex", _relativevigorindex);
            // Plot all properties of abands
            Plot("RelativeVigorIndex", "signal", _relativevigorindex.Signal);
        }
    }
}
```

For more information about this indicator, see its reference .

Rho

Introduction

Option Rho indicator that calculate the rho of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using R Indicator

To create an automatic indicator for `Rho` , call the `R` helper method from the `QCAlgorithm` class. The `R` method creates a `Rho` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class RhoAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Rho _r;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _r = R(_option, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (_r.IsReady)
        {
            // The current value of _r is represented by itself (_r)
            // or _r.Current.Value
            Plot("Rho", "r", _r);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Rho` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class RhoAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Rho _rho;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        var interestRateModel = new InterestRateProvider();
        var dividendYieldModel = new DividendYieldProvider(_symbol);

        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _rho = new Rho(_option, interestRateModel, dividendYieldModel, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _rho.Update(new IndicatorDataPoint(_symbol, bar.EndTime, bar.Close));
        if (data.QuoteBars.TryGetValue(_option, out var quoteBar))
            _rho.Update(new IndicatorDataPoint(_option, quoteBar.EndTime, quoteBar.Close));
        if (data.QuoteBars.TryGetValue(_mirrorOption, out quoteBar))
            _rho.Update(new IndicatorDataPoint(_mirrorOption, quoteBar.EndTime, quoteBar.Close));

        if (_rho.IsReady)
        {
            // The current value of _rho is represented by itself (_rho)
            // or _rho.Current.Value
            Plot("Rho", "rho", _rho);
        }
    }
}
```

For more information about this indicator, see its reference .

Rogers Satchell Volatility

Introduction

This indicator computes the Rogers-Satchell Volatility It is an estimator for measuring the volatility of securities with an average return not equal to zero.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using RSV Indicator

To create an automatic indicator for `RogersSatchellVolatility` , call the `RSV` helper method from the `QCAlgorithm` class. The `RSV` method creates a `RogersSatchellVolatility` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class RogersSatchellVolatilityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RogersSatchellVolatility _rsv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rsv = RSV(_symbol, 30);
    }

    public override void OnData(Slice data)
    {

        if (_rsv.IsReady)
        {
            // The current value of _rsv is represented by itself (_rsv)
            // or _rsv.Current.Value
            Plot("RogersSatchellVolatility", "rsv", _rsv);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `RogersSatchellVolatility` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class RogersSatchellVolatilityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RogersSatchellVolatility _rogerssatchellvolatility;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rogerssatchellvolatility = new RogersSatchellVolatility(30);
    }

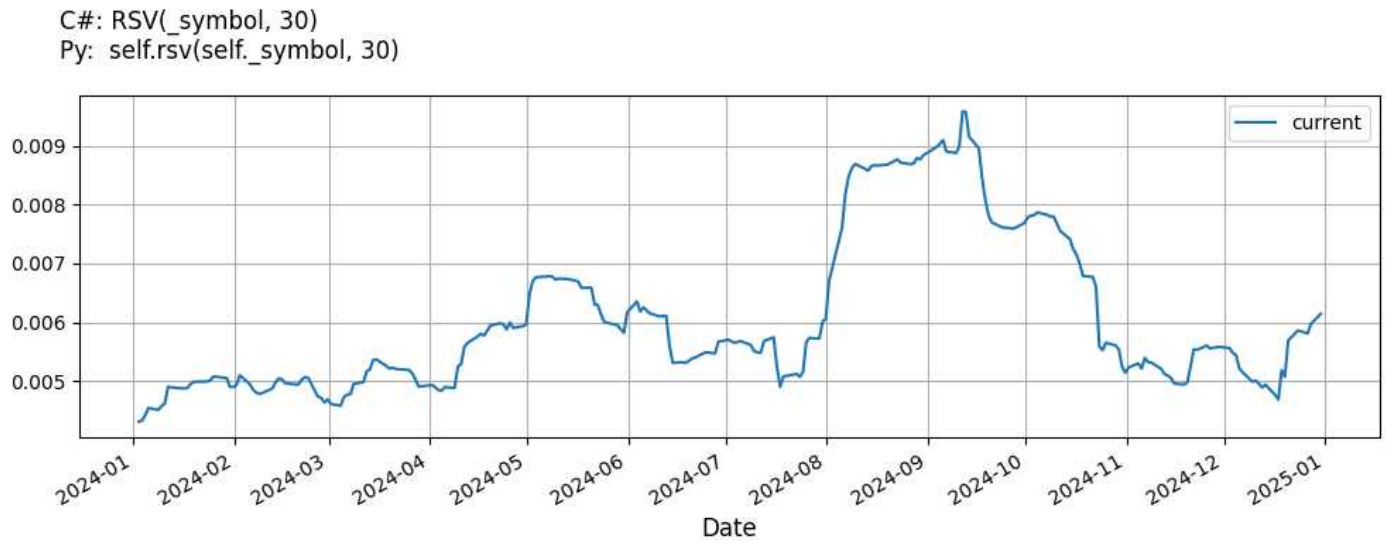
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _rogerssatchellvolatility.Update(bar);

        if (_rogerssatchellvolatility.IsReady)
        {
            // The current value of _rogerssatchellvolatility is represented by itself (_rogerssatchellvolatility)
            // or _rogerssatchellvolatility.Current.Value
            Plot("RogersSatchellVolatility", "rogerssatchellvolatility", _rogerssatchellvolatility);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `RogersSatchellVolatility` indicator properties:



Indicator History

To get the historical data of the `RogersSatchellVolatility` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class RogersSatchellVolatilityAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RogersSatchellVolatility _rsv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rsv = RSV(_symbol, 30);

        var indicatorHistory = IndicatorHistory(_rsv, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_rsv, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_rsv, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Schaff Trend Cycle

Introduction

This indicator creates the Schaff Trend Cycle

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STC Indicator

To create an automatic indicator for `SchaffTrendCycle` , call the `STC` helper method from the `QCAlgorithm` class. The `STC` method creates a `SchaffTrendCycle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class SchaffTrendCycleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SchaffTrendCycle _stc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stc = STC(_symbol, 5, 10, 20, MovingAverageType.Exponential);
    }

    public override void OnData(Slice data)
    {

        if (_stc.IsReady)
        {
            // The current value of _stc is represented by itself (_stc)
            // or _stc.Current.Value
            Plot("SchaffTrendCycle", "stc", _stc);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SchaffTrendCycle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SchaffTrendCycleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SchaffTrendCycle _schafftrendcycle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _schafftrendcycle = new SchaffTrendCycle(5, 10, 20, MovingAverageType.Exponential);
    }

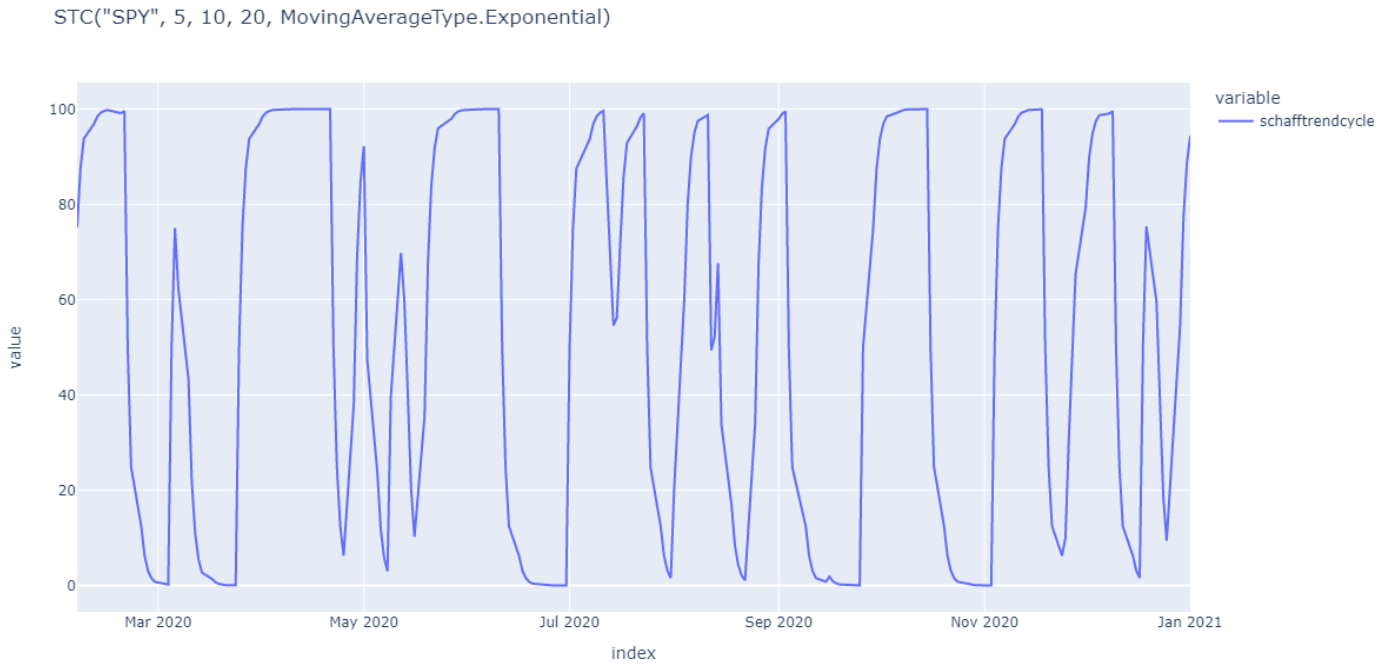
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _schafftrendcycle.Update(bar.EndTime, bar.Close);

        if (_schafftrendcycle.IsReady)
        {
            // The current value of _schafftrendcycle is represented by itself (_schafftrendcycle)
            // or _schafftrendcycle.Current.Value
            Plot("SchaffTrendCycle", "schafftrendcycle", _schafftrendcycle);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SchaffTrendCycle` indicator properties:



Indicator History

To get the historical data of the `SchaffTrendCycle` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class SchaffTrendCycleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SchaffTrendCycle _stc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stc = STC(_symbol, 5, 10, 20, MovingAverageType.Exponential);

        var indicatorHistory = IndicatorHistory(_stc, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_stc, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_stc, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Sharpe Ratio

Introduction

Calculation of the Sharpe Ratio (SR) developed by William F. Sharpe. Reference: https://www.investopedia.com/articles/07/sharpe_ratio.asp Formula: S(x) = (Rx - Rf) / stdDev(Rx) Where: S(x) - sharpe ratio of x Rx - average rate of return for x Rf - risk-free rate

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SR Indicator

To create an automatic indicator for `SharpeRatio` , call the `SR` helper method from the `QCAlgorithm` class. The `SR` method creates a `SharpeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class SharpeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SharpeRatio _sr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sr = SR(_symbol, 22, 0.03m);
    }

    public override void OnData(Slice data)
    {

        if (_sr.IsReady)
        {
            // The current value of _sr is represented by itself (_sr)
            // or _sr.Current.Value
            Plot("SharpeRatio", "sr", _sr);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SharpeRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SharpeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SharpeRatio _sharperatio;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sharperatio = new SharpeRatio(22, 0.03m);
    }

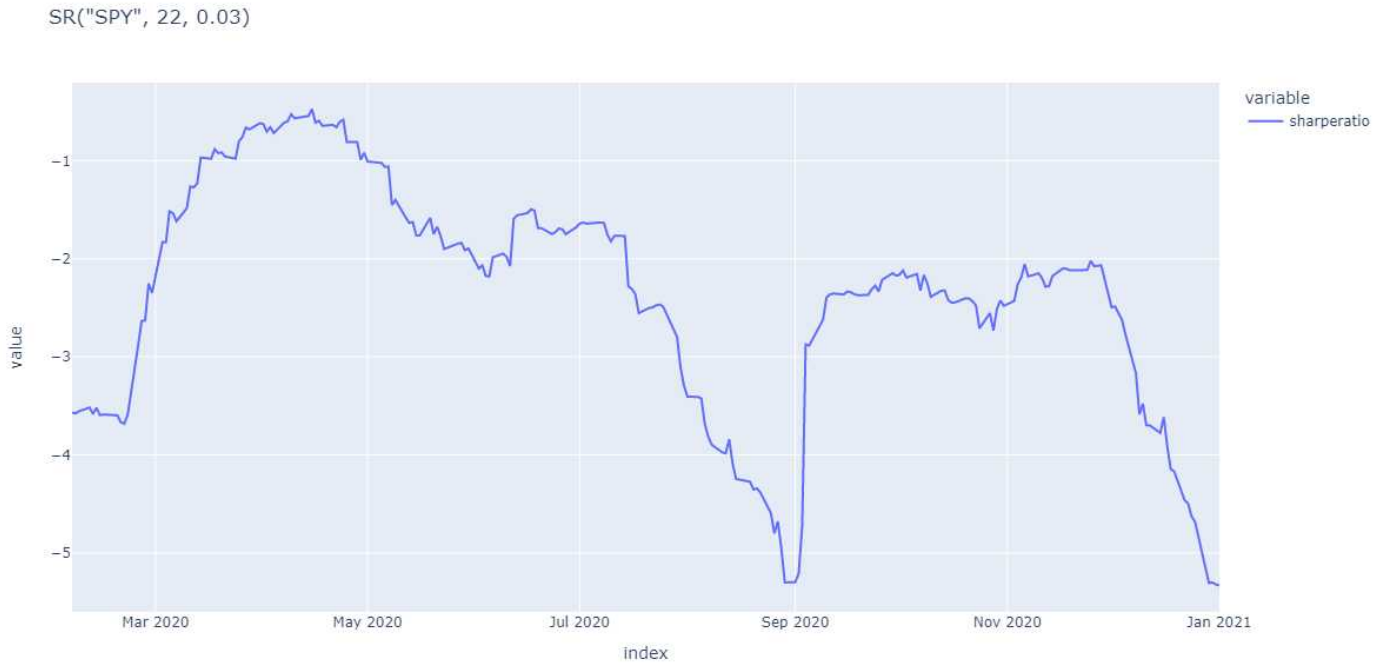
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _sharperatio.Update(bar.EndTime, bar.Close);

        if (_sharperatio.IsReady)
        {
            // The current value of _sharperatio is represented by itself (_sharperatio)
            // or _sharperatio.Current.Value
            Plot("SharpeRatio", "sharperatio", _sharperatio);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SharpeRatio` indicator properties:



Indicator History

To get the historical data of the `SharpeRatio` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class SharpeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SharpeRatio _sr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sr = SR(_symbol, 22, 0.03m);

        var indicatorHistory = IndicatorHistory(_sr, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_sr, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_sr, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Simple Moving Average

Introduction

This indicator represents the traditional simple moving average indicator (SMA)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SMA Indicator

To create an automatic indicator for `SimpleMovingAverage` , call the `SMA` helper method from the `QCAlgorithm` class. The `SMA` method creates a `SimpleMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class SimpleMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SimpleMovingAverage _sma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sma = SMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_sma.IsReady)
        {
            // The current value of _sma is represented by itself (_sma)
            // or _sma.Current.Value
            Plot("SimpleMovingAverage", "sma", _sma);
            // Plot all properties of abands
            Plot("SimpleMovingAverage", "rollingsum", _sma.RollingSum);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SimpleMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SimpleMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SimpleMovingAverage _simplemovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _simplemovingaverage = new SimpleMovingAverage(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _simplemovingaverage.Update(bar.EndTime, bar.Close);

        if (_simplemovingaverage.IsReady)
        {
            // The current value of _simplemovingaverage is represented by itself (_simplemovingaverage)
            // or _simplemovingaverage.Current.Value
            Plot("SimpleMovingAverage", "simplemovingaverage", _simplemovingaverage);
            // Plot all properties of abands
            Plot("SimpleMovingAverage", "rollingsum", _simplemovingaverage.RollingSum);
        }
    }
}
```

For more information about this indicator, see its reference .

Smoothed On Balance Volume

Introduction

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SOBV Indicator

To create an automatic indicator for `SmoothedOnBalanceVolume` , call the `SOBV` helper method from the `QCAlgorithm` class. The `SOBV` method creates a `SmoothedOnBalanceVolume` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class SmoothedOnBalanceVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SmoothedOnBalanceVolume _sobv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sobv = SOBV(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_sobv.IsReady)
        {
            // The current value of _sobv is represented by itself (_sobv)
            // or _sobv.Current.Value
            Plot("SmoothedOnBalanceVolume", "sobv", _sobv);
            // Plot all properties of abands
            Plot("SmoothedOnBalanceVolume", "onbalancevolume", _sobv.OnBalanceVolume);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SmoothedOnBalanceVolume` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SmoothedOnBalanceVolumeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SmoothedOnBalanceVolume _smoothedonbalancevolume;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _smoothedonbalancevolume = new SmoothedOnBalanceVolume(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _smoothedonbalancevolume.Update(bar);

        if (_smoothedonbalancevolume.IsReady)
        {
            // The current value of _smoothedonbalancevolume is represented by itself (_smoothedonbalancevolume)
            // or _smoothedonbalancevolume.Current.Value
            Plot("SmoothedOnBalanceVolume", "smoothedonbalancevolume", _smoothedonbalancevolume);
            // Plot all properties of abands
            Plot("SmoothedOnBalanceVolume", "onbalancevolume", _smoothedonbalancevolume.OnBalanceVolume);
        }
    }
}
```

For more information about this indicator, see its reference .

    private SmoothedOnBalanceVolume _sobv;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sobv = SOBV(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_sobv, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_sobv, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_sobv, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var onBalanceVolume = indicatorHistory.Select(x => ((dynamic)x).OnBalanceVolume).ToList();
    }
}
```

Supported Indicators

Sortino Ratio

Introduction

Calculation of the Sortino Ratio, a modification of the . Reference: https://www.cmegroup.com/education/files/rr-sortino-a-sharper-ratio.pdf Formula: S(x) = (R - T) / TDD Where: S(x) - Sortino ratio of x R - the average period return T - the target or required rate of return for the investment strategy under consideration. In Sortino's early work, T was originally known as the minimum acceptable return, or MAR. In his more recent work, MAR is now referred to as the Desired Target Return. TDD - the target downside deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SORTINO Indicator

To create an automatic indicator for `SortinoRatio` , call the `SORTINO` helper method from the `QCAlgorithm` class. The `SORTINO` method creates a `SortinoRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class SortinoRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SortinoRatio _sortino;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sortino = SORTINO(_symbol, 22);
    }

    public override void OnData(Slice data)
    {

        if (_sortino.IsReady)
        {
            // The current value of _sortino is represented by itself (_sortino)
            // or _sortino.Current.Value
            Plot("SortinoRatio", "sortino", _sortino);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SortinoRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SortinoRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SortinoRatio _sortinoratio;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sortinoratio = new SortinoRatio(22);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _sortinoratio.Update(bar.EndTime, bar.Close);

        if (_sortinoratio.IsReady)
        {
            // The current value of _sortinoratio is represented by itself (_sortinoratio)
            // or _sortinoratio.Current.Value
            Plot("SortinoRatio", "sortinoratio", _sortinoratio);
        }
    }
}
```

For more information about this indicator, see its reference .

```
public class SortinoRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SortinoRatio _sortino;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sortino = SORTINO(_symbol, 22);

        var indicatorHistory = IndicatorHistory(_sortino, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_sortino, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_sortino, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Squeeze Momentum

Introduction

The SqueezeMomentum indicator calculates whether the market is in a "squeeze" condition, determined by comparing Bollinger Bands to Keltner Channels. When the Bollinger Bands are inside the Keltner Channels, the indicator returns 1 (squeeze on). Otherwise, it returns -1 (squeeze off).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SM Indicator

To create an automatic indicator for `SqueezeMomentum` , call the `SM` helper method from the `QCAlgorithm` class. The `SM` method creates a `SqueezeMomentum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class SqueezeMomentumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SqueezeMomentum _sm;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sm = SM(_symbol, 20, 2, 20, 1.5m);
    }

    public override void OnData(Slice data)
    {

        if (_sm.IsReady)
        {
            // The current value of _sm is represented by itself (_sm)
            // or _sm.Current.Value
            Plot("SqueezeMomentum", "sm", _sm);
            // Plot all properties of abands
            Plot("SqueezeMomentum", "bollingerbands", _sm.BollingerBands);
            Plot("SqueezeMomentum", "keltnerchannels", _sm.KeltnerChannels);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SqueezeMomentum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SqueezeMomentumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SqueezeMomentum _squeezemomentum;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _squeezemomentum = new SqueezeMomentum("SPY", 20, 2m, 20, 1.5m);
    }

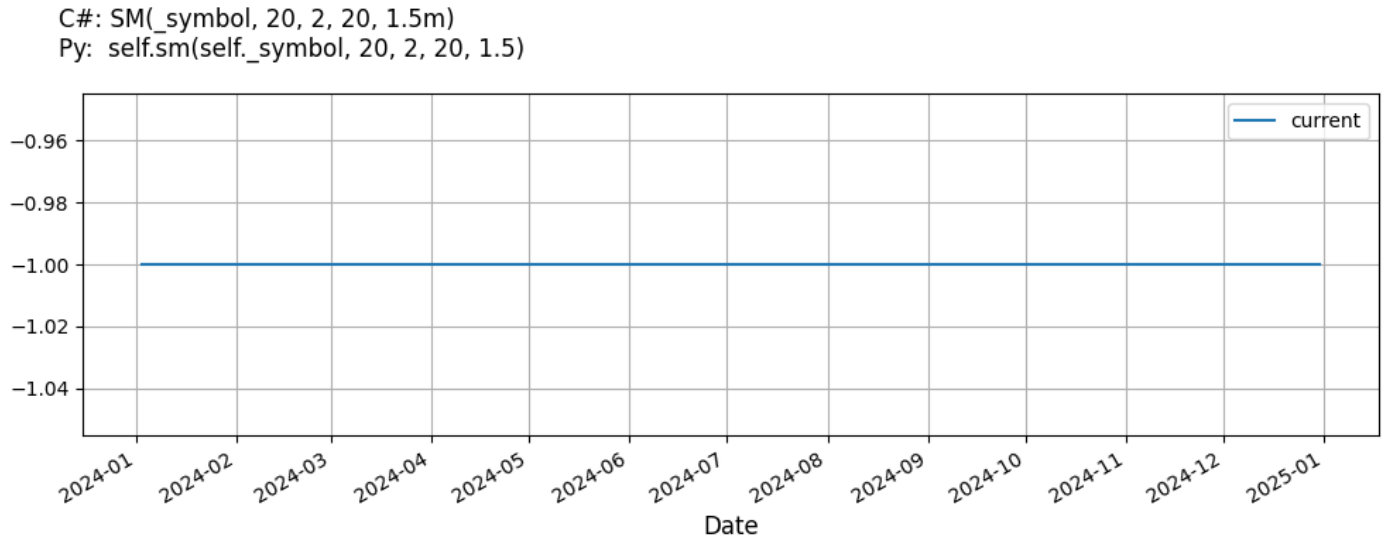
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _squeezemomentum.Update(bar);

        if (_squeezemomentum.IsReady)
        {
            // The current value of _squeezemomentum is represented by itself (_squeezemomentum)
            // or _squeezemomentum.Current.Value
            Plot("SqueezeMomentum", "squeezemomentum", _squeezemomentum);
            // Plot all properties of abands
            Plot("SqueezeMomentum", "bollingerbands", _squeezemomentum.BollingerBands);
            Plot("SqueezeMomentum", "keltnerchannels", _squeezemomentum.KeltnerChannels);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SqueezeMomentum` indicator properties:



Indicator History

To get the historical data of the `SqueezeMomentum` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class SqueezeMomentumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SqueezeMomentum _sm;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sm = SM(_symbol, 20, 2, 20, 1.5m);

        var indicatorHistory = IndicatorHistory(_sm, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_sm, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_sm, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var bollingerBands = indicatorHistory.Select(x => ((dynamic)x).BollingerBands).ToList();
        var keltnerChannels = indicatorHistory.Select(x => ((dynamic)x).KeltnerChannels).ToList();
    }
}
```

Supported Indicators

Standard Deviation

Introduction

This indicator computes the n-period population standard deviation.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STD Indicator

To create an automatic indicator for `StandardDeviation` , call the `STD` helper method from the `QCAlgorithm` class. The `STD` method creates a `StandardDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class StandardDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StandardDeviation _std;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _std = STD(_symbol, 22);
    }

    public override void OnData(Slice data)
    {

        if (_std.IsReady)
        {
            // The current value of _std is represented by itself (_std)
            // or _std.Current.Value
            Plot("StandardDeviation", "std", _std);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `StandardDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class StandardDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StandardDeviation _standarddeviation;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _standarddeviation = new StandardDeviation(22);
    }

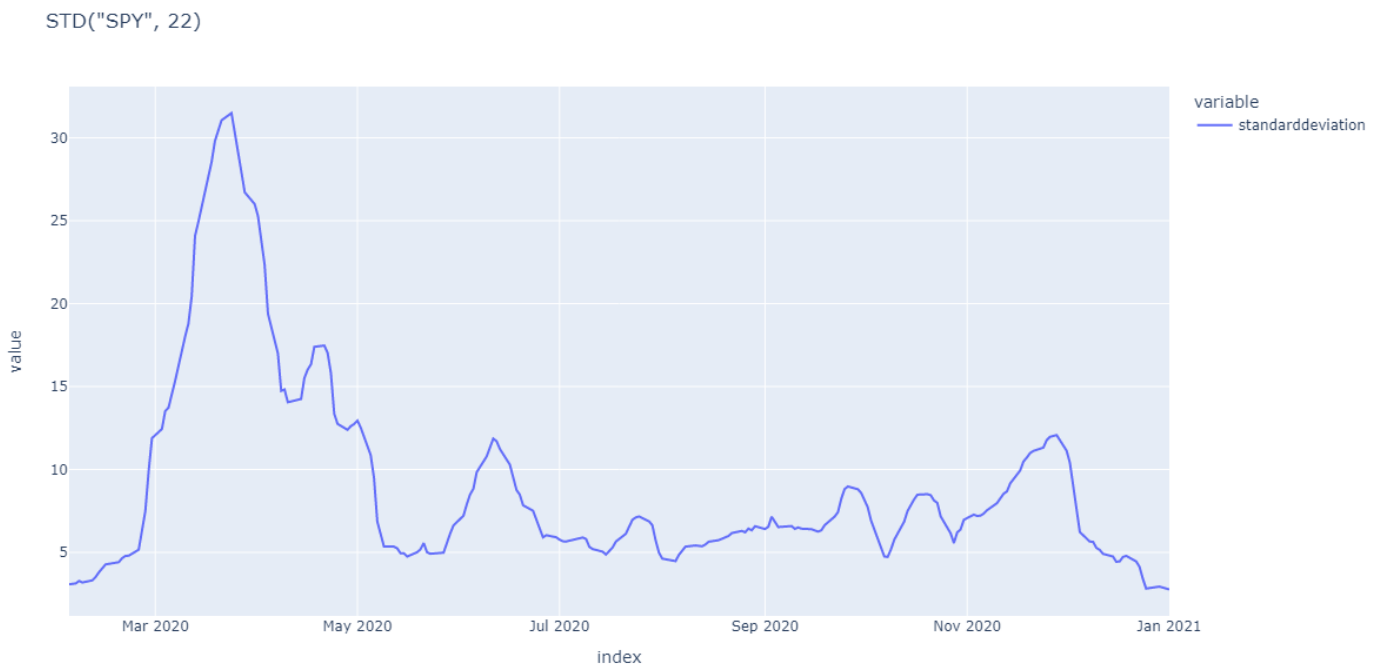
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _standarddeviation.Update(bar.EndTime, bar.Close);

        if (_standarddeviation.IsReady)
        {
            // The current value of _standarddeviation is represented by itself (_standarddeviation)
            // or _standarddeviation.Current.Value
            Plot("StandardDeviation", "standarddeviation", _standarddeviation);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `StandardDeviation` indicator properties:



Indicator History

To get the historical data of the `StandardDeviation` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class StandardDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StandardDeviation _std;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _std = STD(_symbol, 22);

        var indicatorHistory = IndicatorHistory(_std, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_std, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_std, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Stochastic

Introduction

This indicator computes the Slow Stochastics %K and %D. The Fast Stochastic %K is is computed by (Current Close Price - Lowest Price of given Period) / (Highest Price of given Period - Lowest Price of given Period) multiplied by 100. Once the Fast Stochastic %K is calculated the Slow Stochastic %K is calculated by the average/smoothed price of of the Fast %K with the given period. The Slow Stochastic %D is then derived from the Slow Stochastic %K with the given period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STO Indicator

To create an automatic indicator for `Stochastic` , call the `STO` helper method from the `QCAlgorithm` class. The `STO` method creates a `Stochastic` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class StochasticAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Stochastic _sto;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sto = STO(_symbol, 20, 10, 20);
    }

    public override void OnData(Slice data)
    {

        if (_sto.IsReady)
        {
            // The current value of _sto is represented by itself (_sto)
            // or _sto.Current.Value
            Plot("Stochastic", "sto", _sto);
            // Plot all properties of abands
            Plot("Stochastic", "faststoch", _sto.FastStoch);
            Plot("Stochastic", "stochk", _sto.StochK);
            Plot("Stochastic", "stochd", _sto.StochD);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Stochastic` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class StochasticAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Stochastic _stochastic;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stochastic = new Stochastic(20, 10, 20);
    }

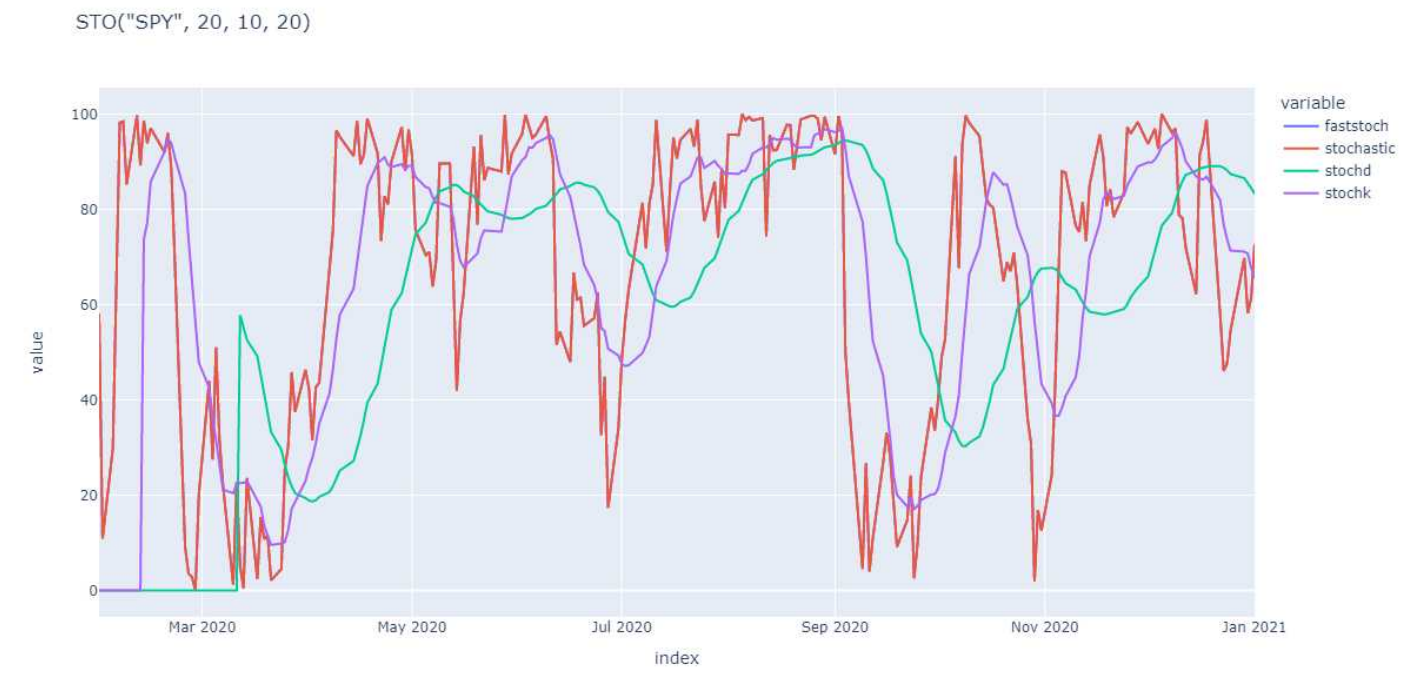
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _stochastic.Update(bar);

        if (_stochastic.IsReady)
        {
            // The current value of _stochastic is represented by itself (_stochastic)
            // or _stochastic.Current.Value
            Plot("Stochastic", "stochastic", _stochastic);
            // Plot all properties of abands
            Plot("Stochastic", "faststoch", _stochastic.FastStoch);
            Plot("Stochastic", "stochk", _stochastic.StochK);
            Plot("Stochastic", "stochd", _stochastic.StochD);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Stochastic` indicator properties:



Indicator History

To get the historical data of the `Stochastic` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class StochasticAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Stochastic _sto;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sto = STO(_symbol, 20, 10, 20);

        var indicatorHistory = IndicatorHistory(_sto, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_sto, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_sto, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var fastStoch = indicatorHistory.Select(x => ((dynamic)x).FastStoch).ToList();
        var stochK = indicatorHistory.Select(x => ((dynamic)x).StochK).ToList();
        var stochD = indicatorHistory.Select(x => ((dynamic)x).StochD).ToList();
    }
}
```

Supported Indicators

Stochastic Relative Strength Index

Introduction

Stochastic RSI, or simply StochRSI, is a technical analysis indicator used to determine whether an asset is overbought or oversold, as well as to identify current market trends. As the name suggests, the StochRSI is a derivative of the standard Relative Strength Index (RSI) and, as such, is considered an indicator of an indicator. It is a type of oscillator, meaning that it fluctuates above and below a center line.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SRSI Indicator

To create an automatic indicator for `StochasticRelativeStrengthIndex` , call the `SRSI` helper method from the `QCAlgorithm` class. The `SRSI` method creates a `StochasticRelativeStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class StochasticRelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StochasticRelativeStrengthIndex _srsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _srsi = SRSI(_symbol, 14, 14, 3, 3);
    }

    public override void OnData(Slice data)
    {

        if (_srsi.IsReady)
        {
            // The current value of _srsi is represented by itself (_srsi)
            // or _srsi.Current.Value
            Plot("StochasticRelativeStrengthIndex", "srsi", _srsi);
            // Plot all properties of abands
            Plot("StochasticRelativeStrengthIndex", "k", _srsi.K);
            Plot("StochasticRelativeStrengthIndex", "d", _srsi.D);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `StochasticRelativeStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class StochasticRelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StochasticRelativeStrengthIndex _stochasticrelativestrengthindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stochasticrelativestrengthindex = new StochasticRelativeStrengthIndex(14, 14, 3, 3);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _stochasticrelativestrengthindex.Update(bar.EndTime, bar.Close);

        if (_stochasticrelativestrengthindex.IsReady)
        {
            // The current value of _stochasticrelativestrengthindex is represented by itself
(_stochasticrelativestrengthindex)
            // or _stochasticrelativestrengthindex.Current.Value
            Plot("StochasticRelativeStrengthIndex", "stochasticrelativestrengthindex",
_stochasticrelativestrengthindex);
            // Plot all properties of abands
            Plot("StochasticRelativeStrengthIndex", "k", _stochasticrelativestrengthindex.K);
            Plot("StochasticRelativeStrengthIndex", "d", _stochasticrelativestrengthindex.D);
        }
    }
}
```

For more information about this indicator, see its reference .

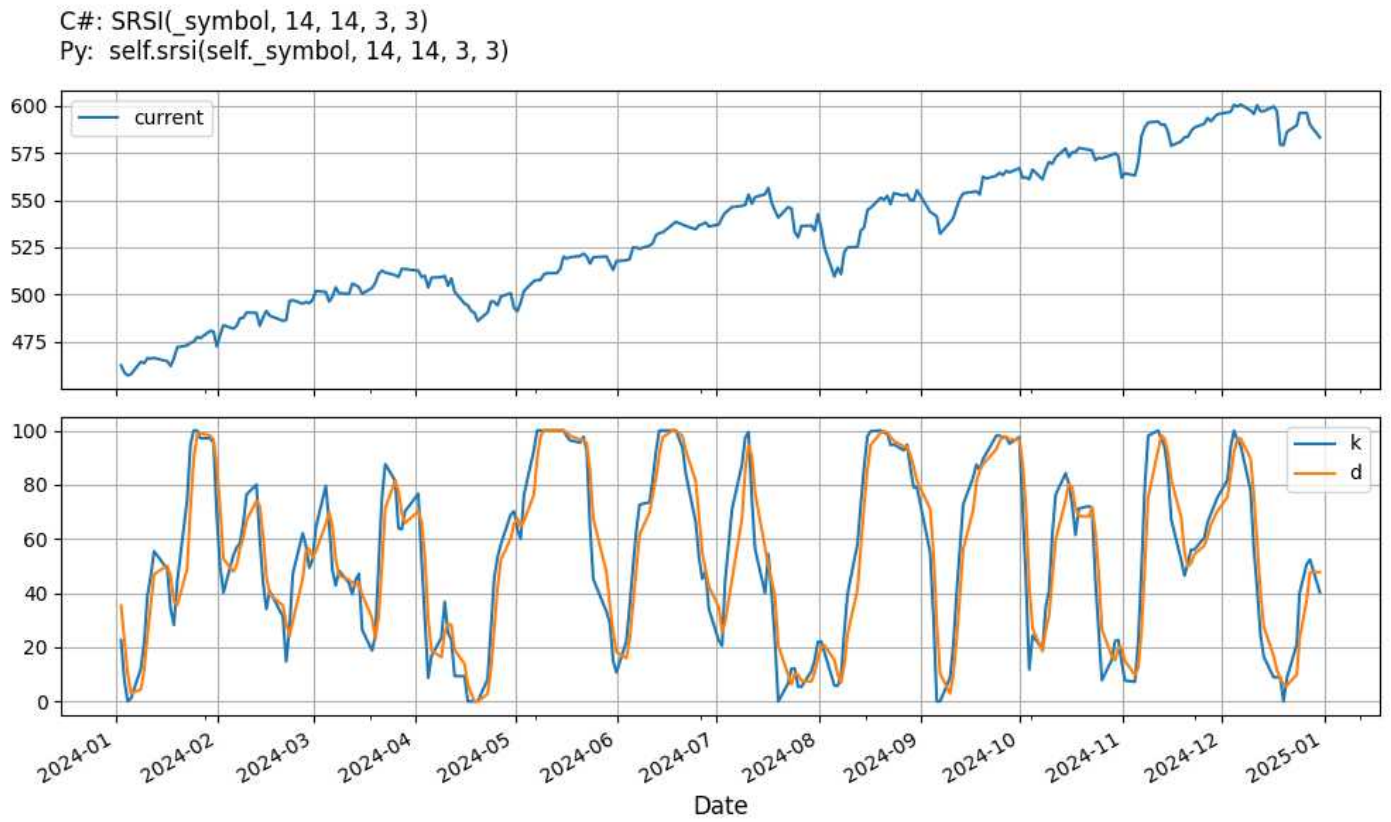
The following plot shows values for some of the `StochasticRelativeStrengthIndex` indicator properties:



Indicator History

To get the historical data of the `StochasticRelativeStrengthIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history

requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class StochasticRelativeStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StochasticRelativeStrengthIndex _srsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _srsi = SRSI(_symbol, 14, 14, 3, 3);

        var indicatorHistory = IndicatorHistory(_srsi, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_srsi, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_srsi, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var k = indicatorHistory.Select(x => ((dynamic)x).K).ToList();
        var d = indicatorHistory.Select(x => ((dynamic)x).D).ToList();
    }
}
```

Supported Indicators

Sum

Introduction

This indicator represents an indicator capable of tracking the sum for the given period

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SUM Indicator

To create an automatic indicator for `Sum` , call the `SUM` helper method from the `QCAlgorithm` class. The `SUM` method creates a `Sum` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class SumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Sum _sum;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sum = SUM(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_sum.IsReady)
        {
            // The current value of _sum is represented by itself (_sum)
            // or _sum.Current.Value
            Plot("Sum", "sum", _sum);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Sum` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Sum _sum;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sum = new Sum(20);
    }

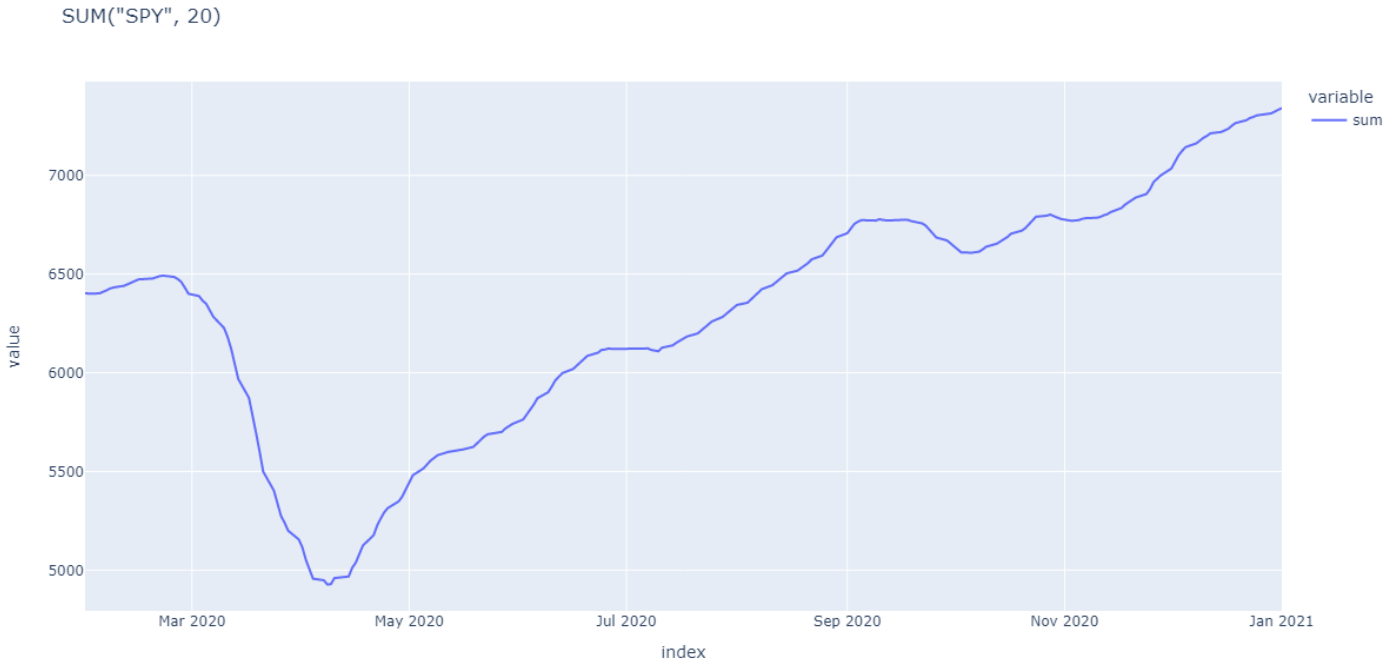
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _sum.Update(bar.EndTime, bar.Close);

        if (_sum.IsReady)
        {
            // The current value of _sum is represented by itself (_sum)
            // or _sum.Current.Value
            Plot("Sum", "sum", _sum);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Sum` indicator properties:



Indicator History

To get the historical data of the `Sum` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class SumAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Sum _sum;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _sum = SUM(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_sum, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_sum, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_sum, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Super Trend

Introduction

Super trend indicator. Formula can be found here via the excel file: https://tradingtuitions.com/supertrend-indicator-excel-sheet-with-realtime-buy-sell-signals/

To view the implementation of this indicator, see the LEAN GitHub repository .

Using STR Indicator

To create an automatic indicator for `SuperTrend` , call the `STR` helper method from the `QCAlgorithm` class. The `STR` method creates a `SuperTrend` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class SuperTrendAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SuperTrend _str;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _str = STR(_symbol, 20, 2, MovingAverageType.Wilders);
    }

    public override void OnData(Slice data)
    {

        if (_str.IsReady)
        {
            // The current value of _str is represented by itself (_str)
            // or _str.Current.Value
            Plot("SuperTrend", "str", _str);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SuperTrend` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class SuperTrendAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SuperTrend _supertrend;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _supertrend = new SuperTrend(20, 2, MovingAverageType.Wilders);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _supertrend.Update(bar);

        if (_supertrend.IsReady)
        {
            // The current value of _supertrend is represented by itself (_supertrend)
            // or _supertrend.Current.Value
            Plot("SuperTrend", "supertrend", _supertrend);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

Swiss Army Knife

Introduction

Swiss Army Knife indicator by John Ehlers

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SWISS Indicator

To create an automatic indicator for `SwissArmyKnife` , call the `SWISS` helper method from the `QCAlgorithm` class. The `SWISS` method creates a `SwissArmyKnife` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class SwissArmyKnifeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SwissArmyKnife _swiss;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _swiss = SWISS(_symbol, 20, 0.2, SwissArmyKnifeTool.Gauss);
    }

    public override void OnData(Slice data)
    {

        if (_swiss.IsReady)
        {
            // The current value of _swiss is represented by itself (_swiss)
            // or _swiss.Current.Value
            Plot("SwissArmyKnife", "swiss", _swiss);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `SwissArmyKnife` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class SwissArmyKnifeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SwissArmyKnife _swissarmyknife;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _swissarmyknife = new SwissArmyKnife(20, 0.2, SwissArmyKnifeTool.Gauss);
    }

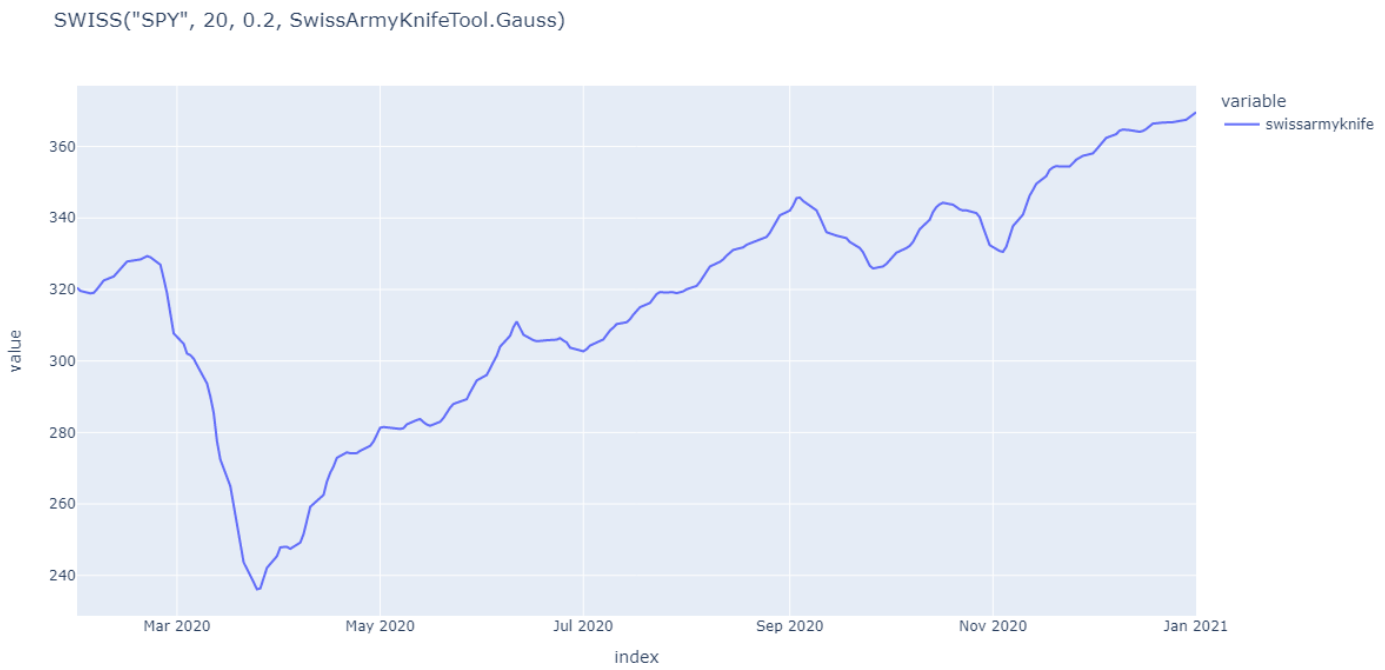
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _swissarmyknife.Update(bar.EndTime, bar.Close);

        if (_swissarmyknife.IsReady)
        {
            // The current value of _swissarmyknife is represented by itself (_swissarmyknife)
            // or _swissarmyknife.Current.Value
            Plot("SwissArmyKnife", "swissarmyknife", _swissarmyknife);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `SwissArmyKnife` indicator properties:



Indicator History

To get the historical data of the `SwissArmyKnife` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class SwissArmyKnifeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SwissArmyKnife _swiss;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _swiss = SWISS(_symbol, 20, 0.2, SwissArmyKnifeTool.Gauss);

        var indicatorHistory = IndicatorHistory(_swiss, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_swiss, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_swiss, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

T3 Moving Average

Introduction

This indicator computes the T3 Moving Average (T3). The T3 Moving Average is calculated with the following formula: EMA1(x, Period) = EMA(x, Period) EMA2(x, Period) = EMA(EMA1(x, Period),Period) GD(x, Period, volumeFactor) = (EMA1(x, Period)* (1+volumeFactor)) - (EMA2(x, Period)* volumeFactor) T3 = GD(GD(GD(t, Period, volumeFactor), Period, volumeFactor), Period, volumeFactor);

To view the implementation of this indicator, see the LEAN GitHub repository .

Using T3 Indicator

To create an automatic indicator for `T3MovingAverage` , call the `T3` helper method from the `QCAlgorithm` class. The `T3` method creates a `T3MovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class T3MovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private T3MovingAverage _t3;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _t3 = T3(_symbol, 30, 0.7m);
    }

    public override void OnData(Slice data)
    {

        if (_t3.IsReady)
        {
            // The current value of _t3 is represented by itself (_t3)
            // or _t3.Current.Value
            Plot("T3MovingAverage", "t3", _t3);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `T3MovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class T3MovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private T3MovingAverage _t3movingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _t3movingaverage = new T3MovingAverage(30, 0.7m);
    }

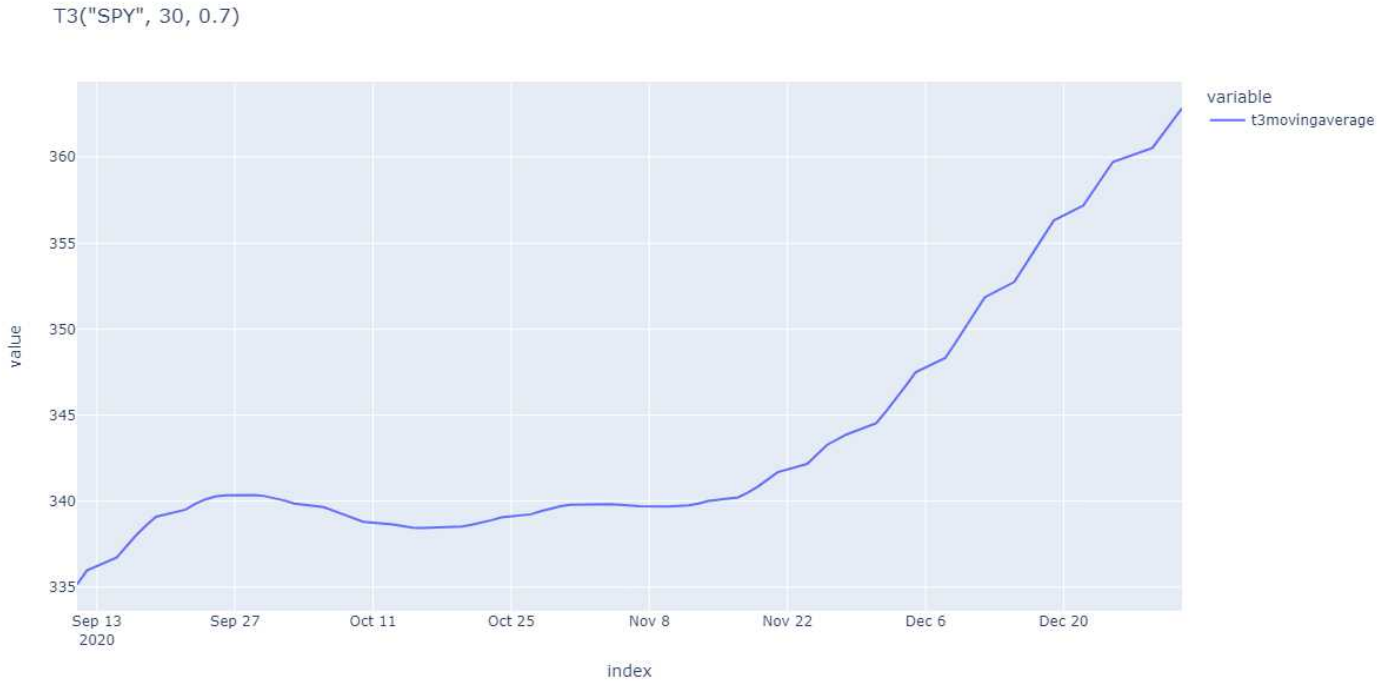
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _t3movingaverage.Update(bar.EndTime, bar.Close);

        if (_t3movingaverage.IsReady)
        {
            // The current value of _t3movingaverage is represented by itself (_t3movingaverage)
            // or _t3movingaverage.Current.Value
            Plot("T3MovingAverage", "t3movingaverage", _t3movingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `T3MovingAverage` indicator properties:



Indicator History

To get the historical data of the `T3MovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class T3MovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private T3MovingAverage _t3;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _t3 = T3(_symbol, 30, 0.7m);

        var indicatorHistory = IndicatorHistory(_t3, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_t3, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_t3, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Target Downside Deviation

Introduction

This indicator computes the n-period target downside deviation. The target downside deviation is defined as the root-mean-square, or RMS, of the deviations of the realized return's underperformance from the target return where all returns above the target return are treated as underperformance of 0. Reference: https://www.cmegroup.com/education/files/rr-sortino-a-sharper-ratio.pdf

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TDD Indicator

To create an automatic indicator for `TargetDownsideDeviation` , call the `TDD` helper method from the `QCAlgorithm` class. The `TDD` method creates a `TargetDownsideDeviation` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class TargetDownsideDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TargetDownsideDeviation _tdd;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tdd = TDD(_symbol, 50);
    }

    public override void OnData(Slice data)
    {

        if (_tdd.IsReady)
        {
            // The current value of _tdd is represented by itself (_tdd)
            // or _tdd.Current.Value
            Plot("TargetDownsideDeviation", "tdd", _tdd);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TargetDownsideDeviation` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TargetDownsideDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TargetDownsideDeviation _targetdownsidedeviation;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _targetdownsidedeviation = new TargetDownsideDeviation(50).Of(new RateOfChange(1));
    }

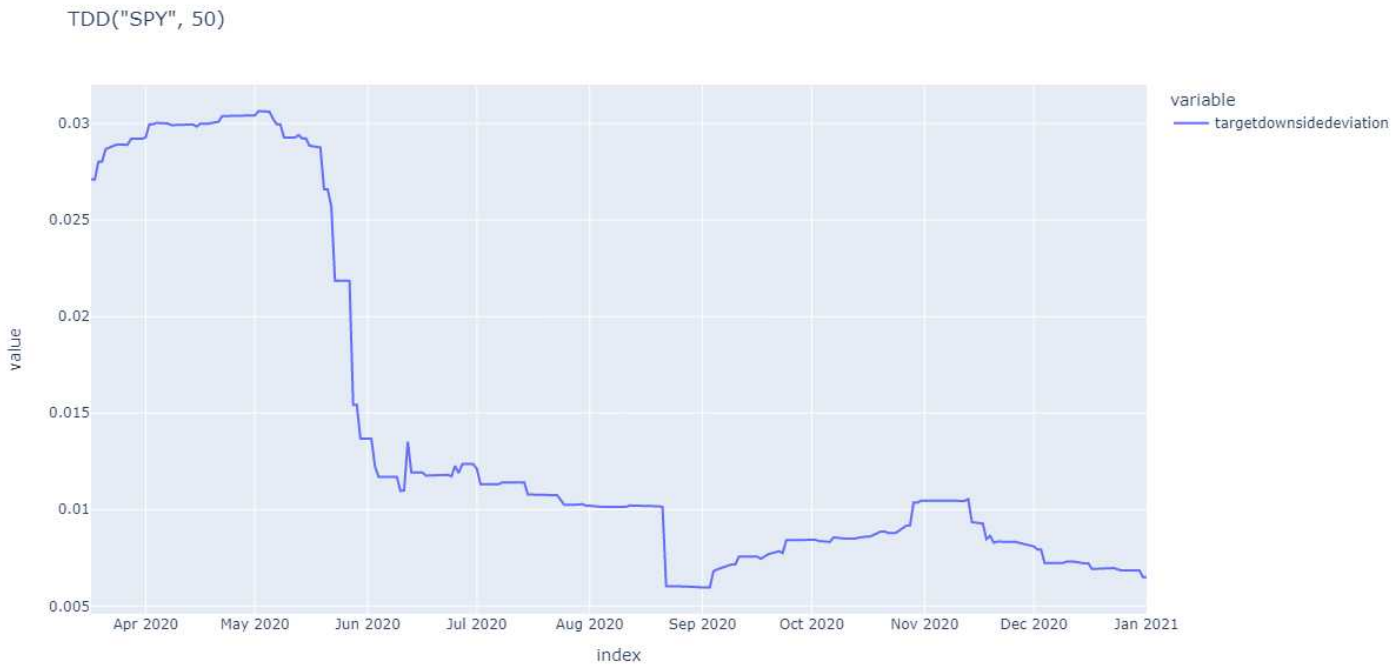
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _targetdownsidedeviation.Update(bar.EndTime, bar.Close);

        if (_targetdownsidedeviation.IsReady)
        {
            // The current value of _targetdownsidedeviation is represented by itself (_targetdownsidedeviation)
            // or _targetdownsidedeviation.Current.Value
            Plot("TargetDownsideDeviation", "targetdownsidedeviation", _targetdownsidedeviation);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TargetDownsideDeviation` indicator properties:



Indicator History

To get the historical data of the `TargetDownsideDeviation` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class TargetDownsideDeviationAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TargetDownsideDeviation _tdd;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tdd = TDD(_symbol, 50);

        var indicatorHistory = IndicatorHistory(_tdd, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_tdd, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_tdd, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Theta

Introduction

Option Theta indicator that calculate the theta of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using T Indicator

To create an automatic indicator for `Theta` , call the `T` helper method from the `QCAlgorithm` class. The `T` method creates a `Theta` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ThetaAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Theta _t;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _t = T(_option, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (_t.IsReady)
        {
            // The current value of _t is represented by itself (_t)
            // or _t.Current.Value
            Plot("Theta", "t", _t);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Theta` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ThetaAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Theta _theta;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        var interestRateModel = new InterestRateProvider();
        var dividendYieldModel = new DividendYieldProvider(_symbol);

        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _theta = new Theta(_option, interestRateModel, dividendYieldModel, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _theta.Update(new IndicatorDataPoint(_symbol, bar.EndTime, bar.Close));
        if (data.QuoteBars.TryGetValue(_option, out var quoteBar))
            _theta.Update(new IndicatorDataPoint(_option, quoteBar.EndTime, quoteBar.Close));
        if (data.QuoteBars.TryGetValue(_mirrorOption, out quoteBar))
            _theta.Update(new IndicatorDataPoint(_mirrorOption, quoteBar.EndTime, quoteBar.Close));

        if (_theta.IsReady)
        {
            // The current value of _theta is represented by itself (_theta)
            // or _theta.Current.Value
            Plot("Theta", "theta", _theta);
        }
    }
}
```

For more information about this indicator, see its reference .

Time Profile

Introduction

This indicator represents an Indicator of the Market Profile with Time Price Opportunity (TPO) mode and its attributes

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TP Indicator

To create an automatic indicator for `TimeProfile` , call the `TP` helper method from the `QCAlgorithm` class. The `TP` method creates a `TimeProfile` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class TimeProfileAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TimeProfile _tp;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tp = TP(_symbol, 3, 0.70m, 0.05m);
    }

    public override void OnData(Slice data)
    {

        if (_tp.IsReady)
        {
            // The current value of _tp is represented by itself (_tp)
            // or _tp.Current.Value
            Plot("TimeProfile", "tp", _tp);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TimeProfile` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TimeProfileAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TimeProfile _timeprofile;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _timeprofile = new TimeProfile(3, 0.70m, 0.05m);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _timeprofile.Update(bar);

        if (_timeprofile.IsReady)
        {
            // The current value of _timeprofile is represented by itself (_timeprofile)
            // or _timeprofile.Current.Value
            Plot("TimeProfile", "timeprofile", _timeprofile);
        }
    }
}
```

For more information about this indicator, see its reference .

Time Series Forecast

Introduction

This indicator represents an indicator capable of predicting new values given previous data from a window. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TSF Indicator

To create an automatic indicator for `TimeSeriesForecast` , call the `TSF` helper method from the `QCAlgorithm` class. The `TSF` method creates a `TimeSeriesForecast` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class TimeSeriesForecastAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TimeSeriesForecast _tsf;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tsf = TSF(_symbol, 3);
    }

    public override void OnData(Slice data)
    {

        if (_tsf.IsReady)
        {
            // The current value of _tsf is represented by itself (_tsf)
            // or _tsf.Current.Value
            Plot("TimeSeriesForecast", "tsf", _tsf);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TimeSeriesForecast` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TimeSeriesForecastAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TimeSeriesForecast _timeseriesforecast;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _timeseriesforecast = new TimeSeriesForecast(3);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _timeseriesforecast.Update(bar.EndTime, bar.Close);

        if (_timeseriesforecast.IsReady)
        {
            // The current value of _timeseriesforecast is represented by itself (_timeseriesforecast)
            // or _timeseriesforecast.Current.Value
            Plot("TimeSeriesForecast", "timeseriesforecast", _timeseriesforecast);
        }
    }
}
```

Supported Indicators

Tom Demark Sequential

Introduction

This indicator represents the Tom Demark Sequential indicator, which is used to identify potential trend exhaustion points. This implementation tracks both the setup and countdown phases, and can be extended to handle bullish and bearish setups, as well as qualifiers such as Perfect Setups and Countdown completions. - **Setup Phase**: Detects a trend by counting 9 consecutive bars where the close is less than (Buy Setup) or greater than (Sell Setup) the close 4 bars earlier. - **TDST Support/Resistance**: After a valid 9-bar setup completes, the indicator records the **lowest low** (for Sell Setup) or **highest high** (for Buy Setup) among the 9 bars. These are referred to as Support Price(for Buy Setup) and Resistance Price (for Sell Setup), and serve as critical thresholds that validate the continuation of the countdown phase. - **Countdown Phase**: Once a valid setup is completed, the indicator attempts to count 13 qualifying bars (not necessarily consecutive) where the close is less than (Buy Countdown) or greater than (Sell Countdown) the low/high 2 bars earlier. During this phase, the TDST Support/Resistance levels are checked — if the price breaks these levels, the countdown phase is reset, as the trend reversal condition is considered invalidated.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TDS Indicator

To create an automatic indicator for `TomDemarkSequential` , call the `TDS` helper method from the `QCAlgorithm` class. The `TDS` method creates a `TomDemarkSequential` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class TomDemarkSequentialAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TomDemarkSequential _tds;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tds = TDS(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_tds.IsReady)
        {
            // The current value of _tds is represented by itself (_tds)
            // or _tds.Current.Value
            Plot("TomDemarkSequential", "tds", _tds);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TomDemarkSequential` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To

manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TomDemarkSequentialAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TomDemarkSequential _tomdemarksequential;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tomdemarksequential = new TomDemarkSequential();
    }

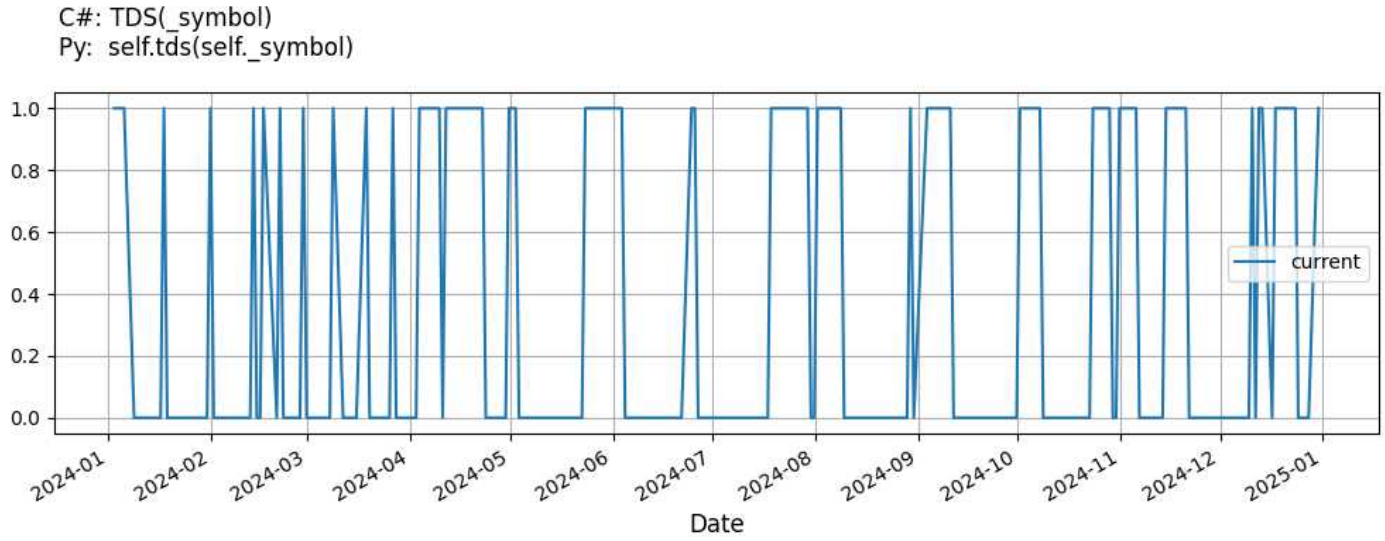
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _tomdemarksequential.Update(bar);

        if (_tomdemarksequential.IsReady)
        {
            // The current value of _tomdemarksequential is represented by itself (_tomdemarksequential)
            // or _tomdemarksequential.Current.Value
            Plot("TomDemarkSequential", "tomdemarksequential", _tomdemarksequential);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TomDemarkSequential` indicator properties:



Indicator History

To get the historical data of the `TomDemarkSequential` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class TomDemarkSequentialAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TomDemarkSequential _tds;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tds = TDS(_symbol);

        var indicatorHistory = IndicatorHistory(_tds, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_tds, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_tds, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}

Supported Indicators

Triangular Moving Average

Introduction

This indicator computes the Triangular Moving Average (TRIMA). The Triangular Moving Average is calculated with the following formula: (1) When the period is even, TRIMA(x,period)=SMA(SMA(x,period/2),(period/2)+1) (2) When the period is odd, TRIMA(x,period)=SMA(SMA(x,(period+1)/2),(period+1)/2)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIMA Indicator

To create an automatic indicator for `TriangularMovingAverage` , call the `TRIMA` helper method from the `QCAlgorithm` class. The `TRIMA` method creates a `TriangularMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class TriangularMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TriangularMovingAverage _trima;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _trima = TRIMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_trima.IsReady)
        {
            // The current value of _trima is represented by itself (_trima)
            // or _trima.Current.Value
            Plot("TriangularMovingAverage", "trima", _trima);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TriangularMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TriangularMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TriangularMovingAverage _triangularmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _triangularmovingaverage = new TriangularMovingAverage(20);
    }

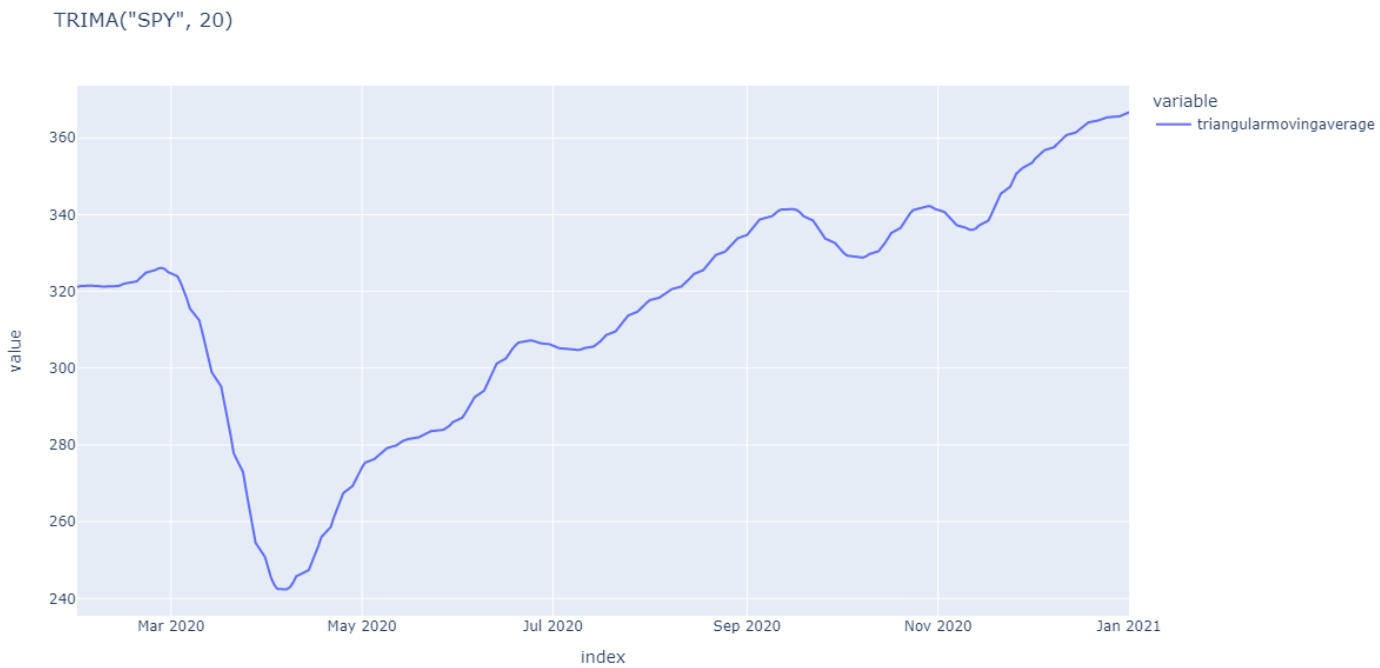
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _triangularmovingaverage.Update(bar.EndTime, bar.Close);

        if (_triangularmovingaverage.IsReady)
        {
            // The current value of _triangularmovingaverage is represented by itself (_triangularmovingaverage)
            // or _triangularmovingaverage.Current.Value
            Plot("TriangularMovingAverage", "triangularmovingaverage", _triangularmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `TriangularMovingAverage` indicator properties:



Indicator History

To get the historical data of the `TriangularMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class TriangularMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TriangularMovingAverage _trima;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _trima = TRIMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_trima, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_trima, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_trima, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Triple Exponential Moving Average

Introduction

This indicator computes the Triple Exponential Moving Average (TEMA). The Triple Exponential Moving Average is calculated with the following formula: EMA1 = EMA(t,period) EMA2 = EMA(EMA(t,period),period) EMA3 = EMA(EMA(EMA(t,period),period),period) TEMA = 3 * EMA1 - 3 * EMA2 + EMA3

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TEMA Indicator

To create an automatic indicator for `TripleExponentialMovingAverage` , call the `TEMA` helper method from the `QCAlgorithm` class. The `TEMA` method creates a `TripleExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class TripleExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TripleExponentialMovingAverage _tema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tema = TEMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_tema.IsReady)
        {
            // The current value of _tema is represented by itself (_tema)
            // or _tema.Current.Value
            Plot("TripleExponentialMovingAverage", "tema", _tema);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TripleExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TripleExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TripleExponentialMovingAverage _tripleexponentialmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tripleexponentialmovingaverage = new TripleExponentialMovingAverage(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _tripleexponentialmovingaverage.Update(bar.EndTime, bar.Close);

        if (_tripleexponentialmovingaverage.IsReady)
        {
            // The current value of _tripleexponentialmovingaverage is represented by itself
(_tripleexponentialmovingaverage)
            // or _tripleexponentialmovingaverage.Current.Value
            Plot("TripleExponentialMovingAverage", "tripleexponentialmovingaverage",
_tripleexponentialmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

The following plot shows values for some of the `TripleExponentialMovingAverage` indicator properties:

Indicator History

To get the historical data of the `TripleExponentialMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class TripleExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TripleExponentialMovingAverage _tema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tema = TEMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_tema, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_tema, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_tema, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Trix

Introduction

This indicator computes the TRIX (1-period ROC of a Triple EMA) The TRIX is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:trix

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIX Indicator

To create an automatic indicator for `Trix` , call the `TRIX` helper method from the `QCAlgorithm` class. The `TRIX` method creates a `Trix` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class TrixAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Trix _trix;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _trix = TRIX(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_trix.IsReady)
        {
            // The current value of _trix is represented by itself (_trix)
            // or _trix.Current.Value
            Plot("Trix", "trix", _trix);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Trix` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class TrixAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Trix _trix;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _trix = new Trix(20);
    }

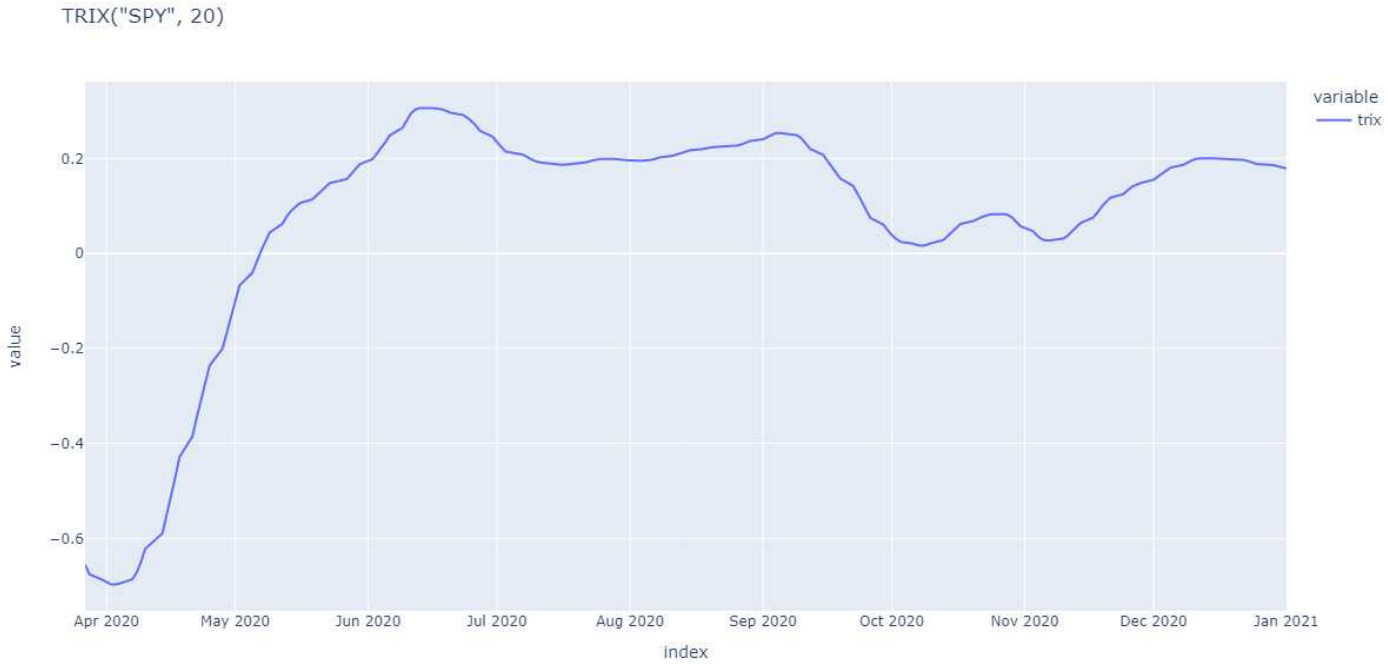
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _trix.Update(bar.EndTime, bar.Close);

        if (_trix.IsReady)
        {
            // The current value of _trix is represented by itself (_trix)
            // or _trix.Current.Value
            Plot("Trix", "trix", _trix);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Trix` indicator properties:



Indicator History

To get the historical data of the `Trix` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class TrixAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Trix _trix;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _trix = TRIX(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_trix, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_trix, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_trix, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

True Range

Introduction

This indicator computes the True Range (TR). The True Range is the greatest of the following values: value1 = distance from today's high to today's low. value2 = distance from yesterday's close to today's high. value3 = distance from yesterday's close to today's low.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TR Indicator

To create an automatic indicator for `TrueRange` , call the `TR` helper method from the `QCAlgorithm` class. The `TR` method creates a `TrueRange` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class TrueRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TrueRange _tr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tr = TR(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_tr.IsReady)
        {
            // The current value of _tr is represented by itself (_tr)
            // or _tr.Current.Value
            Plot("TrueRange", "tr", _tr);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TrueRange` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TrueRangeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TrueRange _truerange;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _truerange = new TrueRange();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _truerange.Update(bar);

        if (_truerange.IsReady)
        {
            // The current value of _truerange is represented by itself (_truerange)
            // or _truerange.Current.Value
            Plot("TrueRange", "truerange", _truerange);
        }
    }
}
```

For more information about this indicator, see its reference .

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tr = TR(_symbol);

        var indicatorHistory = IndicatorHistory(_tr, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_tr, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_tr, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

True Strength Index

Introduction

This indicator computes the True Strength Index (TSI). The True Strength Index is calculated as explained here: https://school.stockcharts.com/doku.php?id=technical_indicators:True_strength_index Briefly, the calculation has three steps: 1. Smooth the momentum and the absolute momentum by getting an EMA of them (typically of period 25) 2. Double smooth the momentum and the absolute momentum by getting an EMA of their EMA (typically of period 13) 3. The TSI formula itself: divide the double-smoothed momentum over the double-smoothed absolute momentum and multiply by 100 The signal is typically a 7-to-12-EMA of the TSI.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TSI Indicator

To create an automatic indicator for `TrueStrengthIndex` , call the `TSI` helper method from the `QCAlgorithm` class. The `TSI` method creates a `TrueStrengthIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class TrueStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TrueStrengthIndex _tsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tsi = TSI(_symbol, 25, 13, 7, MovingAverageType.Exponential);
    }

    public override void OnData(Slice data)
    {

        if (_tsi.IsReady)
        {
            // The current value of _tsi is represented by itself (_tsi)
            // or _tsi.Current.Value
            Plot("TrueStrengthIndex", "tsi", _tsi);
            // Plot all properties of abands
            Plot("TrueStrengthIndex", "signal", _tsi.Signal);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `TrueStrengthIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class TrueStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TrueStrengthIndex _truestrengthindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _truestrengthindex = new TrueStrengthIndex(25, 13, 7, MovingAverageType.Exponential);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _truestrengthindex.Update(bar.EndTime, bar.Close);

        if (_truestrengthindex.IsReady)
        {
            // The current value of _truestrengthindex is represented by itself (_truestrengthindex)
            // or _truestrengthindex.Current.Value
            Plot("TrueStrengthIndex", "truestrengthindex", _truestrengthindex);
            // Plot all properties of abands
            Plot("TrueStrengthIndex", "signal", _truestrengthindex.Signal);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `TrueStrengthIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class TrueStrengthIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TrueStrengthIndex _tsi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tsi = TSI(_symbol, 25, 13, 7, MovingAverageType.Exponential);

        var indicatorHistory = IndicatorHistory(_tsi, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_tsi, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_tsi, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var signal = indicatorHistory.Select(x => ((dynamic)x).Signal).ToList();
    }
}
```

Supported Indicators

Ultimate Oscillator

Introduction

This indicator computes the Ultimate Oscillator (ULTOSC) The Ultimate Oscillator is calculated as explained here: http://stockcharts.com/school/doku.php?id=chart_school:technical_indicators:ultimate_oscillator

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ULTOSC Indicator

To create an automatic indicator for `UltimateOscillator` , call the `ULTOSC` helper method from the `QCAlgorithm` class. The `ULTOSC` method creates a `UltimateOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class UltimateOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UltimateOscillator _ultosc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ultosc = ULTOSC(_symbol, 5, 10, 20);
    }

    public override void OnData(Slice data)
    {

        if (_ultosc.IsReady)
        {
            // The current value of _ultosc is represented by itself (_ultosc)
            // or _ultosc.Current.Value
            Plot("UltimateOscillator", "ultosc", _ultosc);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `UltimateOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class UltimateOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UltimateOscillator _ultimateoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ultimateoscillator = new UltimateOscillator(5, 10, 20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _ultimateoscillator.Update(bar);

        if (_ultimateoscillator.IsReady)
        {
            // The current value of _ultimateoscillator is represented by itself (_ultimateoscillator)
            // or _ultimateoscillator.Current.Value
            Plot("UltimateOscillator", "ultimateoscillator", _ultimateoscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

Value At Risk

Introduction

This indicator computes 1-day VaR for a specified confidence level and lookback period

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VAR Indicator

To create an automatic indicator for `ValueAtRisk` , call the `VAR` helper method from the `QCAlgorithm` class. The `VAR` method creates a `ValueAtRisk` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ValueAtRiskAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ValueAtRisk _var;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _var = VAR(_symbol, 252, 0.95);
    }

    public override void OnData(Slice data)
    {

        if (_var.IsReady)
        {
            // The current value of _var is represented by itself (_var)
            // or _var.Current.Value
            Plot("ValueAtRisk", "var", _var);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ValueAtRisk` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ValueAtRiskAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ValueAtRisk _valueatrisk;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _valueatrisk = new ValueAtRisk(252, 0.95);
    }

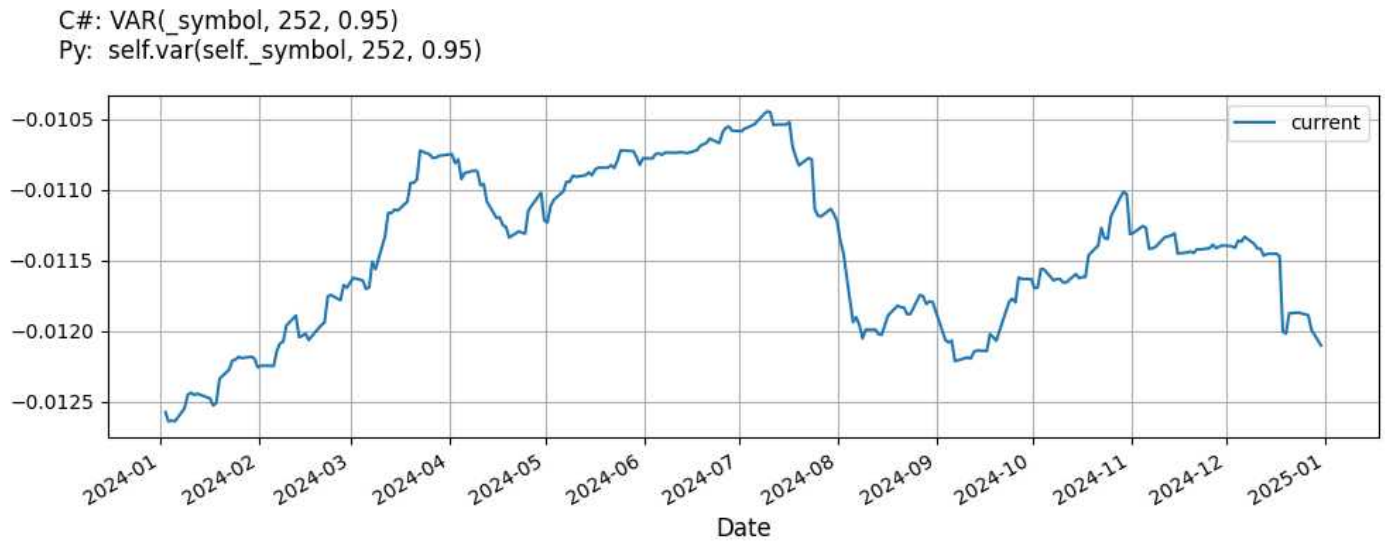
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _valueatrisk.Update(bar.EndTime, bar.Close);

        if (_valueatrisk.IsReady)
        {
            // The current value of _valueatrisk is represented by itself (_valueatrisk)
            // or _valueatrisk.Current.Value
            Plot("ValueAtRisk", "valueatrisk", _valueatrisk);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ValueAtRisk` indicator properties:



Indicator History

To get the historical data of the `ValueAtRisk` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class ValueAtRiskAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ValueAtRisk _var;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _var = VAR(_symbol, 252, 0.95);

        var indicatorHistory = IndicatorHistory(_var, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_var, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_var, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Variable Index Dynamic Average

Introduction

This indicator computes the n-period adaptive weighted moving average indicator. VIDYAi = Pricei x F x ABS(CMOi) + VIDYAi-1 x (1 - F x ABS(CMOi)) where: VIDYAi - is the value of the current period. Pricei - is the source price of the period being calculated. F = 2/(Period_EMA+1) - is a smoothing factor. ABS(CMOi) - is the absolute current value of CMO. VIDYAi-1 - is the value of the period immediately preceding the period being calculated.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VIDYA Indicator

To create an automatic indicator for `VariableIndexDynamicAverage` , call the `VIDYA` helper method from the `QCAlgorithm` class. The `VIDYA` method creates a `VariableIndexDynamicAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class VariableIndexDynamicAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VariableIndexDynamicAverage _vidya;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vidya = VIDYA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_vidya.IsReady)
        {
            // The current value of _vidya is represented by itself (_vidya)
            // or _vidya.Current.Value
            Plot("VariableIndexDynamicAverage", "vidya", _vidya);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `VariableIndexDynamicAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class VariableIndexDynamicAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VariableIndexDynamicAverage _variableindexdynamicaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _variableindexdynamicaverage = new VariableIndexDynamicAverage(20);
    }

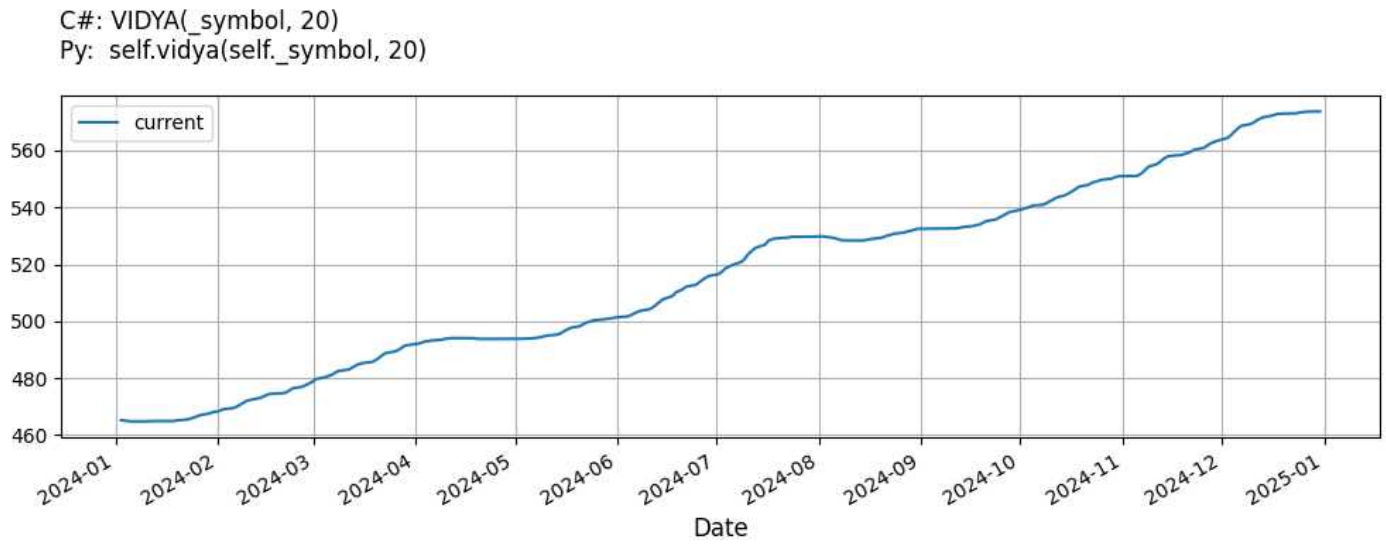
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _variableindexdynamicaverage.Update(bar.EndTime, bar.Close);

        if (_variableindexdynamicaverage.IsReady)
        {
            // The current value of _variableindexdynamicaverage is represented by itself
(_variableindexdynamicaverage)
            // or _variableindexdynamicaverage.Current.Value
            Plot("VariableIndexDynamicAverage", "variableindexdynamicaverage", _variableindexdynamicaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `VariableIndexDynamicAverage` indicator properties:



Indicator History

To get the historical data of the `VariableIndexDynamicAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class VariableIndexDynamicAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VariableIndexDynamicAverage _vidya;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vidya = VIDYA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_vidya, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_vidya, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_vidya, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Variance

Introduction

This indicator computes the n-period population variance.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using V Indicator

To create an automatic indicator for `Variance` , call the `V` helper method from the `QCAlgorithm` class. The `V` method creates a `Variance` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class VarianceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Variance _v;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _v = V(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_v.IsReady)
        {
            // The current value of _v is represented by itself (_v)
            // or _v.Current.Value
            Plot("Variance", "v", _v);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Variance` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class VarianceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Variance _variance;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _variance = new Variance(20);
    }

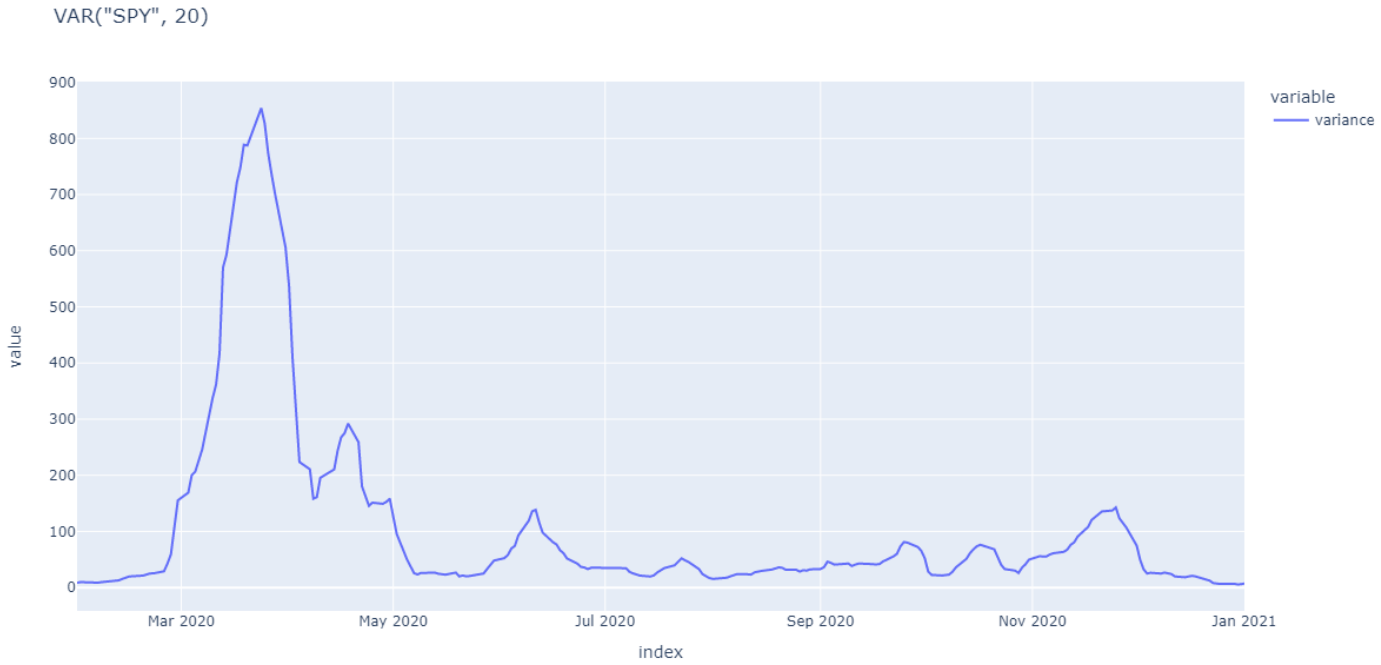
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _variance.Update(bar.EndTime, bar.Close);

        if (_variance.IsReady)
        {
            // The current value of _variance is represented by itself (_variance)
            // or _variance.Current.Value
            Plot("Variance", "variance", _variance);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Variance` indicator properties:



Indicator History

To get the historical data of the `Variance` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class VarianceAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Variance _v;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _v = V(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_v, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_v, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_v, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Vega

Introduction

Option Vega indicator that calculate the Vega of an option

To view the implementation of this indicator, see the LEAN GitHub repository .

Using V Indicator

To create an automatic indicator for `Vega` , call the `V` helper method from the `QCAlgorithm` class. The `V` method creates a `Vega` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class VegaAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _option, _mirrorOption;
    private Vega _v;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _v = V(_option, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (_v.IsReady)
        {
            // The current value of _v is represented by itself (_v)
            // or _v.Current.Value
            Plot("Vega", "v", _v);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Vega` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class VegaAlgorithm : QCAlgorithm

    private Symbol _symbol, _option, _mirrorOption;
    private Vega _vega;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 20);

        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        var interestRateModel = new InterestRateProvider();
        var dividendYieldModel = new DividendYieldProvider(_symbol);

        _option = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920C00564000");
        _mirrorOption = SymbolRepresentation.ParseOptionTickerOSI("SPY 240920P00564000");
        AddOptionContract(_option, Resolution.Daily);
        AddOptionContract(_mirrorOption, Resolution.Daily);

        _vega = new Vega(_option, interestRateModel, dividendYieldModel, _mirrorOption);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _vega.Update(new IndicatorDataPoint(_symbol, bar.EndTime, bar.Close));
        if (data.QuoteBars.TryGetValue(_option, out var quoteBar))
            _vega.Update(new IndicatorDataPoint(_option, quoteBar.EndTime, quoteBar.Close));
        if (data.QuoteBars.TryGetValue(_mirrorOption, out quoteBar))
            _vega.Update(new IndicatorDataPoint(_mirrorOption, quoteBar.EndTime, quoteBar.Close));

        if (_vega.IsReady)
        {
            // The current value of _vega is represented by itself (_vega)
            // or _vega.Current.Value
            Plot("Vega", "vega", _vega);
        }
    }
}
```

For more information about this indicator, see its reference .

Volume Profile

Introduction

This indicator represents an Indicator of the Market Profile with Volume Profile mode and its attributes

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VP Indicator

To create an automatic indicator for `VolumeProfile` , call the `VP` helper method from the `QCAlgorithm` class. The `VP` method creates a `VolumeProfile` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class VolumeProfileAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VolumeProfile _vp;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vp = VP(_symbol, 3, 0.70m, 0.05m);
    }

    public override void OnData(Slice data)
    {

        if (_vp.IsReady)
        {
            // The current value of _vp is represented by itself (_vp)
            // or _vp.Current.Value
            Plot("VolumeProfile", "vp", _vp);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `VolumeProfile` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class VolumeProfileAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VolumeProfile _volumeprofile;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _volumeprofile = new VolumeProfile(3, 0.70m, 0.05m);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _volumeprofile.Update(bar);

        if (_volumeprofile.IsReady)
        {
            // The current value of _volumeprofile is represented by itself (_volumeprofile)
            // or _volumeprofile.Current.Value
            Plot("VolumeProfile", "volumeprofile", _volumeprofile);
        }
    }
}
```

For more information about this indicator, see its reference .

Volume Weighted Average Price Indicator

Introduction

Volume Weighted Average Price (VWAP) Indicator: It is calculated by adding up the dollars traded for every transaction (price multiplied by number of shares traded) and then dividing by the total shares traded for the day.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWAP Indicator

To create an automatic indicator for `VolumeWeightedAveragePriceIndicator` , call the `VWAP` helper method from the `QCAlgorithm` class. The `VWAP` method creates a `VolumeWeightedAveragePriceIndicator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class VolumeWeightedAveragePriceIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VolumeWeightedAveragePriceIndicator _vwap;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vwap = VWAP(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_vwap.IsReady)
        {
            // The current value of _vwap is represented by itself (_vwap)
            // or _vwap.Current.Value
            Plot("VolumeWeightedAveragePriceIndicator", "vwap", _vwap);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `VolumeWeightedAveragePriceIndicator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class VolumeWeightedAveragePriceIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VolumeWeightedAveragePriceIndicator _volumeweightedaveragepriceindicator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _volumeweightedaveragepriceindicator = new VolumeWeightedAveragePriceIndicator(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _volumeweightedaveragepriceindicator.Update(bar);

        if (_volumeweightedaveragepriceindicator.IsReady)
        {
            // The current value of _volumeweightedaveragepriceindicator is represented by itself
(_volumeweightedaveragepriceindicator)
            // or _volumeweightedaveragepriceindicator.Current.Value
            Plot("VolumeWeightedAveragePriceIndicator", "volumeweightedaveragepriceindicator",
_volumeweightedaveragepriceindicator);
        }
    }
}
```

For more information about this indicator, see its reference .

Volume Weighted Moving Average

Introduction

This indicator computes the Volume Weighted Moving Average (VWMA) It is a technical analysis indicator used by traders to determine the average price of an asset over a given period of time, taking into account both price and volume.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VWMA Indicator

To create an automatic indicator for `VolumeWeightedMovingAverage` , call the `VWMA` helper method from the `QCAlgorithm` class. The `VWMA` method creates a `VolumeWeightedMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class VolumeWeightedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VolumeWeightedMovingAverage _vwma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vwma = VWMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_vwma.IsReady)
        {
            // The current value of _vwma is represented by itself (_vwma)
            // or _vwma.Current.Value
            Plot("VolumeWeightedMovingAverage", "vwma", _vwma);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `VolumeWeightedMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class VolumeWeightedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VolumeWeightedMovingAverage _volumeweightedmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _volumeweightedmovingaverage = new VolumeWeightedMovingAverage(20);
    }

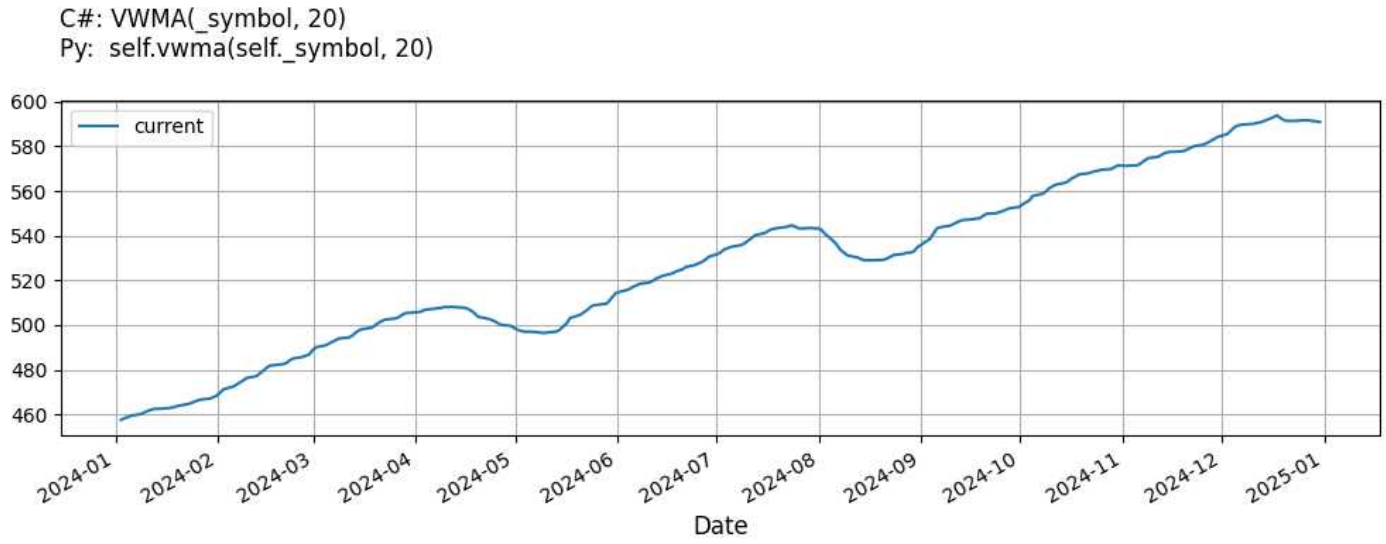
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _volumeweightedmovingaverage.Update(bar);

        if (_volumeweightedmovingaverage.IsReady)
        {
            // The current value of _volumeweightedmovingaverage is represented by itself
(_volumeweightedmovingaverage)
            // or _volumeweightedmovingaverage.Current.Value
            Plot("VolumeWeightedMovingAverage", "volumeweightedmovingaverage", _volumeweightedmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `VolumeWeightedMovingAverage` indicator properties:



Indicator History

To get the historical data of the `VolumeWeightedMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class VolumeWeightedMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private VolumeWeightedMovingAverage _vwma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vwma = VWMA(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_vwma, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_vwma, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_vwma, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Vortex

Introduction

This indicator represents the Vortex Indicator, which identifies the start and continuation of market trends. It includes components that capture positive (upward) and negative (downward) trend movements. This indicator compares the ranges within the current period to previous periods to calculate upward and downward movement trends.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using VTX Indicator

To create an automatic indicator for `Vortex` , call the `VTX` helper method from the `QCAlgorithm` class. The `VTX` method creates a `Vortex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class VortexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Vortex _vtx;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vtx = VTX(_symbol, 14);
    }

    public override void OnData(Slice data)
    {

        if (_vtx.IsReady)
        {
            // The current value of _vtx is represented by itself (_vtx)
            // or _vtx.Current.Value
            Plot("Vortex", "vtx", _vtx);
            // Plot all properties of abands
            Plot("Vortex", "plusvortex", _vtx.PlusVortex);
            Plot("Vortex", "minusvortex", _vtx.MinusVortex);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Vortex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class VortexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Vortex _vortex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vortex = new Vortex(14);
    }

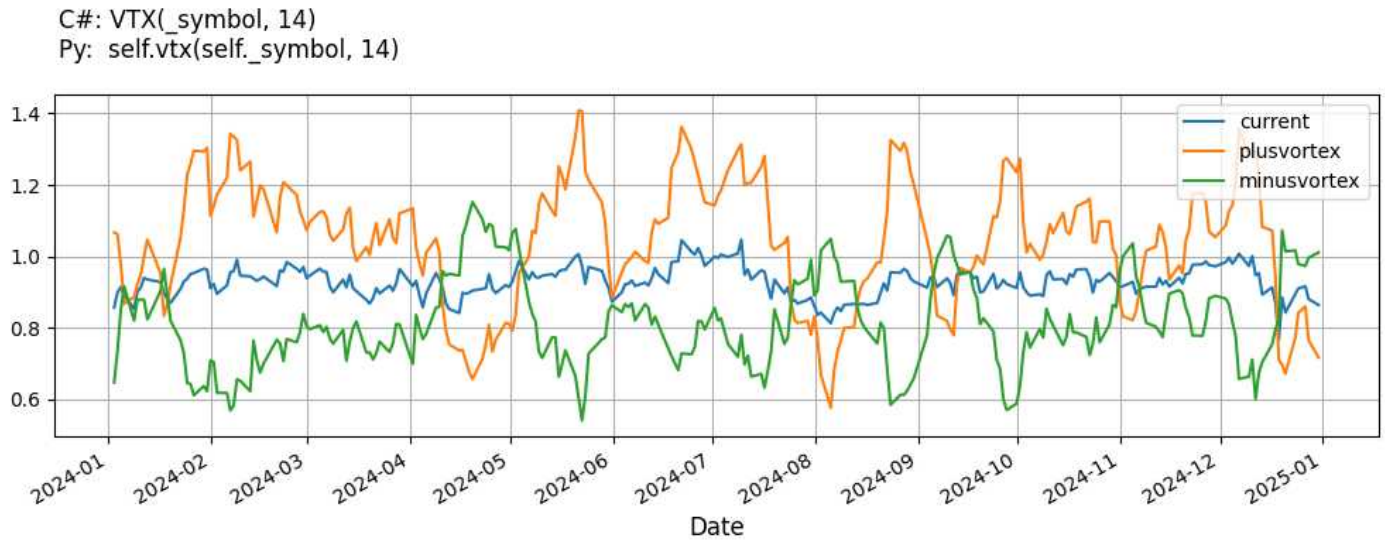
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _vortex.Update(bar);

        if (_vortex.IsReady)
        {
            // The current value of _vortex is represented by itself (_vortex)
            // or _vortex.Current.Value
            Plot("Vortex", "vortex", _vortex);
            // Plot all properties of abands
            Plot("Vortex", "plusvortex", _vortex.PlusVortex);
            Plot("Vortex", "minusvortex", _vortex.MinusVortex);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Vortex` indicator properties:



Indicator History

To get the historical data of the `Vortex` indicator, call the `IndicatorHistory` method. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class VortexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Vortex _vtx;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _vtx = VTX(_symbol, 14);

        var indicatorHistory = IndicatorHistory(_vtx, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_vtx, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_vtx, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var plusVortex = indicatorHistory.Select(x => ((dynamic)x).PlusVortex).ToList();
        var minusVortex = indicatorHistory.Select(x => ((dynamic)x).MinusVortex).ToList();
    }
}
```

Supported Indicators

Wilder Accumulative Swing Index

Introduction

This indicator calculates the Accumulative Swing Index (ASI) as defined by Welles Wilder in his book 'New Concepts in Technical Trading Systems'. $ASI_t = ASI_{t-1} + SI_t$ Where: ASI_{t-1} The for the previous period. SI_t The calculated for the current period.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ASI Indicator

To create an automatic indicator for `WilderAccumulativeSwingIndex` , call the `ASI` helper method from the `QCAlgorithm` class. The `ASI` method creates a `WilderAccumulativeSwingIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class WilderAccumulativeSwingIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilderAccumulativeSwingIndex _asi;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _asi = ASI(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_asi.IsReady)
        {
            // The current value of _asi is represented by itself (_asi)
            // or _asi.Current.Value
            Plot("WilderAccumulativeSwingIndex", "asi", _asi);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `WilderAccumulativeSwingIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class WilderAccumulativeSwingIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilderAccumulativeSwingIndex _wilderaccumulativeswingindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _wilderaccumulativeswingindex = new WilderAccumulativeSwingIndex(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _wilderaccumulativeswingindex.Update(bar);

        if (_wilderaccumulativeswingindex.IsReady)
        {
            // The current value of _wilderaccumulativeswingindex is represented by itself
(_wilderaccumulativeswingindex)
            // or _wilderaccumulativeswingindex.Current.Value
            Plot("WilderAccumulativeSwingIndex", "wilderaccumulativeswingindex", _wilderaccumulativeswingindex);
        }
    }
}
```

For more information about this indicator, see its reference .

Wilder Moving Average

Introduction

This indicator represents the moving average indicator defined by Welles Wilder in his book: New Concepts in Technical Trading Systems.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using WWMA Indicator

To create an automatic indicator for `WilderMovingAverage` , call the `WWMA` helper method from the `QCAlgorithm` class. The `WWMA` method creates a `WilderMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class WilderMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilderMovingAverage _wwma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _wwma = WWMA(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_wwma.IsReady)
        {
            // The current value of _wwma is represented by itself (_wwma)
            // or _wwma.Current.Value
            Plot("WilderMovingAverage", "wwma", _wwma);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `WilderMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class WilderMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilderMovingAverage _wildermovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _wildermovingaverage = new WilderMovingAverage(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _wildermovingaverage.Update(bar.EndTime, bar.Close);

        if (_wildermovingaverage.IsReady)
        {
            // The current value of _wildermovingaverage is represented by itself (_wildermovingaverage)
            // or _wildermovingaverage.Current.Value
            Plot("WilderMovingAverage", "wildermovingaverage", _wildermovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Supported Indicators

Wilder Swing Index

Introduction

This indicator calculates the Swing Index (SI) as defined by Welles Wilder in his book 'New Concepts in Technical Trading Systems'. SI_t = 50 * (N / R) * (K / T) Where: N Equals: C_t - C_{t-1} + 0.5 * (C_t - O_t) + 0.25 * (C_{t-1} - O_{t-1}) *See* R Found by selecting the expression with the largest value and then using the corresponding formula. Expression => Formula $|H_t - C_{t-1}|$ => $|H_t - C_t|$ - 0.5 * $|L_t - C_{t-1}|$ + 0.25 * $|C_{t-1} - O_{t-1}|$ $|L_t - C_{t-1}|$ => $|L_t - C_t|$ - 0.5 * $|H_t - C_{t-1}|$ + 0.25 * $|C_{t-1} - O_{t-1}|$ $|H_t - L_t|$ => $|H_t - L_{t-1}|$ + 0.25 * $|C_{t-1} - O_{t-1}|$ *See* K Found by selecting the larger of the two expressions: $|H_t - C_{t-1}|$, $|L_t - C_{t-1}|$ *See* T The limit move, or the maximum change in price during the time period for the bar. Passed as limitMove via the constructor. *See*

To view the implementation of this indicator, see the LEAN GitHub repository .

Using SI Indicator

To create an automatic indicator for `WilderSwingIndex` , call the `SI` helper method from the `QCAlgorithm` class. The `SI` method creates a `WilderSwingIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class WilderSwingIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilderSwingIndex _si;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _si = SI(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_si.IsReady)
        {
            // The current value of _si is represented by itself (_si)
            // or _si.Current.Value
            Plot("WilderSwingIndex", "si", _si);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `WilderSwingIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class WilderSwingIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilderSwingIndex _wilderswingindex;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _wilderswingindex = new WilderSwingIndex(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _wilderswingindex.Update(bar);

        if (_wilderswingindex.IsReady)
        {
            // The current value of _wilderswingindex is represented by itself (_wilderswingindex)
            // or _wilderswingindex.Current.Value
            Plot("WilderSwingIndex", "wilderswingindex", _wilderswingindex);
        }
    }
}
```

For more information about this indicator, see its reference .

Supported Indicators

Williams Percent R

Introduction

Williams %R, or just %R, is the current closing price in relation to the high and low of the past N days (for a given N). The value of this indicator fluctuates between -100 and 0. The symbol is said to be oversold when the oscillator is below -80%, and overbought when the oscillator is above -20%.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using WILR Indicator

To create an automatic indicator for `WilliamsPercentR` , call the `WILR` helper method from the `QCAlgorithm` class. The `WILR` method creates a `WilliamsPercentR` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class WilliamsPercentRAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilliamsPercentR _wilr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _wilr = WILR(_symbol, 20);
    }

    public override void OnData(Slice data)
    {

        if (_wilr.IsReady)
        {
            // The current value of _wilr is represented by itself (_wilr)
            // or _wilr.Current.Value
            Plot("WilliamsPercentR", "wilr", _wilr);
            // Plot all properties of abands
            Plot("WilliamsPercentR", "maximum", _wilr.Maximum);
            Plot("WilliamsPercentR", "minimum", _wilr.Minimum);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `WilliamsPercentR` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class WilliamsPercentRAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private WilliamsPercentR _williamspercentr;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _williamspercentr = new WilliamsPercentR(20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _williamspercentr.Update(bar);

        if (_williamspercentr.IsReady)
        {
            // The current value of _williamspercentr is represented by itself (_williamspercentr)
            // or _williamspercentr.Current.Value
            Plot("WilliamsPercentR", "williamspercentr", _williamspercentr);
            // Plot all properties of abands
            Plot("WilliamsPercentR", "maximum", _williamspercentr.Maximum);
            Plot("WilliamsPercentR", "minimum", _williamspercentr.Minimum);
        }
    }
}
```

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _wilr = WILR(_symbol, 20);

        var indicatorHistory = IndicatorHistory(_wilr, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_wilr, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_wilr, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var maximum = indicatorHistory.Select(x => ((dynamic)x).Maximum).ToList();
        var minimum = indicatorHistory.Select(x => ((dynamic)x).Minimum).ToList();
    }
}
```

Supported Indicators

Zero Lag Exponential Moving Average

Introduction

This indicator represents the zero lag moving average indicator (ZLEMA) ie a technical indicator that aims is to eliminate the inherent lag associated to all trend following indicators which average a price over time.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ZLEMA Indicator

To create an automatic indicator for `ZeroLagExponentialMovingAverage` , call the `ZLEMA` helper method from the `QCAlgorithm` class. The `ZLEMA` method creates a `ZeroLagExponentialMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ZeroLagExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ZeroLagExponentialMovingAverage _zlema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _zlema = ZLEMA(_symbol, 10);
    }

    public override void OnData(Slice data)
    {

        if (_zlema.IsReady)
        {
            // The current value of _zlema is represented by itself (_zlema)
            // or _zlema.Current.Value
            Plot("ZeroLagExponentialMovingAverage", "zlema", _zlema);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ZeroLagExponentialMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ZeroLagExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ZeroLagExponentialMovingAverage _zerolagexponentialmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _zerolagexponentialmovingaverage = new ZeroLagExponentialMovingAverage(10);
    }

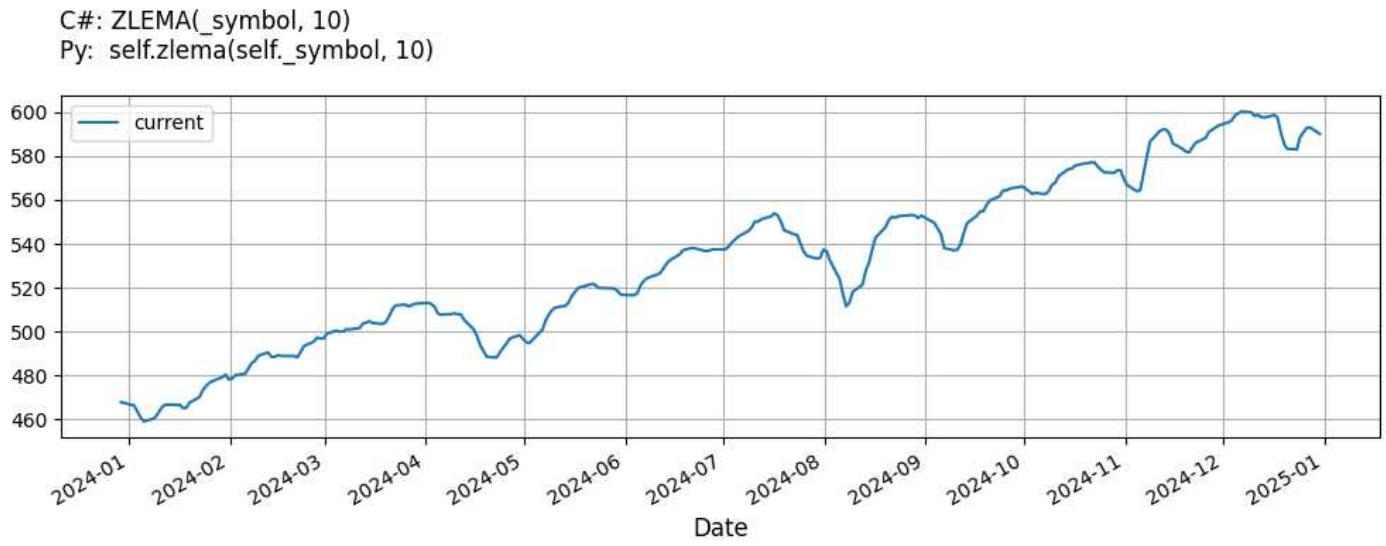
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _zerolagexponentialmovingaverage.Update(bar.EndTime, bar.Close);

        if (_zerolagexponentialmovingaverage.IsReady)
        {
            // The current value of _zerolagexponentialmovingaverage is represented by itself
(_zerolagexponentialmovingaverage)
            // or _zerolagexponentialmovingaverage.Current.Value
            Plot("ZeroLagExponentialMovingAverage", "zerolagexponentialmovingaverage",
_zerolagexponentialmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ZeroLagExponentialMovingAverage` indicator properties:



Indicator History

To get the historical data of the `ZeroLagExponentialMovingAverage` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class ZeroLagExponentialMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ZeroLagExponentialMovingAverage _zlema;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _zlema = ZLEMA(_symbol, 10);

        var indicatorHistory = IndicatorHistory(_zlema, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_zlema, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_zlema, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Zig Zag

Introduction

The ZigZag indicator identifies significant turning points in price movements, filtering out noise using a sensitivity threshold and a minimum trend length. It alternates between high and low pivots to determine market trends.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ZZ Indicator

To create an automatic indicator for `ZigZag` , call the `ZZ` helper method from the `QCAlgorithm` class. The `ZZ` method creates a `ZigZag` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ZigZagAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ZigZag _zz;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _zz = ZZ(_symbol, 0.05m, 1);
    }

    public override void OnData(Slice data)
    {

        if (_zz.IsReady)
        {
            // The current value of _zz is represented by itself (_zz)
            // or _zz.Current.Value
            Plot("ZigZag", "zz", _zz);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ZigZag` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ZigZagAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ZigZag _zigzag;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _zigzag = new ZigZag(0.05m, 1);
    }

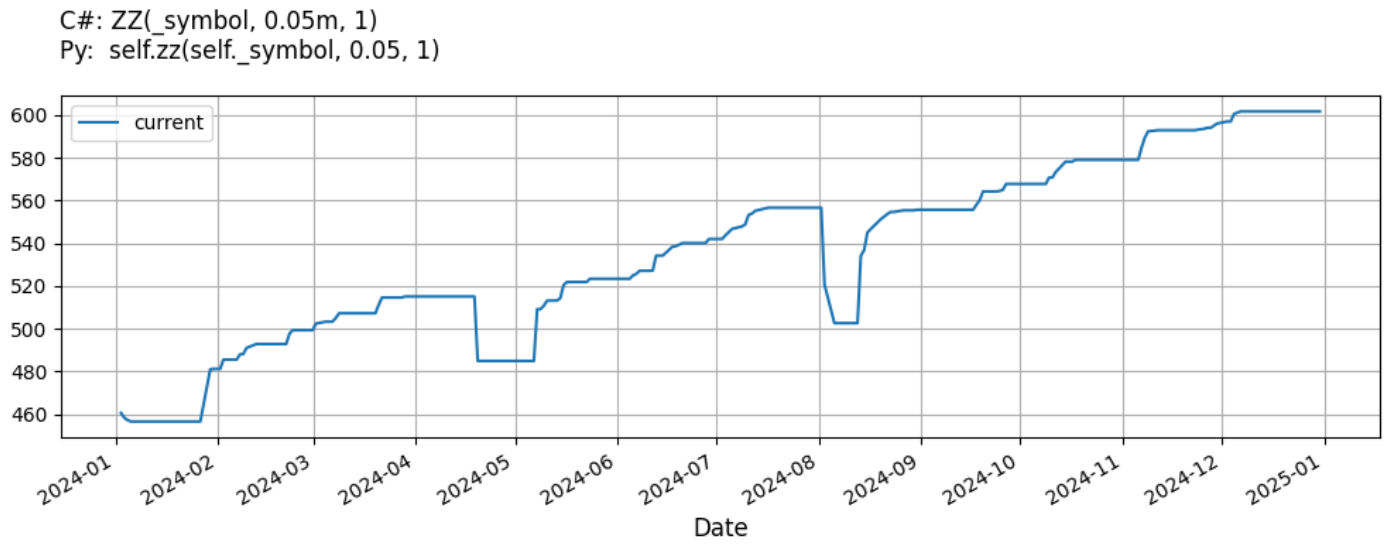
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _zigzag.Update(bar);

        if (_zigzag.IsReady)
        {
            // The current value of _zigzag is represented by itself (_zigzag)
            // or _zigzag.Current.Value
            Plot("ZigZag", "zigzag", _zigzag);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `ZigZag` indicator properties:



Indicator History

To get the historical data of the `ZigZag` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class ZigZagAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ZigZag _zz;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _zz = ZZ(_symbol, 0.05m, 1);

        var indicatorHistory = IndicatorHistory(_zz, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_zz, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_zz, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Indicators

Key Concepts

Introduction

Indicators translate a stream of data points into a numerical value you can use to detect trading opportunities. LEAN provides more than 100 pre-built technical indicators and candlestick patterns you can use in your algorithms. To view a list of all the indicators, see the Supported Indicators . One simple indicator to learn is the Identity indicator, which just returns the value of the asset.

```
var pep = Identity("PEP"); // Pepsi ticker
```

C#

Design Philosophy

Technical indicators take in a stream of data points, `Bar` objects, or `TradeBar` objects and produce a continuous value. Candlestick patterns take in a stream of `Bar` or `TradeBar` objects and produce a value that's either 0, 1, or -1 to signify the presence of the pattern.

You can configure technical indicators and candlestick patterns to receive manual or automatic updates. With manual indicators, you update the indicator with whatever data you want and whenever you want. With automatic indicators, the algorithm automatically uses the security data to update the indicator value.

LEAN's indicators are implemented "on-line". This means as data pipes through, it updates the internal state of the indicator. Other platforms perform indicator math on an array of values in bulk which can be very inefficient when working on large volumes of data. You need to warm up your indicators and prime them with data to get them ready.

Indicator Types

You can classify an indicator as either a data point, bar, or TradeBar indicator. Their classification depends on the type of data they receive.

Data Point Indicators

Data point indicators use `IndicatorDataPoint` objects to compute their value. Some examples of data point indicators include the following:

- SimpleMovingAverage
- ExponentialMovingAverage
- Momentum

Bar Indicators

Bar indicators use `QuoteBar` or `TradeBar` objects to compute their value. Since Forex and CFD securities don't have `TradeBar` data, they use bar indicators. Candlestick patterns are examples of bar indicators. Some other examples of bar indicators include the following:

- WilliamsPercentR
- Stochastics

- AverageTrueRange

TradeBar Indicators

`TradeBar` indicators use `TradeBar` objects to compute their value. Some `TradeBar` indicators use the volume property of the `TradeBar` to compute their value. Some examples of `TradeBar` indicators include the following:

- Beta
- AdvanceDeclineVolumeRatio
- VolumeWeightedAveragePriceIndicator

Naming Convention

The class name to create a manual indicator is the indicator name spelled in pascal case. For example, to create a manual simple moving average indicator , use the `SimpleMovingAverage` class.

The method to create an automatic indicator is usually named after the acronym of the indicator name. For example, to create an automatic simple moving average indicator , use the `SMA` method.

To view the class name and shortcut method of each indicator, see the Supported Indicators .

Create Indicators

There are two ways to create indicators. You can create indicators with the indicator constructor or use a helper method in the `QCAlgorithm` class. If you use the helper method, the indicator automatically updates as your algorithm receives new data.

```
C#
private BollingerBands _manualBB;
private BollingerBands _autoBB;
private Symbol _symbol;
public override void Initialize()
{
    // Create a manual indicator with the indicator constructor
    _manualBB = new BollingerBands(20, 2);
    // Create an automatic indicator with the helper method
    _symbol = AddCrypto("BTCUSD").Symbol;
    _autoBB = BB(_symbol, 20, 2, Resolution.Daily);
}
```

Set Historical Values Window Size

Indicators have a built-in `RollingWindow` that stores their historical values. The default window size is 2. To change the window size, set the `Window.Size` member.

```
C#
// Increase the window size to 10 for the Bollinger Band
_manualBB.Window.Size = 10;
_autoBB.Window.Size = 10;

// Increase the Size to 20 for the middle band
_manualBB.MiddleBand.Window.Size = 20;
_autoBB.MiddleBand.Window.Size = 20;
```

When you decrease the size, it removes the oldest values that no longer fit in the `RollingWindow` . When you explicitly increase the `Size` member, it doesn't automatically add any new elements to the `RollingWindow` . However, if you set the value of an index in the `RollingWindow` and the index doesn't currently exist, it fills the empty indices with `null` . For example, the following code increases the `Size` to 10, sets the 10th element to the indicator current value, and sets the 6th-9th elements to `null` :

```
_manualBB.Window[9] = _manualBB.Current;
_autoBB.Window[9] = _autoBB.Current;
```

Check Readiness

Indicators aren't always ready when you first create them. The length of time it takes to trust the indicator values depends on the indicator period. To know if an indicator is ready to use, use the `IsReady` property.

```
if (!_autoBB.IsReady) return;
```

To get the number of samples the indicator has processed, use the `Samples` property.

```
var samples = _autoBB.Samples;
```

The `RollingWindow` objects that store the historical values may not be full when the indicator is ready to use. To check if the `Window` is full, use its `IsReady` flag.

```
if (!_autoBB.Window.IsReady) return;
```

Track Update Events

When an indicator receives a new data point and updates its state, it triggers an update event. To be notified of update events, attach an event handler to the indicator object. The event handler receives 2 arguments: the indicator object and the latest `IndicatorDataPoint` it produced.

```
// After you create the indicator, attach an event handler
_autoBB.Updated += updateEventHandler;

// Define the event handler within the same class
private void updateEventHandler(object indicator, IndicatorDataPoint indicatorDataPoint)
{
    if (indicator.IsReady)
    {
        Plot("Indicator", "Value", indicatorDataPoint.Value);
    }
}
```

Get Current Values

To access the indicator value, use the `Current.Value` property. Some indicators have one output and some indicators have multiple outputs. The `SimpleMovingAverage` indicator only has one output, the average price over the last n periods, so the `Current.Value` property returns this value. The `BollingerBand` indicator has multiple outputs because it has a simple moving average, an upper band, and a lower band. For indicators that have multiple outputs, refer to the Supported Indicators to see how to access the output values.

```
C#
var sma = _sma.Current.Value;

var currentPrice = _autoBB.Current.Value;
var bbUpperBand = _autoBB.UpperBand.Current.Value;
var bbLowerBand = _autoBB.LowerBand.Current.Value;
```

You can implicitly cast indicators to the decimal version of their `Current.Value` property.

```
C#
if (_sma > _autoBB.UpperBand)
{
    SetHoldings(_symbol, -0.1);
}
```

Get Historical Values

To access historical indicator values, you can use the indicator's built-in `RollingWindow` or you can call the `IndicatorHistory` method to request values over a specific period of time.

Get Trailing Values

To access trailing indicator values, use reverse list access semantics with positive and negative indexing. The current (most recent) indicator value is at index 0, the previous value is at index 1 or the `Previous` property, and so on until the length of the window. By default, the window length is 2. If you index the window with a number that's greater than the maximum index of the window, you get a `null` value and the window length grows to support the new index.

```
C#
var currentBB = _autoBB.Current; // or _autoBB[0];
var previousBB = _autoBB.Previous; // or _autoBB[1];
var oldestBB = _autoBB.Window[-1];
var nullValue = _autoBB.Window[100];

var previousUpperBand = _autoBB.UpperBand.Previous;
var oldestUpperBand = _autoBB.UpperBand.Window[-1];
```

To access all of an indicator's historical values in the window, iterate through the indicator object.

```
C#
foreach (var value in _autoBB)
{
    Log(value.ToString());
}
```

Request Historical Values

The `IndicatorHistory` method also provides historical indicator values. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
// Get historical indicator values.
var history = IndicatorHistory(_sma, _symbol, TimeSpan.FromDays(30));

// Iterate through the historical values.
foreach (var indicatorDataPoint in history)
{
    var t = indicatorDataPoint.EndTime;
    var value = indicatorDataPoint.Value;
}
```

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
var history = IndicatorHistory(_sma, _symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of two assets to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
var spy = AddEquity("SPY").Symbol;
var aapl = AddEquity("AAPL").Symbol;
var beta = new Beta("", aapl, spy, 21);
var history = IndicatorHistory(beta, new[] {spy, aapl}, 10, Resolution.Daily);
```

If the indicator is an Option indicator with an underlying Equity, the `IndicatorHistory` uses the `ScaledRaw` data normalization mode when requesting historical prices.

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```
var slices = History(new[] {_symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(_sma, slices);
```

Reset Indicators

To reset indicators, call the `Reset` method.

```
_autoBB.Reset();
```

The process to warm up your indicator depends on if it's a manual or automatic indicator .

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your indicators when splits and dividends occur. If a split or dividend occurs, the data in your indicators becomes invalid because it doesn't account for the price adjustments that the split or dividend causes. To replace your indicator history with the newly-adjusted prices, call the `Reset` method and then warm up the indicator with `ScaledRaw` data from a history request .

```C#
// In OnData
if (data.Splits.ContainsKey(_symbol) || data.Dividends.ContainsKey(_symbol))
{
    // Reset the indicator
    _sma.Reset();

    // Warm up the indicator
    var tradeBars = History<TradeBar>(_symbol, _sma.WarmUpPeriod, Resolution.Daily, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
    foreach (var tradeBar in tradeBars)
    {
        _sma.Update(tradeBar.EndTime, tradeBar.Close);
    }
}
```

Common Design Patterns

The location in your algorithm where you create and manage indicators depends on the type of universe you use.

One Asset In a Static Universe

If you only have one security in your algorithm, you can create indicators for it during initialization .

```C#
private Symbol _symbol;
private SimpleMovingAverage _sma;

public override void Initialize()
{
    _symbol = AddEquity("SPY").Symbol;
    Settings.AutomaticIndicatorWarmUp = true;
    _sma = SMA(_symbol, 20, Resolution.Daily);
}
```

Multiple Assets or a Dynamic Universe

If your algorithm has multiple assets or a dynamic universe of assets, as you receive new `Security` objects in `OnSecuritiesChanged` , cast them to `dynamic` objects and add custom members to them.

```C#
public override void OnSecuritiesChanged(SecurityChanges changes)
{
    foreach (var security in changes.AddedSecurities)
    {
        var dynamicSecurity = security as dynamic;

        // Create an indicator
        dynamicSecurity.Indicator = SMA(security.Symbol, 10);

        // Warm up the indicator
        WarmUpIndicator(security.Symbol, dynamicSecurity.Indicator);
    }

    foreach (var security in changes.RemovedSecurities)
    {
        DeregisterIndicator((security as dynamic).Indicator);
    }
}
```

Differences From Third-Party Indicators

The values of our indicators can sometimes produce different results than the indicators on other platforms. There can be several reasons for these discrepancies.

Price Differences

If you find differences in indicator values, compare the prices that are fed into the indicator on each platform. If the input data is slightly different, the indicator values will be different. To test if it's a difference in price data, feed in the data from the third-party platform into our indicators. We validate the indicators against third-party sources and when the values are the same, the indicator values are similar too.

Timestamp Differences

We timestamp our data to the time when the period ends. Many other platforms timestamp to the beginning of the candle.

Implementation Differences

Some indicators can have slightly different default arguments for their implementation. A common difference across platforms is to use a different `MovingAverageType` for the indicators. To view the default arguments for all our indicators, see Supported Indicators . To view the full implementation of our indicators, see the LEAN GitHub repository .

Warm Up Period Differences

Some platforms use all of the historical data to warm up their indicators while LEAN indicators have a fixed number of bars they need to warm up. As a result, indicators with long memory like the Exponential Moving Average can have slightly different values across platforms.

Risk Free Interest Rate Differences

Some indicators, like Sharpe ratios and Sortino ratios , are a function of the risk free interest rate . LEAN provides several different ways to define the interest rate, which can lead to different indicator values compared to other platforms.

Indicators

Manual Indicators

Introduction

Manual indicators are indicators that don't automatically update from the underlying security data. Manual updates let you customize how you update the indicator, such as using a custom field or using Renko Bars . It's not always necessary to create manual indicators though. Automatic indicators are easier to create and update.

Naming Convention

The class name to create a manual indicator is the indicator name spelled in pascal case. For example, to create a manual simple moving average indicator , use the `SimpleMovingAverage` class.

Create Manual Indicators

To create manual indicators, instantiate an indicator with its constructor. To view all of the available indicators and their constructors, see Supported Indicators .

```C#
// Create an indicator
private Delay _delay;
_delay = new Delay(20);

// Create a candlestick pattern
private TwoCrows _twoCrows;
_twoCrows = new TwoCrows();
```

You can track indicators by their name. To name a manual indicator, pass a string as the first argument to the constructor.

```C#
// Name an indicator
_delay = new Delay("AAPL Past Price", 20);
Log(_delay.Name);

// Name a candlestick pattern
_twoCrows = new TwoCrows("Two Crows Pattern");
Log(_twoCrows.Name);
```

If you don't name an indicator, it's given a default name. For example, the default name for a `Delay` indicator is "Delay(period)".

Manual Updates

With manual updates, you control what data you use to update the indicator. For instance, you can use the 3:30 PM price in your daily moving average instead of the daily closing price or you can use the maximum temperature of the past 10 cloudy days.

To update an indicator, call the `Update` method. The `Update` method expects one of the following arguments:

- Time/decimal pair
- `IndicatorDataPoint`
- `QuoteBar`
- `TradeBar`

- Custom data bar

To view what data type you should use to update an indicator, see Supported Indicators .

You can update indicators at any point in your algorithm, but the most common places are during the `OnData` event handler or during a consolidation event handler.

```
C#

private Symbol _symbol;
private RelativeStrengthIndex _rsi;
private AccumulationDistribution _ad;

public override void Initialize()
{
    _symbol = AddEquity("SPY", Resolution.Daily).Symbol;

    _rsi = new RelativeStrengthIndex(10, MovingAverageType.Simple);
    _ad = new AccumulationDistribution();

    var consolidator = new TradeBarConsolidator(TimeSpan.FromDays(3));   // 10 x 3 daily trade bars to warm up the
RSI.
    consolidator = new QuoteBarConsolidator(TimeSpan.FromDays(3));       // 10 x 3 daily quote bars to warm up the
RSI.
    consolidator = new RenkoBarConsolidator(1);     // Renko consolidator that emits a bar when the price moves $1
    //Update the AD indicator with the consolidated bar
    consolidator.DataConsolidated += (_, bar) => _ad.Update(bar);
    SubscriptionManager.AddConsolidator(_symbol, consolidator);
}

public override void OnData(Slice slice)
{
    // Update the RSI indicator value with the new input close price every day
    if (slice.Bars.ContainsKey(_symbol))
    {
        var bar = slice.Bars[_symbol];
        _rsi.Update(bar.EndTime, bar.Close);
    }
}
```

Automatic Updates

With automatic updates, your indicators automatically update with the security data on a schedule you set. To configure automatic updates, create a consolidator and then call the `RegisterIndicator` method. If you register an indicator for automatic updates, don't call the indicator's `Update` method or else the indicator will receive double updates.

```
C#

// Create a security subscription
_symbol = AddEquity("SPY", Resolution.Hour);

// Create a manual indicator
_indicator = new RelativeStrengthIndex(10, MovingAverageType.Simple);

// Create a consolidator
var consolidator = new TradeBarConsolidator(3);   // 10 x 3 min trade bars to warm up the RSI.
consolidator = new QuoteBarConsolidator(4);       // 10 x 4 min quote bars to warm up the RSI.
consolidator = new RenkoConsolidator(1);          // Renko consolidator that emits a bar when the price moves $1

// Register the indicator to update with the consolidated data
RegisterIndicator(_symbol, _indicator, consolidator);
```

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar` data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `Open` , `High` , `Low` , or `Close` , provide a `selector` argument to the `RegisterIndicator` method.

```
RegisterIndicator(_symbol, _rsi, consolidator, Field.High);
```

The `Field` class has the following `selector` properties:

To create a custom `selector` , define a function that calculates the value.

```
RegisterIndicator(_symbol, _indicator, _consolidator, x =>
{
    var bar = x as IBaseDataBar;
    return (bar.Low + bar.High) / 2;
});
```

To stop automatically updating an indicator, pass the indicator to the `DeregisterIndicator` property method.

```
DeregisterIndicator(_indicator);
// Alias:
// UnregisterIndicator(_indicator);
```

Warm Up Indicators

Indicators use historical data to compute their value. Before you start trading with an indicator, warm it up. There are several ways to warm-up manual indicators.

Manual Indicator Warm-up

If you have access to the `QCAlgorithm` object, you can manually warmup indicators with a history request .

```
private SimpleMovingAverage _sma;
// Create a manual indicator.
_sma = SimpleMovingAverage(20);
// Get 20 bars of daily data.
var history = algorithm.History(_symbol, 20, Resolution.Daily);
// Manually warm up the indicator with the historical close prices.
foreach (var bar in history)
{
    sma.Update(bar.Time, bar.Close);
}
```

Warm-up Helper Method

If an indicator inherits (implements) the `IIndicatorWarmUpPeriodProvider` interface, you can warm it up with the `WarmUpIndicator` method.

```
// Warm up the indicator using the warm-up helper.
_sma = SimpleMovingAverage(20);
algorithm.WarmUpIndicator(_symbol, _sma);
```

To warm up the indicator with a resolution that's different from the security resolution, pass a resolution or `TimeSpan` argument to the `WarmUpIndicator` method. The resolution you provide should be greater than or equal to the security resolution. For example, if the security has minute resolution data, you should warm up the indicator with data that spans at least one minute.

```
// Warm-up with daily bars.
algorithm.WarmUpIndicator(_symbol, _sma, Resolution.Daily);

// Warm-up with 3-day bars.
algorithm.WarmUpIndicator(_symbol, _sma, TimeSpan.FromDays(3));
```

The `WarmUpIndicator` method uses the default `Value` of the historical data to warm up the indicator. In most cases, this is the closing price. To warm up the indicator with an alternative price field, pass a `Field` argument to the method.

```
// Warm up the indicator using daily high prices instead of close prices.
algorithm.WarmUpIndicator(_symbol, _sma, Resolution.Daily, Field.High);
```

Some indicators require the prices of two assets to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
// Use the warm-up helper for an indicator that needs the data of 2 assets.
var spy = AddEquity("SPY").Symbol;
var aapl = AddEquity("AAPL").Symbol;
var beta = new Beta("", aapl, spy, 21);
WarmUpIndicator(new[] {aapl, spy}, beta, Resolution.Daily);
```

Algorithm Warm-up

If you create indicators at the beginning of your algorithm, you can set an algorithm warm-up period to warm up the indicators. When you set an algorithm warm-up period, the engine pumps data in and automatically updates all the indicators from before the start date of the algorithm. To ensure that all the indicators are ready after the algorithm warm-up period, choose a lookback period that contains sufficient data.

```
private SimpleMovingAverage _sma;

// In the Initialize method, request data and construct the indicators you need.
var symbol = AddEquity("SPY", Resolution.Daily).Symbol;
_sma = SimpleMovingAverage(20);
SetWarmUp(20);

// In the OnData event handler, update your indicators.
// Use the IsWarmingUp flag to skip some code execution.
_sma.Update(data["SPY"]); // Delete this line if you registered the indicator for automatic updates.
if (IsWarmingUp)
{
    return;
}
```

Timing Considerations

In some cases, you might create and warm up the indicator during its sampling period. For example, say the security resolution is minute, the indicator resolution is daily, and you create and warm-up the indicator at noon without using the `SetWarmUp` method. In this example, the history request that gathers data to warm up the indicator won't contain any data from the current day. Furthermore, if you set up a consolidator to update the indicator, the consolidator also won't aggregate any data from before noon. It doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate some common practices for using manual indicators.

Example 1: Universe Selection

The following algorithm selects the stocks within 5% of the 1-year maximum price among the top 100 liquid stocks. To do so, we make use of Maximum indicator to do so. Then, we hold the stocks with price > EMA > SMA , which indicates an upward accelerating trend.

```C#
public class ManualIndicatorAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, Maximum> _maximumBySymbol = new();
    private Dictionary<Symbol, SymbolData> _symbolData = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Select a popularity-based universe with indicators in a Selection function.
        AddUniverse(Selection);

        // Set a scheduled event to rebalance daily on the daily indicator signals.
        Schedule.On(
            DateRules.EveryDay(),
            TimeRules.At(9, 31),
            Rebalance
        );
    }

    private IEnumerable<Symbol> Selection(IEnumerable<Fundamental> fundamentals)
    {
        var selected = new List<Symbol>();

        // Initially filtered for the top 100 liquid stocks first.
        var filtered = fundamentals.OrderByDescending(f => f.DollarVolume)
            .Take(100)
            .ToList();

        foreach (var f in filtered)
        {
            if (!_maximumBySymbol.TryGetValue(f.Symbol, out var maximum))
            {
                maximum = new(252);
                // Warm up the Maximum indicator for its readiness to use immediately.
                var history = History<TradeBar>(f.Symbol, 252, Resolution.Daily);
                foreach (var bar in history)
                {
                    maximum.Update(bar.EndTime, bar.Close);
                }
                _maximumBySymbol[f.Symbol] = maximum;
            }
            else
            {
                // Update the indicator with the last known adjusted price daily.
                maximum.Update(f.EndTime, f.AdjustedPrice);
            }

            // Select to trade if the current price is within 5% of the maximum price of the last year.
            // Close to the maximum price provides evidence of high popularity for the fund to support the trend.
            if (f.AdjustedPrice >= maximum * 0.95m)
            {
                selected.Add(f.Symbol);
            }
        }

        return selected;
    }

    private void Rebalance()
    {
        var symbolsToBuy = new List<Symbol>();

        foreach (var (symbol, symbolData) in _symbolData)
        {
```

```
        {
            // Buy the stocks whose prices are above the EMA and the EMA is above the SMA, meaning their trend is
upward accelerating.
            if (symbolData.IsReady && Securities[symbol].Price > symbolData.Ema && symbolData.Ema > symbolData.Sma)
            {
                symbolsToBuy.Add(symbol);
            }
        }

        // Equally invest in selected stocks to dissipate capital risk evenly.
        var count = symbolsToBuy.Count;
        if (count > 0)
        {
            var targets = symbolsToBuy.Select(symbol => new PortfolioTarget(symbol, 1m / count)).ToList();
            // Liquidate the positions that are not on an upward trend or are not popular anymore.
            SetHoldings(targets, liquidateExistingHoldings: true);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var added in changes.AddedSecurities)
        {
            // Instantiate a new instance of SymbolData object to hold indicators to use.
            _symbolData[added.Symbol] = new SymbolData(this, added.Symbol);
        }

        foreach (var removed in changes.RemovedSecurities)
        {
            // Remove the data subscription of indicators to release computation resources when leaving the universe.
            if (_symbolData.Remove(removed.Symbol, out var symbolData))
            {
                symbolData.Dispose();
            }
        }
    }

    private class SymbolData
    {
        private QCAlgorithm _algorithm;
        public Symbol Symbol { get; set; }
        public ExponentialMovingAverage Ema { get; set; }
        public SimpleMovingAverage Sma { get; set; }

        public bool IsReady => Ema.IsReady && Sma.IsReady;

        public SymbolData(QCAlgorithm algorithm, Symbol symbol)
        {
            _algorithm = algorithm;
            Symbol = symbol;

            // Create an EMA and an SMA manual indicator for trade signal generation.
            Ema = new ExponentialMovingAverage(20);
            Sma = new SimpleMovingAverage(20);

            // Warm up the indicators to ensure their readiness to use them immediately.
            algorithm.WarmUpIndicator(symbol, Ema, Resolution.Daily);
            algorithm.WarmUpIndicator(symbol, Sma, Resolution.Daily);

            // Subscribe to the indicators to update daily price data for updated trade signal generation.
            algorithm.RegisterIndicator(symbol, Ema, Resolution.Daily);
            algorithm.RegisterIndicator(symbol, Sma, Resolution.Daily);
        }

        public void Dispose()
        {
            Ema.Reset();
            Sma.Reset();
            // Cancel data subscription to release computation resources.
            _algorithm.DeregisterIndicator(Ema);
            _algorithm.DeregisterIndicator(Sma);
        }
    }
}
```

Indicators

Automatic Indicators

Introduction

Automatic indicators are indicators that automatically update from the underlying security data. Automatic indicators do everything that manual indicators do, but with automatic updates registered for you.

Naming Convention

The method to create an automatic indicator is usually named after the acronym of the indicator name. For example, to create an automatic simple moving average indicator , use the `SMA` method.

Create Automatic Indicators

To create automatic indicators, call the indicator helper method from the `QCAlgorithm` class. The indicator helper methods create an indicator object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. To view the helper method for each indicator, see Supported Indicators . In most cases, you should call the helper method in the `Initialize` method.

The indicator resolution must be greater than or equal to the resolution of the security subscription. For instance, if your security subscription is for minute resolution data, the indicator resolution should be minute, hour, or daily resolution.

```C#
private SimpleMovingAverage _sma;
private TwoCrows _twoCrows;

// In Initialize()
var symbol = AddEquity("SPY").Symbol;

//  - Create an indicator
_sma = SMA(symbol, 20, Resolution.Daily);

// - Create a candlestick pattern
var patterns = new CandlestickPatterns(this);
_twoCrows = patterns.TwoCrows(_symbol);
```

When you create an indicator with a helper method, the indicator is given a default name. You can track indicators by their name. The default name for the `SimpleMovingAverage` indicator is " SMA (period , ticker _ resolution)". For example, in the preceding code snippet, the `SimpleMovingAverage` indicator is named " SMA (20,SPY_day)". To get the name of an indicator, inspect its `Name` property.

```C#
Log(_sma.Name);
Log(_twoCrows.Name);
```

Alternative Price Fields

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with `TradeBar` data, that price is the `TradeBar` close price. For assets with `QuoteBar` data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the `Open` , `High` , `Low` , or `Close` , provide a `selector` argument to the indicator helper method.

```
// Define a 10-period daily RSI indicator with shortcut helper method
// Select the Open price to update the indicator
_rsi = RSI("SPY", 10,  MovingAverageType.Simple, Resolution.Daily, Field.Open);
```

The `Field` class has the following `selector` properties:

To create a custom `selector` , define a function that calculates the value.

```
_rsi = RSI("SPY", 10,  MovingAverageType.Simple, Resolution.Daily, x =>
{
    var bar = x as IBaseDataBar;
    return (bar.Low + bar.High) / 2;
});
```

Warm Up Indicators

Indicators compute their value based on historical data. Before you start trading with an indicator, warm it up. There are several ways to warm-up automatic indicators.

Algorithm Warm-up

You can set an algorithm warm-up period to warm up the indicators. When you set an algorithm warm-up period, the engine pumps data in and automatically updates all the indicators from before the start date. To ensure that all the indicators are ready after the algorithm warm-up period, choose a look-back period that contains sufficient data.

```
private SimpleMovingAverage _sma;

// In Initialize
var symbol = AddEquity("SPY").Symbol;
_sma = SMA(symbol, 20, Resolution.Daily);
SetWarmUp(20, Resolution.Daily);

// In OnData
if (IsWarmingUp)
{
    return;
}
```

Manual Indicator Warm-up

You can manually warm up indicators with a history request .

```
private SimpleMovingAverage _sma;

// In Initialize
var symbol = AddEquity("SPY").Symbol;
_sma = SMA(symbol, 20, Resolution.Daily);

var history = History(symbol, 20, Resolution.Daily);
foreach (var bar in history)
{
    sma.Update(bar.Time, bar.Close);
}
```

Automatic Indicator Warm-up

You can set the `Settings.AutomaticIndicatorWarmUp` property to true before you create most indicators to automatically warm

them up. This technique doesn't work for all indicators.

```
C#
private SimpleMovingAverage _sma;

// In Initialize
var symbol = AddEquity("SPY").Symbol;
Settings.AutomaticIndicatorWarmUp = true;
_sma = SMA(symbol, 20, Resolution.Daily);
```

Warm-up Helper Method

If an indicator inherits the `IIndicatorWarmUpPeriodProvider` class, you can warm it up with the `WarmUpIndicator` method.

```
C#
_sma = SMA(_symbol, 20);
WarmUpIndicator(_symbol, _sma);
```

To warm up the indicator with a resolution that's different from the security resolution, pass a resolution or `TimeSpan` argument to the `WarmUpIndicator` method. The resolution you provide should be greater than or equal to the security resolution. For example, if the security has minute resolution data, you should warm up the indicator with data that spans at least one minute. If the indicator resolution is different from the security resolution, provide the indicator resolution as the argument to properly warm up the indicator.

```
C#
// Warm up with daily bars
WarmUpIndicator(_symbol, _sma, Resolution.Daily);

// Warm up with 3-day bars
WarmUpIndicator(_symbol, _sma, TimeSpan.FromDays(3));
```

The `WarmUpIndicator` method uses the default `Value` of the historical data to warm up the indicator. In most cases, this is the closing price. To warm up the indicator with a different data field, pass a `Field` argument to the method.

```
C#
WarmUpIndicator(_symbol, _sma, Resolution.Daily, Field.High);
```

Some indicators require the prices of two assets to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
C#
var spy = AddEquity("SPY").Symbol;
var aapl = AddEquity("AAPL").Symbol;
var beta = B(aapl, spy, 21, Resolution.Daily);
WarmUpIndicator(new[] {aapl, spy}, beta, Resolution.Daily);
```

Timing Considerations

In some cases, you might create and warm up the indicator during its sampling period. For example, say the security resolution is minute, the indicator resolution is daily, and you create and warm-up the indicator at noon without using the `SetWarmUp` method. In this example, the history request that gathers data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. It doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just

the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Deregister Indicators

To stop the automatic updates of an indicator, pass the indicator to the `DeregisterIndicator` property method.

```
C#

DeregisterIndicator(_sma);
// Alias:
// UnregisterIndicator(_sma);
```

Common Mistakes

Avoid the following common mistakes when you use automatic indicators.

Using Indicator Values Before the Indicator Is Warmed Up

Indicators can provide inaccurate output values before they are warmed up. To avoid issues, always check the `IsReady` flag before you use indicator output values.

```
C#

// IsReady signals whether the indicator values are accurate and ready to use.
if (_indicator.IsReady)
{
    var value = _indicator.Current.Value;
}
```

Manually Registering an Automatic Indicator for Updates

If you create an automatic indicator and then register it for automatics updates or call the `Update` method, the indicator receives multiple input values during each update cycle. To avoid issues, create automatic indicators but don't register them for automatic updates or call the `Update` method.

```
C#

// Automatic indicator short-cuts create the indicator and register it for data updates.
_indicator = SMA(_symbol, 5);

// Don't register the automatic indicators for data. They automatically get data.
// RegisterIndicator(_symbol, _indicator, Resolution.Daily)
```

Examples

The following examples demonstrate some common practices for using automatic indicators.

Example 1: Trade With Automatic Indicators in a Dynamic Universe

The following algorithm selects a universe of the 20 most liquid US Equities each day. At the start of each trading session, it then forms an equal-weighted portfolio of the stocks that have price > EMA > SMA , which indicates an upward accelerating trend. As assets enter the universe, it creates automatic indicators for them. As assets leave the universe, it deregisters the indicators.

```
C#

public class AutomaticIndicatorAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, SymbolData> _symbolData = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
```

```
        // Add a universe of the 20 most liquid stocks to trade trends more efficiently.
        AddUniverse(Universe.Top(20));

        // Set a Scheduled Event to rebalance at the start of each day with the daily indicator signals.
        Schedule.On(DateRules.EveryDay(), TimeRules.At(9, 31), Rebalance);
    }

    private void Rebalance()
    {
        // Buy the stocks where price is above EMA and EMA is above SMA, meaning its trend is upward and
accelerating.
        var symbolsToBuy = _symbolData.Where(
                kvp => kvp.Value.IsReady && Securities[kvp.Key].Price > kvp.Value.Ema && kvp.Value.Ema >
kvp.Value.Sma
            )
            .Select(kvp => kvp.Key)
            .ToList();

        // Equally invest in the selected stocks to evenly distribute the capital risk.
        var count = symbolsToBuy.Count;
        if (count > 0)
        {
            var targets = symbolsToBuy.Select(symbol => new PortfolioTarget(symbol, 1m / count)).ToList();
            // Liquidate the positions that are no longer popular or in an uptrend.
            SetHoldings(targets, liquidateExistingHoldings: true);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var added in changes.AddedSecurities)
        {
            // Create a SymbolData object for this asset, which is an object that contains the indicators.
            _symbolData[added.Symbol] = new SymbolData(this, added.Symbol);
        }

        foreach (var removed in changes.RemovedSecurities)
        {
            // Stop updating the indicators of assets that leave the universe to release computation resources.
            if (_symbolData.Remove(removed.Symbol, out var symbolData))
            {
                symbolData.Dispose();
            }
        }
    }

    private class SymbolData
    {
        private QCAlgorithm _algorithm;
        public Symbol Symbol { get; set; }
        public ExponentialMovingAverage Ema { get; set; }
        public SimpleMovingAverage Sma { get; set; }

        public bool IsReady => Ema.IsReady && Sma.IsReady;

        public SymbolData(QCAlgorithm algorithm, Symbol symbol)
        {
            _algorithm = algorithm;
            Symbol = symbol;

            // Create EMA & SMA indicators to generate trade signals.
            Ema = algorithm.EMA(symbol, 20, Resolution.Daily);
            Sma = algorithm.SMA(symbol, 20, Resolution.Daily);

            // Warm up the indicators so they are ready to use immediately.
            algorithm.WarmUpIndicator(symbol, Ema, Resolution.Daily);
            algorithm.WarmUpIndicator(symbol, Sma, Resolution.Daily);
        }

        public void Dispose()
        {
            // Stop updating the indicators of assets that leave the universe to release computation resources.
            _algorithm.DeregisterIndicator(Ema);
            _algorithm.DeregisterIndicator(Sma);
        }
    }
}
```

Indicators

Plotting Indicators

Introduction

LEAN provides helper methods to make it simple to create indicator plots.

Plot Update Events

To plot all of the values of some indicators, in the `Initialize` method, call the `PlotIndicator` method. The method plots each indicator value as the indicator updates. The method accepts up to four indicators.

```C#
var symbol = AddEquity("SPY");
var smaShort = SMA(symbol, 10);
var smaLong = SMA(symbol, 20);
PlotIndicator("<chartName>", smaShort, smaLong)
```

Plot Current Values

To plot the current value of indicators, call the `Plot` method. The method accepts up to four indicators.

```C#
// In Initialize
var symbol = AddEquity("SPY");
var smaShort = SMA(symbol, 10);
var smaLong = SMA(symbol, 20);

// In OnData
Plot("<chartName>", smaShort, smaLong)
```

View Charts

The following table describes where you can access your charts, depending on how to deploy your algorithms:

Location	Algorithm Lab Algorithms	CLI Cloud Algorithms	CLI Local Algorithms
Backtest results page	✓	✓	
Live results page	✓	✓	
/backtests/read endpoint	✓	✓	
/live/read endpoint	✓	✓	
ReadBacktest method	✓	✓	
ReadLiveAlgorithm method	✓	✓	
Local JSON file in your <projectName> / backtests / <timestamp> or <projectName> / live / <timestamp> directory		✓	✓

Chart Limits

Not all indicators share the same base type(T), so you may not be able to plot them together since some indicators require points while others require `TradeBars` .

```
// Plot indicators that extend the "Indicator" type
PlotIndicators("All Indicator Values", sma, rsi);
Plot("Current Indicator Values", sma, rsi);

// Plot indicators that extend the "TradeBarIndicator" type
PlotIndicators("All Indicator Values", atr, aroon);
Plot("Current Indicator Values", atr, aroon);
```

If your indicator plots are complex, call the `Plot` method with one indicator and plot its `Current.Value` property. For more information about plotting, see Charting .

Examples

The following examples demonstrate some common practices for plotting indicators.

Example 1: SMA Ribbon

The following algorithm trades simple moving average (SMA) crossings, which involves five SMA indicators to form an SMA ribbon. To visualize the ribbon, it plots each indicator with a different color.

```
public class PlottingIndicatorAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private Dictionary<int, SimpleMovingAverage> _smas;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data to update indicators and trade.
        _spy = AddEquity("SPY", Resolution.Daily).Symbol;

        // Create a chart to plot the ribbon. To better visualize the plot, use different colors per series.
        var chart = new Chart("Ribbon");
        chart.AddSeries(new Series("Price", SeriesType.Candle, "$"));
        chart.AddSeries(new Series("SMA10", SeriesType.Line, "$", Color.Violet));
        chart.AddSeries(new Series("SMA20", SeriesType.Line, "$", Color.Blue));
        chart.AddSeries(new Series("SMA30", SeriesType.Line, "$", Color.Green));
        chart.AddSeries(new Series("SMA40", SeriesType.Line, "$", Color.Yellow));
        chart.AddSeries(new Series("SMA50", SeriesType.Line, "$", Color.Red));

        // Create 5 SMA indicators to create the SMA ribbon.
        _smas = new[]{10, 20, 30, 40, 50}.ToDictionary(k => k, v =>
        {
            var sma = SMA(_spy, v, Resolution.Daily);
            // Plot the indicator value to create the ribbon when the indicator updates.
            sma.Updated += (_, point) => Plot("Ribbon", $"SMA{v}", point.Value);
            // Warm up the indicator so it's ready to use immediately.
            WarmUpIndicator(_spy, sma);
            return sma;
        });
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Plot the candlestick when you get the daily bar.
            Plot("Ribbon", "Price", bar.Open, bar.High, bar.Low, bar.Close);

            // Follow strong upward trend.
            if (IsUptrend(bar.Close, _smas))
            {
```

```
                SetHoldings(_spy, 1m);
            }
            // Follow strong downward trend.
            else if (IsDowntrend(bar.Close, _smas))
            {
                SetHoldings(_spy, -1m);
            }
            // Liquidate positions if the trend is less deterministic.
            else
            {
                Liquidate();
            }
        }
    }

    public bool IsUptrend(decimal price, IDictionary<int, SimpleMovingAverage> smas)
    {
        // Uptrend occurs when price is above all SMAs and shorter SMAs are above longer SMAs.
        var smasList = smas.OrderBy(kvp => kvp.Key)
            .Select(kvp => kvp.Value)
            .ToList();
        return Enumerable.Range(1, smasList.Count-1).All(i => smasList[i] < smasList[i-1])
            && price > smasList[0];
    }

    public bool IsDowntrend(decimal price, IDictionary<int, SimpleMovingAverage> smas)
    {
        // Downtrend occurs when price is below all SMAs and shorter SMAs are below longer SMAs.
        var smasList = smas.OrderBy(kvp => kvp.Key)
            .Select(kvp => kvp.Value)
            .ToList();
        return Enumerable.Range(1, smasList.Count-1).All(i => smasList[i] > smasList[i-1])
            && price < smasList[0];
    }
}
```

Indicators

Combining Indicators

Introduction

Indicator extensions let you chain indications together like Lego blocks to create unique combinations. When you chain indicators together, the `Current.Value` property output of one indicator is the input of the following indicator. To chain indicators together with values other than the `Current.Value` property, create a custom indicator .

Addition

The `Plus` extension sums the `Current.Value` property of two indicators or sums the `Current.Value` property of an indicator and a fixed value.

```C#
// Sum the output of two indicators
var min = MIN("SPY", 21);
var std = STD("SPY", 21);
var minPlusStd = min.Plus(std);

// Sum the output of an indicator and a fixed value
var rsiPlusValue = min.Plus(10);
```

If you pass an indicator to the `Plus` extension, you can name the composite indicator.

```C#
var namedIndicator = min.Plus(std, "Buy Zone");
```

Subtraction

The `Minus` extension subtracts the `Current.Value` property of two indicators or subtracts a fixed value from the `Current.Value` property of an indicator.

```C#
// Subtract the output of two indicators
var smaShort = SMA("SPY", 14);
var smaLong = SMA("SPY", 21);
var smaDifference = smaShort.Minus(smaLong);

// Subtract a fixed value from the output of an indicator
var smaMinusValue = smaShort.Minus(10);
```

If you pass an indicator to the `Minus` extension, you can name the composite indicator.

```C#
var namedIndicator = smaShort.Minus(smaLong, "SMA Difference");
```

Multiplication

The `Times` extension multiplies the `Current.Value` property of two indicators or multiplies a fixed value and the `Current.Value` property of an indicator.

```
// Multiply the output of two indicators
var emaShort = EMA("SPY", 14);
var emaLong = EMA("SPY", 21);
var emaProduct = emaShort.Times(emaLong);

// Multiply the output of an indicator and a fixed value
var emaTimesValue = emaShort.Times(10);
```

If you pass an indicator to the `Times property` extension, you can name the composite indicator.

```
var namedIndicator = emaShort.Times(emaLong, "EMA Product");
```

Division

The `Over` extension divides the `Current.Value` property of an indicator by the `Current.Value` property of another indicator or a fixed value.

```
// Divide the output of two indicators
var rsiShort = RSI("SPY", 14);
var rsiLong = RSI("SPY", 21);
var rsiDivision = rsiShort.Over(rsiLong);

// Divide the output of an indicator by a fixed value
var rsiAverage = rsiShort.Plus(rsiLong).Over(2);
```

If you pass an indicator to the `Over` extension, you can name the composite indicator.

```
var namedIndicator = rsiShort.Over(rsiLong, "RSI Division");
```

Weighted Average

The `WeightedBy` extension calculates the average `Current.Value` property of an indicator over a lookback period, weighted by another indicator over the same lookback period. The value of the calculation is

$$\frac{\textbf{x} \cdot \textbf{y}}{ \sum\limits_{i=1}^{n} y_{i} }$$

where $\textbf{x}$ is a vector that contains the historical values of the first indicator,$\textbf{y}$ is a vector that contains the historical values of the second indicator, and n is the lookback period.

```
var smaShort = SMA("SPY", 14);
var smaLong = SMA("SPY", 21);
var weightedSMA = smaShort.WeightedBy(smaLong, 3);
```

Custom Chains

The `Of` extension feeds an indicator's `Current.Value` property into the input of another indicator. The first argument of the `IndicatorExtensions.Of` method must be a manual indicator with no automatic updates. If you pass an indicator that has automatic updates as the argument, that first indicator is updated twice. The first update is from the security data and the second update is from the `IndicatorExtensions` class.

```
var rsi = RSI("SPY", 14);
var rsiSMA = (new SimpleMovingAverage(10)).Of(rsi); // 10-period SMA of the 14-period RSI
```

If you pass a manual indicator as the second argument, to update the indicator chain, update the second indicator. If you call the `Update` method of the entire indicator chain, it won't update the chain properly.

Simple Moving Average

The `SMA` extension calculates the simple moving average of an indicator's `Current.Value` property.

```
var rsi = RSI("SPY", 14); // Create a RSI indicator
var rsiSMA = rsi.SMA(3); // Create an indicator to calculate the 3-period SMA of the RSI indicator
```

Exponential Moving Average

The `EMA` extension calculates the exponential moving average of an indicator's `Current.Value` property.

```
var rsi = RSI("SPY", 14); // Create a RSI indicator
var rsiEMA = _rsi.EMA(3); // Create an indicator to calculate the 3-period EMA of the RSI indicator
```

The `EMA` extension can also accept a smoothing parameter that sets the percentage of data from the previous value that's carried into the next value.

```
var rsiEMA = rsi.EMA(3, 0.1m); // 10% smoothing factor
```

Maximum

The `MAX` extension calculates an indicator's maximum `Current.Value` property over a lookback window.

```
var ema = EMA("SPY", 14); // Create an EMA indicator
var emaMax = ema.MAX(10); // Create an indicator to calculate the maximum EMA over the last 10 periods
```

Minimum

The `MIN` extension calculates an indicator's minimum `Current.Value` property over a lookback window.

```
var ema = EMA("SPY", 14); // Create an EMA indicator
var emaMin = ema.MIN(10); // Create an indicator to calculate the minimum EMA over the last 10 periods
```

Examples

The following examples demonstrate some common practices for combining indicators.

Example 1: Volatility

The following algorithm trades a volatility strategy. By comparing SMA and the current value of the standard deviation of the return, we can estimate the current volatility regime is above or below average to trade the price volatility through strangle.

C#

```
public class CombiningIndicatorsAlgorithm : QCAlgorithm
{
    private Symbol _spy, _option;
    private SimpleMovingAverage _sma;
    private StandardDeviation _sd;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request daily SPY data to feed the indicators and generate trade signals.
        // Use Raw data normalization mode to compare the strike price fairly.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Request option data to trade.
        var option = AddOption(_spy);
        _option = option.Symbol;
        // Filter for 7-day expiring options with $5 apart from the current price to trade volatility using strangle.
        option.SetFilter((universe) => universe.IncludeWeeklys().Strangle(7, 5, -5));

        // Create a return indicator to get the daily return of SPY.
        var ret = ROC(_spy, 1, Resolution.Daily);
        // Create an SD indicator to measure the 252-day SD of return to measure SPY's volatility.
        _sd = IndicatorExtensions.Of(new StandardDeviation(252), ret);
        // Create a 20-day SMA indicator of the SD indicator to compare the average volatility.
        _sma = IndicatorExtensions.Of(new SimpleMovingAverage(20), _sd);

        // Warm up for immediate usage of indicators.
        SetWarmUp(400, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (IsWarmingUp)
        {
            return;
        }
        if (!Portfolio.Invested && slice.OptionChains.TryGetValue(_option, out var chain))
        {
            // Create a strangle strategy to trade the volatility forecast.
            var otmCallStrike = chain.Max(x => x.Strike);
            var otmPutStrike = chain.Min(x => x.Strike);
            var expiry = chain.Min(x => x.Expiry);
            var strangle = OptionStrategies.Strangle(_option, otmCallStrike, otmPutStrike, expiry);

            // If the current STD is above its SMA, we estimate the volatility will remain high due to volatility
clustering.
            // Thus, we long the strangle to earn from the price displacement from the current level.
            if (_sd > _sma)
            {
                Buy(strangle, 2);
            }
            // If the current STD is below its SMA, we estimate the volatility will remain lower due to volatility
clustering.
            // Thus, we short the strangle to earn from the price staying at the current level.
            if (_sd < _sma)
            {
                Sell(strangle, 2);
            }
        }
        else if (Portfolio[_spy].Invested)
        {
            // Liquidate any assigned underlying positions.
            Liquidate(_spy);
        }
    }
}
```

Example 2: Displaced SMA Ribbon

The following algorithm trades trends indicated by SMA crossings. We use the

`IndicatorExtensions to confirm the trend better.Of` method to create a Delay indicator on SMA indicator.

C#

```
public class DisplacedMovingAverageRibbon : QCAlgorithm
{
    private Symbol _spy;
    private IndicatorBase<IndicatorDataPoint>[] _ribbon;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request daily SPY data for feeding indicator and trading.
        _spy = AddEquity("SPY", Resolution.Daily).Symbol;

        // Create 6 15-day SMA indicators, with a 5-day delay between each indicator.
        const int count = 6;
        const int offset = 5;
        const int period = 15;

        // Define our sma as the base of the ribbon.
        var sma = new SimpleMovingAverage(period);

        _ribbon = Enumerable.Range(0, count).Select(x =>
        {
            // Define our offset to the zero SMA; these various offsets will create our 'displaced' ribbon.
            var delay = new Delay(offset*(x+1));
            // Using Delay indicator to create displaced SMA indicators.
            var delayedSma = delay.Of(sma);
            // Register our new 'delayed_sma' for automatic updates on a daily resolution.
            RegisterIndicator(_spy, delayedSma, Resolution.Daily, data => data.Value);
            return delayedSma;
        }).ToArray();
    }

    public override void OnData(Slice slice)
    {
        // Trade only on updated data with ready-to-use indicators.
        if (!_ribbon.All(x => x.IsReady)) return;
        if (!slice.Bars.TryGetValue(_spy, out var data))
        {
            return;
        }
        // Plot indicators each time they update.
        Plot("Ribbon", "Price", data.Price);
        Plot("Ribbon", _ribbon);

        var values = _ribbon.Select(x => x.Current.Value).ToArray();
        var holding = Portfolio[_spy];
        // Buy SPY if the trend is upward.
        if (holding.Quantity <= 0 && IsAscending(values))
        {
            SetHoldings(_spy, 1.0);
        }
        // Liquidate if the trend is downwards.
        else if (holding.Quantity > 0 && IsDescending(values))
        {
            Liquidate(_spy);
        }
    }

    // Returns true if the SMA values are in ascending order, indicating an upward trend
    private bool IsAscending(IEnumerable<decimal> values)
    {
        decimal? last = null;
        foreach (var val in values)
        {
            if (last == null)
            {
                last = val;
                continue;
            }

            if (last.Value < val)
            {
                return false;
            }
            last = val;
        }
        return true;
    }

    // Returns true if the SMA values are in descending order, indicating a downward trend
```

```
    // Returns true if the SMA values are in descending order, indicating a downward trend
    private bool IsDescending(IEnumerable<decimal> values)
    {
        decimal? last = null;
        foreach (var val in values)
        {
            if (last == null)
            {
                last = val;
                continue;
            }

            if (last.Value > val)
            {
                return false;
            }
            last = val;
        }
        return true;
    }
}
```

Demonstration Algorithm

Indicators

Custom Indicators

Introduction

LEAN supports over 100 pre-built indicators, but a custom indicator is an indicator you define. It receives input, performs some calculation, and sets its output value. Custom indicators are helpful when you want to achieve any of the following results:

- Use an indicator that LEAN doesn't currently implement
- Combine built-in indicators beyond the logic of Indicator Extensions
- Create your own unique indicator for trading

Define Indicators

Custom indicators subsclass the `IndicatorBase<IndicatorDataPoint>` , `BarIndicator` , or `TradeBarIndicator` class, depending on the indicator type . The following definition provides an example of a custom simple moving average indicator that inherits the `IndicatorBase<IndicatorDataPoint>` class. To view examples of indicators that inherit the `BarIndicator` or `TradeBarIndicator` class, see the AverageTrueRange or VolumeWeightedAveragePriceIndicator implementation in the LEAN GitHub repository.

```C#
public class CustomSimpleMovingAverage : IndicatorBase<IndicatorDataPoint>, IIndicatorWarmUpPeriodProvider
{
    private RollingWindow<decimal> _window;
    public override bool IsReady => _window.IsReady;
    public int WarmUpPeriod => _window.Size;

    public CustomSimpleMovingAverage(string name, int period) : base(name)
    {
        _window = new RollingWindow<decimal>(period);
    }

    protected override decimal ComputeNextValue(IndicatorDataPoint input)
    {
        _window.Add(input.Value);
        return _window.Sum() / _window.Size;
    }

    public override void Reset()
    {
        _window.Reset();
        base.Reset();
    }
}
```

The following definition provides an example of a custom money flow index indicator.

```C#
public class CustomMoneyFlowIndex : TradeBarIndicator, IIndicatorWarmUpPeriodProvider
{
    private decimal _previousTypicalPrice;
    private RollingWindow<decimal> _negativeMoneyFlow;
    private RollingWindow<decimal> _positiveMoneyFlow;
    public override bool IsReady => _positiveMoneyFlow.IsReady;
    public int WarmUpPeriod => _positiveMoneyFlow.Size;

    public CustomMoneyFlowIndex(string name, int period) : base(name)
    {
        _negativeMoneyFlow = new(period);
        _positiveMoneyFlow = new(period);
        _previousTypicalPrice = 0m;
    }

    protected override decimal ComputeNextValue(TradeBar input)
    {
        var typicalPrice = (input.High + input.Low + input.Close) / 3;
        var moneyFlow = typicalPrice * input.Volume;

        _negativeMoneyFlow.Add(typicalPrice < _previousTypicalPrice ? moneyFlow: 0);
        _positiveMoneyFlow.Add(typicalPrice > _previousTypicalPrice ? moneyFlow: 0);
        _previousTypicalPrice = moneyFlow;

        var positiveMoneyFlowSum = _positiveMoneyFlow.Sum();
        var totalMoneyFlow = positiveMoneyFlowSum + _negativeMoneyFlow.Sum();

        return totalMoneyFlow == 0 ? 100m : 100m * positiveMoneyFlowSum / totalMoneyFlow;
    }

    public override void Reset()
    {
        _previousTypicalPrice = 0m;
        _negativeMoneyFlow.Reset();
        _positiveMoneyFlow.Reset();
        base.Reset();
    }
}
```

Create Indicators

You must define a custom indicator before you can create an instance of it.

To create a custom indicator, call the indicator constructor.

```C#
private CustomSimpleMovingAverage _sma;

_sma = new CustomSimpleMovingAverage("My SMA", 10);
```

Updates

The process to update custom indicators is the same process you use to update manual indicators. For more information about updating manual indicators, see Manual Updates or Automatic Updates .

Warm Up Indicators

The process to warm up custom indicators is the same process you use to warm up manual indicators .

Examples

The following examples demonstrate some common practices for implementing custom indicators.

Example 1: Multiple Symbol Custom Indicator

The following algorithm implements a custom Cointegration price divergence indicator involving 2 symbols: GOOGL & GOOG. It trades the arbitrage between 2 cointegrated stocks on their price convergence after deviating more than 2 standard deviations.

C#

```
using Accord.Statistics;
using MathNet.Numerics.LinearRegression;

public class CombiningIndicatorsAlgorithm : QCAlgorithm
{
    private Symbol _goog1, _goog2;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request 2 classes of Google stock data to feed the indicators and generate trade signals.
        var goog1 = AddEquity("GOOGL").Symbol;
        var goog2 = AddEquity("GOOG").Symbol;

        // Create a custom money flow index to generate a trade signal.
        var cointegration = new Cointegration(this, goog1, goog2, 252, DateRules.MonthStart());
        // Add a handler to trade on updates.
        cointegration.Updated += OnUpdated;
        // Register the indicator to update automatically with daily data.
        RegisterIndicator(goog1, cointegration, Resolution.Daily);
        RegisterIndicator(goog2, cointegration, Resolution.Daily);

        // Warm up for immediate usage of indicators.
        WarmUpIndicator(goog1, cointegration, Resolution.Daily);
        WarmUpIndicator(goog2, cointegration, Resolution.Daily);
    }

    private void OnUpdated(object sender, IndicatorDataPoint point)
    {
        var indicator = (sender as Cointegration);
        if (indicator.IsReady)
        {
            var holding = Portfolio[indicator.Symbol1];

            // If the residual is lower than -2x SD, it means class A price is much higher than what it should be
compared to class C.
            // We sell class A and buy class C to bet on their price convergence.
            if (point < -2m && !holding.IsShort)
            {
                SetHoldings(indicator.Symbol1, -0.5m);
                SetHoldings(indicator.Symbol2, 0.5m * indicator.Ratio);
            }
            // If the residual is higher than the threshold, it means class A price is much lower than what it should
be compared to class C.
            // We buy class A and sell class C to bet on their price convergence.
            else if (point > 2m && !holding.IsLong)
            {
                SetHoldings(indicator.Symbol1, 0.5m);
                SetHoldings(indicator.Symbol2, -0.5m * indicator.Ratio);
            }
            // Close positions of the price are converged.
            else if ((holding.IsShort && point > 0m) || (holding.IsLong && point < 0m))
            {
                Liquidate();
            }
        }
    }
}

public class Cointegration : IndicatorBase<IndicatorDataPoint>, IIndicatorWarmUpPeriodProvider
{
    // The standard deviation of the residuals, such that the returned indicator value is relative to the SD.
    private decimal _residualSD = 1e10m;
    // Store the coefficient and intercept of the cointegrated series for calculating the spread of a new data point.
    private decimal[] _coefficients = new[] { 0m, 0m };

    private readonly int _period;

    public Symbol Symbol1 { get; set; }

    public Symbol Symbol2 { get; set; }

    // The ratio of Symbol2 within the ocintegration relationship compared to Symbol1.
    public decimal Ratio => _coefficients[0];

    public int WarmUpPeriod => _period;
```

```
    public override bool IsReady => _windows.All(kvp => kvp.Value.IsReady) && _coefficients.All(x => x != 0m);

    public Cointegration(QCAlgorithm algorithm, Symbol symbol1, Symbol symbol2, int period, IDateRule
recalibratingDateRule)
        : base("Cointegration")
    {
        Symbol1 = symbol1;
        Symbol2 = symbol2;

        // Use rolling windows to save the price data for cointegration analysis.
        _windows[symbol1] = new(period);
        _windows[symbol2] = new(period);

        // Adjust the cointegration factor between the 2 classes' price series.
        algorithm.Schedule.On(
            recalibratingDateRule,
            algorithm.TimeRules.At(23, 59),
            CalculateCointegration
        );

        _period = period;
    }

    public override bool Update(IBaseData input)
    {
        // Update the rolling windows for cointegration analysis.
        if (!_windows.TryGetValue(input.Symbol, out var window))
        {
            throw new ArgumentException($"{input.Symbol} is not part of the Cointegration relation.");
        }
        window.Add(new IndicatorDataPoint(input.Symbol, input.EndTime, input.Value));

        var nextResult = ValidateAndComputeNextValue((IndicatorDataPoint)input);
        if (nextResult.Status == IndicatorStatus.Success)
        {
            Current = new IndicatorDataPoint(input.EndTime, nextResult.Value);
            OnUpdated(Current);
        }

        return IsReady;
    }

    protected override IndicatorResult ValidateAndComputeNextValue(IndicatorDataPoint input)
    {
        // If no cointegration relationship is found, an invalid result will always be returned.
        if (_coefficients.All(x => x == 0m))
        {
            return new IndicatorResult(0m, IndicatorStatus.ValueNotReady);
        }
        return new IndicatorResult(ComputeNextValue(input));
    }

    protected override decimal ComputeNextValue(IndicatorDataPoint input)
    {
        // Calculate the updated cointegrated series spread only if all symbol data points are updated.
        if (_windows.All(kvp => kvp.Value[0].EndTime == input.EndTime))
        {
            return (_coefficients[0] * _windows[Symbol2][0].Value + _coefficients[1] - _windows[Symbol1][0].Value) /
_residualSD;
        }
        return Current.Value;
    }

    private void CalculateCointegration()
    {
        // Lag direction is unimportant; it is just a sign flip in the linear regression, so we don't need to flip
the window order.
        var y = _windows[Symbol1].Select(x => (double)x.Value).ToArray();
        var x = _windows[Symbol2].Select(x => (double)x.Value).ToArray();
        if (x.Length < 2 || y.Length < 2)
        {
            return;
        }

        // Perform Linear Regression on both price series to investigate their relationship.
        var regressionResult = SimpleRegression.Fit(x, y);
        var intercept = regressionResult.Item1;
        var slope = regressionResult.Item2;

        // Calculate the residuals series to check if it is stationary, meaning if the 2 price series move together.
```

```
        var residuals = new double[x.Length];
        for (int i = 0; i < x.Length; i++)
        {
            residuals[i] = y[i] - (intercept + slope * x[i]);
        }

        // Check if the residuals are stationary using the augmented Dickey-Fuller test.
        if (ADFTest(residuals, Convert.ToDouble(_period)))
        {
            // If cointegrated, update the positional sizing ratio and the spread threshold of the trade trigger.
            _coefficients = new[] { Convert.ToDecimal(slope), Convert.ToDecimal(intercept) };
            _residualSD = Convert.ToDecimal(Measures.StandardDeviation(residuals));
        }
        else
        {
            _coefficients = new[] { 0m, 0m };
            _residualSD = 1e10m;             // An arbitrarily large number that the class A price will never reach.
        }
    }

    private static bool ADFTest(double[] series, double N)
    {
        var n = series.Length;
        var lagged = new double[n - 1];
        var differences = new double[n - 1];

        // Fit linear regression for the residual series on unit root: ΔY_t = α + βY_{t-1} + ε_t.
        for (int i = 1; i < n; i++)
        {
            lagged[i - 1] = series[i - 1];
            differences[i - 1] = series[i] - series[i - 1];
        }

        var regressionResult = SimpleRegression.Fit(lagged, differences);
        var alpha = regressionResult.Item1;  // Intercept
        var beta = regressionResult.Item2;   // Coefficient of lagged term

        // Calculate the ADF statistic and check if the null hypothesis is rejected.
        var adfStatistic = beta / Measures.StandardError(differences);

        // Reject the null hypothesis of a unit root is present if test statistic <= critical value
        //This means no unit root exists for the difference series, and the residuals are stationary.
        var critical = -1.941d + -0.2686d / N + -3.365d / N / N + 31.223d / N / N / N;
        return adfStatistic <= critical;
    }
}
```

Example 2: Custom Money Flow Index

The following algorithm implements a custom Money Flow Index indicator, and updates it manually. We estimate the supply-demand balance of SPY and trade using the average money flow direction.

```
C#

public class CombiningIndicatorsAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private CustomMoneyFlowIndex _customMfi;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request daily SPY data to feed the indicators to generate trade signals and trade.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Create a custom money flow index to generate a trade signal.
        _customMfi = new CustomMoneyFlowIndex(20);

        // Warm up for immediate usage of indicators.
        SetWarmUp(20, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (!slice.Bars.TryGetValue(_spy, out var bar))
        {
```

```
        {
            return;
        }
        // Update the custom MFI with the updated trade bar to obtain the updated trade signal.
        _customMfi.Update(bar);
        // Don't trade until warm-up is done.
        if (IsWarmingUp)
        {
            return;
        }
        // Buy if the positive money flow is above the negative, which indicates demand is greater than supply,
driving up the price.
        if (_customMfi > 50)
        {
            SetHoldings(_spy, 1);
        }
        // Sell if the positive money flow is below negative, indicating demand is less than supply, driving down the
price.
        else
        {
            SetHoldings(_spy, -1);
        }
    }

    public class CustomMoneyFlowIndex : TradeBarIndicator, IIndicatorWarmUpPeriodProvider
    {
        private decimal _previousTypicalPrice;
        private RollingWindow<decimal> _negativeMoneyFlow;
        private RollingWindow<decimal> _positiveMoneyFlow;
        public override bool IsReady => _positiveMoneyFlow.IsReady;
        public int WarmUpPeriod => _positiveMoneyFlow.Size;

        public CustomMoneyFlowIndex(int period) : base("CustomMFI")
        {
            _negativeMoneyFlow = new(period);
            _positiveMoneyFlow = new(period);
            _previousTypicalPrice = 0m;
        }

        protected override decimal ComputeNextValue(TradeBar input)
        {
            // Estimate the money flow by averaging the price multiplied by volume.
            var typicalPrice = (input.High + input.Low + input.Close) / 3;
            var moneyFlow = typicalPrice * input.Volume;

            // We need to avoid double rounding errors.
            _negativeMoneyFlow.Add(typicalPrice < _previousTypicalPrice ? moneyFlow: 0);
            _positiveMoneyFlow.Add(typicalPrice > _previousTypicalPrice ? moneyFlow: 0);
            _previousTypicalPrice = moneyFlow;

            // Add the period money flow to calculate the aggregated money flow.
            var positiveMoneyFlowSum = _positiveMoneyFlow.Sum();
            var totalMoneyFlow = positiveMoneyFlowSum + _negativeMoneyFlow.Sum();

            // Set the value to be the positive money flow ratio.
            return totalMoneyFlow == 0 ? 100m : 100m * positiveMoneyFlowSum / totalMoneyFlow;
        }

        public override void Reset()
        {
            _previousTypicalPrice = 0m;
            _negativeMoneyFlow.Reset();
            _positiveMoneyFlow.Reset();
            base.Reset();
        }
    }
}
```

Indicators

Indicator Universes

Introduction

An indicator universe uses technical indicators to determine the constituents of the universe. Imagine a universe that only contains assets above their 10-day simple moving average. You can incorporate indicators into any of the types of universes in the Universes chapter . To create an indicator universe, define a helper class that contains the indicators and then define a universe that updates the indicators and selects assets.

Define SymbolData Objects

To make it easy to create and update indicators for each security in the universe, move the indicator logic into a class. In the universe definition, you can create an instance of this class for each security in the universe. The indicators you create in this class should be manual indicators so you can ensure they only update during universe selection.

C#

```
private class SelectionData
{
    public readonly ExponentialMovingAverage Fast;
    public readonly ExponentialMovingAverage Slow;

    public SelectionData()
    {
        Fast = new ExponentialMovingAverage(100);
        Slow = new ExponentialMovingAverage(300);
    }

    public decimal ScaledDelta
    {
        get { return (Fast - Slow)/((Fast + Slow)/2m); }
    }

    public bool Update(DateTime time, decimal value)
    {
        return Fast.Update(time, value) && Slow.Update(time, value);
    }
}
```

You need to use a `SymbolData` class instead of assigning the indicators to the `Fundamental` object because you can't create custom properties on `Fundamental` objects like you can with `Security` objects.

Define the Universe

You need to define SymbolData objects before you define the universe that selects securities.

When your universe function receives an object that contains all the possible securities, create a `SymbolData` object for each new security and update the remaining `SymbolData` objects with their daily price or some other data point. For example, the following universe definition selects US Equities that have the greatest difference between two moving averages.

```C#
using System.Collections.Concurrent;
public class EmaCrossUniverseSelectionAlgorithm : QCAlgorithm
{
    // tolerance to prevent bouncing
    const decimal Tolerance = 0.01m;
    private const int Count = 10;
    // use Buffer+Count to leave a little in cash
    private const decimal TargetPercent = 0.1m;
    private SecurityChanges _changes = SecurityChanges.None;
    // holds our fundamental indicators by symbol
    private readonly ConcurrentDictionary<Symbol, SelectionData> _averages = new ConcurrentDictionary<Symbol,
SelectionData>();

    public override void Initialize()
    {
        UniverseSettings.Asynchronous = true;
        UniverseSettings.Leverage = 2.0m;
        UniverseSettings.Resolution = Resolution.Daily;
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        AddUniverse(fundamental =>
        {
            return (from f in fundamental
                    // grab th SelectionData instance for this symbol
                    let avg = _averages.GetOrAdd(f.Symbol, sym => new SelectionData())
                    // Update returns true when the indicators are ready, so don't accept until they are
                    where avg.Update(f.EndTime, f.AdjustedPrice)
                    // only pick symbols who have their 50 day ema over their 100 day ema
                    where avg.Fast > avg.Slow*(1 + Tolerance)
                    // prefer symbols with a larger delta by percentage between the two averages
                    orderby avg.ScaledDelta descending
                    // we only need to return the symbol and return 'Count' symbols
                    select f.Symbol).Take(Count);
        });
    }
}
```

Examples

The following examples demonstrate some common practices for using indicator universes.

Example 1: Universe Selection

The following algorithm selects the stocks within 5% of the 1-year maximum price among the top 100 liquid stocks. To do so, we make use of Maximum indicator to do so. Then, we hold the stocks with price > EMA > SMA , which indicates an upward accelerating trend.

```C#
public class ManualIndicatorAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, Maximum> _maximumBySymbol = new();
    private Dictionary<Symbol, SymbolData> _symbolData = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Select a popularity-based universe with indicators in a Selection function.
        AddUniverse(Selection);

        // Set a scheduled event to rebalance daily on the daily indicator signals.
        Schedule.On(
            DateRules.EveryDay(),
            TimeRules.At(9, 31),
            Rebalance
        );
    }

    private IEnumerable<Symbol> Selection(IEnumerable<Fundamental> fundamentals)
    {
```

```
        var selected = new List<Symbol>();

        // Initially filtered for the top 100 liquid stocks first.
        var filtered = fundamentals.OrderByDescending(f => f.DollarVolume)
            .Take(100)
            .ToList();

        foreach (var f in filtered)
        {
            if (!_maximumBySymbol.TryGetValue(f.Symbol, out var maximum))
            {
                maximum = new(252);
                // Warm up the Maximum indicator for its readiness to use immediately.
                var history = History<TradeBar>(f.Symbol, 252, Resolution.Daily);
                foreach (var bar in history)
                {
                    maximum.Update(bar.EndTime, bar.Close);
                }
                _maximumBySymbol[f.Symbol] = maximum;
            }
            else
            {
                // Update the indicator with the last known adjusted price daily.
                maximum.Update(f.EndTime, f.AdjustedPrice);
            }

            // Select to trade if the current price is within 5% of the maximum price of the last year.
            // Close to the maximum price provides evidence of high popularity for the fund to support the trend.
            if (f.AdjustedPrice >= maximum * 0.95m)
            {
                selected.Add(f.Symbol);
            }
        }

        return selected;
    }

    private void Rebalance()
    {
        var symbolsToBuy = new List<Symbol>();

        foreach (var (symbol, symbolData) in _symbolData)
        {
            // Buy the stocks whose prices are above the EMA and the EMA is above the SMA, meaning their trend is
upward accelerating.
            if (symbolData.IsReady && Securities[symbol].Price > symbolData.Ema && symbolData.Ema > symbolData.Sma)
            {
                symbolsToBuy.Add(symbol);
            }
        }

        // Equally invest in selected stocks to dissipate capital risk evenly.
        var count = symbolsToBuy.Count;
        if (count > 0)
        {
            var targets = symbolsToBuy.Select(symbol => new PortfolioTarget(symbol, 1m / count)).ToList();
            // Liquidate the positions that are not on an upward trend or are not popular anymore.
            SetHoldings(targets, liquidateExistingHoldings: true);
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var added in changes.AddedSecurities)
        {
            // Instantiate a new instance of SymbolData object to hold indicators to use.
            _symbolData[added.Symbol] = new SymbolData(this, added.Symbol);
        }

        foreach (var removed in changes.RemovedSecurities)
        {
            // Remove the data subscription of indicators to release computation resources when leaving the universe.
            if (_symbolData.Remove(removed.Symbol, out var symbolData))
            {
                symbolData.Dispose();
            }
        }
    }

    private class SymbolData
    {
```

```
    {
        private QCAlgorithm _algorithm;
        public Symbol Symbol { get; set; }
        public ExponentialMovingAverage Ema { get; set; }
        public SimpleMovingAverage Sma { get; set; }

        public bool IsReady => Ema.IsReady && Sma.IsReady;

        public SymbolData(QCAlgorithm algorithm, Symbol symbol)
        {
            _algorithm = algorithm;
            Symbol = symbol;

            // Create an EMA and an SMA manual indicator for trade signal generation.
            Ema = new ExponentialMovingAverage(20);
            Sma = new SimpleMovingAverage(20);

            // Warm up the indicators to ensure their readiness to use them immediately.
            algorithm.WarmUpIndicator(symbol, Ema, Resolution.Daily);
            algorithm.WarmUpIndicator(symbol, Sma, Resolution.Daily);

            // Subscribe to the indicators to update daily price data for updated trade signal generation.
            algorithm.RegisterIndicator(symbol, Ema, Resolution.Daily);
            algorithm.RegisterIndicator(symbol, Sma, Resolution.Daily);
        }

        public void Dispose()
        {
            Ema.Reset();
            Sma.Reset();
            // Cancel data subscription to release computation resources.
            _algorithm.DeregisterIndicator(Ema);
            _algorithm.DeregisterIndicator(Sma);
        }
    }
}
```

Indicators

Rolling Window

Introduction

A `RollingWindow` is an array of a fixed-size that holds trailing data. It's more efficient to use `RollingWindow` objects to hold periods of data than to make multiple historical data requests . With a `RollingWindow` , you just update the latest data point while a `History` call fetches all of the data over the period you request. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

Create Rolling Windows

To create rolling windows, instantiate the `RollingWindow` object of a given type with a maximum size.

```
C#

closePriceWindow = new RollingWindow<decimal>(4);
tradeBarWindow = new RollingWindow<TradeBar>(2);
quoteBarWindow = new RollingWindow<QuoteBar>(2);
```

Add Data

To add data to a `RollingWindow` , call the `Add` method.

```
C#

closePriceWindow.Add(data["SPY"].Close);
tradeBarWindow.Add(data["SPY"]);
quoteBarWindow.Add(data["EURUSD"]);
```

To update the data at a specific index, set the value for that index. If the index doesn't currently exist, it increases the size and fills the empty indices with a default value (zero or `null`).

```
C#

closePriceWindow[0] = data["SPY"].Close;
tradeBarWindow[0] = data["SPY"];
quoteBarWindow[0] = data["EURUSD"];
```

Warm Up

To warm up a `RollingWindow` , make a history request and then iterate through the result to add the data to the `RollingWindow` .

```C#
public class WarmUpRollingWindowAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var spy = AddEquity("SPY", Resolution.Daily).Symbol;
        var historyTradeBar = History<TradeBar>(spy, 10, Resolution.Daily);
        var historyQuoteBar = History<QuoteBar>(spy, 10, Resolution.Minute);

        // Warm up the close price and trade bar rolling windows with the previous 10-day trade bar data
        var closePriceWindow = new RollingWindow<decimal>(10);
        var tradeBarWindow = new RollingWindow<TradeBar>(10);
        foreach (var tradeBar in historyTradeBar)
        {
            closePriceWindow.Add(tradeBar.Close);
            tradeBarWindow.Add(tradeBar);
        }

        // Warm up the quote bar rolling window with the previous 10-minute quote bar data
        var quoteBarWindow = new RollingWindow<QuoteBar>(10);
        foreach (var quoteBar in historyQuoteBar)
        {
            quoteBarWindow.Add(quoteBar);
        }
    }
}
```

Check Readiness

To check if a `RollingWindow` is full, use its `IsReady` flag.

```C#
if (!closePriceWindow.IsReady)
{
    return;
}
```

Adjust Size

To adjust the `RollingWindow` size, set the `Size` property.

```C#
closePriceWindow.Size = 3;
tradeBarWindow.Size = 3;
quoteBarWindow.Size = 3;
```

When you decrease the size, it removes the oldest values that no longer fit in the `RollingWindow` . When you explicitly increase the `Size` member, it doesn't automatically add any new elements to the `RollingWindow` . However, if you set the value of an index in the `RollingWindow` and the index doesn't currently exist, it fills the empty indices with a default value (zero or `null`). For example, the following code increases the `Size` to 10, sets the 10th element to 3, and sets the 4th-9th elements to the default value:

```C#
closePriceWindow[9] = 3;
```

Access Data

`RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

```
var currentClose = closePriceWindow[0];
var previousClose = closePriceWindow[1];
var oldestClose = closePriceWindow[closePriceWindow.Count-1];
oldestClose = closePriceWindow[-1];   // Negative indexing
```

To get the item that was most recently removed from the `RollingWindow` , use the `MostRecentlyRemoved` property.

```
var removedClose = closePriceWindow.MostRecentlyRemoved;
```

Combine with Indicators

The `Window` property of the indicators is a built-in `RollingWindow` that stores historical values. It holds a collection of `IndicatorDataPoint` objects, enabling quick access to the most recent historical indicator values for analysis, calculations, or comparisons in trading and financial strategies. Its default size 2, but you can adjust its size. To warm up the indicator and its `RollingWindow` , call the `IndicatorHistory` method with the window size as an argument.

```
public class IndicatorRollingWindowAlgorithm : QCAlgorithm
{
    // Manual SMA indicator example.
    private SimpleMovingAverage _sma = new(20);
    private Beta _beta;

    public override void Initialize()
    {
        var spy = AddEquity("SPY").Symbol;
        var qqq = AddEquity("QQQ").Symbol;

        // Automatic Beta indicator example.
        _beta = B(spy, qqq, 20);

        // Adjust the window size to 5 to access the previous 5 indicator data points.
        _sma.Window.Size = 5;
        _beta.Window.Size = 5;

        // Warm up the indicator and window for immediate usage.
        IndicatorHistory(_sma, spy, _sma.Window.Size, Resolution.Daily);
        // For indicators using 2+ symbols, use an iterable symbol list.
        IndicatorHistory(_beta, new[] { spy, qqq },  _beta.Window.Size, Resolution.Daily);
    }
}
```

Combine with Consolidators

To store a history of consolidated bars , in the consolidation handler, add the consolidated bar to the `RollingWindow` .

```
_consolidator.DataConsolidated += (sender, consolidatedBar) => tradeBarWindow.Add(consolidatedBar);
```

Market Session

The `session` property of a `Security` object contains the open, high, low, close, volume, and open interest of trading sessions. The `Session` object is a `RollingWindow` object with size of zero by default. To enable market session tracking, set the size of the `Session` object to 2, so the previous session data is at index 1.

```
var session = Securities[_symbol].Session;
session.Size = 2;
var todayOpen = session.Open;
var todayHigh = session.High;
var todayLow = session.Low;
var todayCumulativeVolume = session.Volume;
if (session.IsReady)
{
    var yesterdayClose = session[1].Close;
}
```

Increase the size of the `Session` object to store more session data. You can use cached data in the `session` property instead of requesting historical daily data .

```
var equity = AddEquity("SPY");
// Increase the session lookback to 252 from default (0)
equity.Session.Size = 252;
// Get all closing prices in the session history
var closes = session.OrderBy(x => x.EndTime).Select(x => x.Close);
```

Cast to Other Types

You can cast a `RollingWindow` to a list. If you cast it to a list, reverse the list so the most recent element is at the last index of the list. This is the order the elements would be in if you added the elements to the list with the `Add` method.

```
var closes = closePriceWindow.Reverse().ToList();
```

Delete Data

To remove all of the elements from a `RollingWindow` , call the `Reset` method.

```
closePriceWindow.Reset();
```

Examples

The following examples demonstrate some common practices for rolling windows.

Example 1: Price Actions

The following algorithm saves the trailing 3 `TradeBar` objects into a `RollingWindow` . When it identifies a volume contraction breakout price action pattern on the SPY, it buys to ride on the capital inflow. To exit positions, it places a 2% take profit and 1% stop loss order in the `OnOrderEvent` method.

```
public class RollingWindowAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Set up a rolling window to hold the last 3 trade bars for price action detection as the trade signal.
    private RollingWindow<TradeBar> _windows = new(3);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;
```

```
        // Warm up the rolling window.
        var history = History<TradeBar>(_spy, 3, Resolution.Minute);
        foreach (var bar in history)
        {
            _windows.Add(bar);
        }
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trade the price action if the previous bars fulfill a contraction breakout.
            if (ContractionAction() && BreakoutAction(bar.Close))
            {
                SetHoldings(_spy, 0.5m);
            }

            _windows.Add(bar);
        }
    }

    private bool ContractionAction()
    {
        // We trade contraction type price action, where the buying preesure is increasing.
        // 1. The last 3 bars are green.
        // 2. The price is increasing in trend.
        // 3. The trading Volume is increasing as well.
        // 4. The range of the bars are decreasing.
        return _windows[2].Close > _windows[2].Open &&
            _windows[1].Close > _windows[1].Open &&
            _windows[0].Close > _windows[0].Open &&
            _windows[0].Close > _windows[1].Close && _windows[1].Close > _windows[2].Close &&
            _windows[0].Volume > _windows[1].Volume && _windows[1].Volume > _windows[2].Volume &&
            _windows[2].Close - _windows[2].Open > _windows[1].Close - _windows[1].Open &&
            _windows[1].Close - _windows[1].Open > _windows[0].Close - _windows[0].Open;
    }

    private bool BreakoutAction(decimal currentPrice)
    {
        // Trade breakout from contraction: the breakout should be much greater than the contracted range of the last
bar.
        return currentPrice - _windows[0].Close > (_windows[0].Close - _windows[0].Open) * 2m;
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            if (orderEvent.Ticket.OrderType == OrderType.Market)
            {
                // Stop loss order at 1%.
                var stopPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 0.99m : orderEvent.FillPrice *
1.01m;
                StopMarketOrder(_spy, -Portfolio[_spy].Quantity, stopPrice);
                // Take profit order at 2%.
                var takeProfitPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 1.02m :
orderEvent.FillPrice * 0.98m;
                LimitOrder(_spy, -Portfolio[_spy].Quantity, takeProfitPrice);
            }
            else if (orderEvent.Ticket.OrderType == OrderType.StopMarket || orderEvent.Ticket.OrderType ==
OrderType.Limit)
            {
                // Cancel open orders if the stop loss or take profit order fills.
                Transactions.CancelOpenOrders();
            }
        }
    }
}
```

Example 2: Bid-Ask Spread

The following algorithm trades the microeconomy of SPY's supply-demand relationship. It buys when the current bid-ask spread is less than average spread over the last 20 QuoteBar objects, indicating demand is approaching supply. When the

spread is greater than the average, it shorts SPY. To save the last spread values, it uses a `RollingWindow` .

```C#
public class RollingWindowAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Set up a rolling window to hold the last 20 bar's bid-ask spread for trade signal generation.
    private RollingWindow<decimal> _windows = new(20);

    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // Warm up for the rolling window with quote data.
        var history = History<QuoteBar>(_spy, 20, Resolution.Minute);
        foreach (var bar in history)
        {
            _windows.Add(bar.Ask.Close - bar.Bid.Close);
        }
    }

    public override void OnData(Slice slice)
    {
        if (slice.QuoteBars.TryGetValue(_spy, out var bar))
        {
            // Update the window with the current bid-ask spread.
            var spread = bar.Ask.Close - bar.Bid.Close;
            _windows.Add(spread);

            // Buy if the current spread is smaller than average, indicating demand is approaching supply. Buy force
will drive up price.
            if (spread < _windows.Average())
            {
                SetHoldings(_spy, -0.5m);
            }
            // Short if the current spread is larger than average, indicating supply is gradually overwhelming
demand.
            else if (spread > _windows.Average())
            {
                SetHoldings(_spy, 0.5m);
            }
        }
    }
}
```

Example 3: EMA Acceleration

The following algorithm trades SPY based on the direction and acceleration of its exponential moving average (EMA). It buys when the EMA is increasing and accelerating upward, indicating a strong uptrend. It short sells when the EMA is decreasing and accelerating downward, indicating a strong downtrend. To compare the current EMA value to its previous values, the algorithm utilizes the EMA's internal `RollingWindow` .

```C#
public class RollingWindowAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data for trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // Set up an automatic EMA indicator for trade signal generation.
        _ema = EMA(_spy, 20, Resolution.Daily);
        // Extend the size of the EMA's internal rolling window so we can access its historical values.
        _ema.Window.Size = 3;
        // Warm-up the indicator and its internal rolling window
        IndicatorHistory(_ema, _spy, _ema.Window.Size);

        // Schedule an event to rebalance SPY position at daily market open.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.AfterMarketOpen(_spy, 0), Rebalance);
    }

    private void Rebalance()
    {
        // Buy if the current EMA is increasing with acceleration, indicating a strong uptrend.
        if (_ema.Window[1] < _ema && _ema.Window[0] - _ema.Window[1] > _ema.Window[1] - _ema.Window[2])
        {
            SetHoldings(_spy, 0.5m);
        }
        // Short if the current EMA is decreasing with acceleration, indicating a strong downtrend.
        else if (_ema.Window[1] > _ema && _ema.Window[0] - _ema.Window[1] < _ema.Window[1] - _ema.Window[2])
        {
            SetHoldings(_spy, -0.5m);
        }
        // Liquidate if no strong trend indicated.
        else if (Portfolio.Invested)
        {
            Liquidate(_spy);
        }
    }
}
```

Example 4: Market Session as History

Using `Session` instead of history requests or rolling window to cache the last 252 OHLCV bars, the following algorithm buys SPY accordingly when the market opens above the 252-day max of closing prices.

C#

```
public class MarketSessionAsDailyHistory : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var equity = AddEquity("SPY");

        // Increase the session lookback to 252 from default (0)
        // since our strategy break out the 252-day max of closing prices
        equity.Session.Size = 252;
        // Warm up with daily data for speed
        SetWarmUp(equity.Session.Size, Resolution.Daily);

        Schedule.On(DateRules.EveryDay("SPY"), TimeRules.AfterMarketOpen("SPY", 1), () =>
        {
            // Break-out strategy. If the market opens above the 252-day max of closing prices,
            // allocate all in SPY. Liquidate if it opens below the mean.

            var session = Securities["SPY"].Session;
            // The session is ready when the number of samples is greater than the size (252)
            if (IsWarmingUp || !session.IsReady)
                return;

            var closes = session.OrderBy(x => x.EndTime).Select(x => x.Close);
            var open = session.Open;
            var max = closes.Max();
            var mean = closes.Average();

            // Invest all in SPY if the open break out the 252-day max and liquidate below the mean
            if (open > max)
                SetHoldings("SPY", 1, tag: $"_open={open:F2}, _max={max:F2}");
            if (open < mean)
                Liquidate(symbol: "SPY", tag:$"_open={open:F2}, _mean={mean:F2}");
        });
    }
}
```

Other Examples

For more examples, see the following algorithms:

Demonstration Algorithm
RollingWindowAlgorithm.cs C# MultipleSymbolConsolidationAlgorithm.cs C#

Object Store

Introduction

The Object Store is a file system that you can use in your algorithms to save, read, and delete data. The Object Store is organization-specific, so you can save or read data from the same Object Store in all of your organization's projects. The Object Store works like a key-value storage system where you can store regular strings, JSON encoded strings, XML encoded strings, and bytes. You can access the data you store in the Object Store from backtests, the Research Environment, and live algorithms.

Get All Stored Data

To get all of the keys and values in the Object Store, iterate through the `ObjectStore` property.

```
C#
foreach (var kvp in ObjectStore)
{
    var key = kvp.Key;
    var value = kvp.Value;
}
```

To iterate through just the keys in the Object Store, iterate through the `Keys` property.

```
C#
foreach (var key in ObjectStore.Keys)
{
    continue;
}
```

Create Sample Data

You need some data to store data in the Object Store.

Follow these steps to create some sample data:

1. Create a dictionary.

   ```
   C#
   var dictSample = new Dictionary<string, int> { {"One", 1}, {"Two", 2}, {"Three", 3} };
   ```

2. Create a `string` .

   ```
   C#
   var stringSample = "My string";
   ```

3. Create a `Bytes` object.

   ```
   C#
   var bytesSample = Encoding.UTF8.GetBytes("My String");
   ```

4. Convert the dictionary to an `XML` -formatted object.

```
var xmlSample = new XElement("sample",
    dictSample.Select(kvp => new XElement(kvp.Key, kvp.Value)));
Log(xmlSample.ToString());
```

```
<sample>
  <One>1</One>
  <Two>2</Two>
  <Three>3</Three>
</sample>
```

Save Data

The Object Store saves objects under a key-value system. If you save objects in backtests, you can access them from the Research Environment. To avoid slowing down your backtests, save data once in the `OnEndOfAlgorithm` event handler. In live trading, you can save data more frequently like at the end of a `Train` method or after universe selection.

If you run algorithms in QuantConnect Cloud, you need storage create permissions to save data in the Object Store.

If you don't have data to store, create some sample data .

You can save the following types of objects in the Object Store:

- `Bytes` objects
- `string` objects
- JSON objects
- XML-formatted objects

To store data, you need to provide a key. If you provide a key that is already in the Object Store, it will overwrite the data at that location. To avoid overwriting objects from other projects in your organization, prefix the key with your project ID. You can find the project ID in the URL of your browser when you open a project. For example, the ID of the project at quantconnect.com/project/12345 is 12345.

Strings

To save a `string` object, call the `Save` or `SaveString` method.

```
var saveSuccessful = ObjectStore.Save($"{ProjectId}/stringKey", stringSample);
```

JSON

To save a JSON object, call the `SaveJson<T>` method. This method helps to serialize the data into JSON format.

```
var saveSuccessful = ObjectStore.SaveJson<Dictionary<string, int>>($"{ProjectId}/jsonKey", dictSample);
```

XML

To save an XML-formatted object, call the `SaveXml<T>` method.

```
var saveSuccessful = ObjectStore.SaveXml<XElement>($"{ProjectId}/xmlKey", xmlSample);
```

Bytes

To save a `Bytes` object (for example, zipped data), call the `SaveBytes` method.

```C#
var saveSuccessful = ObjectStore.SaveBytes($"{ProjectId}/bytesKey", bytesSample)

var zippedDataSample = Compression.ZipBytes(Encoding.UTF8.GetBytes(stringSample), "data");
var saveSuccessful = ObjectStore.SaveBytes($"{ProjectId}/bytesKey.zip", zippedDataSample);
```

Read Data

Read data from the Object Store to import algorithm variables between deployments, import data from the Research Environment, or load trained machine learning models. To read data from the Object Store, you need to provide the key you used to store the object.

You can load the following types of objects from the Object Store:

- `Bytes` objects
- `string` objects
- JSON objects
- XML-formatted objects

Before you read data from the Object Store, check if the key exists.

```C#
if (ObjectStore.ContainsKey(key))
{
    // Read data
}
```

Strings

To read a `string` object, call the `Read` or `ReadString` method.

```C#
var stringData = ObjectStore.Read($"{ProjectId}/stringKey");
```

JSON

To read a JSON object, call the `ReadJson<T>` method.

```C#
var jsonData = ObjectStore.ReadJson<Dictionary<string, int>>($"{ProjectId}/jsonKey");
```

XML

To read an XML-formatted object, call the `ReadXml<T>` method.

```C#
var xmlData = ObjectStore.ReadXml<XElement>($"{ProjectId}/xmlKey");
```

If you created the XML object from a dictionary, reconstruct the dictionary.

```C#
var dict = xmlData.Elements().ToDictionary(x => x.Name.LocalName, x => int.Parse(x.Value));
```

Bytes

To read a `Bytes` object, call the `ReadBytes` method.

```C#
var bytesData = ObjectStore.ReadBytes($"{ProjectId}/bytesKey");
```

Delete Data

Delete objects in the Object Store to remove objects that you no longer need. If you run algorithms in QuantConnect Cloud, you need storage delete permissions to delete data from the Object Store.

To delete objects from the Object Store, call the `Delete` method. Before you delete data, check if the key exists. If you try to delete an object with a key that doesn't exist in the Object Store, the method raises an exception.

```C#
if (ObjectStore.ContainsKey(key))
{
    ObjectStore.Delete(key);
}
```

To delete all of the content in the Object Store, iterate through all the stored data.

```C#
foreach (var kvp in ObjectStore)
{
    ObjectStore.Delete(kvp.Key);
}
```

Cache Data

When you write to or read from the Object Store, the algorithm caches the data. The cache speeds up the algorithm execution because if you try to read the Object Store data again with the same key, it returns the cached data instead of downloading the data again. The cache speeds up execution, but it can cause problems if you are trying to share data between two nodes under the same Object Store key. For example, consider the following scenario:

1. You open project A and save data under the key `123` .
2. You open project B and save new data under the same key `123` .
3. In project A, you read the Object Store data under the key `123` , expecting the data from project B, but you get the original data you saved in step #1 instead.

   You get the data from step 1 instead of step 2 because the cache contains the data from step 1.

To clear the cache, call the `Clear` method.

```C#
ObjectStore.Clear();
```

Get File Path

To get the file path for a specific key in the Object Store, call the `GetFilePath` method. If the key you pass to the method doesn't already exist in the Object Store, it's added to the Object Store.

```
C#
var filePath = ObjectStore.GetFilePath(key);
```

Storage Quotas

If you run algorithms locally, you can store as much data as your hardware will allow. If you run algorithms in QuantConnect Cloud, you must stay within your storage quota . To find your storage quota programmatically, use the `MaxSize` property for storage size and `MaxFiles` property for the maximum number of files.

```
C#
var maxSize = ObjectStore.MaxSize;
var maxFiles = ObjectStore.MaxFiles;
```

If you need more storage space, edit your storage plan .

Example for DataFrames

Follow these steps to create a DataFrame, save it into the Object Store, and load it from the Object Store:

1. Get some historical data.

   ```
   C#
   var spy = AddEquity("SPY").Symbol;
   var history = History(Securities.Keys, 360, Resolution.Daily);
   ```

2. Create a DataFrame.

   ```
   C#
   using Microsoft.Data.Analysis; //

   var columns = new DataFrameColumn[] {
       new DateTimeDataFrameColumn("Time", history.Select(x => (DateTime)x[spy].EndTime)),
       new DecimalDataFrameColumn("SPY Open", history.Select(x => (decimal)x[spy].Open)),
       new DecimalDataFrameColumn("SPY High", history.Select(x => (decimal)x[spy].High)),
       new DecimalDataFrameColumn("SPY Low", history.Select(x => (decimal)x[spy].Low)),
       new DecimalDataFrameColumn("SPY Close", history.Select(x => (decimal)x[spy].Close))
   };
   var df = new DataFrame(columns);
   ```

3. Get the file path for a specific key in the Object Store.

   ```
   C#
   var filePath = ObjectStore.GetFilePath("df_to_csv");
   ```

4. Call the SaveCsv method to save the DataFrame in the Object Store as a CSV file.

   ```
   C#
   DataFrame.SaveCsv(df, filePath);    // File size: 26520 bytes
   ```

5. Call the LoadCsv method to load the CSV file from the Object Store.

```
C#

var reread = DataFrame.LoadCsv(filePath);
```

Example for Plotting

You can use the Object Store to plot data from your backtests and live algorithm in the Research Environment. The following example demonstrates how to plot a Simple Moving Average indicator that's generated during a backtest.

1. Create a algorithm, add a data subscription, and add a simple moving average indicator.

```
C#

public class ObjectStoreChartingAlgorithm : QCAlgorithm
{
    private SimpleMovingAverage _sma;
    private string _content;

    public override void Initialize()
    {
        AddEquity("SPY", Resolution.Minute);
        _sma = SMA("SPY", 22);
    }
}
```

   The algorithm will save `_content` to the Object Store.

2. Save the indicator data as `string` in `_content` .

```
C#

public override void OnData(Slice data)
{
    _content += $"{_sma.Current.EndTime},{_sma}\n";
}
```

3. In the OnEndOfAlgorithm method, save the indicator data to the Object Store.

```
C#

public override void OnEndOfAlgorithm()
{
    ObjectStore.Save("sma_values_csharp", _content);
}
```

4. Open the Research Environment and create a `QuantBook` .

```
C#

// Execute the following command in first
#load "../Initialize.csx"

// Create a QuantBook object
#load "../QuantConnect.csx"
using QuantConnect;
using QuantConnect.Research;

var qb = new QuantBook();
```

5. Read the indicator data from the Object Store.

```
C#

var content = qb.ObjectStore.Read("sma_values_csharp");
```

   The key you provide must be the same key you used to save the object.

6. Import the `Plotly.NET` and `Plotly.NET.LayoutObjects` packages.

```C#
#r "../Plotly.NET.dll"
using Plotly.NET;
using Plotly.NET.LayoutObjects;
```

7. Create the `Layout` object and set the `title` , `xaxis` , and `yaxis` properties.

```C#
var layout = new Layout();
layout.SetValue("title", Title.init("SMA"));

var xAxis = new LinearAxis();
xAxis.SetValue("title", "Time");
layout.SetValue("xaxis", xAxis);

var yAxis = new LinearAxis();
yAxis.SetValue("title", "SMA");
layout.SetValue("yaxis", yAxis);
```

8. Convert the data to a list of `DateTime` objects for the chart x-axis and a list of `decimal` objects for the chart y-axis, then create a `Chart2D.Chart.Line` object with the data.

```C#
var index = new List<DateTimee>();
var values = new List<decimal>();

foreach (var line in content.Split('\n'))
{
    var csv = line.Split(',');
    if (csv.Length > 1)
    {
        index.Add(Parse.DateTime(csv[0]));
        values.Add(decimal.Parse(csv[1]));
    }
}

var chart = Chart2D.Chart.Linee<DateTime, decimal, stringe>(index, values);
```

9. Apply the layout to the `Line` object and create the `HTML` object.

```C#
chart.WithLayout(layout);
var result = HTML(GenericChart.toChartHTML(chart));
```

```
C#
public class ObjectStoreChartingAlgorithm : QCAlgorithm
{
    private SimpleMovingAverage _sma;
    private string _content;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        AddEquity("SPY", Resolution.Minute);
        // Create SMA indicator for referencing.
        _sma = SMA("SPY", 22);
    }

    public override void OnData(Slice data)
    {
        // Cache the indicator data point to save it.
        _content += $"{_sma.Current.EndTime},{_sma}\n";
    }

    public override void OnEndOfAlgorithm()
    {
        // Save the indicator values to object store for logging.
        ObjectStore.Save("sma_values_csharp", _content);
    }
}
```

Example of Custom Data

Follow these steps to use the Object Store as a data source for custom data :

1. Create a custom data class that defines a storage key and implements the `GetSource` method.

```
C#
public class Bitstamp : TradeBar
{
    public static string KEY = "bitstampusd.csv";

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool
isLiveMode)
    {
        return new SubscriptionDataSource(KEY, SubscriptionTransportMedium.ObjectStore);
    }
}
```

2. Create an algorithm that downloads data from an external source and saves it to the Object Store .

```
C#
public class ObjectStoreCustomDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        if (!ObjectStore.ContainsKey(Bitstamp.KEY))
        {
            var url =
"https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/bitstampusd.csv";
            var content = Download(url);
            ObjectStore.Save(Bitstamp.KEY, content);
        }
    }
}
```

3. Call the `AddData` method to subscribe to the custom type .

```C#
public class ObjectStoreCustomDataAlgorithm : QCAlgorithm
{
    private Symbol _customDataSymbol;
    public override void Initialize()
    {
        _customDataSymbol = AddData<Bitstamp>("BTC").Symbol;
    }
}
```

4. Implement the `Reader` method for the custom data class.

```C#
public class Bitstamp : TradeBar
{
    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        //Example Line Format:
        //Date      Open   High    Low     Close   Volume (BTC)    Volume (Currency)   Weighted Price
        //2011-09-13 5.8    6.0     5.65    5.97    58.37138238,    346.0973893944      5.929230648356
        if (!char.IsDigit(line.Trim()[0]))
        {
            return null;
        }

        var coin = new Bitstamp() {Symbol = config.Symbol};

        var data = line.Split(',');
        coin.Value = data[4].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        if (coin.Value == 0)
        {
            return null;
        }

        coin.Time = DateTime.Parse(data[0], CultureInfo.InvariantCulture);
        coin.EndTime = coin.Time.AddDays(1);
        coin.Open = data[1].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.High = data[2].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.Low = data[3].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.VolumeBTC = data[5].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.Volume = data[6].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.WeightedPrice = data[7].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
        coin.Close = coin.Value;
        return coin;
    }
}
```

5. To confirm your algorithm is receiving the custom data, request some historical data , then log and plot the data from the `Slice` object.

```C#
public class ObjectStoreCustomDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var history = History(_customDataSymbol, 200, Resolution.Daily);
        Debug($"We got {history.Count()} items from historical data request of {_customDataSymbol}.");
    }
    public void OnData(Bitstamp data)
    {
        Log($"{data.EndTime}: Close: {data.Close}");
        Plot(_customDataSymbol, "Price", data.Close);
    }
}
```

The following algorithm provides a full example of a sourcing custom data from the Object Store:

C#

```
public class CustomDataBitstampAlgorithm : QCAlgorithm
{
    private Symbol _customDataSymbol;

    public override void Initialize()
    {
        SetStartDate(2012, 9, 13);
        SetEndDate(2021, 6, 20);

        // Load the custom data from ObjectStore.
        if (!ObjectStore.ContainsKey(Bitstamp.KEY))
        {
            var url = "https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/bitstampusd.csv";
            var content = Download(url);
            ObjectStore.Save(Bitstamp.KEY, content);
        }

        // Request custom data for plotting.
        // Define the symbol and "type" of our generic data.
        _customDataSymbol = AddData<Bitstamp>("BTC", Resolution.Daily).Symbol;

        // Example historical call.
        var history = History(_customDataSymbol, 200, Resolution.Daily);
        Debug($"We got {history.Count()} items from historical data request of {_customDataSymbol}.");
    }

    public void OnData(Bitstamp data)
    {
        // Plot on updated data.
        Log($"{data.EndTime}: Close: {data.Close}");
        Plot(_customDataSymbol, "Price", data.Close);
    }

    public class Bitstamp : TradeBar
    {
        public static string KEY = "bitstampusd.csv";

        public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool
isLiveMode)
        {
            // Load data from object store.
            return new SubscriptionDataSource(KEY, SubscriptionTransportMedium.ObjectStore);
        }

        public decimal WeightedPrice = 0;
        public decimal VolumeBTC = 0;

        public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
        {
            //Example Line Format:
            //Date      Open   High    Low     Close   Volume (BTC)    Volume (Currency)   Weighted Price
            //2011-09-13 5.8    6.0     5.65    5.97    58.37138238,    346.0973893944      5.929230648356
            if (!char.IsDigit(line.Trim()[0]))
            {
                return null;
            }

            var coin = new Bitstamp() {Symbol = config.Symbol};

            var data = line.Split(',');
            coin.Value = data[4].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            if (coin.Value == 0)
            {
                return null;
            }

            coin.Time = DateTime.Parse(data[0], CultureInfo.InvariantCulture);
            coin.EndTime = coin.Time.AddDays(1);
            coin.Open = data[1].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.High = data[2].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.Low = data[3].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.VolumeBTC = data[5].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any
```

```
            coin.VolumeBTC = data[5].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.Volume = data[6].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.WeightedPrice = data[7].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.Close = coin.Value;
            return coin;
        }
    }
}
```

Preserve Insights Between Deployments

Follow these steps to use the Object Store to preserve the algorithm state across live deployments:

1. Create an algorithm that defines a storage key and adds insights to the Insight Manager .

```
C#
public class ObjectStoreChartingAlgorithm : QCAlgorithm
{
    private string _insightKey;
    public override void Initialize()
    {
        _insightKey = $"{ProjectId}/insights";
        SetUniverseSelection(new ManualUniverseSelectionModel(QuantConnect.Symbol.Create("SPY",
SecurityType.Equity, Market.USA)));
        SetAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(5), 0.025,
null));
    }
}
```

2. In the OnEndOfAlgorithm event handler of the algorithm, get the Insight objects and save them in the Object Store as a JSON object.

```
C#
public override void OnEndOfAlgorithm()
{
    var insights = Insights.GetInsights(x => x.IsActive(UtcTime));
    ObjectStore.SaveJson(_insightKey, insights);
}
```

3. At the bottom of the `Initialize` method, read the Insight objects from the Object Store and add them to the Insight Manager .

```
C#
if (ObjectStore.ContainsKey(_insightKey))
{
    var insights = ObjectStore.ReadJson<List<Insight>>(_insightKey);
    Insights.AddRange(insights);
}
```

The following algorithm provides a full example of preserving the Insight state between deployments:

```C#
public class ObjectStoreInsightsAlgorithm : QCAlgorithm
{
    private string _insightsKey = "insights";

    public override void Initialize()
    {
        UniverseSettings.Resolution = Resolution.Daily;

        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _insightsKey = $"{ProjectId}/{_insightsKey}";

        // Read the file with the insights
        if (ObjectStore.ContainsKey(_insightsKey))
        {
            // Load cached JSON key value pair from object store, then add to algorithm insights.
            var insights = ObjectStore.ReadJson<List<Insight>>(_insightsKey);
            Log($"Read {insights.Count} insight(s) from the Object Store");
            Insights.AddRange(insights);

            // Delete the key to reuse it
            ObjectStore.Delete(_insightsKey);
        }

        SetUniverseSelection(new ManualUniverseSelectionModel(QuantConnect.Symbol.Create("SPY", SecurityType.Equity,
Market.USA)));
        SetAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(5), 0.025, null));
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Resolution.Daily));
    }

    public override void OnEndOfAlgorithm()
    {
        // Get all active insights.
        var insights = Insights.GetInsights(x => x.IsActive(UtcTime));
        // If we want to save all insights (expired and active), we can use.
        // var insights = Insights.GetInsights(x => true);
        Log($"Save {insights.Count} insight(s) to the Object Store.");
        ObjectStore.SaveJson(_insightsKey, insights);
    }
}
```

Live Trading Considerations

If you update the Object Store from outside of your live trading node and then try to read the new content from inside your live trading algorithm, you may not get the new content because the Object Store caches data to speed up execution. To ensure you get the latest value for a specific key in the Object Store, clear the cache and then read the data .

```C#
ObjectStore.Clear();
if (ObjectStore.ContainsKey(key))
{
    var value = ObjectStore.Read(key);
}
```

Optimization

Optimization

Parameters

Introduction

Parameters are project variables that your algorithm uses to define the value of internal variables like indicator arguments or the length of lookback windows. Parameters are stored outside of your algorithm code, but we inject the values of the parameters into your algorithm when you run a backtest, deploy a live algorithm, or launch an optimization job. To use parameters, set some parameters in your project and then load them into your algorithm.

Set Parameters

The process to set parameter values depends on the environment you use to write algorithms. See the tutorial in one of the following environments:

- Cloud Platform
- Local Platform
- LEAN CLI

Get Parameters

To get a parameter value into your algorithm, call the `GetParameter` method of the algorithm class.

```
C#
// Get the parameter string-value with this matching key.
// Project parameters are useful for optimization or securing variables outside the source-code.
var parameterValue = GetParameter("Parameter Name");
```

The `GetParameter` method returns a string by default. If you provide a default parameter value, the method returns the parameter value as the same data type as the default value. If there are no parameters in your project that match the name you pass to the method and you provide a default value to the method, it returns the default value. The following table describes the arguments the `GetParameter` method accepts:

Argument	Data Type	Description	Default Value
`name`	`string`	The name of the parameter to get	
`defaultValue`	`string/int/double/decimal`	The default value to return	`null`

The following example algorithm gets the values of parameters of each data type:

```C#
// Example to get the values of parameters of each data type:
public class ParameterizedAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // Get the parameter value and return an integer.
        var intParameterValue = GetParameter("intParameterName", 100);

        // Get the parameter value and return a double.
        var doubleParameterValue = GetParameter("doubleParameterName", 0.95);

        // Get the parameter value and return a decimal.
        var decimalParameterValue = GetParameter("decimalParameterName", 0.05m);

        // Get the parameter value as a string.
        var stringParameterValue = GetParameter("parameterName", "defaultStringValue");

        // Cast the string to an integer.
        var castedParameterValue = Convert.ToInt32(stringParameterValue);
    }
}
```

Alternatively, you can use the `Parameter(name)` attribute on top of class fields or properties to set their values. If there are no parameters in your project that match the name you pass to the attribute and you provide a default value to the method, it returns the default value.

```C#
// Use the Parameter attribute to set field values externally, enabling flexible configuration with default fallback.
public class ParameterizedAlgorithm : QCAlgorithm
{
    [Parameter("intParameterName")]
    public int IntParameterValue = 100;

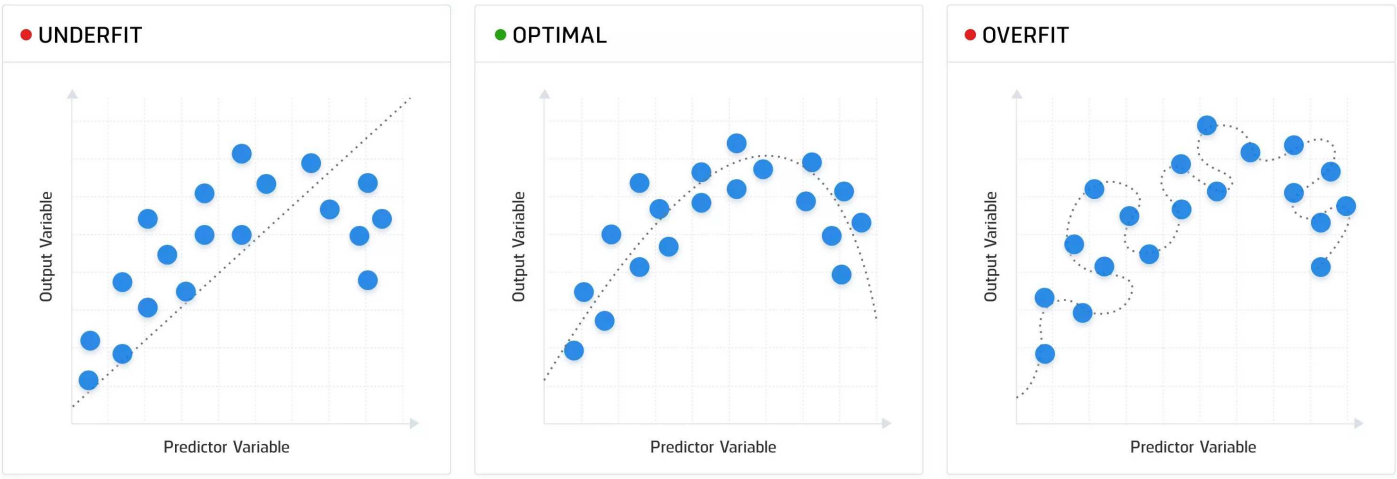
    [Parameter("doubleParameterName")]
    public double DoubleParameterValue = 0.95;

    [Parameter("decimalParameterName")]
    public decimal DecimalParameterValue = 0.05m;
}
```

The parameter values are sent to your algorithm when you deploy the algorithm, so it's not possible to change the parameter values while the algorithm runs.

Overfitting

Overfitting occurs when a function is fit too closely fit to a limited set of training data. Overfitting can occur in your trading algorithms if you have many parameters or select parameters values that worked very well in the past but are sensitive to small changes in their values. In these cases, your algorithm will likely be fine-tuned to fit the detail and noise of the historical data to the extent that it negatively impacts the live performance of your algorithm. The following image shows examples of underfit, optimally-fit, and overfit functions:



An algorithm that is dynamic and generalizes to new data is more likely to survive across different market conditions and apply to other markets.

Look-Ahead Bias

Look-ahead bias occurs when an algorithm makes decisions using data that would not have yet been available. For instance, in optimization jobs, you optimize a set of parameters over a historical backtesting period. After the optimizer finds the optimal parameter values, the backtest period becomes part of the in-sample data. If you run a backtest over the same period using the optimal parameters, look-ahead bias has seeped into your research. In reality, it would not be possible to know the optimal parameters during the testing period until after the testing period is over. To avoid issues with look-ahead bias, optimize on older historical data and test the optimal parameter values on recent historical data. Alternatively, apply walk forward optimization to optimize the parameters on smaller batches of history.

Live Trading Considerations

To update parameters in live mode, add a Schedule Event that downloads a remote file and uses its contents to update the parameter values.

```C#
private Dictionary _parameters = new();
public override void Initialize()
{
    if (LiveMode)
    {
        Schedule.On(
            DateRules.EveryDay(),
            TimeRules.Every(TimeSpan.FromMinutes(1)),
            ()=>
            {
                var content = Download(urlToRemoteFile);
                // Convert content to _parameters
            });
    }
}
```

Examples

The following examples demonstrate common practices for using optimization parameters.

Example 1: Bond Candidate Selection

The following algorithm holds a 60/40 stock-bond portfolio rebalancing monthly. To select the best bond ETF to act as a proxy to trade bonds, we create a list of bond tickers and grid search the best using each to backtest. Using a `bond-id` parameter, which is an integer ranging from 0 to the list size - 1 with a step size of 1, we can perform optimization to test each of them.

```C#
public class OptimizationParameterAlgorithm : QCAlgorithm
{
    // A list of bond ETFs candidates to trade as bond proxies.
    private static readonly List<string> _bondList = new()
    {
        "TLT", "IEF", "SHY", "VCSH", "VCLT"
    };
    private Symbol _spy, _bond;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Get the bond candidate to be tested.
        var bondId = GetParameter("bond-id", 0);

        // Request SPY and the selected bond data for trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;
        _bond = AddEquity(_bondList[bondId], Resolution.Minute).Symbol;

        // Rebalance for a stock-bond portfolio monthly.
        Schedule.On(
            DateRules.MonthStart(_spy),
            TimeRules.AfterMarketOpen(_spy, 1),
            Rebalance
        );
    }

    private void Rebalance()
    {
        // Hold an all-weather stock-bond 60/40 portfolio.
        SetHoldings(_spy, 0.6m);
        SetHoldings(_bond, 0.4m);
    }
}
```

Example 2: Test Different Period

This algorithm holds SPY for the whole day following the direction from the previous day. To test which period is the most effective for this momentum-following strategy, we can set an `offset` parameter and adjust the backtest period accordingly.

You can also load the parameter values with the `Parameter` attribute.

```C#
[Parameter("offset")]
private int _offset = 0;
```

```C#
public class OptimizationParameterAlgorithm : QCAlgorithm
{
    // Get the number of months to offset the start date.
    [Parameter("offset")]
    private int _offset = 0;

    private Symbol _spy;
    private decimal _lastPrice = 0m;

    public override void Initialize()
    {
        // Create a variable start date with offset to test which periods the algorithm performs better.
        var startDate = new DateTime(2024, 1, 1);
        SetStartDate(startDate.AddMonths(_offset));
        // One-month fixed period test per backtest.
        SetEndDate(StartDate.AddMonths(1));

        // Request daily SPY data for trading.
        _spy = AddEquity("SPY", Resolution.Daily).Symbol;

        SetWarmUp(1);
    }

    public override void OnData(Slice slice)
    {
        // Trade based on updated data.
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trade with riding on the last day's momentum.
            if (_lastPrice != 0m && bar.Close > _lastPrice && !Portfolio[_spy].IsLong)
            {
                SetHoldings(_spy, 0.5m);
            }
            else if (_lastPrice != 0m && bar.Close < _lastPrice && !Portfolio[_spy].IsShort)
            {
                SetHoldings(_spy, -0.5m);
            }

            _lastPrice = bar.Close;
        }
    }
}
```

Example 3: Hyperparameter Tuning

The following example algorithm demonstrates an EMA cross strategy. To optimize for the best setup to attain the greatest Sharpe Ratio, the algorithm grid searches the best hyperparameters (the EMA periods) that do so.

C#

```
public class ParameterizedAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _fast;
    private ExponentialMovingAverage _slow;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // For warming up indicators.
        Settings.AutomaticIndicatorWarmUp = true;

        // Request SPY data to feed the indicator and trade.
        _spy = AddEquity("SPY").Symbol;

        // Get and store the EMA settings to local parameters.
        var fastPeriod = GetParameter("ema-fast", 50);
        var slowPeriod = GetParameter("ema-slow", 200);

        // Set up the 2 EMA indicators for trade signal generation with the fast and slow periods from parameters.
        _fast = EMA("SPY", fastPeriod, Resolution.Daily);
        _slow = EMA("SPY", slowPeriod, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Following the uptrend indicated by price up in nearer periods.
            if (bar.Close > _fast && _fast > _slow)
            {
                SetHoldings(_spy, 0.5m);
            }
            // Following the downtrend indicated by price down in nearer periods.
            else if (bar.Close < _fast && _fast < _slow)
            {
                SetHoldings(_spy, -0.5m);
            }
            // Liquidate if the trend is not strong.
            else
            {
                Liquidate();
            }
        }
    }
}
```

Optimization

Walk Forward Optimization

Introduction

Walk forward optimization is the practice of periodically adjusting the logic or parameters of a strategy to optimize some objective function over a trailing window of time. For example, say your strategy is to hold a long position when an asset is trading above its simple moving average (SMA) and to hold a short position when it's trading below the SMA. If your objective is to maximize returns, how many trailing data points should you use to compute the SMA?

Benefits

The parameter values that maximize your algorithm's performance are typically a function of the start and end dates of your training dataset. Market conditions change over time and a strategy that works well during one period may not perform as well during another. By continually adjusting the strategy parameters based on recent data, walk-forward optimization tailors your strategy to the latest market trends and patterns.

Optimization Frequency

There is a tradeoff when it comes to how often you optimize your algorithm's parameters. On one hand, if you frequently optimize your parameters, your parameters will be fit to the most recent, most meaningful market data. On the other hand, if you wait a long time between optimization sessions, your algorithm will run faster and you reduce the chance of overfitting. To define your optimization schedule, pass DateRules and TimeRules arguments to the train method.

EMA Crossover Example

Follow these steps to implement walk forward optimization for an exponential moving average (EMA) crossover strategy:

1. Define the backtest dates and starting cash.
2. Enable the automatic indicator warm up setting .
3. Subscribe to an asset .
4. Add some members for the EMA indicators.
5. Define the trading rules.
6. Define a method that will adjust the algorithm's behavior, given a set of optimal parameters.
7. Back in `initialize` method, generate all the possible combinations of parameter values.
8. Define the objective function.
9. Define the optimization function.
10. Schedule the optimization sessions.
11. Add a warm-up period .

    The warm-up period ensures that the algorithm calls the `_do_wfo` method at least one time before the algorithm starts trading.

For a full working example algorithm, see the following backtest:

Ideas

The following list provides some ideas on how you could use walk forward optimization:

1. Find the range of PE ratios that mazimize your algorithm's performance, and then use that range in your fundamental universe filter.
2. Experiment with asset universe diversity and counts.
3. Take 10 fundamental factors (PE, market cap, etc...). For each optimization session, step through and picks one factor at a time, using it as a ranking factor for the universe. Find the factor that leads to the greatest return over the lookback window and use it as the sole factor for the following month.

Machine Learning

Machine Learning

Key Concepts

Introduction

Machine learning is a field of study that combines statistics and computer science to build intelligent systems that predict outcomes. You can use machine learning techniques in your trading strategies.

Supported Libraries

LEAN supports several machine learning libraries. You can import these packages and use them in your algorithms.

Name	Version	Language	Import Statement	Exam
TensorFlow	2.19.1	Python	`import tensorflow`	
SciKit Learn	1.6.1	Python	`import sklearn`	
Py Torch	2.8.0	Python	`import torch`	
Keras	3.11.3	Python	`import keras`	
hmmlearn	0.3.3	Python	`import hmmlearn`	
tsfresh	0.20.2	Python	`import tsfresh`

Add New Libraries

To request a new library, contact us . We will add the library to the queue for review and deployment. Since the libraries run on our servers, we need to ensure they are secure and won't cause harm. The process of adding new libraries takes 2-4 weeks to complete. View the list of libraries currently under review on the Issues list of the Lean GitHub repository .

Save Models

After you train a model, you can save it into the Object Store . In QuantConnect Cloud, we back up your Object Store data on QuantConnect servers. In local algorithms, your local machine saves the Object Store data. If you save models in live algorithms, save them at the end of the training method so you can access the trained model again if your algorithm stops executing. If you save models in backtests, save them during the `OnEndOfAlgorithm` event handler so that saving multiple times doesn't slow down your backtest.

To view examples of storing library-specific models, see Popular Libraries .

Load Models

You can load machine learning models from the Object Store or a custom data file like pickle. If you load models from the Object Store, before you load the model into your algorithm, in the `Initialize` method, check if the Object Store already contains the model. To avoid look-ahead bias in backtests, don't train your model on the same data you use to test the model.

Library Errors

LEAN gracefully handles runtime errors that your code raises. It generally informs the location and cause of the error before the algorithm is terminated. FATAL ERROR EXCEPTION refers to a critical failure from third-party libraries, such as machine learning models, that LEAN doesn't handle.

Most QuantConnect members experience the invalid memory access error (SIGBUS) or division by zero error (SIGFPE) marked as "7 Killed" and "8 Killed" in the error message, respectively. The following sections explain some common errors and what causes them.

Memory Issues

You may experience the following memory issues:

- Out of Memory (OOM) : The process requires more memory (RAM or GPU memory) than is available, leading to a crash.
- Memory Leaks : If the program fails to properly release memoryy, it can eventually exhaust available resources.
- Invalid Memory Access : Bugs in custom C/C++ extensions, kernels, or libraries (for example, CUDA kernels for GPU acceleration) can cause misaligned memory access or invalid memory operations.

Numerical Instability

You may experience the following numerical instability errors:

- Division by Zero : This can occur due to input data with zeroes or during calculations, especially in custom loss functions or optimization algorithms.
- NaN or Infinity Values : These can arise due to data with NaN values, improper initialization, exploding gradients, or unstable mathematical operations.

Software Bugs

You may experience the following software bugs:

- Code Errors : Bugs in the implementation of the model, data preprocessing, or training loop can cause crashes.
- Library Incompatibility : Using incompatible versions of libraries (for example, TensorFlow or PyTorch) or dependencies can lead to fatal errors.

Machine Learning

Training Models

Introduction

Algorithms usually must process each timeslice within 10 minutes, but the `Train` method allows you to increase this time to train machine learning models. The length of time you can train depends on your training quotas.

Train Models

To train models immediately, call the `Train` method and pass in the name of your training method.

```
C#
# Run an ML model training session and extend method call timeouts.
Train(MyTrainingMethod);
```

Immediate training is most useful for training your model when you first deploy your strategy to production or when the model's performance begins to degrade.

Schedule Training Sessions

You can schedule model training sessions in a similar way to a Scheduled Event. To schedule a training session do this, pass in a DateRules and TimeRules argument to the `Train` method.

```
C#
// Set TrainingMethod to be executed at 8:00 am every Sunday
Train(DateRules.Every(DayOfWeek.Sunday), TimeRules.At(8, 0), MyTrainingMethod);
```

We recommend you schedule your training sessions for when the market is closed to get the best compute allocation. While the market is open, your CPU is occupied with processing incoming tick data and handling other LEAN events.

Training Quotas

Training resources are allocated with a leaky bucket algorithm where you can use a maximum of n-minutes in a single training session and the number of available minutes refills over time. This design gives you burst allocations when you need them and recharges the allowance to prepare for the next training.

Cloud Quotas

If you execute algorithms in QuantConnect Cloud, see Training Quotas for more information about the training quotas.

Local Quotas

If you execute algorithms locally, the following table shows the default settings for the leaky bucket algorithm:

Setting	Value
Capacity (minutes)	120
Time interval (minutes)	1440
Refill amount (minutes per time interval)	Capacity / 7

To allow virtually unlimited training for local algorithms, add the following key-value pairs to your Lean / Launcher / config.json file:

```
"scheduled-event-leaky-bucket-capacity" : 99999999,
"scheduled-event-leaky-bucket-time-interval-minutes" : 1,
"scheduled-event-leaky-bucket-refill-amount": 999999,
```

Check Model Readiness

In backtests, the `Train` method is synchronous, so it blocks your algorithm execution while the model trains. In live trading, the `Train` method is asynchronous, so ensure your model is trained before you continue the algorithm execution. Training occurs on a separate thread, so set a boolean flag to notify your algorithm of the model state. A semaphore is a thread-safe flag you can use to synchronize program operations across different threads.

C#

```
// Example of using a flag to signal the model is ready to use:
public class SemaphoreTrainingAlgorithm : QCAlgorithm
{
    // Initialize the model.
    private object _model;
    // Initialize the training state flag.
    private bool _modelIsTraining;

    public override void Initialize()
    {
        Train(MyTrainingMethod);
    }

    private void MyTrainingMethod()
    {
        _modelIsTraining = true;
        // Train the model here.
        _modelIsTraining = false;
    }

    public override void OnData(Slice slice)
    {
        // Don't use the model while it is training.
        if (_modelIsTraining)
        {
            return;
        }
        // Once training is complete, use the model.
        var result = _model.Predict();
    }
}
```

Examples

The following examples demonstrate some common practices for training the machine learning model.

Example 1: Scikit-Learn

The below algorithm makes use of `Scikit-Learn` library to predict the future price movement using the previous 5 OHLCV data.

The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

Aesera

Introduction

This page explains how to build, train, deploy and store `Aesera` models.

To access Aesara, use the Legacy package environment. To set this environment, see the documentation in Cloud Platform or Local Platform .

Import Libraries

Import the `aesera` and `sklearn` libraries.

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `sklearn` model and make predictions.

Build Models

In this example, build a logistic regression prediction model that uses the following features and labels:

Data Category	**Description**
Features	Normalized daily close price of the SPY over the last 5 days
Labels	Return direction of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow the below steps to build the model:

1. Initialize variables.
2. Construct the model graph.

3. Compile the model.

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `sklearn` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.
2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.
3. Call the `dump` method the file path.

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `sklearn` models that you saved in the Object Store. To load a `sklearn` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Aesera` library.

Example 1: Aesera

The below algorithm makes use of `Aesera` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

Copula

Introduction

This page explains how to build, train, deploy and store `Copula` models.

Import Libraries

Import the `copula` , `scipy` , and `sklearn` libraries.

You need the `joblib` library to store models.

Create Subscriptions

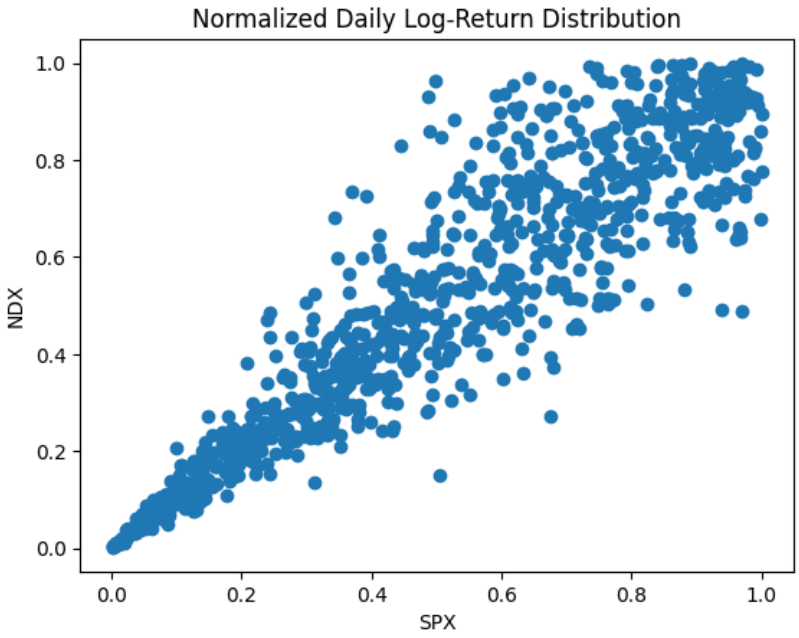
In the `Initialize` method, subscribe to some data so you can train the `copula` model and make predictions.

Since the algorithm is trading on options as speculation tools, to avoid insufficient buying power limited at the algorithm level, use `NullBuyingPowerModel` to bypass that.

Build Models

In this example, build a copula model to estimate the log-return bivariate distribution of the paired securities, such that it can predict the correlated future price movement more accurately.

The following image shows the 1-year daily log-return bivariate distribution (normalized) of SPX and NDX indices as an example. As shown in the plot, although they exhibit a certain level of correlation, the tail is fat in both side, making normal distribution assumption unsuitable. In such case, we can make use of distributions from the extreme value theorem (Frank, Gumbel, or Clayton).



Follow the below steps to build the model:

1. Create a helper class to handle the copula trading.
2. Create a method to transform the raw data into daily log-return, such that the series is more stationary while capturing

sufficient variance to accurately estimate the bivariate distribution.

3. Create a method to fit the copula with the distribution yielding the best log-likelihood.
4. (Optional) Reconfirm it by a 2-sample KS test.
5. Instantiate the helper class and fit the copula model.

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, make use of a consolidator to automatically update the rolling windows when a daily bar is consolidated through a consolidator handler.

Trading

In this example, we trade option mispricing arbitration using the copula model. More precisely, we are using the copula model to generate forward price series samples to price the options and do arbitration between options of the 2 correlated underlying. Since the copula can provide a distribution more accurately, we have an edge on the option pricing information.

Follow the below steps to trade the above logic:

1. Create a method to generate the forward price series samples of the 2 underlyings.
2. Create a method to price the options through averaging the payoff over all simulated paths.
3. Create a method to calculate the probability of winning (price converges to our model).

   We use the ratio of paths that the underlyings ever reach the strikes of the options, since ATM options are most efficiently priced and equal among all option pricing engine.

4. Create a method to calculate the aboves and output the mispriced option pairs.
5. Create a method to get the optimal position sizings for the top-expected-return trading opportunities.
6. Create a method to handle the portfolio and exit the positions when price converges.
7. Create a method in the base algorithm to open trades. Schedule its run.

   To simply implementation, this example will only open trades after the previous positions are all expired, but you can change it to scan by some time interval.

8. Scan every N minutes to exit the positions if the price discrepancy between a pair is converged.

Save Models

Follow these steps to save `copula` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.
2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `copula` models that you saved in the Object Store. To load a `copula` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The below demonstrates the full algorithm of the above example.

Popular Libraries

GPlearn

Introduction

This page explains how to build, train, deploy and store `GPlearn` models.

To access GPlearn, use the Legacy package environment. To set this environment, see the documentation in Cloud Platform or Local Platform .

Import Libraries

Import the `gplearn` and `joblib` libraries.

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `GPLearn` model and make predictions.

Build Models

In this example, build a genetic programming feature transformation model and a genetic programming regression prediction model using the following features and labels:

Data Category	Description
Features	Daily percent change of the close price of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow these steps to create a method to build the model:

1. Declare a set of functions to use for feature engineering.

2. Call the `SymbolicTransformer` constructor with the preceding set of functions and then save it as a class variable.
3. Call the `SymbolicRegressor` constructor to instantiate the regression model.

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current close price to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `GPLearn` models into the Object Store :

1. Set the key names you want to store the models under in the Object Store.
2. Call the `GetFilePath` method with the keys.

   This method returns the file paths where the models will be stored.

3. Call the `dump` method the file paths.

   If you dump the models using the `joblib` module before you save the models, you don't need to retrain the models.

Load Models

You can load and trade with pre-trained `GPLearn` models that you saved in the Object Store. To load a `GPLearn` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

The `ContainsKey` method returns a boolean that represents if `transformer_model_key` and `regressor_model_key` are in the Object Store. If the Object Store does not contain the keys, save the model using them before you proceed.

Examples

The following examples demonstrate some common practices for using `GPLearn` library.

Example 1: Genetic Learning

The below algorithm makes use of `GPLearn` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

Hmmlearn

Introduction

This page explains how to build, train, deploy and store `Hmmlearn` models.

Import Libraries

Import the `hmmlearn` and `joblib` libraries.

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `hmmlearn` model and make predictions.

Build Models

In this example, assume the market has only 2 regimes and the market returns follow a Gaussian distribution. Therefore, create a 2-component Hidden Markov Model with Gaussian emissions, which is equivalent to a Gaussian mixture model with 2 means.

To build the model, call the `GaussianHMM` constructor with the number of components, a covariance type, and the number of iterations:

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current close price to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `hmmlearn` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.
2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `hmmlearn` models that you saved in the Object Store. To load a `hmmlearn` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Hmmlearn` library.

Example 1: Hidden Markov Model Regime Detection

The below algorithm makes use of `Hmmlearn` library to predict the future market regime through a hidden markov model using return data. If the regime is upward market, we hold SPY. Otherwise, we liquidate the portfolio. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

Keras

Introduction

This page explains how to build, train, deploy and store `Keras` models.

Import Libraries

Import the `keras` libraries.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `keras` model and make predictions.

Build Models

In this example, build a neural-network regression model that uses the following features and labels:

Data Category	Description
Features	Daily percent change of the open, high, low, close, and volume of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

Follow the below steps to build the model:

1. In the `Initialize` method, create a `Sequential` object with several layers.

   Set the `input_shape` of the first layer to `(5, 5)` because each sample contains the percent change of 5 factors (percent change of the open, high, low, close, and volume) over the previous 5 days. Call the `Flatten` constructor because the input is 2-dimensional but the output is just a single value.

2. Call the `compile` method with a loss function, an optimizer, and a list of metrics to monitor.

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `keras` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.

   The key must end with a .keras extension for the native Keras format (recommended) or a .h5 extension.

2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Call the `save` method with the file path.

Load Models

You can load and trade with pre-trained `keras` models that you saved in the Object Store. To load a `keras` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load_model` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Keras` library.

Example 1: Multi-layer Perceptron Model

The below algorithm makes use of `Keras` library to predict the future price movement using the previous 5 OHLCV data. The model is built with multi-layer perceptrons, ReLu activation function, and Adam optimization. It is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

PyTorch

Introduction

This page explains how to build, train, deploy and store `PyTorch` models.

Import Libraries

Import the `torch` and `joblib` libraries.

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `torch` model and make predictions.

Build Models

In this example, build a neural-network regression model that uses the following features and labels:

Data Category	**Description**
Features	The last 5 closing prices.
Labels	The following day's closing price

The following image shows the time difference between the features and labels:

Follow these steps to create a method to build the model:

1. Define a subclass of `nn.Module` to be the model.

   In this example, use the ReLU activation function for each layer.

2. Create an instance of the model and set its configuration to train on the GPU if it's available.

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and pass it to the model.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `PyTorch` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.
2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `PyTorch` models that you saved in the Object Store. To load a `PyTorch` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `PyTorch` library.

Example 1: Multi-layer Perceptron Model

The below algorithm makes use of `PyTorch` library to predict the future price movement using the previous 5 OHLCV data. The

model is built with multi-layer perceptrons, ReLu activation function, and stochastic gradient descent optimization. It is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

Scikit-Learn

Introduction

This page explains how to build, train, deploy and store `Scikit-Learn` models.

Import Libraries

Import the `sklearn` and `joblib` libraries.

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `sklearn` model and make predictions.

Build Models

In this example, build a support vector regression prediction model that uses the following features and labels:

Data Category	Description
Features	Daily percent change of the open, high, low, close, and volume of the SPY over the last 5 days
Labels	Daily percent return of the SPY over the next day

The following image shows the time difference between the features and labels:

To build the model, call the `GridSearchCV` constructor with the SVR model, the parameter grid, a scoring method, the number of cross-validation folds:

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `sklearn` models into the Object Store :

1. Set the key name you want to store the model under in the Object Store.
2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `sklearn` models that you saved in the Object Store. To load a `sklearn` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using Scikit-Learn library.

Example 1: Scikit-Learn

The below algorithm makes use of `Scikit-Learn` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

Tensorflow

Introduction

This page explains how to build, train, deploy and store `Tensorflow` models.

Import Libraries

Import the `tensorflow` library.

Create Subscriptions

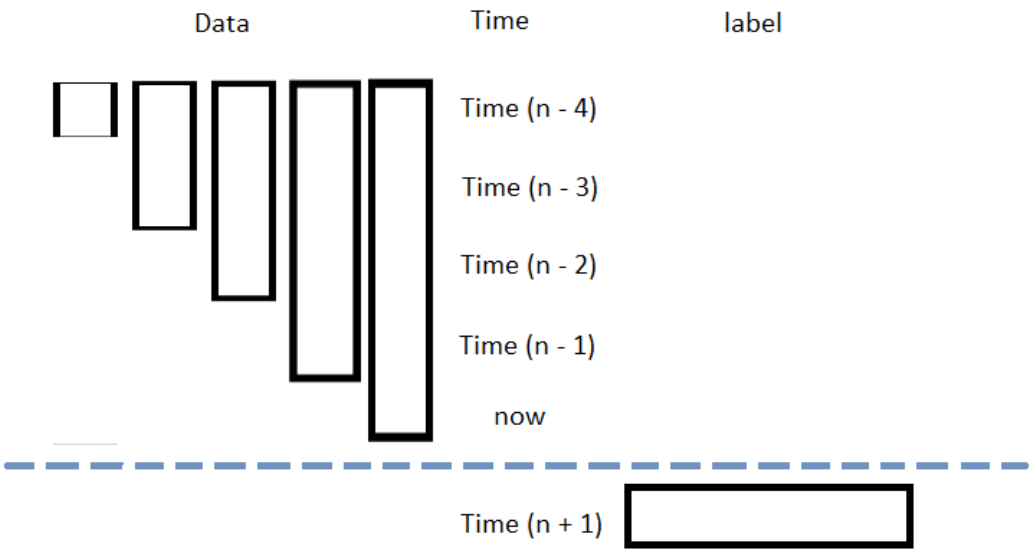
In the `Initialize` method, subscribe to some data so you can train the `tensorflow` model and make predictions.

Build Models

In this example, build a neural-network regression prediction model that uses the following features and labels:

Data Category	Description
Features	The last 5 close price differencing compared to current price
Labels	The following day's price change

The following image shows the time difference between the features and labels:



Follow these steps to create a method to build the model:

1. Define some parameters, including the number of factors, neurons, and epochs.
2. Create the model using built-in Keras API.

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, schedule some training sessions .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current close price to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `run` method with new features.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `Tensorflow` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.

   Note that the model has to have the suffix `.keras` .

2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Call the `save` method with the model and file path.
4. Save the model to the file path.

Load Models

You can load and trade with pre-trained `tensorflow` models that you saved in the Object Store. To load a `tensorflow` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then recall the graph and weights of the model.

The `ContainsKey` method returns a boolean that represents if the `model.keras` is in the Object Store. If the Object Store doesn't contain the keys, save the model using them before you proceed.

Examples

The following examples demonstrate some common practices for using `Keras` library.

Example 1: Multi-layer Perceptron Model

The below algorithm makes use of `Keras` library to predict the future price movement using the previous 5 OHLCV data. The model is built with multi-layer perceptrons, ReLu activation function, and Adam optimization. It is trained using rolling 2-year

data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

Tslearn

Introduction

This page explains how to build, train, deploy and store `Tslearn` models.

Import Libraries

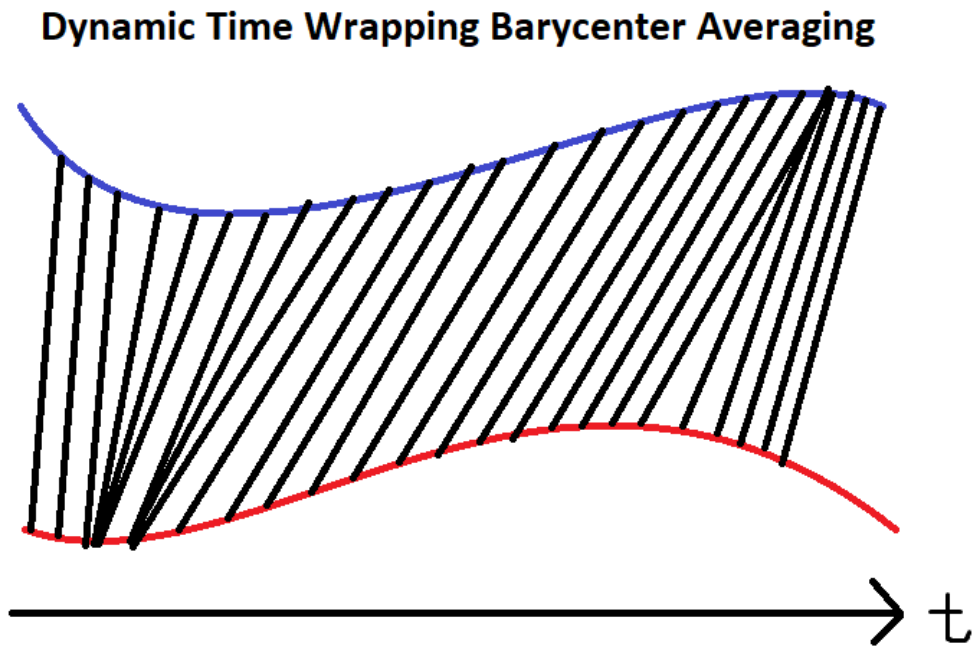
Import the `tslearn` libraries.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `tslearn` model.

Build Models

In this example, train a model that clusters the universe of Equities into distinct groups and then allocate an equal portion of the portfolio to each cluster. To cluster the securities, instead of using a real-time comparison, apply Dynamic Time Wrapping Barycenter Averaging (DBA) to their historical prices and then run a k-means clustering algorithm. DBA is a technique of averaging a few time-series into a single one without losing much of their information. Since not all time-series move efficiently like in ideal EMH assumption, this technique allows similarity analysis of different time-series with sticky lags. The following image shows a visualization of the process. For more information about the technical details, see Dynamic Time Warping in the tslearn documentation .



To perform DBA and then cluster the securities by k-means, create a TimeSeriesKMeans model:

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize` method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `tslearn` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.
2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Delete the current file to avoid a `FileExistsError` error when you save the model.
4. Call the `to_hdf5` method with the file path.

Load Models

You can load and trade with pre-trained `tslearn` models that saved in Object Store. To load a `tslearn` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `from_hdf5` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `Tslearn` library.

Example 1: Dynamic Time Wrapping (DTW) Clustering

The below algorithm makes use of `Tslearn` library to cluster stocks based on their recent year's price movement through DTW Barycenter Averaging. Then, we invest each cluster equally, while investing stocks within cluster equally as well. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Popular Libraries

XGBoost

Introduction

This page explains how to build, train, deploy and store `XGBoost` models.

Import Libraries

Import the `XGBoost` and `joblib` libraries.

You need the `joblib` library to store models.

Create Subscriptions

In the `Initialize` method, subscribe to some data so you can train the `xgboost` model and make predictions.

Build Models

In this example, build a gradient boost tree regression prediction model that uses the following features and labels:

Data Category	Description
Features	The last 5 closing prices
Labels	The following day's closing price

The following image shows the time difference between the features and labels:

Train Models

You can train the model at the beginning of your algorithm and you can periodically re-train it as the algorithm executes.

Warm Up Training Data

You need historical data to initially train the model at the start of your algorithm. To get the initial training data, in the `Initialize`

method, make a history request .

Define a Training Method

To train the model, define a method that fits the model with the training data.

Set Training Schedule

To train the model at the beginning of your algorithm, in the `Initialize` method, call the `Train` method.

To periodically re-train the model as your algorithm executes, in the `Initialize` method, call the `Train` method as a Scheduled Event .

Update Training Data

To update the training data as the algorithm executes, in the `OnData` method, add the current `TradeBar` to the `RollingWindow` that holds the training data.

Predict Labels

To predict the labels of new data, in the `OnData` method, get the most recent set of features and then call the `predict` method.

You can use the label prediction to place orders.

Save Models

Follow these steps to save `xgboost` models into the Object Store :

1. Set the key name of the model to be stored in the Object Store.
2. Call the `GetFilePath` method with the key.

   This method returns the file path where the model will be stored.

3. Call the `dump` method the file path.

   If you dump the model using the `joblib` module before you save the model, you don't need to retrain the model.

Load Models

You can load and trade with pre-trained `xgboost` models that saved in Object Store. To load a `xgboost` model from the Object Store, in the `Initialize` method, get the file path to the saved model and then call the `load` method.

The `ContainsKey` method returns a boolean that represents if the `model_key` is in the Object Store. If the Object Store does not contain the `model_key` , save the model using the `model_key` before you proceed.

Examples

The following examples demonstrate some common practices for using `XGBoost` library.

Example 1: Gradient Boosting Model

The below algorithm makes use of `XGBoost` library to predict the future price movement using the previous 5 OHLCV data. The model is trained using rolling 2-year data. To ensure the model applicable to the current market environment, we recalibrate the model on every Sunday.

Hugging Face

Hugging Face

Key Concepts

Introduction

Hugging Face is a leading company in natural language processing (NLP), providing powerful tools and pre-trained models that can significantly enhance your trading algorithms on QuantConnect. By integrating Hugging Face's models, you can easily leverage advanced NLP capabilities for tasks such as sentiment analysis, news classification, and market forecasting without defining and training the model yourself. Hugging Face provides an easy way to leverage the research of community members to increase the sophistication of your trading algorithms.

Supported Models

Hundreds of thousands of Hugging Face models are publicly available and ready to use. To view all of them, see the Model Hub on the Hugging Face website. The Model card tab of each model repository explains an overview of how the model works, its requirements, and a quick start guide.

QuantConnect Cloud caches some of the most popular models to speed up your development workflow. The following table shows the cached models:

Name	Category	Example
ahmedrachid/FinancialBERT-Sentiment-Analysis	Text Classification	
amazon/chronos-t5-base	Time Series Forecasting	
amazon/chronos-t5-large	Time Series Forecasting	
amazon/chronos-t5-small	Time Series Forecasting

Chronos-T5

Introduction

This page explains how to use Chronos-T5 in LEAN trading algorithms. The model repository provides the following description:

> Chronos is a family of **pretrained time series forecasting models** based on language model architectures. A time series is transformed into a sequence of tokens via scaling and quantization, and a language model is trained on these tokens using the cross-entropy loss. Once trained, probabilistic forecasts are obtained by sampling multiple future trajectories given the historical context. Chronos models have been trained on a large corpus of publicly available time series data, as well as synthetic data generated using Gaussian processes.
>
> For details on Chronos models, training data and procedures, and experimental results, please refer to the paper Chronos: Learning the Language of Time Series .

Use Cases

The Chronos-T5 model is a time series forecasting model. The following use cases explain how you might utilize it in trading algorithms:

- Forecast the future equity curves for a set of assets, then pass them to an optimizer to determine the weights that maximize the future Sharpe ratio of the portfolio.
- Forecast the future volatility of an asset to manage risk and opimize portfolio allocations.
- Train the model to forecast the impact of specific events on an asset and then adjust your holdings in response to the event. For example, you could train the model to forecast the impact of news , corporate actions , or financial reports .

Load Pre-Trained Model

Follow these steps to load the pre-trained Chronos-T5 model:

1. Add the following imports to the top of your code file:
2. Call the `ChronosPipeline.from_pretrained` method with the model path.

   In QuantConnect Cloud, the path to the tiny model is amazon / chronos-t5-tiny .

3. (Optional) Set the seed to enable reproducibility.

Fine-Tune Model

The Chronos-T5 model is pre-trained, so you don't need to fine-tune it. Fine-tuning the model just tailors it to your specific use case. Follow these steps to fine-tune it:

1. Add the following imports to the top of your code file:
2. In the `initialize` method, define the model and some of its settings.

   In QuantConnect Cloud, the path to the tiny model is amazon/chronos-t5-tiny .

3. Define the fine-tuning method.
4. Create DataFrame(s) that contain your training samples.

Each DataFrame should have one column, named "target". The rows throughout the DataFrame should span a consistent time. If there is no data for the time step (for example, the weekend price of an Equity asset), put NaN as the value for the time step. The following example demonstrates how to create DataFrames that contain one year of trailing prices for a set of Equities:

For more information about history requests, see History Requests .

5. Call the fine-tuning method with the training data.
6. Load the fine-tuned model.

Forecast Time Series

Follow these steps to forecast time series with Chronos-T5:

1. Get some historical data .
2. Load the pre-trained or fine-tuned model.
3. Forecast the future time series.

   In this example, the model returns several future price paths for each asset.

4. Aggregate the future prices paths of each asset into a single price path for each asset.

   For example, take the median value of each time step in the future price paths.

Examples

The following examples demonstrate usage of the Chronos-T5 model.

Example 1: Price Prediction

The following algorithm selects the most liquid assets at the beginning of each month. Once a quarter, it gets the trailing year of prices for all the assets in the universe and then forecasts the prices paths of all the assets over the upcoming quarter. It then uses the SciPy package to find the weights that maximize the future Sharpe ratio of the portfolio and rebalances the portfolio to those weights.

Example 2: Fine Tuning

The following algorithm expands the preceding algorithm by fine-tuning the model before each forecast:

Popular Models

DistilBERT

Introduction

This page explains how to use DistilBERT in LEAN trading algorithms. The model repository provides the following description:

> The DistilBERT model was proposed in the blog post Smaller, faster, cheaper, lighter: Introducing DistilBERT, adistilled version of BERT , and the paper DistilBERT, adistilled version of BERT: smaller, faster, cheaper and lighter . DistilBERT is a small, fast, cheap and light Transformer model trained by distilling BERT base. It has 40% less parameters than bert-base-uncased, runs 60% faster while preserving over 95% of BERT's performances as measured on the GLUE language understanding benchmark. This model is a fine-tune checkpoint of DistilBERT-base-cased , fine-tuned using (a second step of) knowledge distillation on SQuAD v1.1 .

Use Cases

The DistilBERT model is a question answering model. The following use cases explain how you might utilize it in trading algorithms:

- Summarize the upcoming changes reported through regulatory articles in preparation of sentiment analysis.
- Extract relevant information from news feeds like Tiingo and Benzinga while reducing noise.
- Parse through US SEC Filings to find critical information about company performance, legal issues, or changes in management.

Load Pre-Trained Model

Follow these steps to load the pre-trained DistilBERT model:

1. Import the pipeline.
2. Create a pipeline object with the DistilBERT model.

   In QuantConnect Cloud, the path is distilbert / distilbert-base-cased-distilled-squad .

Answer Questions

Follow these steps to answer questions with DistilBERT:

1. Load the model .
2. Define the context.
3. Create the question.
4. Pass the question and context to the pipeline.

   The following dictionary is an example result:

Examples

Popular Models

FinBERT

Introduction

This page explains how to use FinBERT in LEAN trading algorithms. The model repository provides the following description:

> FinBERT is a pre-trained NLP model to analyze sentiment of financial text. It is built by further training the BERT language model in the finance domain, using a large financial corpus and thereby fine-tuning it for financial sentiment classification. Financial PhraseBank by Malo et al. (2014) is used for fine-tuning. For more details, please see the paper FinBERT: Financial Sentiment Analysis with Pre-trained Language Models and our related blog post on Medium.
>
> The model will give softmax outputs for three labels: positive, negative or neutral.

Use Cases

The FinBERT model is a sentiment analysis model. The following use cases explain how you might utilize it in trading algorithms:

- Analyze the sentiment of the latest news articles for specific companies , then form a long-short portfolio with assets that have the most postive and most negative news sentiment.
- Monitor the sentiment of regulatory alerts in a risk management model and liquidate holdings when sentiment is extremely negative.
- Generate sentences based on information from other datasets and then feed them into the model to determine the sentiment. For example, you could use the US Government Contracts dataset to create the string "The Department of State grants AAPL a contract for the purchase of mobile phones".

Load Pre-Trained Model

Follow these steps to load the pre-trained FinBERT model:

1. Import the model and tokenizer classes.
2. Define the path were the model is stored.

   In QuantConnect Cloud, the path is ProsusAI / finbert .

3. Create a TFBertForSequenceClassification model.
4. Create a BertTokenizer object.
5. (Optional) Set the seed to enable reproducibility.

Fine-Tune Model

The FinBERT model is pre-trained, so you don't need to fine-tune it. Fine-tuning the model just tailors it to your specific use case. Follow these steps to fine-tune it:

1. Import the `Dataset` class.
2. Load the pre-trained model .
3. Compile the model with an optimizer and loss function.

   You only need to compile the model once. TensorFlow offers many other optimizer and loss classes you can use.

4. Create a DataFrame that contains your training samples.

The DataFrame should have two columns, named "text" and "label". The label must be an integer that represents the sentiment class. By default, the FinBERT model has three classes. Class zero represents negative sentiment, class one represents neutral sentiment, and class two represents positive sentiment.

5. Convert the samples DataFrame to a `tf.data.Dataset` object.
6. Tokenize the text in each training sample.
7. Call the model's prepare_tf_dataset method.
8. Call the model's fit method.

Analyze Sentiment

Follow these steps to analyze the sentiment of some text with FinBERT:

1. Load the model .
2. (Optional) Fine-tune the model .
3. Get the text you want the model to analyze.

   The model can analyze a single sentence or a list of sentences.

4. Tokenize the text(s).

   For more information about how to tokenize, see the PreTrainedTokenizer.__call__ reference on the Hugging Face website.

5. Perform dictionary unpacking on the preceding result and pass it to the model as input.
6. Apply softmax to the outputs to get probabilities of each sentiment class.

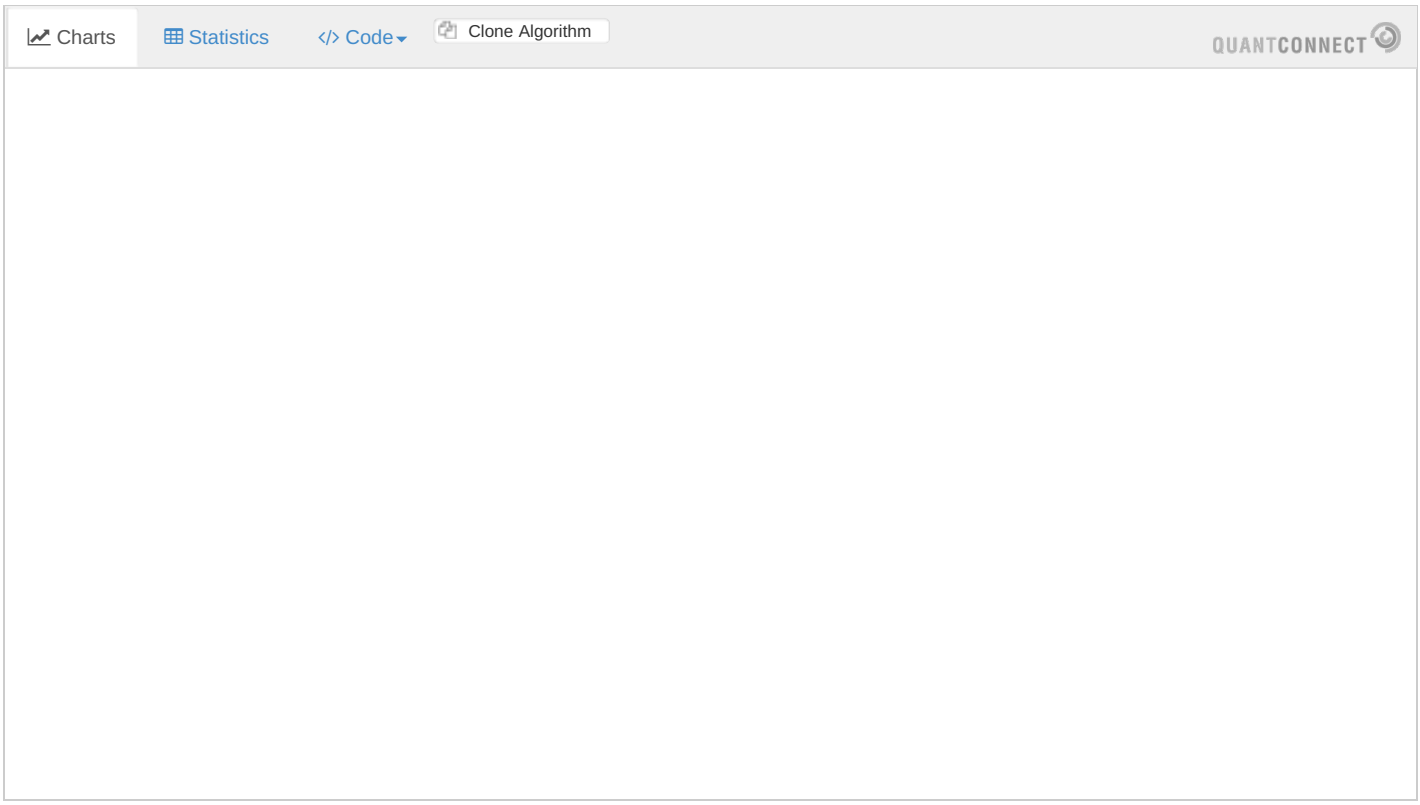
   The result of the preceding operation is a two dimensional numpy array. Each element in the two dimensional array is a list that contains the probability that the sentiment of the corresponding sentence is negative, neutral, or postiive, respectively. For example, you may get the following result if you use a single sentence as input. The result shows that the input is more positive than negative, but is likely neutral.

Examples

The following examples demonstrate usage of the FinBERT model.

Example 1: 10-day Sentiment Score

The following algorithm selects a volatile asset at the beginning of each month. It gets the Tiingo News articles that were released for the asset over the previous 10 days and then feeds them into the pre-trained FinBERT model. It then aggregates the sentiment scores of all the news releases. If the aggregated sentiment score is positive, it enters a long position for the month. If it's negative, it enters a short position for the month.



Example 2: 30-day Sentiment Score With Fine Tuning

The following algorithm selects a volatile asset at the beginning of each month. It gets the Tiingo News articles that were released for the asset over the previous 30 days to generate the training set. The label is the market return that occurs from the current news release to the next news release. The algorithm then fine-tunes the model, calculates the sentiment, and rebalances the portfolio.

These algorithms require a GPU node.

Algorithm Framework

Algorithm Framework

Overview

Introduction

Since QuantConnect was formed in 2013, the community has created more than 2 million algorithms. Although they all seek to achieve different results, they can all be abstracted into the same core features. The Algorithm Framework is our attempt to provide this well-defined structure to the community, encouraging good design and making your work more reusable. LEAN provides many pre-built Algorithm Framework models you can use in your algorithms.

Strategy Styles

The algorithm framework works best for portfolio rebalancing, ranking, and multi-factor style strategies. The default portfolio construction models are designed to weigh and invest in the assets as the signals values shift, aiming to be fully invested as much as possible.

Some strategies might find it difficult to fit this model. Technical entry signals are often tightly coupled with their exit criteria, they may not have defined hold periods, and they might follow the market to determine when to exit. This style of strategy can be addressed in a few ways:

1. Short Term Signals - Emitting insights for short periods until they are no longer valid.
2. Cancel Signals - Updating an insight's expiry time so that it's expired upon the exit signal.
3. Alpha Exit Signal - Treating exit as its own signal, a separate Alpha model could indicate exit.
4. Risk Model - Tracking exit using a risk model that attempts to lock in gains.

These techniques are still not ideal for many strategies. For example, with only a single signal, the built in `EqualWeightingPortfolioConstructionModel` will allocate 100% of buying power to a single asset, over concentrating risk. If a second signal comes a few days later, it would sell 50% of the portfolio to free cash and invest in the second asset. This can create high trading costs through portfolio churn.

With a custom portfolio construction model , signals can mean what you need for your specific strategy style. For example, you might create a " `MultiBetPortfolioConstructionModel` " that uses each insight to open a specific "bet" that is separately allocated capital and tracked.

Important Terminology

The following table defines important Algorithm Framework terminology:

Term	Description
Universe Selection model	A framework module that selects assets for your algorithm.
Alpha model	A framework module that generates trading signals on the assets in your universe.
Insight	An object that represents a trading signal. The Alpha model generates these objects for the Portfolio Construction model.
Portfolio Construction model	A framework module that determines position size targets based on the `Insight` objects it receives from the Alpha model.
PortfolioTarget	An object that represents the target position size for an asset in the universe. The Portfolio Construction model generates these objects for the Risk Management model.
Risk Management	A framework module that manages market risks and ensures the algorithm remains within target parameters. This model adjusts the `PortfolioTarget` objects it receives from the Portfolio Construction model before they reach the Execution model.
Execution	A framework module that places trades to reach the target risk-adjust portfolio based on the `PortfolioTarget` objects it receives from the Risk Management model.

Framework Advantages

We recommend you design strategies with the Algorithm Framework in most cases. The Algorithm Framework has many advantages over the classic algorithm design.

Pluggable Algorithm Modules

With the Algorithm Framework, your code can instantly utilize all modules built within the framework. The modules clip together in well-defined ways, which enable them to be shared and swapped interchangeably.

Focus On Your Strengths

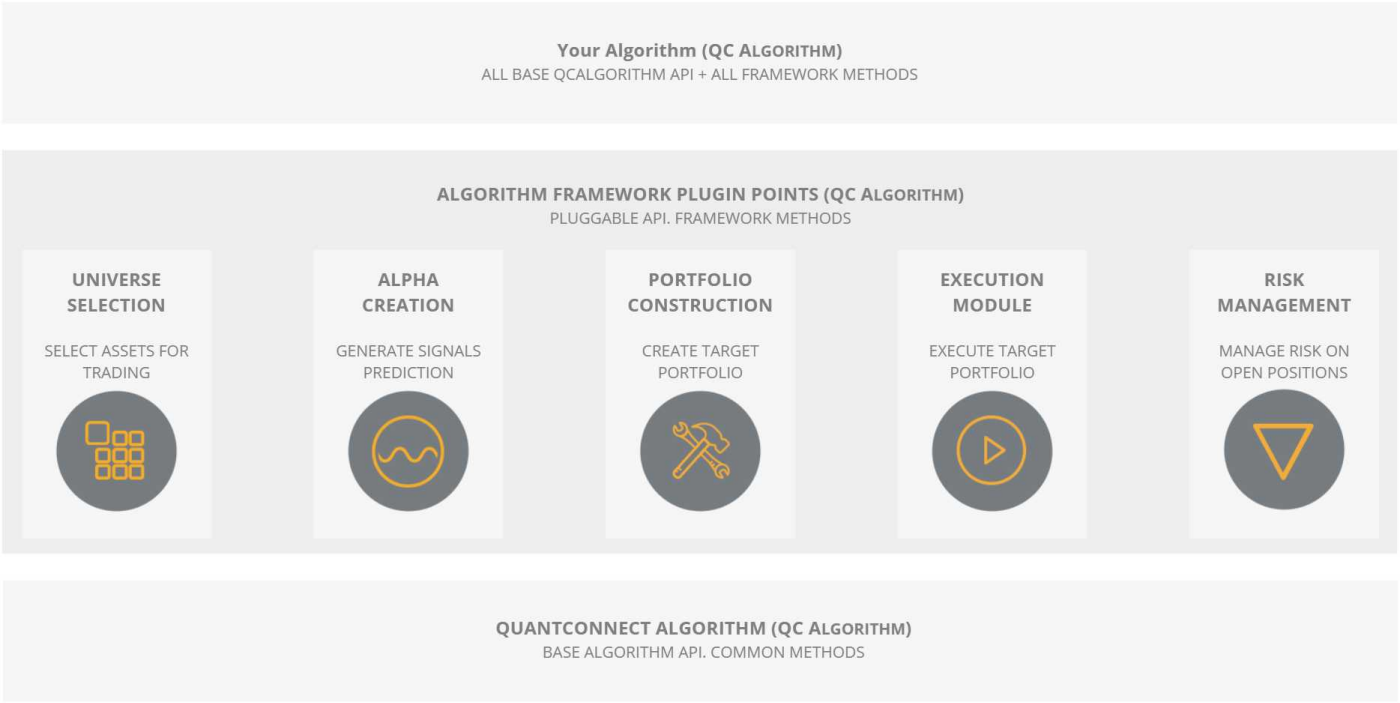
If you write code in modules, you can focus on your strengths. If you are great at building universes, you can build Universe Selection modules. If you have risk management experience, you could write reusable risk monitoring technology.

Reduce Development By Using Community Modules

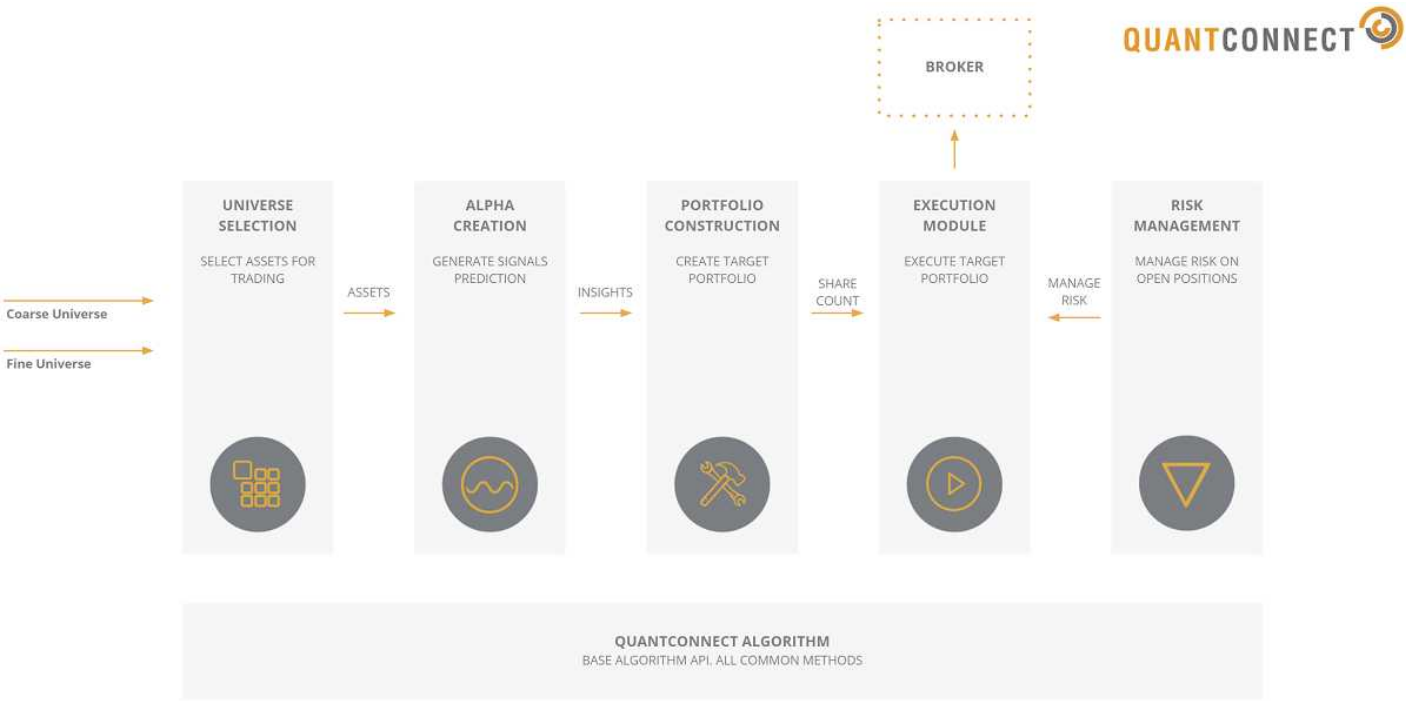
Easily share modules you've made between algorithms or pull in ones produced by the community. The strict separation of duties makes the Algorithm Framework perfect for reusing code between strategies.

System Architecture

The Algorithm Framework is built into the `QCAlgorithm` class, so your strategy can access all the normal methods you use for algorithm development. You should be able to copy and paste your algorithms across without any changes. You don't need a separate class.



The framework data output of each module flows into the following module. The assets that the Universe Selection model selects are fed into the Alpha model to generate trade signals (`Insight` objects). The `Insight` objects from the Alpha model are fed into the Portfolio Construction model to create `PortfolioTarget` objects, which contain the target number of units to hold for each asset. The `PortfolioTarget` objects from the Portfolio Construction model are fed into the Risk Management model to ensure the targets are within safe risk parameters and to adjust the `PortfolioTarget` objects if necessary. The `PortfolioTarget` objects from the Risk Management model are fed into the Execution model, which efficiently places trades to acquire the target portfolio.



```C#
public class MyFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetUniverseSelection(new EmaCrossUniverseSelectionModel());
        AddAlpha(new RsiAlphaModel());
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
        AddRiskManagement(new NullRiskManagementModel());
    }
}
```

For simple strategies, it may seem like overkill to abstract out your algorithm concepts. However, even simple strategies can benefit from reusing the ecosystem of modules available in QuantConnect. Imagine pairing your EMA-cross Alpha model with a better execution system or plugging in an open-source trailing stop Risk Management model .

Separation of Concerns

The separation of concerns principle is an algorithm design principle where individual components are isolated and their responsibilities don't overlap. The Algorithm Framework is designed to uphold this design principle. The individual framework components shouldn't rely on the state of the other framework components in order to operate.

In the Algorithm Framework, the models should not communicate. The universe constituents and the `Insight` objects you emit should be the same, regardless of what you select for the Portfolio Construction, Risk Management, and Execution models. If your algorithm logic naturally violates the separation of concerns design principle, it's more appropriate to use the classic or hybrid design .

Framework vs Classic Design

Select the classic or Algorithm Framework design based on the needs of your algorithm. If your algorithm uses special order types or passes information between the different algorithm components, use the classic design. If you can reuse existing modules and the Algorithm Framework modules can work in isolation, use the Algorithm Framework design.

Algorithm Framework

Universe Selection

Universe Selection

Key Concepts

Introduction

The Universe Selection model creates `Universe` objects, which select the assets for your algorithm. As the universe changes, we notify your algorithm through the `OnSecuritiesChanged` event handler. With this event handler, you can track the current universe constituents in other parts of your algorithm without breaking the separation of concerns design principle.

Types of Universe Selection

We have identified several types of universes that cover most people's requirements and built helper classes to make their implementation easier. The following table describes the types of pre-built Universe Selection models:

Universe Type	Description
Manual Universes	Universes that use a fixed, static set of assets
Fundamental Universes	Universes for US Equities that are based on coarse price or fundamental data
Scheduled Universes	Universes that trigger on regular, custom intervals
Futures Universes	Universes that subscribe to Future chains
Option Universes	Universes that subscribe to Option chains

Add Models

To add a Universe Selection model, in the `Initialize` method, call the `AddUniverseSelection` method.

```
C#
var symbols = new [] {QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)};
AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
```

To view all the pre-built Universe Selection models, see Types of Universe Selection .

Multi-Universe Algorithms

You can add multiple Universe Selection models to a single algorithm.

```
// Configures asynchronous universe settings for faster updates and includes both manual and EMA cross universe
selection models for dynamic and static selection.
UniverseSettings.Asynchronous = true;
var symbols = new [] {QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)};
AddUniverseSelection(new ManualUniverseSelectionModel(symbols));

AddUniverseSelection(new EmaCrossUniverseSelectionModel());
```

If you add multiple Universe Selection models, the algorithm subscribes to the constituents of all the models.

Model Structure

Universe Selection models should extend the `UniverseSelectionModel` class. Extensions of the `UniverseSelectionModel` class must implement the `CreateUniverses` method, which receives an `algorithm` object and returns an array of `Universe` objects.

```
// Extend UniverseSelectionModel to define a custom security universe tailored to the algorithm.
public class MyUniverseSelectionModel : UniverseSelectionModel
{
    // Creates the universes for this algorithm
    public override IEnumerable<Universe> CreateUniverses(QCAlgorithm algorithm)
    {
        return new List<Universe>();
    }

    // Gets the next time the framework should invoke the `CreateUniverses` method to refresh the set of universes.
    public override DateTime GetNextRefreshTimeUtc()
    {
        return DateTime.MaxValue;
    }
}
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

Generally, you should be able to extend one of the pre-built Universe Selection types. If you need to do something that doesn't fit into the pre-built types, let us know and we'll create a new foundational type of Universe Selection model.

Track Security Changes

When the Universe Selection model adjusts the universe constituents, we notify your algorithm through the `OnSecuritiesChanged` event handler on your other framework components. The method receives `QCAlgorithm` and `SecurityChanges` objects. The `QCAlgorithm` object is an instance of the base QCAlgorithm class, not a reference to your algorithm object. To access the added securities, check the `changes.AddedSecurities` method property. To access the removed securities, check the `changes.RemovedSecurities` method property.

```
// Log added and removed securities to update the universe and adapt the strategy.
public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
{
    foreach (var security in changes.AddedSecurities)
    {
        Log($"Added {security.Symbol}");
    }

    foreach (var security in changes.RemovedSecurities)
    {
        Log($"Removed {security.Symbol}");
    }
}
```

Live Trading Considerations

In live trading, the securities in your brokerage account are added to your user-defined universe. If your Universe Selection model doesn't select these securities, they are not removed from your user-defined universe. When you liquidate the positions, you can remove them from the user-defined universe. If you call the `RemoveSecurity` method, it automatically liquidates the position.

To see the securities in your user-defined universe that were loaded from your brokerage account, check your algorithm's ActiveSecurities in the OnWarmupFinished event handler.

Examples

The following examples demonstrate some common practices for implementing the universe selection model.

Example 1: Liquid Universe Selection Model

The following algorithm selects a universe of the top 20 liquid equity through the framework universe selection model. Then, buying and holding these popular equities equally to bet on their high demand will drive up the price.

```C#
public class FrameworkUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Rebalance weekly to allow time to capitalize on the trend
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        // Since the selection is based on daily data, we only require daily data to trade daily.
        UniverseSettings.Resolution = Resolution.Daily;
        // Add universe selection model to select the most liquid stocks to trade with.
        AddUniverseSelection(new FundamentalUniverseSelectionModel(Selection));

        // Sent insights on buying and holding the most liquid stocks for a week.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Evenly dissipate the capital risk among selected stocks.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> Selection(IEnumerable<Fundamental> fundamental)
    {
        // Select the top 20 liquid equity to trade the popularity, suggesting a higher demand to drive the price.
        return fundamental.OrderByDescending(x => x.DollarVolume)
            .Take(20)
            .Select(x => x.Symbol);
    }
}
```

Example 2: Multiple Universe Selection Models

The following algorithm implements two framework universe selection models to manually select the most liquid market ETFs and those with EMA crossing events to trade on trend changes. Then, buy and hold these equities equally to bet on the insights and dissipate the capital risk.

```
C#
public class FrameworkUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Rebalance weekly to allow time to capitalize on the trend
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        // Since the selection is based on daily data, we only require daily data to trade daily.
        UniverseSettings.Resolution = Resolution.Daily;
        // Add a universe selection model to select the most liquid ETFs manually.
        var symbols = new [] {
            QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA),
            QuantConnect.Symbol.Create("QQQ", SecurityType.Equity, Market.USA)
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // Add another universe selection model to select the ones with EMA crosses.
        AddUniverseSelection(new EmaCrossUniverseSelectionModel());

        // Sent insights on buying and holding the most liquid stocks for a week.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Evenly dissipate the capital risk among selected stocks.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}
```

Universe Selection

Universe Settings

Introduction

Universe settings and security initializers enable you to configure some properties of the securities in a universe.

Resolution

The `Resolution` setting defines the time period of the asset data. The `Resolution` enumeration has the following members:

To view which resolutions are available for the asset class of your universe, follow these steps:

1. Open the Asset Classes documentation page.
2. Click an asset class.
3. Click Requesting Data .
4. On the Requesting Data page, in the table of contents, click Resolutions .

The default value is `Resolution.Minute` . To change the resolution, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
C#
// Set universe settings to subscribe to daily data and select SPY ETF constituents as the trading universe.
UniverseSettings.Resolution = Resolution.Daily;
AddUniverseSelection(new ETFConstituentsUniverseSelectionModel("SPY"));
```

Leverage

The `Leverage` setting is a `decimal` that defines the maximum amount of leverage you can use for a single asset in a non-derivative universe. The default value is `Security.NullLeverage` (0). To change the leverage, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
C#
// Set unviverse leverage to 2x to increase potential returns from each asset in the non-derivative universe to
increase potential returns.
UniverseSettings.Leverage = 2.0m;
// Select universe based on EMA cross signals to identify and trade assets with trending behaviors.
AddUniverseSelection(new EmaCrossUniverseSelectionModel());
```

Fill Forward

The `FillForward` setting is a `bool` that defines whether or not too fill forward data. The default value is `true` . To disable fill forward in non-derivative universes, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
// Disable fill forward to ensure each day's data is used exclusively, preventing previous day's data from
influencing decisions and select options for SPY with a daily update interval to track specific option contracts.
UniverseSettings.FillForward = false;
AddUniverseSelection(
    new OptionUniverseSelectionModel(
        TimeSpan.FromDays(1),
        _ => new [] { QuantConnect.Symbol.Create("SPY", SecurityType.Option, Market.USA) }
    )
);
```

Extended Market Hours

The `ExtendedMarketHours` setting is a `bool` that defines the trading schedule. If it's `true` , your algorithm receives price data for all trading hours. If it's `false` , your algorithm receives price data only for regular trading hours. The default value is `false` .

You only receive extended market hours data if you create the subscription with an intraday resolution. If you create the subscription with daily resolution, the daily bars only reflect the regular trading hours.

To view the trading schedule of an asset, open Asset Classes , click an asset class, then click Market Hours .

To enable extended market hours, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
// Enable extended market hours for universe and manually select equity symbols for SPY, QQQ, and IWM to ensure
trading during pre-market and after-hours sessions.
UniverseSettings.ExtendedMarketHours = true;
var tickers = new[] {"SPY", "QQQ", "IWM"};
var symbols = tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.Equity, Market.USA));
AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
```

Minimum Time in Universe

The `MinimumTimeInUniverse` setting is a `TimeSpan` object that defines the minimum amount of time an asset must be in the universe before the universe can remove it. The default value is `TimeSpan.FromDays(1)` . To change the minimum time, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
// Keep each security in the universe for a minimum of 7 days.
UniverseSettings.MinimumTimeInUniverse = TimeSpan.FromDays(7);
AddUniverseSelection(new ETFConstituentsUniverseSelectionModel("QQQ"));
```

Data Normalization Mode

The `DataNormalizationMode` setting is an enumeration that defines how historical data is adjusted. This setting is only applicable for US Equities and Futures.

In the case of US Equities, the data normalization mode affects how historical data is adjusted for corporate actions . To view all the available options, see Data Normalization . To change the data normalization mode, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

In the case of Futures, the data normalization mode affects how historical data of two contracts is stitched together to form the continuous contract . To view all the available options, see Data Normalization .

The default value is `DataNormalizationMode.Adjusted` . To change the data normalization mode, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
C#
// Set universe data normalization to use raw prices to reflect actual traded values without adjustments and manually
select equities MSTR, MSFT, and IBM.
UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;

var tickers = new[] {"MSTR", "MSFT", "IBM"};
var symbols = tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.Equity, Market.USA));
AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
```

Contract Depth Offset

The `ContractDepthOffset` setting is an `int` that defines which contract to use for the continuous Futures contract. 0 is the front month contract, 1 is the following back month contract, and 3 is the second back month contract. The default value is 0. To change the contract depth offset, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
C#
// Select the following month contract dynamically to avoid low liquidity and high volatility, for S&P 500 E-mini
futures with daily updates.
UniverseSettings.ContractDepthOffset = 1;
AddUniverseSelection(
    new FutureUniverseSelectionModel(
        TimeSpan.FromDays(1),
        _ => new List<Symbol> {{ QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future,
Market.CME) }}
    )
);
```

Asynchronous Selection

The `Asynchronous` setting is a `bool` that defines whether or not LEAN can run universe selection asynchronously, utilizing concurrent execution to increase the speed of your algorithm. The default value for this setting is `false` . If you enable this setting, abide by the following rules:

- Don't make any history requests in your filter function . History requests can only provide data up to the algorithm time , but if your filter function runs asynchronously, the algorithm time may not be what you expect.
- Don't use the portfolio, security, or orders state. The `Portfolio` , `Securities` , and `Transactions` objects are also functions of the algorithm time.
- If your filter function updates a class variable, don't update the class variable anywhere else in your algorithm.

To enable asynchronous universe selection, in the Initialize method, adjust the algorithm's `UniverseSettings` before you create the Universe Selection model.

```
C#
// Run universe selection asynchronously to speed up your algorithm.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new EmaCrossUniverseSelectionModel());
```

Schedule

The `Schedule` setting defines the selection schedule of the universe. Most universes run on a daily schedule. To change the selection schedule, call the `UniverseSettings.Schedule.On` method with an `IDateRule` object before you create the Universe Selection model.

```C#
// Trigger selections at the begining of each month.
UniverseSettings.Schedule.On(DateRules.MonthStart());
AddUniverseSelection(new ETFConstituentsUniverseSelectionModel("QQQ"));
```

The following table describes the supported `DateRules` :

Member	Description
`DateRules.SetDefaultTimeZone(DateTimeZone timeZone);`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`DateRules.On(int year, int month, int day)`	Trigger an event on a specific date.
`DateRules.On(params DateTime[] dates)`	Trigger an event on specific dates.
`DateRules.EveryDay()`	Trigger an event all seven days of the week.
`DateRules.EveryDay(Symbol symbol, bool extendedMarketHours = false)`	Trigger an event every day a specific symbol is trading.
`DateRules.Every(params DayOfWeek[] days)`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`DateRules.MonthStart(int daysOffset = 0)`	Trigger an event on the first day of each month plus an offset.
`DateRules.MonthStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`DateRules.MonthEnd(int daysOffset = 0)`	Trigger an event on the last day of each month minus an offset.
`DateRules.MonthEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`DateRules.WeekStart(int daysOffset = 0)`	Trigger an event on the first day of each week plus an offset.
`DateRules.WeekStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`DateRules.WeekEnd(int daysOffset = 0)`	Trigger an event on the last day of each week minus an offset.
`DateRules.WeekEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`DateRules.YearStart(int daysOffset = 0)`	Trigger an event on the first day of each year plus an offset.
`DateRules.YearStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`DateRules.YearEnd(int daysOffset = 0)`	Trigger an event on the last day of each year minus an offset.
`DateRules.YearEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`DateRules.Today`	Trigger an event once today.
`DateRules.Tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `string` and a `getDatesFunction` argument of type `Func<DateTime, DateTime, IEnumerable<DateTime>>` . The `getDatesFunction` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```
C#

// Create a date rule that specifies the 10th day of each month.
var dateRule = new FuncDateRule(
    name: "10th_day_of_the_month",
    getDatesFunction: (start, end) => Enumerable.Range(start.Year, end.Year - start.Year + 1)
        .SelectMany(year => Enumerable.Range(1, 12).Select(month => new DateTime(year, month, 10)))
);
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `DateRules.EveryDay("ES")` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```
C#

var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

In live trading, scheduled universes run at roughly 8 AM Eastern Time to ensure there is enough time for the data to process.

Configure Securities

Instead of configuring global universe settings, you can individually configure the settings of each security in the universe with a security initializer. Security initializers let you apply any security-level reality model or special data requests on a per-security basis. To set the security initializer, in the `Initialize` method, call the `SetSecurityInitializer` method and then define the security initializer.

```
C#

// A custom security initializer can override default models such as
// setting new fee and fill models for the security.
SetSecurityInitializer(CustomSecurityInitializer);

private void CustomSecurityInitializer(Security security)
{
    security.SetFeeModel(new ConstantFeeModel(0, "USD"));
}
```

For simple requests, you can use the functional implementation of the security initializer. This style lets you configure the security object with one line of code.

```
C#

// Disable the trading fees for each security by passing a functional
// implementation for the SetSecurityInitializer argument.
SetSecurityInitializer(security => security.SetFeeModel(new ConstantFeeModel(0, "USD")));
```

If you call the `SetSecurityInitializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage

- Fee
- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

The default security initializer also sets the leverage of each security and intializes each security with a seeder function. To extend upon the default security initializer instead of overwriting it, call `AddSecurityInitializer` before you create the subscriptions.

```
C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetFeeModel(new ConstantFeeModel(0, "USD"));
    }
}
```

Examples

The following examples demonstrate some common practices for universe settings.

Example 1: Weekly-Updating Liquid Universe

The following algorithm demonstrates daily EMA cross, trading on the most liquid stocks. The universe is set to be updated weekly. Various universe settings have been set to simulate the brokerage environment best and for trading needs.

C#

```
public class UniverseSettingsAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // To avoid over-updating the universe, which causes insufficient time to earn the trend, update the universe
weekly.
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        UniverseSettings.MinimumTimeInUniverse = TimeSpan.FromDays(7);
        // Rebalancing frequency is daily, so we only need to subscribe to daily resolution.
        UniverseSettings.Resolution = Resolution.Daily;
        // To best simulate IB's margin requirement set the leverage to 50%.
        UniverseSettings.Leverage = 2;
        // Since we trade by market order, we cannot use extended market hours data to fill.
        UniverseSettings.ExtendedMarketHours = false;
        // We want to trade the EMA with raw price but not altered by splits.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.SplitAdjusted;

                // Only trade on the top 10 most traded stocks since they have the most popularity to drive trends.
        AddUniverse(Universe.Top(10));
            }

    public override void OnData(Slice slice)
    {
        foreach (var (symbol, bar) in slice.Bars)
        {
            // Trade the trend by EMA crossing.
            var ema = (Securities[symbol] as dynamic).ema;
            if (bar.Close > ema)
            {
                SetHoldings(symbol, 0.05m);
            }
            else
            {
                SetHoldings(symbol, -0.05m);
            }
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var removed in changes.RemovedSecurities)
        {
            // Liquidate the ones leaving the universe since we will not trade their EMA anymore.
            Liquidate(removed.Symbol);
            // Deregister the EMA indicator to free resources
            DeregisterIndicator((removed as dynamic).ema as ExponentialMovingAverage);
        }

        foreach (var added in changes.AddedSecurities)
        {
            var security = added as dynamic;
            // Create EMA indicator for trend trading signals.
            security.ema = EMA(added.Symbol, 50, Resolution.Daily);
            // Warm up the EMA indicator to ensure its readiness for immediate use.
            WarmUpIndicator(added.Symbol, (ExponentialMovingAverage)security.ema, Resolution.Daily);
        }
    }
}
```

Universe Selection

Manual Universes

Introduction

The `ManualUniverseSelectionModel` selects a static, fixed set of assets. It is similar to adding securities with the traditional `AddSecurity` API methods. If your algorithm has a static universe, you can use automatic indicators instead of manual indicators in your algorithm.

Manual universes can be prone to look-ahead bias . For example, if you select a set of securities that have performed well during the backtest period, you are incorporating information from the future into the backtest and the algorithm may underperform in live mode.

Add Manual Universe Selection

To add a `ManualUniverseSelectionModel` to your algorithm, in the `Initialize` method, call the `AddUniverseSelection` method. The `ManualUniverseSelectionModel` constructor expects a list of `Symbol` objects that represent the universe constituents.

```
C#
// Use ManualUniverseSelectionModel method to select a static set of equities, similar to traditional add_security
methods, for a fixed trading universe.
var tickers = new[] {"SPY", "QQQ", "IWM"};
var symbols = tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.Equity, Market.USA));
AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`symbols`	`IEnumerable<Symbol>`	Universe constituents	
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	

To move the universe tickers and `Symbol` objects outside of the algorithm class, create a universe selection model that inherits the `ManualUniverseSelectionModel` class.

```
// Create a custom universe selection model to move universe tickers and Symbol objects outside of the algorithm
class for improved modularity, reusability, and maintainability.
AddUniverseSelection(new IndexUniverseSelectionModel());

// Outside of the algorithm class
class IndexUniverseSelectionModel : ManualUniverseSelectionModel
{
    public IndexUniverseSelectionModel()
        : base(SelectSymbols()) {}

    public static IEnumerable<Symbol> SelectSymbols()
    {
        var tickers = new[] {"SPY", "QQQ", "IWM"};
        return tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.Equity, Market.USA));
    }
}
```

C#

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing a manual universe selection model.

Example 1: Crypto List Selection Model

The following algorithm selects a list of preset cryptos, given we have information that they will perform better. So, we can use `ManualUniverseSelectionModel` to select this list and buy the listed cryptos.

```
public class FrameworkManualUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Add a universe selection model to select the most liquid cryptos manually.
        var symbols = new [] {
            QuantConnect.Symbol.Create("BTCUSD", SecurityType.Crypto, Market.Coinbase),
            QuantConnect.Symbol.Create("ETHUSD", SecurityType.Crypto, Market.Coinbase)
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));

        // Sent insights on buying and holding the most liquid cryptos for one week.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Evenly dissipate the capital risk among selected cryptos.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}
```

C#

Universe Selection

Fundamental Universes

Introduction

A `FundamentalUniverseSelectionModel` selects a universe of US Equities based on `Fundamental` data. Depending on the `Fundamental` properties you use, these universes rely on the US Equity Coarse Universe dataset, the US Fundamental dataset, or both.

These types of universes operate on daily schedule by default. In backtests, they select assets at midnight. In live trading, the selection timing depends on the data provider you use. To adjust the selection schedule, see Schedule .

If you use a fundamental Universe Selection model, the only way to unsubscribe from a security is to return a list from the selection function that doesn't include the security `Symbol` . The `RemoveSecurity` method doesn't work with these types of Universe Selection models.

Fundamental Selection

The `FundamentalUniverseSelectionModel` lets you select stocks based on corporate `Fundamental` data. You can specific the selection method, which takes a list of `Fundamental` objects as argument and returns a list of `Symbol` objects.

C#

```
public override void Initialize()
{
    // Run asynchronous universe selection to speed up your algorithm.
    // In this case, you can't rely on the method or algorithm state between filter calls.
    UniverseSettings.Asynchronous = true;
    AddUniverseSelection(new FundamentalUniverseSelectionModel(FundamentalFilterFunction));
}

public override List<Symbol> FundamentalFilterFunction(List<Fundamental> fundamental)
{
    return (from f in fundamental
            // Select symbols with fundamental data and a price above $10.
            where f.Price > 10 && !Double.IsNaN(f.ValuationRatios.PERatio)
            // Sort the assets in ascending order by their P/E ratio.
            orderby f.ValuationRatios.PERatio
            // Select the first 10 assets.
            select f.Symbol).Take(10);
}
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`selector`	`Func<IEnumerable<Fundamental>, IEnumerable<Symbol>>`	Filter function to select assets based on fundamental data.	
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`null`

The `Fundamental` objects have the following properties:

To move the selection function outside of the algorithm class, create a universe selection model that inherits the `FundamentalUniverseSelectionModel` class and override its `Select` method.

```
C#

// In the Initialize method, enable asynchronous universe selection to speed up your algorithm.
UniverseSettings.Asynchronous = true;
// Add a custom universe selection model that selects undervalued, liquid stocks.
AddUniverseSelection(new LiquidAndLowPEUniverseSelectionModel());

// Outside of the algorithm class, define the universe selection model.
public class LiquidAndLowPEUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamental)
    {
        return fundamental
            // Select symbols with fundamental data and a price above $1.
            .Where(x => x.HasFundamentalData && x.Price > 1 && !Double.IsNaN(x.ValuationRatios.PERatio))
            // Select the 100 assets with the greatest daily dollar volume.
            .OrderByDescending(x => x.DollarVolume)
            .Take(100)
            // Select the 10 assets with the lowest PE ratio.
            .OrderByDescending(x => x.ValuationRatios.PERatio)
            .Take(10)
            .Select(x => x.Symbol);
    }
}
```

To return the current universe constituents from the selection function, return `Universe. Unchanged` .

For more information about this model, see the class reference and implementation .

EMA Cross Selection

The `EmaCrossUniverseSelectionModel` applies two exponential moving average (EMA) indicators to the price history of assets and then selects the assets that have their fast EMA furthest above their slow EMA on a percentage basis.

```
C#

// Initialize asynchronous universe settings for faster processing and add EmaCrossUniverseSelectionModel to
dynamically manage the universe based on EMA cross signals to identify trending assets.
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    AddUniverseSelection(new EmaCrossUniverseSelectionModel());
}
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fastPeriod`	`int`	Fast EMA period	100
`slowPeriod`	`int`	Slow EMA period	300
`universeCount`	`int`	Maximum number of members of this universe selection	500
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`null`

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing the framework fundamental universe model.

Example 1: 50 Stocks >10/Share and >10M in Daily Trading Volume

The following algorithm selects the 50 most liquid US Equities above 10/share and 10M daily volume. We pass a function to the `FundamentalUniverseSelectionModel` to filter the fundamental data for stock selection.

C#

```
public class FrameworkFundamentalUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 8);
        SetCash(100000);

        // Configure the universe to update at the start of each month. Most of the top 500 don't change very
frequently.
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        // Add a fundamental universe with custom selection rules for filtering.
        AddUniverseSelection(new FundamentalUniverseSelectionModel(fundamental =>
            (from f in fundamental
            //Large-cap non-penny stocks have more stable trends and demand.
            where f.Price > 10 && f.DollarVolume > 10000000
            orderby f.DollarVolume descending
            select f.Symbol).Take(500)
        ));

        // Sent insights on buying and holding the selected securities.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(30)));
        // Evenly dissipate the capital risk among selected securities.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}
```

Example 2: 10 Stocks Above Their 200-Day EMA With >$1B of Daily Trading Volume

Another common request is to filter the universe by a technical indicator, such as only picking stocks above their 200-day Exponential Moving Average (EMA). The `Fundamental` object has adjusted price and volume information so that you can do any price-related analysis. The following algorithm defines a separate class to contain the indicator of each asset. We pass a function to the `FundamentalUniverseSelectionModel` to filter the fundamental data for stock selection.

```C#
using System.Collections.Concurrent;

public class FrameworkFrameworkUniverseSelectionAlgorithm : QCAlgorithm
{
    // Create a concurrent dictionary to store the EMA data for universe selection.
    private ConcurrentDictionary<Symbol, SelectionData> _selectionDataBySymbol = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Add a fundamental universe with custom selection rules for filtering.
        AddUniverseSelection(new FundamentalUniverseSelectionModel(Selection));

        // Sent insights on buying and holding the selected securities.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));
        // Evenly dissipate the capital risk among selected securities.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> Selection(IEnumerable<Fundamental> fundamental)
    {
        return (from f in fundamental
            // Create/Update the EMA indicators of each stock.
            let avg = _selectionDataBySymbol.GetOrAdd(f.Symbol, sym => new SelectionData(this, f.Symbol, 200))
            where avg.Update(f.EndTime, f.AdjustedPrice)
            // Select the Equities above their EMA and have a daily volume of $1B.
            // These assets are in an uptrend and are very liquid.
            where avg.Ema.IsReady && f.Price > avg.Ema.Current.Value && f.DollarVolume > 1000000000
            // Select the 10 most liquid Equities to avoid extra slippage, and their trend can be capitalized more
efficiently.
            orderby f.DollarVolume descending
            select f.Symbol).Take(10);
    }
}

// Create a separate class to contain the EMA information of each asset.
public class SelectionData
{
    public readonly ExponentialMovingAverage Ema;

    // Create an EMA indicator for trend estimation and filtering.
    public SelectionData(QCAlgorithm algorithm, Symbol symbol, int period)
    {
        Ema = new ExponentialMovingAverage(period);

        // Warm up the EMA indicator.
        algorithm.WarmUpIndicator(symbol, Ema, Resolution.Daily);
    }

    // Update your variables and indicators with the latest data.
    // You may also want to use the History API here to warm up the indicator.
    public bool Update(DateTime time, decimal value)
    {
        return Ema.Update(time, value);
    }
}
```

In this example, the `SelectionData` class group variables for the universe selection and update the indicator of each asset. We highly recommend you follow this pattern to keep your algorithm tidy and bug-free. The following snippet shows an example implementation of the `SelectionData` class, but you can make whatever you need to store your custom universe filters. Note that the preceding `SelectionData` class uses a manual EMA indicator instead of the automatic version . For more information about universes that select assets based on indicators, see Indicator Universes . You need to use a `SelectionData` class instead of assigning the EMA to the `Fundamental` object because you can't create custom properties on `Fundamental` objects like you can with `Security` objects.

Example 3: 10 Stocks Furthest Above their 10-day SMA of Volume

The process to get the 10-day Simple Moving Average (SMA) stock volume is the same process as in Example 2. First, define a

`SelectionData` class that performs the averaging. This class tracks the ratio of today's volume relative to historical volumes. You can use this ratio to select assets above their 10-day SMA and sort the results by the Equities that have had the most significant jump since yesterday.

We inherit the `FundamentalUniverseSelectionModel` to create a custom universe selection model. Overriding the `Select` method, we filter the fundamental data for stocks selection.

```C#
using System.Collections.Concurrent;

public class FrameworkFrameworkUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Add a fundamental universe with custom selection rules for filtering.
        AddUniverseSelection(new VolumeSMAUniverseSelectionModel(10));

        // Sent insights on buying and holding the selected securities.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));
        // Evenly dissipate the capital risk among selected securities.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}

public class VolumeSMAUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    // Create a concurrent dictionary to store the EMA data for universe selection.
    private ConcurrentDictionary<Symbol, SelectionData> _selectionDataBySymbol = new();
    private int _period;

    public VolumeSMAUniverseSelectionModel(int period)
        : base()
    {
        _period = period;
    }

    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamental)
    {
        return (from f in fundamental
            // Create/Update the volume SMA indicator of each stock.
            let avg = _selectionDataBySymbol.GetOrAdd(f.Symbol, sym => new SelectionData(algorithm, f.Symbol,
_period))
            where avg.Update(f.EndTime, f.Volume)
            // Select the Equities with higher trading volume than their SMA, indicating higher capital flow.
            where avg.VolumeRatio > 1
            // Select the 10 Equities with the highest relative volume since they have the highest capacity
            // for scalp-trading or intra-day movement.
            orderby avg.VolumeRatio descending
            select f.Symbol).Take(10);
    }

    // Define a separate class to contain and calculate the SMA of each Equity.
    private class SelectionData
    {
        public readonly Symbol Symbol;
        public readonly SimpleMovingAverage VolumeSma;
        public decimal VolumeRatio;

        public SelectionData(QCAlgorithm algorithm, Symbol symbol, int period)
        {
            // Create an SMA of volume to track the popularity of the stock.
            Symbol = symbol;
            VolumeSma = new SimpleMovingAverage(period);

            // Warm up the volume SMA indicator.
            algorithm.WarmUpIndicator(symbol, VolumeSma, Resolution.Daily, (data) => (data as TradeBar).Volume);
        }

        public bool Update(DateTime time, decimal value)
        {
            // Update the SMA with today's data and calculate the relative volume position for filtering.
            var ready = VolumeSma.Update(time, value);
```

```
            var sma = VolumeSma.Current.Value;
            if (sma > 0)
            {
                VolumeRatio = value / VolumeSma.Current.Value;
                return ready;
            }
            return false;
        }
    }
}
```

Example 4: 10 "Fastest Moving" Stocks With a 50-Day EMA > 200 Day EMA

You can construct complex universe filters with the `SelectionData` helper class pattern. To view a full example of this algorithm, see the EmaCrossUniverseSelectionAlgorithm in the LEAN GitHub repository or take the related Boot Camp lesson .

C#

```
using System.Collections.Concurrent;

public class FrameworkFrameworkUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Add a fundamental universe with custom selection rules for filtering.
        AddUniverseSelection(new EmaUniverseSelectionModel(10));

        // Sent insights on buying and holding the selected securities.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));
        // Evenly dissipate the capital risk among selected securities.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}

public class EmaUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    // tolerance to prevent bouncing
    const decimal Tolerance = 0.01m;
    // Create a concurrent dictionary to store the indicator data for universe selection.
    private ConcurrentDictionary<Symbol, SelectionData> _averages = new();
    private int _selectionNumber;

    public EmaUniverseSelectionModel(int selectionNumber = 10)
        : base()
    {
        _selectionNumber = selectionNumber;
    }

    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamental)
    {
        return (from f in fundamental
            // Grab the SelectionData instance for this symbol
            let avg = _averages.GetOrAdd(f.Symbol, sym => new SelectionData(algorithm, f.Symbol))
            // Update returns true when the indicators are ready, so don't accept until they are
            where avg.Update(f.EndTime, f.AdjustedPrice)
            //Only pick symbols that have their 50-day ema over their 100-day ema
            where avg.Fast > avg.Slow * (1 + Tolerance)
            // prefer symbols with a larger delta by percentage between the two averages
            orderby avg.ScaledDelta descending
            // We only need to return the symbol and return selectionNumber symbols
            select f.Symbol).Take(_selectionNumber);
    }

    // class used to improve the readability of the coarse selection function
    private class SelectionData
    {
        public readonly ExponentialMovingAverage Fast;
        public readonly ExponentialMovingAverage Slow;

        public SelectionData(QCAlgorithm algorithm, Symbol symbol)
        {
            Fast = new ExponentialMovingAverage(100);
            Slow = new ExponentialMovingAverage(300);
```

```
            // Warm up the indicators.
            algorithm.WarmUpIndicator(symbol, Fast, Resolution.Daily);
            algorithm.WarmUpIndicator(symbol, Slow, Resolution.Daily);
        }

        // computes an object score of how large the fast is than the slow
        public decimal ScaledDelta
        {
            get { return (Fast - Slow)/((Fast + Slow)/2m); }
        }

        // updates the EMA50 and EMA100 indicators, returning true when they're both ready
        public bool Update(DateTime time, decimal value)
        {
            return Fast.Update(time, value) && Slow.Update(time, value);
        }
    }
}
```

Universe Selection

ETF Constituents Universes

Introduction

The `ETFConstituentsUniverseSelectionModel` selects a universe of US Equities based on the constituents of an ETF. These Universe Selection models rely on the US ETF Constituents dataset. They run on a daily schedule by default. To adjust the selection schedule, see Schedule .

Add ETF Constituents Universe Selection

To add an `ETFConstituentsUniverseSelectionModel` to your algorithm, in the `Initialize` method, call the `AddUniverseSelection` method. The `ETFConstituentsUniverseSelectionModel` constructor expects an ETF ticker.

```
C#
// Run universe selection asynchronously to speed up your algorithm.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new ETFConstituentsUniverseSelectionModel("SPY"));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`etfTicker`	`string`	Ticker of the ETF to get constituents for. To view the available ETFs, see Supported ETFs .	
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	
`universeFilterFunc`	`Func<IEnumerable<ETFConstituentUniverse>, IEnumerable<Symbol>>`	Function to filter ETF constituents. If you don't provide an argument, the model selects all of the ETF constituents by default.	`null`

If you provide a `universeFilterFunc` argument, you can use the following attributes of the `ETFConstituentUniverse` objects to select your universe:

The following example shows how to select the 10 Equities with the largest weight in the SPY ETF:

```C#
// Initialize asynchronous settings for speed and use the ETFConstituentsUniverseSelectionModel
// to select the top 10 SPY constituents by weight, focusing on blue-chip stocks with minimal risk.
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    AddUniverseSelection(
        new ETFConstituentsUniverseSelectionModel("SPY", universeFilterFunc: ETFConstituentsFilter)
    );
}

private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
{
    // Select the 10 largest Equities in the ETF.
    return constituents.OrderByDescending(c => c.Weight).Take(10).Select(c => c.Symbol);
}
```

To move the ETF `Symbol` and the selection function outside of the algorithm class, create a universe selection model that inherits the `ETFConstituentsUniverseSelectionModel` class.

```C#
// Initialize asynchronous settings for speed and use the LargestWeightSPYETFUniverseSelectionModel
// to select the top 10 blue-chip SPY constituents by weight, focusing on stocks with minimal risk.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new LargestWeightSPYETFUniverseSelectionModel());

// Outside of the algorithm class
class LargestWeightSPYETFUniverseSelectionModel : ETFConstituentsUniverseSelectionModel
{
    public LargestWeightSPYETFUniverseSelectionModel(UniverseSettings universeSettings = null)
        : base("SPY", universeFilterFunc: ETFConstituentsFilter)
    {
    }

    private static IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Select the 10 largest Equities in the ETF.
        return constituents.OrderByDescending(c => c.Weight).Take(10).Select(c => c.Symbol);
    }
}
```

To return the current universe constituents from the selection function, return `Universe. Unchanged` .

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing the framework ETF constituent universe selection model.

Example 1: Weighted ETF Constituents

A subset of the SPY constituents outperform the SPY while many underperform the overall index. In an attempt to buy the ETF constituents that outperform the index, the following algorithm buys the top 50 weighted assets in the ETF. In this example, we will pass a function to the `ETFConstituentsUniverseSelectionModel` for selection.

C#

```
public class FrameworkETFConstituentsUniverseSelectionAlgorithm : QCAlgorithm
{
    public Dictionary<Symbol, double> EtfWeightBySymbol { get; set; } = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);

        // Add a universe of the SPY constituents.
        AddUniverseSelection(
            new ETFConstituentsUniverseSelectionModel("SPY", universeFilterFunc: ETFConstituentsFilter)
        );
        // Add an Alpha model to trade based on the constituent weights.
        AddAlpha(new EtfAlphaModel(this));
        // Position sizing was handled by insight weight (from ETF weight).
        SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Cache the constituent weights in a dictionary for filtering and position sizing.
        EtfWeightBySymbol = constituents
            .Where(c => c.Weight.HasValue)
            .ToDictionary(c => c.Symbol, c => (double)c.Weight.Value);
        // Select the 50 constituents with the largest weight in the ETF.
        // They should have positive excess return.
        return EtfWeightBySymbol
            .OrderByDescending(x => x.Value)
            .Take(50)
            .Select(x => x.Key);
    }
}

public class EtfAlphaModel : AlphaModel
{
    private FrameworkETFConstituentsUniverseSelectionAlgorithm _algorithm;
    private static int _day = -1;

    public EtfAlphaModel(FrameworkETFConstituentsUniverseSelectionAlgorithm algorithm)
    {
        _algorithm = algorithm;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        // Daily rebalance only.
        if (slice.Time.Day == _day)
        {
            return insights;
        }

        foreach (var (symbol, weight) in _algorithm.EtfWeightBySymbol)
        {
            // Get the ETF weight of all the assets currently in the universe.
            // To avoid trading errors, skip assets that have no price yet.
            if (slice.Bars.ContainsKey(symbol))
            {
                if (algorithm.Securities[symbol].Price == 0)
                {
                    continue;
                }
                insights.Add(Insight.Price(symbol, TimeSpan.FromDays(1), InsightDirection.Up, weight: weight));
            }
        }

        _day = slice.Time.Day;

        return insights;
    }
}
```

Example 2: Weight Trend Selection

The following algorithm trades the QQQ constituents with the upward trend of its weight constitution, indicated by an EMA indicator, suggesting its price trend is outperforming other constituents, or its weight was promoted by the NASDAQ index, which brings positive sentiment. To better utilize the EMA indicator, we inherit the `ETFConstituentsUniverseSelectionModel` superclass to create a custom universe selection model.

C#

```
public class FrameworkETFConstituentsUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);

        // Add a universe of the SPY constituents.
        AddUniverseSelection(
            new UptrendETFUniverseSelectionModel("QQQ")
        );
        // Add Alpha model to trade based on the selections.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));
        // Equally invest in insights to dissipate the capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        // Warm up the indicators.
        SetWarmUp(60, Resolution.Daily);
    }
}

class UptrendETFUniverseSelectionModel : ETFConstituentsUniverseSelectionModel
{
    private static Dictionary<Symbol, ExponentialMovingAverage> _emaBySymbol = new();

    public UptrendETFUniverseSelectionModel(string etfTicker)
        : base(etfTicker, universeFilterFunc: ETFConstituentsFilter)
    {
    }

    private static IEnumerable<Symbol> ETFConstituentsFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Remove the ones that are not in the ETF anymore.
        var toRemove = new HashSet<Symbol>(constituents.Select(x => x.Symbol).Except(_emaBySymbol.Keys));
        foreach (var symbol in toRemove)
        {
            _emaBySymbol.Remove(symbol);
        }

        foreach (var c in constituents)
        {
            if (_emaBySymbol.TryGetValue(c.Symbol, out var ema) && c.Weight.HasValue)
            {
                // Update EMA with the latest weight.
                ema.Update(c.EndTime, c.Weight.Value);
            }
            else
            {
                // Create an EMA to filter by trend.
                _emaBySymbol[c.Symbol] = new ExponentialMovingAverage(60);
            }
        }

        // Select the ones with the increasing trend of constituent weight.
        return _emaBySymbol.Where(kvp => kvp.Value.IsReady && kvp.Value > kvp.Value.Previous)
            .Select(kvp => kvp.Key);
    }
}
```

Universe Selection

Scheduled Universes

Introduction

A Scheduled Universe Selection model selects assets at fixed, regular intervals. In live trading, you can use this type of model to fetch tickers from Dropbox or to perform periodic historical analysis and select some assets.

Scheduled Universe Selection

The `ScheduledUniverseSelectionModel` selects assets on the schedule you provide. To use this model, provide a `DateRule` , `TimeRule` , and a selector function. The `DateRule` and `TimeRule` define the selection schedule. The selector function receives a `DateTime` object and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the constituents of the universe.

```C#
// Enable asynchronous universe selection to speed up your algorithm.
UniverseSettings.Asynchronous = true;
// Add a universe that selects assets at the beginning of each month.
AddUniverseSelection(
    new ScheduledUniverseSelectionModel(
        DateRules.MonthStart(),
        TimeRules.Midnight,
        // Select SPY for October. Otherwise, select QQQ.
        dt => new List<Symbol> {
            QuantConnect.Symbol.Create(dt.Month == 10 ? "SPY" : "QQQ", SecurityType.Equity, Market.USA)
        }
    )
);
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`dateRule`	`IDateRule`	Date rule defines what days the universe selection function will be invoked	
`timeRule`	`ITimeRule`	Time rule defines what times on each day selected by date rule the universe selection function will be invoked	
`selector`	`Func<DateTime, IEnumerable<Symbol>>`	Selector function accepting the date time firing time and returning the universe selected symbols	
`settings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`null`

The model assumes the `timeRule` argument is in Coordinated Universal Time (UTC). To use a different timezone, pass a `timeZone` argument of type `DateTimeZone` before the `dateRule` argument.

To return the current universe constituents from the selector function, return `Universe. Unchanged` .

```C#
// Add a universe that selects assets on Monday, Tuesday, and Thursday at 00:00, 06:00, 12:00, and 18:00 UTC.
AddUniverseSelection(new ScheduledUniverseSelectionModel(
    DateRules.Every(DayOfWeek.Monday, DayOfWeek.Tuesday, DayOfWeek.Thursday),
    TimeRules.Every(TimeSpan.FromHours(6)),
    SelectSymbols
));

// Define the selection function.
private IEnumerable<Symbol> SelectSymbols(DateTime dateTime)
{
    var tickers = new[] {"SPY", "AAPL", "IBM"};
    return tickers.Select(ticker =>
        QuantConnect.Symbol.Create(ticker, SecurityType.Equity, Market.USA));
}
```

For more information about this model, see the class reference and implementation .

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`DateRules.SetDefaultTimeZone(DateTimeZone timeZone);`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`DateRules.On(int year, int month, int day)`	Trigger an event on a specific date.
`DateRules.On(params DateTime[] dates)`	Trigger an event on specific dates.
`DateRules.EveryDay()`	Trigger an event all seven days of the week.
`DateRules.EveryDay(Symbol symbol, bool extendedMarketHours = false)`	Trigger an event every day a specific symbol is trading.
`DateRules.Every(params DayOfWeek[] days)`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`DateRules.MonthStart(int daysOffset = 0)`	Trigger an event on the first day of each month plus an offset.
`DateRules.MonthStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`DateRules.MonthEnd(int daysOffset = 0)`	Trigger an event on the last day of each month minus an offset.
`DateRules.MonthEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`DateRules.WeekStart(int daysOffset = 0)`	Trigger an event on the first day of each week plus an offset.
`DateRules.WeekStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`DateRules.WeekEnd(int daysOffset = 0)`	Trigger an event on the last day of each week minus an offset.
`DateRules.WeekEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`DateRules.YearStart(int daysOffset = 0)`	Trigger an event on the first day of each year plus an offset.
`DateRules.YearStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`DateRules.YearEnd(int daysOffset = 0)`	Trigger an event on the last day of each year minus an offset.
`DateRules.YearEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`DateRules.Today`	Trigger an event once today.
`DateRules.Tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `string` and a `getDatesFunction` argument of type `Func<DateTime, DateTime, IEnumerable<DateTime>>` . The `getDatesFunction` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```
C#
// Create a date rule that specifies the 10th day of each month.
var dateRule = new FuncDateRule(
    name: "10th_day_of_the_month",
    getDatesFunction: (start, end) => Enumerable.Range(start.Year, end.Year - start.Year + 1)
        .SelectMany(year => Enumerable.Range(1, 12).Select(month => new DateTime(year, month, 10)))
);
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `DateRules.EveryDay("ES")` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```
C#
var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`TimeRules.SetDefaultTimeZone(DateTimeZone timeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`TimeRules.BeforeMarketOpen(Symbol symbol, double minutesBeforeOpen = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes before market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.AfterMarketOpen(Symbol symbol, double minutesAfterOpen = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.BeforeMarketClose(Symbol symbol, double minutesBeforeClose = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.AfterMarketClose(Symbol symbol, double minutesAfterClose = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes after market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.Every(TimeSpan interval)`	Trigger an event every period interval starting at midnight. This time rule triggers every period, regardless of whether or not the market is open.
`TimeRules.Now`	Trigger an event at the current time of day.
`TimeRules.Midnight`	Trigger an event at midnight.
`TimeRules.Noon`	Trigger an event at noon.
`TimeRules.At(int hour, int minute, int second = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`TimeRules.At(int hour, int minute, int second, DateTimeZone timeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

To define custom time rules, create a `FuncTimeRule` object. The `FuncTimeRule` constructor expects a `name` argument of type `string` and a `createUtcEventTimesFunction` argument of type `Func<IEnumerable<DateTime>, IEnumerable<DateTime>>` . The function receives the list of dates from the date rule and then returns a list of `DateTime` that define the time rule.

```
C#
var timeRule = new FuncTimeRule(
    name: "CustomTimeRule",
    createUtcEventTimesFunction: dates => dates.Select(d => d.AddHours(10)));
```

Some time rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `TimeRules.BeforeMarketOpen("ES", 15)` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```
C#
var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

Examples

The following examples demonstrate some common practices for implementing a dateless scheduled universe selection model.

Example 1: From External Source

The following example selects its universe every week starting before the market opens from a source URL of Dropbox. It reloads on every selection so that you can hook up to the continuously updating source file.

C#

```
public class FrameworkScheduledUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);

        // Add a universe of that read from a Dropbox source to select the stocks 30 minutes before the week's first
trading day.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        AddUniverseSelection(new ScheduledUniverseSelectionModel(
            DateRules.WeekStart(spy),
            TimeRules.BeforeMarketOpen(spy, 10),
            SelectSymbols)
        );
        // Add Alpha model to trade based on the selections; the signals last for a week until the next selection.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Equally invest in insights to dissipate the capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private string DownloadUniverseFile(DateTime dt)
    {
        // Download the universe CSV file. Dropbox links require the "dl=1" URL parameter.
        var file = Download(
            "https://www.dropbox.com/scl/fi/fbrxitk4ec3w91nse1raa/df.csv?
rlkey=7r042rukzkthp7y1srloyhkov&st=5r4sdfwd&dl=1"
        );
        // Convert the CSV file data into a dictionary where the key is the date and
        // the value is a comma-separated string of stock tickers.
        foreach (var line in file.Split('\n').Skip(1))
        {
            // Skip empty lines.
            if (line.IsNullOrEmpty())
            {
                continue;
            }
            var items = line.Split("\"");
            var date = Parse.DateTimeExact(items[0].Split(",")[0], "yyyy-MM-dd").Date;
            // Return the universe if the date matches.
            if (date == dt.Date)
            {
                return items[1];
            }
        }
        return string.Empty;
    }

    private IEnumerable<Symbol> SelectSymbols(DateTime dt)
    {
        // Re-download the CSV file each day to get today's row.
        var tickers = DownloadUniverseFile(dt);
        // If there isn't an entry for the current date, return an empty universe.
        if (tickers.IsNullOrEmpty())
        {
            return Enumerable.Empty<Symbol>();
        }
        // Convert the stock tickers in the CSV file to Symbol objects.
        return tickers
            .Split(',')
            .Select(x => QuantConnect.Symbol.Create(x, SecurityType.Equity, Market.USA));
    }
}
```

Example 2: Seasonality

The following algorithm selects between SPY and short-term bond ETF according to the current month. It holds SPY on May, June, July, November, and December since they are historically better-performing months while holding SHV to preserve funds and earn interest in the remaining months.

```C#
public class FrameworkScheduledUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add a universe of that select based on the time to trade seasonality.
        AddUniverseSelection(new ScheduledUniverseSelectionModel(
            DateRules.WeekStart(),
            TimeRules.At(0, 0),
            SelectSymbols)
        );
        // Add an Alpha model to trade based on the selections; the signals will last until the next selection.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Equally invest in insights to dissipate the capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> SelectSymbols(DateTime dateTime)
    {
        // May/Jun/Jul/Nov/Dec are statistically better-performing months of SPY.
        if (new[] { 5, 6, 7, 11, 12 }.Contains(dateTime.Month))
        {
            return new[] { QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA) };
        }
        // In other months, hold short-term bonds to preserve funds while earning interest.
        return new[] { QuantConnect.Symbol.Create("SHV", SecurityType.Equity, Market.USA) };
    }
}
```

Universe Selection

Futures Universes

Introduction

A Future Universe Selection model selects contracts for a set of Futures.

Future Universe Selection

The `FutureUniverseSelectionModel` selects all the contracts for a set of Futures you specify. To use this model, provide a `refreshInterval` and a selector function. The `refreshInterval` defines how frequently LEAN calls the selector function. The selector function receives a `DateTime` object that represents the current Coordinated Universal Time (UTC) and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the Futures of the universe.

```
C#
// Run universe selection asynchronously to speed up your algorithm.
// This setting means you cannot rely on the method or algorithm state between filter calls.
UniverseSettings.Asynchronous = true;
// Add a universe of E-mini S&P 500 Futures contracts.
AddUniverseSelection(
    new FutureUniverseSelectionModel(
        // Refresh the universe daily.
        TimeSpan.FromDays(1),
        _ => new List<Symbol> {{ QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future,
Market.CME) }}
    )
);
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`refreshInterval`	`TimeSpan`	Time interval between universe refreshes	
`futureChainSymbolSelector`	`Func<DateTime, IEnumerable<Symbol>>`	A function that selects the Future symbols for a given Coordinated Universal Time (UTC). To view the supported assets in the US Futures dataset, see Supported Assets .	
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`null`

The following example shows how to define the Future chain Symbol selector as an isolated method:

```C#
// In the Initialize method, add the FutureUniverseSelectionModel with a custom selection function.
public override void Initialize()
{
    AddUniverseSelection(
        new FutureUniverseSelectionModel(TimeSpan.FromDays(1), SelectFutureChainSymbols)
    );
}

private static IEnumerable<Symbol> SelectFutureChainSymbols(DateTime utcTime)
{
    // Add E-mini S&P 500 and Gold Futures to the universe.
    return new[] {
        QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME),
        QuantConnect.Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX)
    };
}
```

This model uses the default Future contract filter, which doesn't select any Futures contracts. To use a different filter, subclass the `FutureUniverseSelectionModel` and define a `Filter` method. The `Filter` method accepts and returns a `FutureFilterUniverse` object to select the Futures contracts. The following table describes the filter methods of the `FutureFilterUniverse` class:

`StandardsOnly()`	Selects standard contracts
`FrontMonth()`	Selects the front month contract
`BackMonths()`	Selects the non-front month contracts
`BackMonth()`	Selects the back month contracts
`Expiration(TimeSpan minExpiry, TimeSpan maxExpiry)`	Selects contracts that expire within a range of dates relative to the current day
`Expiration(int minExpiryDays, int maxExpiryDays)`	Selects contracts that expire within a range of dates relative to the current day
`Contracts(IEnumerable<Symbol> contracts)`	Selects a list of contracts
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)`	Selects contracts that a selector function selects

The contract filter runs at the first time step of each day.

To move the Future chain Symbol selector and the contract selection function outside of the algorithm class, create a universe selection model that inherits the FundamentalUniverseSelectionModel class and override its Select method.

```
C#
// In the Initialize method, define the universe settings and add data.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new FrontMonthFutureUniverseSelectionModel());

// Outside of the algorithm class, define the universe selection model.
class FrontMonthFutureUniverseSelectionModel : FutureUniverseSelectionModel
{
    public FrontMonthFutureUniverseSelectionModel()
        // Refresh the universe daily.
        : base(TimeSpan.FromDays(1), SelectFutureChainSymbols) {}

    private static IEnumerable<Symbol> SelectFutureChainSymbols(DateTime utcTime)
    {
        // Add E-mini S&P 500 and Gold Futures to the universe.
        return new List<Symbol> {
            QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME),
            QuantConnect.Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX)
        };
    }

    protected override FutureFilterUniverse Filter(FutureFilterUniverse filter)
    {
        // Select the front month contracts.
        return filter.FrontMonth();
    }
}
```

Some of the preceding filter methods only set an internal enumeration in the `FutureFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `FutureFilterUniverse` .

The `AddUniverseSelection` method doesn't return a `Future` object like the AddFuture method. The `Future` object contains `Symbol` and `Mapped` properties, which reference the continuous contract and the currently selected contract in the continuous contract series, respectively. To get the `Future` object, define the `OnSecuritiesChanged` method in your algorithm class or framework models and check the result of the `IsCanonical` method.

```
C#
// Save the Future object if the security added to the universe is the canonical asset.
public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
{
    foreach (var security in changes.AddedSecurities)
    {
        if (security.Symbol.IsCanonical() && security.Type == SecurityType.Future)
        {
            _future = security as Future;
        }
    }
}
```

For more information about this model, see the class reference and implementation .

Open Interest Future Universe Selection

The `OpenInterestFutureUniverseSelectionModel` is an extension of the `FutureUniverseSelectionModel` that selects the contract with the greatest open interest on a daily basis.

```
// Enable asynchronous universe settings for faster performance.
UniverseSettings.Asynchronous = true;
// Add an OpenInterestFutureUniverseSelectionModel for E-mini S&P 500 Futures, incorporating contracts with high
// open interest into the trading universe.
AddUniverseSelection(
    new OpenInterestFutureUniverseSelectionModel(
        this,
        utcTime => new[] { QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME) }
    )
);
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`algorithm`	`IAlgorithm`	Algorithm	
`futureChainSymbolSelector`	`Func<DateTime, IEnumerable<Symbol>>`	A function that selects the Future symbols for a given Coordinated Universal Time (UTC). To view the supported assets in the US Futures dataset, see Supported Assets .	
`chainContractsLookupLimit`	`int?`	Limit on how many contracts to query for open interest	6
`resultsLimit`	`int?`	Limit on how many contracts will be part of the universe	1

The following example shows how to define the Future chain Symbol selector as an isolated method:

```
// In the Initialize method, define the universe settings and add a universe.
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    AddUniverseSelection(
        new OpenInterestFutureUniverseSelectionModel(this, SelectFutureChainSymbols)
    );
}

// Define the selection function, which returns Symbol objects.
private static IEnumerable<Symbol> SelectFutureChainSymbols(DateTime utcTime)
{
    return new[] {
        QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME),
        QuantConnect.Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX)
    };
}
```

To move the Future chain Symbol selector outside of the algorithm class, create a universe selection model that inherits the `OpenInterestFutureUniverseSelectionModel` class.

```C#
// In the Initialize method, define the universe settings and add a universe.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new GoldOpenInterestFutureUniverseSelectionModel(this));

// Outside of the algorithm class, define the universe selection model.
class GoldOpenInterestFutureUniverseSelectionModel : OpenInterestFutureUniverseSelectionModel
{
    public GoldOpenInterestFutureUniverseSelectionModel(QCAlgorithm algorithm,
        int? chainContractsLookupLimit = 6, int? resultsLimit = 1)
        : base(algorithm, SelectFutureChainSymbols, chainContractsLookupLimit, resultsLimit) {}

    private static IEnumerable<Symbol> SelectFutureChainSymbols(DateTime utcTime)
    {
        return new List<Symbol> {
            QuantConnect.Symbol.Create(Futures.Metals.Gold, SecurityType.Future, Market.COMEX)
        };
    }
}
```

The `AddUniverseSelection` method doesn't return a `Future` object like the AddFuture method. The `Future` object contains `Symbol` and `Mapped` properties, which reference the continuous contract and the currently selected contract in the continuous contract series, respectively. To get the `Future` object, define the `OnSecuritiesChanged` method in your algorithm class or framework models and check the result of the `IsCanonical` method.

```C#
// Save the Future object if the security added to the universe is the canonical asset.
public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
{
    foreach (var security in changes.AddedSecurities)
    {
        if (security.Symbol.IsCanonical() && security.Type == SecurityType.Future)
        {
            _future = security as Future;
        }
    }
}
```

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing a Futures universe selection model.

Example 1: Front Month Contracts

The following algorithm selects a list of Futures to buy and hold equally. To ensure liquidity and efficiency, we will select only their front-month contracts. We can do so in the algorithm framework through a child class inheriting the `FutureUniverseSelectionModel` while providing the list of Futures and overriding the `Filter` method to select the front month contracts.

```C#
public class FrameworkFutureUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // It is usual to trade Futures during extended market hours.
        UniverseSettings.ExtendedMarketHours = true;
        // Add a fundamental universe with custom selection rules for filtering.
        AddUniverseSelection(new FrontMonthFutureUniverseSelectionModel(10));

        // Sent insights on buying and holding the selected securities.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));
        // Evenly dissipate the capital risk among selected securities.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private class FrontMonthFutureUniverseSelectionModel : FutureUniverseSelectionModel
    {
        /// Creates futures chain universes that select the front-month contract and run a user-defined
        /// futureChainSymbolSelector every day to enable choosing different futures chains
        public FrontMonthFutureUniverseSelectionModel(int rebalancePeriod)
            : base(TimeSpan.FromDays(rebalancePeriod), SelectFutureChainSymbols)
        {
        }

        protected override FutureFilterUniverse Filter(FutureFilterUniverse filter)
        {
            // Defines the futures chain universe filter to select only the front-month contracts at market open.
            return filter.FrontMonth();
        }

        private static IEnumerable<Symbol> SelectFutureChainSymbols(DateTime utcTime)
        {
            return [
                QuantConnect.Symbol.Create(Futures.Indices.VIX, SecurityType.Future, Market.CFE),
                QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME),
                QuantConnect.Symbol.Create(Futures.Indices.NASDAQ100EMini, SecurityType.Future, Market.CME),
                QuantConnect.Symbol.Create(Futures.Indices.Dow30EMini, SecurityType.Future, Market.CBOT),
                QuantConnect.Symbol.Create(Futures.Energy.Gasoline, SecurityType.Future, Market.NYMEX),
                QuantConnect.Symbol.Create(Futures.Energy.HeatingOil, SecurityType.Future, Market.NYMEX),
                QuantConnect.Symbol.Create(Futures.Energy.NaturalGas, SecurityType.Future, Market.NYMEX),
                QuantConnect.Symbol.Create(Futures.Grains.Corn, SecurityType.Future, Market.CBOT),
                QuantConnect.Symbol.Create(Futures.Grains.Oats, SecurityType.Future, Market.CBOT),
                QuantConnect.Symbol.Create(Futures.Grains.Soybeans, SecurityType.Future, Market.CBOT),
                QuantConnect.Symbol.Create(Futures.Grains.Wheat, SecurityType.Future, Market.CBOT),
            ];
        }
    }
}
```

Example 2: Seasonal Contracts

Some Futures exhibit a seasonality effect, i.e., a yearly cycle in its price fluctuation. Studies show that the Natural Gas contract has a yearly cycle of maximizing its price in early December and minimizing it in early April. It might be due to the high demand for natural gas during winter warming. The following algorithm will hold Natural Gas contracts from summer to winter with a similar universe selection model in Example 1, but using a custom selection function with a time argument to select the contract.

C#

```
public class FrameworkFutureUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // It is usual to trade Futures during extended market hours.
        UniverseSettings.ExtendedMarketHours = true;
        // We hold the Future and will not frequently trade it; Daily resolution is sufficient for computational
efficiency.
        UniverseSettings.Resolution = Resolution.Daily;
        // Add a fundamental universe with custom selection rules for filtering.
        // Rescan every week to ensure we are on our plan.
        AddUniverseSelection(new FrontMonthFutureUniverseSelectionModel(7));

        // Sent insights on buying and holding the selected securities.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Place orders for a single contract to control risk exposure and avoid over-leveraging.
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }

    private class FrontMonthFutureUniverseSelectionModel : FutureUniverseSelectionModel
    {
        /// Creates futures chain universes that select the front-month contract and run a user-defined
        /// futureChainSymbolSelector every day to enable choosing different futures chains
        public FrontMonthFutureUniverseSelectionModel(int rebalancePeriod)
            : base(TimeSpan.FromDays(rebalancePeriod), SelectFutureChainSymbols)
        {
        }

        protected override FutureFilterUniverse Filter(FutureFilterUniverse filter)
        {
            // Defines the futures chain universe filter to select only the front-month contracts at market open.
            return filter.FrontMonth();
        }

        private static IEnumerable<Symbol> SelectFutureChainSymbols(DateTime utcTime)
        {
            // We hold Natural Gas from summer to winter since it is in an upward cycle.
            if (utcTime.Month >= 4 && utcTime.Month <= 11)
            {
                return [ QuantConnect.Symbol.Create(Futures.Energy.NaturalGas, SecurityType.Future, Market.NYMEX) ];
            }
            // We do not hold any contracts during the time of the downward cycle.
            return [];
        }
    }

    private class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
    {
        public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
        {
            var targets = new List<PortfolioTarget>();
            foreach (var insight in insights)
            {
                if (algorithm.Securities[insight.Symbol].IsTradable)
                {
                    // Use integer target to create a portfolio target to trade a single contract
                    targets.Add(new PortfolioTarget(insight.Symbol, (int) insight.Direction));
                }
            }
            return targets;
        }
    }
}
```

Universe Selection

Options Universes

Introduction

An Option Universe Selection model selects contracts for a set of Options.

Options Universe Selection

The `OptionUniverseSelectionModel` selects all the available contracts for the Equity Options, Index Options, and Future Options you specify. To use this model, provide a `refreshInterval` and a selector function. The `refreshInterval` defines how frequently LEAN calls the selector function. The selector function receives a `DateTime` object that represents the current Coordinated Universal Time (UTC) and returns a list of `Symbol` objects. The `Symbol` objects you return from the selector function are the Options of the universe.

```
C#
// Run universe selection asynchronously to speed up your algorithm.
// In this case, you can't rely on the method or algorithm state between filter calls.
UniverseSettings.Asynchronous = true;
// Add a universe of SPY Options.
AddUniverseSelection(
    new OptionUniverseSelectionModel(
        // Refresh the universe daily.
        TimeSpan.FromDays(1),
        _ => new [] { QuantConnect.Symbol.Create("SPY", SecurityType.Option, Market.USA) }
    )
);
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`refreshInterval`	`TimeSpan`	Time interval between universe refreshes	
`optionChainSymbolSelector`	`Func<DateTime, IEnumerable<Symbol>>`	A function that selects the Option symbols	
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`null`

The following example shows how to define the Option chain Symbol selector as an isolated method:

```C#
// In the Initialize method, add the OptionUniverseSelectionModel with a custom selection function.
public override void Initialize()
{
    AddUniverseSelection(
        new OptionUniverseSelectionModel(TimeSpan.FromDays(1), SelectOptionChainSymbols)
    );
}

// Define the selection function.
private IEnumerable<Symbol> SelectOptionChainSymbols(DateTime utcTime)
{
    // Equity Options example:
    //var tickers = new[] {"SPY", "QQQ", "TLT"};
    //return tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.Option, Market.USA));

    // Index Options example:
    //var tickers = new[] {"VIX", "SPX"};
    //return tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.IndexOption, Market.USA));

    // Future Options example:
    var futureSymbol = QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME);
    foreach (var contract in FuturesChain(futureSymbol))
    {
        yield return QuantConnect.Symbol.CreateCanonicalOption(contract.Symbol);
    }
}
```

This model uses the default Option filter, which selects all of the available Option contracts at the current time step. To use a different filter for the contracts, subclass the `OptionUniverseSelectionModel` and define a `Filter filter` method. The `Filter filter` method accepts and returns an `OptionFilterUniverse` object to select the Option contracts. The following table describes the methods of the `OptionFilterUniverse` class:

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.
`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.
`StandardsOnly()` Selects standard contracts.
`IncludeWeeklys()` Selects non-standard weeklys contracts.
`WeeklysOnly()` Selects weekly contracts.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.
`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse`, so you can chain the methods together.

The contract filter runs at the first time step of each day.

To move the Option chain Symbol selector outside of the algorithm class, create a universe selection model that inherits the `OptionUniverseSelectionModel` class.

```
C#
// In the Initialize method, define the universe settings and add data.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new EarliestExpiringAtTheMoneyCallOptionUniverseSelectionModel(this));

// Outside of the algorithm class, define the universe selection model.
class EarliestExpiringAtTheMoneyCallOptionUniverseSelectionModel : OptionUniverseSelectionModel
{
    public EarliestExpiringAtTheMoneyCallOptionUniverseSelectionModel(QCAlgorithm algorithm)
            : base(TimeSpan.FromDays(1), utcTime => SelectOptionChainSymbols(algorithm, utcTime)) {}

    private static IEnumerable<Symbol> SelectOptionChainSymbols(QCAlgorithm algorithm, DateTime utcTime)
    {
        // Equity Options example:
        //var tickers = new[] {"SPY", "QQQ", "TLT"};
        //return tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.Option, Market.USA));

        // Index Options example:
        //var tickers = new[] {"VIX", "SPX"};
        //return tickers.Select(ticker => QuantConnect.Symbol.Create(ticker, SecurityType.IndexOption, Market.USA));

        // Future Options example:
        var futureSymbol = QuantConnect.Symbol.Create(Futures.Indices.SP500EMini, SecurityType.Future, Market.CME);
        foreach (var contract in algorithm.FuturesChain(futureSymbol))
        {
            yield return QuantConnect.Symbol.CreateCanonicalOption(contract.Symbol);
        }
    }

    // Create a filter to select contracts that have the strike price within 1 strike level and expire within 7
days.
    protected override OptionFilterUniverse Filter(OptionFilterUniverse filter)
    {
        return filter.Strikes(-1, -1).Expiration(0, 7).CallsOnly();
    }
}
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse`.

To override the default pricing model of the Options, set a pricing model in a security initializer.

To override the initial guess of implied volatility, set and warm up the underlying volatility model.

For more information about this model, see the class reference and implementation.

Option Chained Universe Selection

An Option chained universe subscribes to Option contracts on the constituents of a US Equity universe.

```
// Configure the universe to use price data unadjusted for splits and dividends ("raw") into the algorithm.
// Options require raw Equity prices.
UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
UniverseSettings.Asynchronous = true;
AddUniverseSelection(
    new OptionChainedUniverseSelectionModel(
        // Add a universe of the 10 most liquid US Equities.
        AddUniverse(Universe.Top(10)),
        // Select call Option contracts on the underlying Equities that have the strike price within 2 strike levels.
        optionFilterUniverse => optionFilterUniverse.Strikes(-2, +2).FrontMonth().CallsOnly()
    )
);
```

C#

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`universe`	`Universe`	The universe to chain onto the Option Universe Selection model	
`optionFilter`	`Func<OptionFilterUniverse, OptionFilterUniverse>`	The Option filter universe to use	
`universeSettings`	`UniverseSettings`	The universe settings . If you don't provide an argument, the model uses the `algorithm.UniverseSettings` by default.	`null`

The `optionFilter` function receives and returns an `OptionFilterUniverse` to select the Option contracts. The following table describes the methods of the `OptionFilterUniverse` class:

The following table describes the filter methods of the `OptionFilterUniverse` class:

`Strikes(int minStrike, int maxStrike)` Selects contracts that are within `minStrike` strikes below the underlying price and `maxStrike` strikes above the underlying price.
`CallsOnly()` Selects call contracts.
`PutsOnly()` Selects put contracts.
`StandardsOnly()` Selects standard contracts.

`IncludeWeeklys()` Selects non-standard weeklys contracts.
`WeeklysOnly()` Selects weekly contracts.
`FrontMonth()` Selects the front month contract.
`BackMonths()` Selects the non-front month contracts.
`BackMonth()` Selects the back month contracts.
`Expiration(int minExpiryDays, int maxExpiryDays)` Selects contracts that expire within a range of dates relative to the current day.
`Contracts(IEnumerable<Symbol> contracts)` Selects a list of contracts.
`Contracts(Func<IEnumerable<Symbol>, IEnumerable< Symbol>> contractSelector)` Selects contracts that a selector function selects.

The preceding methods return an `OptionFilterUniverse` , so you can chain the methods together.

The following example shows how to define the Option filter as an isolated method:

```
C#
```

```
// In the Initialize method, define the universe settings and add the universe selection model.
public override void Initialize()
{
    UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
    UniverseSettings.Asynchronous = true;
    AddUniverseSelection(
        new OptionChainedUniverseSelectionModel(
            AddUniverse(Universe.Top(10)), OptionFilterFunction
        )
    );
}

// Define the contract filter function to select front month call contracts with a strike price within 2 strike
levels.
private OptionFilterUniverse OptionFilterFunction(OptionFilterUniverse optionFilterUniverse)
{
    return optionFilterUniverse.Strikes(-2, +2).FrontMonth().CallsOnly();
}
```

Some of the preceding filter methods only set an internal enumeration in the `OptionFilterUniverse` that it uses later on in the filter process. This subset of filter methods don't immediately reduce the number of contract `Symbol` objects in the `OptionFilterUniverse` .

For more information about this model, see the class reference and implementation .

Examples

The following examples demonstrate some common practices for implementing the framework Option Universe Selection Model.

Example 1: Horizontal Jelly Roll

The following algorithm selects SPX index options to construct a Jelly Roll strategy. It filters for ATM calls and puts with 30 days and 90 days till expiration. Using the SMA indicator to predict the interest rate cycle, it longs Jelly Roll if the cycle is considered uprising, otherwise selling the Jelly Roll.

```C#
public class FrameworkOptionUniverseSelectionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        // Add a universe that selects the needed option contracts.
        AddUniverseSelection(new AtmOptionHorizontalSpreadUniverseSelectionModel());
        // Add Alpha model to trade Jelly Roll, using interest rate data.
        AddAlpha(new JellyRollAlphaModel(this));
        // Invest in the same number of contracts per leg in the Jelly Roll.
        SetPortfolioConstruction(new SingleSharePortfolioConstructionModel());
    }

    private class AtmOptionHorizontalSpreadUniverseSelectionModel : OptionUniverseSelectionModel
    {
        // 30d update with the SelectOptionChainSymbols function since the filter returns at least 30d expiry
options.
        public AtmOptionHorizontalSpreadUniverseSelectionModel()
                : base(TimeSpan.FromDays(30), SelectOptionChainSymbols) {}

        private static IEnumerable<Symbol> SelectOptionChainSymbols(DateTime utcTime)
        {
            // We will focus only on SPX options since they have a relatively stable dividend yield, which we assume
will remain the same over time.
            // Also, assignment handling is not required since it is cash-settled.
            return new[] {QuantConnect.Symbol.Create("SPX", SecurityType.IndexOption, Market.USA)};
        }

        protected override OptionFilterUniverse Filter(OptionFilterUniverse filter)
        {
            // To trade interest rates using options, Jelly Roll is one of the best strategies.
            // It is market-neutral but sensitive to interest rate and dividend yield changes.
            // We target to trade the market speculation between 30d and 90d options interest rate.
            return filter.JellyRoll(0, 30, 90);
        }
    }

    private class JellyRollAlphaModel : AlphaModel
    {
        private QCAlgorithm _algorithm;
        private Symbol _symbol = QuantConnect.Symbol.Create("SPX", SecurityType.IndexOption, Market.USA);
        private bool _wasRising;
        // Use a 365d SMA indicator of daily interest rate to estimate if the interest rate cycle is upward or
downward.
        private SimpleMovingAverage _sma = new(365);

        public JellyRollAlphaModel(QCAlgorithm algorithm)
        {
            _algorithm = algorithm;

            // Warm up the SMA indicator.
            var current = algorithm.Time;
```

```
            var current = algorithm.Time;
            var provider = algorithm.RiskFreeInterestRateModel;
            for (DateTime dt = current.AddDays(-365); dt <= current; dt = dt.AddDays(1))
            {
                var rate = provider.GetInterestRate(dt);
                _sma.Update(dt, rate);
                _wasRising = rate > _sma;
            }

            // Set a schedule to update the interest rate trend indicator daily.
            algorithm.Schedule.On(
                algorithm.DateRules.EveryDay(),
                algorithm.TimeRules.At(0, 1),
                UpdateInterestRate
            );
        }

        private void UpdateInterestRate()
        {
            // Update the interest rate on the SMA indicator to estimate its trend.
            var rate = _algorithm.RiskFreeInterestRateModel.GetInterestRate(_algorithm.Time);
            _sma.Update(_algorithm.Time, rate);
            _wasRising = rate > _sma;
        }

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            // Hold one position group at a time.
            if (algorithm.Portfolio.Invested || !slice.OptionChains.TryGetValue(_symbol, out var chain))
            {
                return insights;
            }

            // Obtain the Jelly Roll constituents from the option chain.
            var calls = chain.Where(x => x.Right == OptionRight.Call)
                .OrderBy(x => x.Expiry)
                .ToList();
            var puts = chain.Where(x => x.Right == OptionRight.Put)
                .OrderBy(x => x.Expiry)
                .ToList();
            var nearCall = calls[0];
            var farCall = calls[^1];
            var nearPut = puts[0];
            var farPut = puts[^1];

            // Emit insight of the Jelly Roll constituents, with directions depending on the interest rate trend
given by SMA.
            var rate = algorithm.RiskFreeInterestRateModel.GetInterestRate(algorithm.Time);
            List<Insight> insightGroup;
            // During the rising interest rate cycle, order a long Jelly Roll.
            if (rate > _sma)
            {
                insightGroup = new() {
                    Insight.Price(nearCall.Symbol, TimeSpan.FromDays(30), InsightDirection.Down),
                    Insight.Price(farCall.Symbol, TimeSpan.FromDays(30), InsightDirection.Up),
                    Insight.Price(nearPut.Symbol, TimeSpan.FromDays(30), InsightDirection.Up),
                    Insight.Price(farPut.Symbol, TimeSpan.FromDays(30), InsightDirection.Down)
                };
            }

                    Insight.Price(nearPut.Symbol, TimeSpan.FromDays(30), InsightDirection.Down),
                    Insight.Price(farPut.Symbol, TimeSpan.FromDays(30), InsightDirection.Up)
                };
            }
            else
```

```
            else
            {
                insightGroup = new() {
                    Insight.Price(nearCall.Symbol, TimeSpan.FromDays(30), InsightDirection.Down),
                    Insight.Price(farCall.Symbol, TimeSpan.FromDays(30), InsightDirection.Up),
                    Insight.Price(nearPut.Symbol, TimeSpan.FromDays(30), InsightDirection.Up),
                    Insight.Price(farPut.Symbol, TimeSpan.FromDays(30), InsightDirection.Down)
                };
            }
            insights.AddRange(insightGroup);

            return insights;
        }
    }

    private class SingleSharePortfolioConstructionModel : PortfolioConstructionModel
    {
        public override IEnumerable<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
        {
            var targets = new List<PortfolioTarget>();
            foreach (var insight in insights)
            {
                if (algorithm.Securities[insight.Symbol].IsTradable)
                {
                    // Use integer target to create a portfolio target to trade a single contract
                    targets.Add(new PortfolioTarget(insight.Symbol, (int) insight.Direction));
                }
            }
            return targets;
        }
    }
}
```

Example 2: Options of an Equity Universe

The following example chains a fundamental universe and an Equity Options universe . It first selects 10 stocks with the lowest PE ratio and then selects their front-month call Option contracts. It buys one front-month call Option contract every day.

To override the default pricing model of the Options, set a pricing model in a security initializer.

To override the initial guess of implied volatility , set and warm up the underlying volatility model .

C#

```
// Example code to chain a fundamental universe and an Equity Options universe by selecting top 10 stocks with lowest
PE, indicating potentially undervalued stocks and then selecting their from-month call Option contracts to target
contracts with high liquidity.
public class ETFUniverseOptions : QCAlgorithm
{
    private int _day;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);

Universe Selection

Legacy Fundamental Universes

Introduction

Warning: This API for Universe Selection was deprecated on November 2023. Please refer to the new Fundamental Selection API .

A `FundamentalUniverseSelectionModel` selects a universe of US Equities based on `CoarseFundamental` and, sometimes, `FineFundamental` data. If the model uses `CoarseFundamental` data, it relies on the US Equity Coarse Universe dataset. If the Universe Selection model uses `FineFundamental` data, it relies on the US Fundamental dataset.

These types of universes operate on daily schedule. In backtests, they select assets at midnight. In live trading, the selection timing depends on the data provider you use.

If you use a fundamental Universe Selection model, the only way to unsubscribe from a security is to return a list from the selection functions that doesn't include the security `Symbol` . The `RemoveSecurity` method doesn't work with these types of Universe Selection models.

Coarse Fundamental Selection

The `CoarseFundamentalUniverseSelectionModel` selects assets based on `CoarseFundamental` data. To use this model, define a coarse selection function. The coarse selection function receives a list of `CoarseFundamental` objects and returns a list of `Symbol` objects. The `Symbol` objects you return from the coarse selection function are the constituents of the universe.

```C#
// Set asynchronous universe settings for improved speed and use CoarseFundamentalUniverseSelectionModel with a
custom function to select the top 100 most liquid assets with available fundamental data, ensuring the universe
consists of liquid and fundamentally strong securities for stable returns.
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    AddUniverseSelection(new CoarseFundamentalUniverseSelectionModel(SelectCoarse));
}

private IEnumerable<Symbol> SelectCoarse(IEnumerable<CoarseFundamental> coarse)
{
    // Return most liquid assets w/ fundamentals
    return coarse.Where(c => c.HasFundamentalData)
                 .OrderByDescending(c => c.DollarVolume)
                 .Take(100)
                 .Select(c => c.Symbol);
}
```

To move the coarse selection function outside of the algorithm class, create a universe selection model that inherits the `CoarseFundamentalUniverseSelectionModel` class.

```C#
// Move the coarse selection function outside of the algorithm class by creating a custom universe selection model
inheriting from CoarseFundamentalUniverseSelectionModel, allowing for modification and reusability of the selection
logic.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new MostLiquidFundamentalUniverseSelectionModel(UniverseSettings));

// Outside of the algorithm class
class MostLiquidFundamentalUniverseSelectionModel : CoarseFundamentalUniverseSelectionModel
{
    public MostLiquidFundamentalUniverseSelectionModel(UniverseSettings universeSettings)
        : base(default(Func<IEnumerable<CoarseFundamental>, IEnumerable<Symbol>>), universeSettings)
    {
    }

    public override IEnumerable<Symbol> SelectCoarse(QCAlgorithm algorithm, IEnumerable<CoarseFundamental> coarse)
    {
        return coarse.Where(c => c.HasFundamentalData)
                     .OrderByDescending(c => c.DollarVolume)
                     .Take(100)
                     .Select(c => c.Symbol);
    }
}
```

To return the current universe constituents from the coarse selection function, return `Universe.Unchanged` .

For more information about this model, see the class reference and implementation .

Fine Fundamental Selection

The `FineFundamentalUniverseSelectionModel` selects assets based on `CoarseFundamental` and `FineFundamental` data. This is the only model that provides corporate fundamental data to your algorithm. To use this model, define a coarse selection function and a fine selection function. The coarse selection function receives a list of `CoarseFundamental` objects and returns a list of `Symbol` objects. To filter the `CoarseFundamental` down to the securities that have fundamental data, add a `HasFundamentalData` filter to the coarse selection function. The fine selection function receives a subset of `FineFundamental` objects generated from coarse selection results and returns a list of `Symbol` objects. The `Symbol` objects you return from the fine selection function are the constituents of the universe.

```C#
// FineFundamentalUniverseSelectionModel integrates corporate fundamental data into the algorithm through a two-step
filtering process: coarse selection ensures liquidity and fundamental data availability, while fine selection focuses
on valuation metrics, refining the universe of selected stocks.
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    AddUniverseSelection(new FineFundamentalUniverseSelectionModel(SelectCoarse, SelectFine));
}

private IEnumerable<Symbol> SelectCoarse(IEnumerable<CoarseFundamental> coarse)
{
    // Return most liquid assets w/ fundamentals
    return coarse.Where(c => c.HasFundamentalData)
                 .OrderByDescending(c => c.DollarVolume)
                 .Take(100)
                 .Select(c => c.Symbol);
}

private IEnumerable<Symbol> SelectFine(IEnumerable<FineFundamental> fine)
{
    // Return assets with lowest P/E ratios
    return fine.OrderBy(f => f.ValuationRatios.PERatio)
               .Take(10)
               .Select(f => f.Symbol);
}
```

To move the selection functions outside of the algorithm class, create a universe selection model that inherits the `FineFundamentalUniverseSelectionModel` class.

C#

```
// Create a custom universe selection model inheriting from FineFundamentalUniverseSelectionModel to move both coarse
and fine selection functions outside the algorithm class, enabling easier modification and reusability of the
filtering and ranking logic.
UniverseSettings.Asynchronous = true;
AddUniverseSelection(new LowPERatioUniverseSelectionModel(UniverseSettings));

// Outside of the algorithm class
class LowPERatioUniverseSelectionModel : FineFundamentalUniverseSelectionModel
{
    public LowPERatioUniverseSelectionModel(UniverseSettings universeSettings = null)
        : base(default(Func<IEnumerable<CoarseFundamental>, IEnumerable<Symbol>>),
               default(Func<IEnumerable<FineFundamental>, IEnumerable<Symbol>>),
               universeSettings)
    {
    }

    public override IEnumerable<Symbol> SelectCoarse(QCAlgorithm algorithm, IEnumerable<CoarseFundamental> coarse)
    {
        return coarse.Where(c => c.HasFundamentalData)
                     .OrderByDescending(c => c.DollarVolume)
                     .Take(100)
                     .Select(c => c.Symbol);
    }

    public override IEnumerable<Symbol> SelectFine(QCAlgorithm algorithm, IEnumerable<FineFundamental> fine)
    {
        return fine.OrderBy(f => f.ValuationRatios.PERatio)
                   .Take(10)
                   .Select(f => f.Symbol);
    }
}
```

To return the current universe constituents from the coarse or fine selection function, return `Universe. Unchanged` .

If you add a `FineFundamentalUniverseSelectionModel` to your algorithm, you can access fundamental data in the fine selection function or from the `Equity` object. To access fundamental data from the `Equity` object, use the `Equity. Fundamentals` property.

For more information about this model, see the class reference and implementation .

Algorithm Framework

Alpha

Alpha

Key Concepts

Introduction

The Alpha model predicts market trends and signals the best moments to trade. These signals, or `Insight` objects, contain the `Direction` , `Magnitude` , and `Confidence` of a market prediction and the suggested portfolio `Weight` . You should generate insights on the set of assets provided by the Universe Selection model and only generate them when your predictions change.

Add Models

To add an Alpha model, in the `Initialize` method, call the `AddAlpha` method.

```
C#
// Add EmaCrossAlphaModel to generate market trend insights and trading signals based on EMA crossovers, providing
Direction, Magnitude, and Confidence for the universe-selected assets.
AddAlpha(new EmaCrossAlphaModel());
```

To view all the pre-built Alpha models, see Supported Models .

Multi-Alpha Algorithms

You can add multiple Alpha models to a single algorithm and generate Insight objects with all of them.

```
C#
// Add RsiAlphaModel and EmaCrossAlphaModel to generate trading signals based on RSI and EMA crossovers, utilizing
multiple alpha models to capture different market signals and trends for robust predictions.
AddAlpha(new RsiAlphaModel());
AddAlpha(new EmaCrossAlphaModel());
```

Each Alpha model has a unique name. The Insight objects they generate are automatically named according to the Alpha model name.

If you add multiple Alpha models, each alpha model receives the current slice in the order that you add the Alphas. The combined stream of Insight objects is passed to the Portfolio Construction model that defines how the Insight collection is combined. If you have a hybrid algorithm, the combined stream of Insight objects is passed to the event handler .

Model Structure

Alpha models should extend the `AlphaModel` class. Extensions of the `AlphaModel` class must implement the `Update` method, which receives a Slice object and returns an array of `Insight` objects. Extensions should also implement the `OnSecuritiesChanged` method to track security changes in the universe.

```C#
// Algorithm framework model that produces insights
class MyAlphaModel : AlphaModel
{
    // Updates this Alpha model with the latest data from the algorithm.
    // This is called each time the algorithm receives data for subscribed securities
    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice data)
    {
        var insights = new List<Insight>();
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        // Security additions and removals are pushed here.
        // This can be used for setting up algorithm state.
        // changes.AddedSecurities
        // changes.RemovedSecurities
    }
}
```

Method Parameters

The `algorithm` parameter that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it. To access members of your algorithm object, either use a global variable or pass an algorithm reference to Alpha model constructor. Both of these approaches violate the separation of concerns principle.

The `data` parameter contains the latest data available to the algorithm.

The `changes` parameter contains the universe changes.

Model Names

To ensure your Alpha model is compatible with all Portfolio Construction models , assign a unique name to your Alpha model. Some Portfolio Construction models can combine multiple Alpha models together, so it can be important to distinguish between the Alpha models.

```C#
// Assign a unique name to RsiAlphaModel to ensure compatibility and distinguish it when combining with other Alpha
models in portfolio construction.
public class RsiAlphaModel : AlphaModel
{
    // Give your alpha a name (perhaps based on its constructor args?)
    public override string Name { get; }
}
```

By default, LEAN uses the string representation of a Guid object to set the Alpha model name. An example default name is "0f8fad5b-d9cb-469f-a165-70867728950e". This default name is different for every backtest you run and every live algorithm you deploy. For consistent behavior, manually set the Alpha model name.

Example

To view a full example of an `AlphaModel` subclass, see the ConstantAlphaModel in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Alpha model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Alpha model. If you need to save data for individual securities, cast the `Security` object to a

`dynamic` object and then save custom members to it .

```C#
// Handle dynamic asset changes by initializing indicators for new securities and removing them for removed
securities to keep the Alpha model adaptive and accurate.
class MyAlphaModel : AlphaModel
{
    private List<Security> _securities = new List<Security>();

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes) {
        foreach (var security in changes.AddedSecurities)
        {
            var dynamicSecurity = security as dynamic;
            dynamicSecurity.Sma = algorithm.SMA(security.Symbol, 20);
            algorithm.WarmUpIndicator(security.Symbol, dynamicSecurity.Sma);
            _securities.Add(security);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            if (_securities.Contains(security))
            {
                algorithm.DeregisterIndicator((security as dynamic).Sma);
                _securities.Remove(security);
            }
        }
    }
}
```

Insights

An Insight is a single prediction for an asset. The `Update` method returns an array of Insight objects. You can think of these as actionable trading signals, indicating the asset direction, magnitude, and confidence in the near future. All insights can take a weight parameter to set the desired weighting for the insight. If you change the cash of the algorithm, it will affect the orders, but not necessarily the insights.

The Portfolio Construction model consumes the Insight objects from the Alpha model. It's up to the Portfolio Construction model to define how Insight objects are converted into `PortfolioTarget` objects. In the pre-built Portfolio Construction models, down insights translate to short-biased trades, up insights translate to long-biased trades, and flat insights usually close open positions, but this doesn't have to be the case in custom Portfolio Construction models .

Insight Properties

`Insight` objects have the following properties:

Create Insights

To create an `Insight` , call the `Insight` constructor.

```C#
// new Insight(symbol, period, type, direction, magnitude=null, confidence=null, sourceModel=null, weight=null,
tag="");
var insight = new Insight("IBM", TimeSpan.FromMinutes(20), InsightType.Price, InsightDirection.Up);
```

In the `Insight` constructor, the `period` argument can be a `TimeSpan` object or a function that receives a `DateTime` object and returns the expiry `DateTime` . Some of the constructor arguments are optional to create the `Insight` object, but some of the Portfolio Construction models may require these properties. To check which `Insight` properties a Portfolio Construction model requires, see Supported Models .

You can also use the helper method to create Insight objects of the Price type.

```C#
// new Insight(symbol, period, direction, magnitude=null, confidence=null, sourceModel=null, weight=null, tag="")
var insight = Insight.Price("IBM", TimeSpan.FromMinutes(20), InsightDirection.Up);

// new Insight(symbol, resolution, barCount, direction, magnitude=null, confidence=null, sourceModel=null,
weight=null, tag="")
var insight = Insight.Price("IBM", Resolution.Minute, 20, InsightDirection.Up);
```

In the `Price` method, the `period` argument can be a `TimeSpan` object, a `DateTime` object, or a function that receives a `DateTime` object and returns the expiry `DateTime` .

Group Insights

Sometimes an algorithm's performance relies on multiple insights being traded together, like in pairs trading and options straddles. These types insights should be grouped. Insight groups signal to the Execution model that the insights need to be acted on as a single unit to maximize the alpha created.

To mark insights as a group, call the `Insight.Group` method.

```C#
// Generate and group insights for a set of tickers with a 20-minute prediction horizon; each Insight object provides
directional signals, magnitudes, and confidence for price movement.
return Insight.Group(
 Insight.price("IBM", TimeSpan.FromMinutes(20), InsightDirection.UP),
 Insight.price("SPY", TimeSpan.FromMinutes(20), InsightDirection.UP),
 Insight.price("AAPL", TimeSpan.FromMinutes(20), InsightDirection.UP)
);
```

Cancel Insights

If an Alpha model in your algorithm emits an Insight to enter a position but it determines the trading opportunity has pre-maturely ended, you should cancel the Insight. For example, say you want your algorithm to enter a long position in a security when its Relative Strength Index (RSI) moves below 20 and then liquidate the position when the security's RSI moves above 30. If you emit an Insight that has a duration of 30 days when the RSI moves below 20 but the RSI moves above 30 in 10 days, you should cancel the Insight.

To cancel an Insight, call its `Cancel` / `Expire` method with the algorithm's Coordinated Universal Time (UTC).

```C#
// Cancel any outstanding insights to ensure only current predictions are considered and to avoid outdated signals
influencing trading decisions.
_insight.Cancel(algorithm.UtcTime);
```

If you don't have a reference to the Insight you want to cancel, get it from the InsightManager .

When you cancel an insight, it's `CloseTimeUtc` property is set to one second into the past.

Stop Loss Orders Workaround

In some cases, if you add a Risk Management model that uses stop loss logic, the Risk Management model generates `PortfolioTarget` objects with a 0 quantity to make the Execution model liquidate your positions, but then the Portfolio Construction model generates `PortfolioTarget` objects with a non-zero quantity to make the Execution model re-enter the same position. This issue can occur if your Portfolio Construction model rebalances and your Alpha model still has an active insight for the liquidated securities. To avoid this issue, add the stop loss order logic to the Alpha model. When the stop loss is hit, emit a flat insight for the security. Note that this is a workaround, but it violates the separation of concerns principle since the Alpha Model shouldn't react to open positions.

Universe Timing Considerations

If the Alpha model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate common practices for implementing the framework alpha model.

Example 1: EMA Cross On Liquid Stocks

The following algorithm selects the top 500 liquid US stocks traded within the SPY ETF, then emits trade signals 60-day versus 200-day EMA cross through the `EmaCrossAlphaModel`. The `EqualWeightingPortfolioConstructionModel` ensures each asset with an insight gets an allocation of equal magnitude.

```
C#
public class FrameworkAlphaModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe of liquid equities since they have capital to support demand and trends.
        UniverseSettings.Resolution = Resolution.Daily;
        AddUniverseSelection(new ETFConstituentsUniverseSelectionModel("SPY"));
        // Using an EMA cross-alpha model to trade medium versus long-term trends.
        AddAlpha(new EmaCrossAlphaModel(60, 200, Resolution.Daily));
        // Equally invested in insights to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}
```

Example 2: Interest Rate Effect On Forex

The following algorithm implements a custom alpha model that uses the interest rate cycle as a signal to trade Forex. We trade the top 6 forexes: AUDUSD, EURUSD, GBPUSD, USDCAD, USDCHF, and USDJPY. For the ones with USD as quote currencies, we buy them during the US interest rate down cycle since USD is relatively weak while shorting them during the upcycle. The opposite is true for the ones with USD as the base currency.

```
C#
public class FrameworkAlphaModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
```

```
        SetEndDate(2024, 12, 31);

        // Use daily resolution since the interest rate signal is on a daily basis.
        UniverseSettings.Resolution = Resolution.Daily;
        // Add a universe of selected lists of Forex.
        var forex = new[] {
            QuantConnect.Symbol.Create("AUDUSD", SecurityType.Forex, Market.Oanda),
            QuantConnect.Symbol.Create("EURUSD", SecurityType.Forex, Market.Oanda),
            QuantConnect.Symbol.Create("GBPUSD", SecurityType.Forex, Market.Oanda),
            QuantConnect.Symbol.Create("USDCAD", SecurityType.Forex, Market.Oanda),
            QuantConnect.Symbol.Create("USDCHF", SecurityType.Forex, Market.Oanda),
            QuantConnect.Symbol.Create("USDJPY", SecurityType.Forex, Market.Oanda)
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(forex));
        // Using a custom alpha model to trade forex based on interest rate.
        AddAlpha(new InterestRateAlphaModel(this));
        // Equally invested in insights to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private class InterestRateAlphaModel : AlphaModel
    {
        private QCAlgorithm _algorithm;
        private bool _wasRising;
        // Use a 365d SMA indicator of daily interest rate to estimate if the interest rate cycle is upward or
downward.
        private SimpleMovingAverage _sma = new(365);

        public InterestRateAlphaModel(QCAlgorithm algorithm)
        {
            _algorithm = algorithm;

            // Warm up the SMA indicator.
            var current = algorithm.Time;
            var provider = algorithm.RiskFreeInterestRateModel;
            for (DateTime dt = current.AddDays(-365); dt <= current; dt = dt.AddDays(1))
            {
                var rate = provider.GetInterestRate(dt);
                _sma.Update(dt, rate);
                _wasRising = rate > _sma;
            }

            // Set schedule to update the interest rate trend indicator daily.
            algorithm.Schedule.On(
                algorithm.DateRules.EveryDay(),
                algorithm.TimeRules.At(0, 1),
                UpdateInterestRate
            );
        }

        private void UpdateInterestRate()
        {
            // Update the interest rate on the SMA indicator to estimate its trend.
            var rate = _algorithm.RiskFreeInterestRateModel.GetInterestRate(_algorithm.Time);
            _sma.Update(_algorithm.Time, rate);
            _wasRising = rate > _sma;
        }

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            // Split the forexes by whether the quote currency is USD.
            var quoteUSD = new List<Symbol>();
            var baseUSD = new List<Symbol>();
            foreach (var (symbol, security) in algorithm.Securities)
            {
                if (security.QuoteCurrency.Symbol == Currencies.USD)
                {
                    quoteUSD.Add(symbol);
                }
                else
                {
                    baseUSD.Add(symbol);
                }
            }

            var rate = algorithm.RiskFreeInterestRateModel.GetInterestRate(algorithm.Time);
            // During the rising interest rate cycle, long the forexes with USD as the base currency and short the
ones with USD as the quote currency.
            if (rate > _sma)
```

```
            {
                insights.AddRange(
                    baseUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Up)).ToList()
                );
                insights.AddRange(
                    quoteUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Down)).ToList()
                );
            }
            // During a downward interest rate cycle, short the forexes with USD as the base currency and long the
ones with USD as the quote currency.
            else if (rate < _sma)
            {
                insights.AddRange(
                    baseUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Down)).ToList()
                );
                insights.AddRange(
                    quoteUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Up)).ToList()
                );
            }
            // If the interest rate cycle remains steady for a long time, we expect a flip in the cycle soon.
            else if (_wasRising)
            {
                insights.AddRange(
                    baseUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Down)).ToList()
                );
                insights.AddRange(
                    quoteUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Up)).ToList()
                );
            }
            else
            {
                insights.AddRange(
                    baseUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Up)).ToList()
                );
                insights.AddRange(
                    quoteUSD.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(1),
InsightDirection.Down)).ToList()
                );
            }

            return insights;
        }
    }
}
```

Alpha

Supported Models

Introduction

This page describes the pre-built Alpha models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Alpha model .

Null Model

The `NullAlphaModel` doesn't emit any insights. It's the default Alpha model.

```
C#
// NullAlphaModel doesn't emit insights.
AddAlpha(new NullAlphaModel());
```

For more information about this model, see the class reference and implementation .

Constant Model

The `ConstantAlphaModel` always returns the same insight for each security.

```
C#
// Emit up insights that expire in 30 days for all assets.
AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(30)));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`type`	`InsightType`	The type of insight	
`direction`	`InsightDirection`	The direction of the insight	
`period`	`TimeSpan`	The period over which the insight will come to fruition	
`magnitude`	`double?`	The predicted change in magnitude as a +/- percentage	`null`
`confidence`	`double?`	The confidence in the insight	`null`
`weight`	`double?`	The portfolio weight of the insights	`null`

For more information about this model, see the class reference and implementation .

Historical Returns Model

The `HistoricalReturnsAlphaModel` buys securities that have a positive trailing return and sells securities that have a negative

trailing return. It sets the magnitude of the Insight objects to the trailing rate of change.

```
// Add HistoricalReturnsAlphaModel to leverage historical return data for generating alpha signals, identifying
trends based on past performance.
AddAlpha(new HistoricalReturnsAlphaModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Historical return lookback period	1
`resolution`	`Resolution`	The resolution of historical data	`Resolution.Daily`

This model cancels all the active insights it has emit for a security when the security has a 0% historical return.

For more information about this model, see the class reference and implementation .

EMA Cross Model

The `EmaCrossAlphaModel` uses an exponential moving average (EMA) cross to create insights. When the fast EMA crosses above the slow EMA, it emits up insights. When the fast EMA crosses below the slow EMA, it emits down insights. It sets the duration of Insight objects to be the product of the `resolution` and `fastPeriod` arguments.

```
// Add EmaCrossAlphaModel to generate trading insights based on the crossing of fast and slow exponential moving
averages identifying trends and potential reversals. The duration of insights is set by the resolution and
fast_period to ensure timely and relevant trading signals.
AddAlpha(new EmaCrossAlphaModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fastPeriod`	`int`	The fast EMA period	12
`slowPeriod`	`int`	The slow EMA period	26
`resolution`	`Resolution`	The resolution of data sent into the EMA indicators	`Resolution.Daily`

For more information about this model, see the class reference and implementation .

MACD Model

The `MacdAlphaModel` emits insights based on moving average convergence divergence (MACD) crossovers. If the MACD signal line is 1% above the security price, the model emits an up insight. If the MACD signal line is 1% below the security price, the model emits a down insight. If the MACD signal line is within 1% of the security price, the model cancels all the active insights it has emitted for the security.

```
// Use MacdAlphaModel to generate insights based on MACD crossovers, emitting up signals when the MACD signal line is
1% above the security price and down signals when it is 1% below, while canceling insights if within 1% capturing
significant trend changes while avoiding noise from minor fluctuations.
AddAlpha(new MacdAlphaModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fastPeriod`	`int`	The MACD fast period	12
`slowPeriod`	`int`	The MACD slow period	26
`signalPeriod`	`int`	The smoothing period for the MACD signal	9
`movingAverageType`	`MovingAverageType`	The type of moving average to use in the MACD	`MovingAverageType. Exponential`
`resolution`	`Resolution`	The resolution of data sent into the MACD indicator	`Resolution.Daily`

For more information about this model, see the class reference and implementation .

RSI Model

The `RsiAlphaModel` generates insights based on the relative strength index (RSI) indicator values. When the RSI value passes above 70, the model emits a down insight. When the RSI value passes below 30, the model emits an up insight. The model uses the Wilder moving average type and sets the duration of Insight objects to be the product of the `resolution` and `period` arguments.

```
// The RsiAlphaModel generates insights based on the RSI indicator: emits a down insight when RSI exceeds 70
(overbought) and an up insight when RSI falls below 30 (oversold). This helps identify potential price reversals
based on momentum.
AddAlpha(new RsiAlphaModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`period`	`int`	The RSI indicator period	14
`resolution`	`Resolution`	The resolution of data sent into the RSI indicator	`Resolution.Daily`

For more information about this model, see the class reference and implementation .

Base Pairs Trading Model

The `BasePairsTradingAlphaModel` analyzes every possible pair combination from securities that the Universe Selection model selects. This model calculates a ratio between the two securities by dividing their historical prices over a lookback window. It then calculates the mean of this ratio by taking the 500-period EMA of the quotient. When the ratio diverges far enough from the mean ratio, this model emits generates alternating long ratio/short ratio insights emitted as a group to capture the reversion

of the ratio.

```C#
// Use BasePairsTradingAlphaModel to analyze security pairs from the universe, generating long/short insights based on deviations from a 500-period EMA of their price ratio to capture mean-reversion opportunities.
AddAlpha(new BasePairsTradingAlphaModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Lookback period of the analysis	1
`resolution`	`Resolution`	Analysis resolution	`Resolution.Daily`
`threshold`	`decimal`	The percent [0, 100] deviation of the ratio from the mean before emitting an insight	1

For more information about this model, see the class reference and implementation .

Pearson Correlation Pairs Trading Model

The `PearsonCorrelationPairsTradingAlphaModel` ranks every pair combination by its Pearson correlation coefficient and trades the pair with the highest correlation. This model follows the same insight logic as the `BasePairsTradingModel` .

```C#
// Add PearsonCorrelationPairsTradingAlphaModel to rank and trade the most correlated security pairs based on Pearson correlation coefficients, using a similar insight logic as BasePairsTradingModel to capture mean-reversion opportunities.
AddAlpha(new PearsonCorrelationPairsTradingAlphaModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lookback`	`int`	Lookback period of the analysis	15
`resolution`	`Resolution`	Analysis resolution	`Resolution.Minute`
`threshold`	`decimal`	The percent [0, 100] deviation of the ratio from the mean before emitting an insight	1
`minimumCorrelation`	`double`	The minimum correlation to consider a tradable pair	0.5

For more information about this model, see the class reference and implementation .

Algorithm Framework

Portfolio Construction

Portfolio Construction

Key Concepts

Introduction

The Portfolio Construction model receives `Insight` objects from the Alpha model and creates `PortfolioTarget` objects for the Risk Management model. A `PortfolioTarget` provides the number of units of an asset to hold.

Set Models

To set a Portfolio Construction model, in the `Initialize` method, call the `SetPortfolioConstruction` method.

```
C#
// Create PortfolioTarget objects to form an equal weighted portfolio based on the Insight objects.
SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
```

To view all the pre-built Portfolio Construction models, see Supported Models .

Model Structure

Portfolio Construction models should extend the `PortfolioConstructionModel` class or one of the supported models . Extensions of the `PortfolioConstructionModel` class should implement the `CreateTargets` method, which receives an array of `Insight` objects from the Alpha model at every time step and returns an array of `PortfolioTarget` objects. The Portfolio Construction model seeks to answer the question, "how many units should I buy based on the insight predictions I've been presented?".

If you don't override the `CreateTargets` method, the base class implementation calls the model's `IsRebalanceDue` , `DetermineTargetPercent` , and `GetTargetInsights` helper methods. The `GetTargetInsights` method, in turn, calls the model's `ShouldCreateTargetForInsight` method. You can override any of these helper methods. If you don't override the `CreateTargets` method from the `PortfolioConstructionModel` class, your class must at least override the `DetermineTargetPercent` method.

```C#
// Portfolio construction scaffolding class; basic method arguments.
class MyPortfolioConstructionModel : PortfolioConstructionModel
{
    // Create list of PortfolioTarget objects from Insights.
    public override List<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
    {
        return (List<PortfolioTarget>) base.CreateTargets(algorithm, insights);
    }

    // Determine if the portfolio should rebalance based on the provided rebalancing function.
    protected override bool IsRebalanceDue(Insight[] insights, DateTime algorithmUtc)
    {
        return base.IsRebalanceDue(insights, algorithmUtc);
    }

    // Determine the target percent for each insight.
    protected override Dictionary<Insight, double> DetermineTargetPercent(List<Insight> activeInsights)
    {
        return new Dictionary<Insight, double>();
    }

    // Get the target insights to calculate a portfolio target percent.
    // They will be piped to the DetermineTargetPercent method.
    protected override List<Insight> GetTargetInsights()
    {
        return base.GetTargetInsights();
    }

    // Determine if the portfolio construction model should create a target for this insight.
    protected override bool ShouldCreateTargetForInsight(Insight insight)
    {
        return base.ShouldCreateTargetForInsight(insight);
    }

    // Track universe changes.
    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        base.OnSecuritiesChanged(algorithm, changes);
    }
}
```

The Portfolio Construction model should remove expired insights from the Insight Manager . The `CreateTargets` definition of the base `PortfolioConstructionModel` class already removes them during each rebalance. Therefore, if you override the `CreateTargets` method and don't call the `CreateTargets` definition of the base class, your new method definition should remove expired insights from the Insight Manager.

The model should also remove all a security's insights from the Insight Manager when the security is removed from the universe . The `OnSecuritiesChanged` definition of the base `PortfolioConstructionModel` class already does this. Therefore, if you override the `OnSecuritiesChanged` method and don't call the `OnSecuritiesChanged` definition of the base class, your new method definition should remove the security's insights from the Insight Manager.

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

You may use the `PortfolioBias` enumeration in the definition of Portfolio Construction model methods. The `PortfolioBias` enumeration has the following members:

To view a full example of a `PortfolioConstructionModel` subclass, see the EqualWeightingPortfolioConstructionModel in the LEAN GitHub repository.

Multi-Alpha Algorithms

If you add multiple Alpha models , each Alpha model receives the current slice in the order that you add the Alphas. The combined stream of Insight objects is passed to the Portfolio Construction model.

Each Portfolio Construction model has a unique method to combine Insight objects. The base `PortfolioConstructionModel` that

most PCM's inherit from doesn't combine information from Insight objects with the same `Symbol` - but just gets the most recent active insight. To combine the active insights differently, override the `GetTargetInsights` , and return all active insights. The `DetermineTargetPercent` method implements the combination criteria and determines the target for each `Symbol` .

```
C#

// Implement MultipleAlphaPortfolioConstructionModel to handle and utilize insights from multiple Alpha models.
// The get_target_insights method retrieves current active insights, and determine_target_percent allocates portfolio
weights accordingly for integrating and balancing multiple Alpha signals within the portfolio.
public class MultipleAlphaPortfolioConstructionModel : PortfolioConstructionModel
{
    protected override List<Insight> GetTargetInsights()
    {
        return Algorithm.Insights.GetActiveInsights(Algorithm.UtcTime).ToList();
    }

    protected override Dictionary<Insight, double> DetermineTargetPercent(List<Insight> activeInsights)
    {
        return new Dictionary<Insight, double>();
    }
}
```

Portfolio Targets

The Portfolio Construction model returns `PortfolioTarget` objects, which are passed to the Risk Management model.

To create a `PortfolioTarget` object based on a quantity, pass the `Symbol` and quantity to the `PortfolioTarget` constructor.

```
C#

// Create a new portfolio target for 1200 IBM shares.
var target = new PortfolioTarget("IBM", 1200);
```

To create a `PortfolioTarget` object based on a portfolio weight, call the `Percent` method. This method is only available for margin accounts.

```
C#

// Calculate target equivalent to 10% of portfolio value
var target = PortfolioTarget.Percent(algorithm, "IBM", 0.1);
```

To include more information in the `PortfolioTarget` object, pass a `tag` argument to the constructor or the `Percent` method.

The `CreateTargets` method of your Portfolio Construction model must return an array of `PortfolioTarget` objects.

```
C#

return new PortfolioTarget[] {  new PortfolioTarget("IBM", 1200)  };
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `Add` method.

```
C#

_targetsCollection.Add(portfolioTarget);
```

To add a list of `PortfolioTarget` objects, call the `AddRange` method.

```C#
_targetsCollection.AddRange(portfolioTargets);
```

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `Contains` method.

```C#
var targetInCollection = _targetsCollection.Contains(portfolioTarget);
```

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `ContainsKey` method.

```C#
var symbolInCollection = _targetsCollection.ContainsKey(symbol);
```

To get all the Symbol objects, use the `Keys` property.

```C#
var symbols = _targetsCollection.Keys;
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```C#
var portfolioTarget = _targetsCollection[symbol];
```

To iterate through the `PortfolioTargetCollection` , call the `GetEnumerator` method.

```C#
var enumerator = _targetsCollection.GetEnumerator();
```

To get all the `PortfolioTarget` objects, use the `Values` property

```C#
var portfolioTargets = _targetsCollection.Values;
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `OrderByMarginImpact` method.

```C#
foreach (var target in _targetsCollection.OrderByMarginImpact(algorithm))
{
    // Place order
}
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of

the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `Remove` method.

```
C#
removeSuccessful = _targetsCollection.Remove(symbol);
```

To remove all the `PortfolioTarget` objects, call the `Clear` method.

```
C#
_targetsCollection.Clear();
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `ClearFulfilled` method.

```
C#
_targetsCollection.ClearFulfilled(algorithm);
```

Rebalance Frequency

If you use a Portfolio Construction model that is a subclass of the `PortfolioConstructionModel` class, you can set the rebalancing frequency of the model with a function. The rebalancing function receives the Coordinated Universal Time (UTC) of the algorithm and should return the next rebalance UTC time or `null` . If the function returns `null` , the model doesn't rebalance unless the rebalance settings trigger a rebalance. For a full example of a custom rebalance function, see the PortfolioRebalanceOnCustomFuncRegressionAlgorithm .

If you use a Portfolio Construction model with the following characteristics, you can also set the rebalancing frequency of the model with a `TimeSpan` , `Resolution` , or DateRules :

- The model is a subclass of the `EqualWeightingPortfolioConstructionModel` class.
- The model constructor calls the `EqualWeightingPortfolioConstructionModel` constructor.
- The model doesn't override the `CreateTargets` method.

To check which of the pre-built Portfolio Construction models support this functionality, see Supported Models .

Rebalance Settings

By default, portfolio construction models create `PortfolioTarget` objects to rebalance the portfolio when any of the following events occur:

- The model's rebalance function signals it's time to rebalance
- The Alpha model emits new insights
- The universe changes

To disable rebalances when the Alpha model emits insights or when insights expire, set `RebalancePortfolioOnInsightChanges` to false.

```
C#
// Disable automatic portfolio rebalancing upon insight change, allowing for manual control over when portfolio
adjustments are made based on insights.
Settings.RebalancePortfolioOnInsightChanges = false;
```

To disable rebalances when security changes occur, set `RebalancePortfolioOnSecurityChanges` to false.

```
// Disable automatic portfolio rebalancing upon security change, allowing for manual control over when portfolio
adjustments are made based on security additions or removals.
Settings.RebalancePortfolioOnSecurityChanges = false;
```

Portfolio Optimizer Structure

Some portfolio construction models contain an optimizer that accepts the historical returns of each security and returns a list of optimized portfolio weights. Portfolio optimizer models must implement the `IPortfolioOptimizer` interface, which has an `Optimize` method.

```
// Implement an equal-weighted portfolio optimizer to assign equal weights to all securities, providing basic
diversification to reduce risk compared to a concentrated portfolio.
public class MyPortfolioOptimizer : IPortfolioOptimizer
{
    public double[] Optimize(double[,] historicalReturns, double[] expectedReturns = null, double[,] covariance =
null)
    {
        // Create weights
        //  For example, equal-weighting:
        int numAssets = historicalReturns.GetLength(1);
        var weights = Enumerable.Repeat(1.0 / numAssets, numAssets).ToArray();

        return weights;
    }
}
```

The following table describes the arguments the `Optimize` method accepts:

Argument	Data Type	Description	Default Value
`historicalReturns`	`double[,]`	Matrix of historical returns where each column represents a security and each row returns for the given date/time (size: K x N)	
`expectedReturns`	`double[]`	Array of double with the portfolio annualized expected returns (size: K x 1)	`null`
`covariance`	`double[,]`	Multi-dimensional array of double with the portfolio covariance of annualized returns (size: K x K)	`null`

The method should return a K x 1 array of double objects that represent the portfolio weights.

To view all the pre-built portfolio optimization algorithms, see Supported Optimizers .

To view a full example of an `IPortfolioOptimizer` implementation, see the MaximumSharpeRatioPortfolioOptimizer in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the

Portfolio Construction model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Portfolio Construction model. If you need to save data for individual securities, cast the `Security` object to a `dynamic` object and then save custom members to it .

```C#
class MyPortfolioConstructionModel : PortfolioConstructionModel{
    private List<Security> _securities = new List<Security>();

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        base.OnSecuritiesChanged(algorithm, changes);
        foreach (var security in changes.AddedSecurities)
        {
            // Store and manage Symbol-specific data
            var dynamicSecurity = security as dynamic;
            dynamicSecurity.Sma = SMA(security.Symbol, 20);

            _securities.Add(security);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            if (_securities.Contains(security))
            {
                algorithm.DeregisterIndicator((security as dynamic).Sma);

                _securities.Remove(security);
            }
        }
    }
}
```

Universe Timing Considerations

If the Portfolio Construction model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate common practices for implementing the framework portfolio construction model.

Example 1: All-Weather Portfolio

The following algorithm uses `RiskParityPortfolioConstructionModel` to construct an all-weather portfolio that dissipates 1-year daily variance equally among ETFs that represent different asset classes, including stock market (SPY), bond (TLT), gold (GLD), oil (USO), and agricultural(DBA).

```C#
public class FrameworkPortfolioConstructionModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 1);

        // Add a universe of selected lists of ETFs that represent various asset classes.
        var etfs = new[] {
            QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA),     // stock market
            QuantConnect.Symbol.Create("TLT", SecurityType.Equity, Market.USA),     // bond
            QuantConnect.Symbol.Create("GLD", SecurityType.Equity, Market.USA),     // gold
            QuantConnect.Symbol.Create("USO", SecurityType.Equity, Market.USA),     // oil
            QuantConnect.Symbol.Create("DBA", SecurityType.Equity, Market.USA)      // agricultural
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(etfs));
        // Emit insights for all selected ETFs.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));
        // Using risk parity PCM to construct an all-weather portfolio to dissipate risk.
        SetPortfolioConstruction(new RiskParityPortfolioConstructionModel());
    }
}
```

Example 2: Protective Position

The following algorithm implements an equal-weighting portfolio on the given insights. To hedge catastrophic downside risk, each position would order a protective call/put 10% OTM.

C#

```
public class FrameworkPortfolioConstructionModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Set to raw data normalization for the strike and underlying price fair comparison.
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        // Add a universe of the market representative SPY.
        var spy = new[] {
            QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)
        };
        AddUniverseSelection(new ManualUniverseSelectionModel(spy));
        // Emit insights for all selected ETFs. Each insight lasts for 7 days for the option hedge expiry.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Using a custom PCM to control the order size and hedge option position order with a 10% OTM threshold.
        SetPortfolioConstruction(new ProtectivePositionPortfolioConstructionModel(0.1m));
    }

    private class ProtectivePositionPortfolioConstructionModel : PortfolioConstructionModel
    {
        private readonly decimal _threshold;

        public ProtectivePositionPortfolioConstructionModel(decimal threshold)
        {
            _threshold = threshold;
        }

        public override List<PortfolioTarget> CreateTargets(QCAlgorithm algorithm, Insight[] insights)
        {
            var targets = new List<PortfolioTarget>();
            if (insights.Length == 0)
            {
                return targets;
            }

            // Equally invest in each position group to dissipate the capital risk.
            var fundPerInsight = algorithm.Portfolio.TotalPortfolioValue / insights.Length;

            foreach (var insight in insights)
            {
                var underlying = insight.Symbol;
                // Hedge position option right: long position should purchase OTM put, while short should purchase
OTM call.
                var right = insight.Direction == InsightDirection.Up ? OptionRight.Put : OptionRight.Call;
                var threshold = insight.Direction == InsightDirection.Up ? 1m - _threshold : 1m + _threshold;

                // Select a protective option position that expires in 7 days.
                var hedge = algorithm.OptionChain(underlying)
                    .Where(x => x.Expiry < algorithm.Time.AddDays(7) && x.Right == right)
                    .OrderByDescending(x => x.Expiry)
                    .ThenBy(x => Math.Abs(x.Strike - x.UnderlyingLastPrice * threshold))
                    .First();
                // Request the protective position data for trading.
                var hedgeSymbol = algorithm.AddOptionContract(hedge).Symbol;

                // Each insight will be ordered by the position group of the underlying and the hedging option
positions.
                var contractMultiplier = algorithm.Securities[underlying].SymbolProperties.ContractMultiplier;
                var quantity = Math.Floor(fundPerInsight / contractMultiplier / (hedge.BidPrice +
hedge.UnderlyingLastPrice));
                targets.Add(new PortfolioTarget(underlying, (int)(quantity * contractMultiplier)));
                targets.Add(new PortfolioTarget(hedgeSymbol, (int)quantity));
            }

            return targets;
        }
    }
}
```

Portfolio Construction

Supported Models

Introduction

This page describes the pre-built Portfolio Construction models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Portfolio Construction model .

Null Model

The `NullPortfolioConstructionModel` is the default Portfolio Construction model. It doesn't return any `PortfolioTarget` objects. It's useful if you need to analyze an Alpha model in isolation.

```
C#
// Set portfolio construction to NullPortfolioConstructionModel to bypass custom logic, useful for simplifying
testing or initial development when you want to manually manage or skip automatic portfolio adjustments.
SetPortfolioConstruction(new NullPortfolioConstructionModel());
```

For more information about this model, see the class reference and implementation .

Equal Weighting Model

The `EqualWeightingPortfolioConstructionModel` assigns an equal share of the portfolio to the securities with active insights. This weighting scheme is useful for universe rotation based on simple portfolio strategies.

```
C#
// Set portfolio construction to EqualWeightingPortfolioConstructionModel to allocate capital equally across selected
securities, ensuring balanced exposure and reducing the influence of any single asset on the portfolio.
SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`resolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Confidence Weighted Model

The `ConfidenceWeightedPortfolioConstructionModel` generates target portfolio weights based on the `Insight. Confidence` for the last Insight of each Symbol. If the Insight has a direction of `InsightDirection. Up` , the model generates long targets. If the Insight has a direction of `InsightDirection. Down` , the model generates short targets. If the sum of all the last active

Insight per Symbol is greater than 1, the model factors down each target percent holdings proportionally so the sum is 1. The model ignores `Insight` objects that have no `Confidence` value.

```
// Use ConfidenceWeightedPortfolioConstructionModel to assign portfolio weights based on the confidence level of the
latest Insights, creating long or short positions accordingly, and normalizing weights if the total exceeds 1,
leveraging the strength of predictions for better allocation and risk management.
SetPortfolioConstruction(new ConfidenceWeightedPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`resolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LongShor t`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Insight Weighting Model

The `InsightWeightingPortfolioConstructionModel` generates target portfolio weights based on the `Insight. Weight` for the last Insight of each Symbol. If the Insight has a direction of `InsightDirection. Up` , the model generates long targets. If the Insight has a direction of `InsightDirection. Down` , the model generates short targets. If the sum of all the last active Insight per Symbol is greater than 1, the model factors down each target percent holdings proportionally so the sum is 1. The model takes the absolute value of the `Weight` of each `Insight` object and ignores `Insight` objects that have no `Weight` value.

```
// Use InsightWeightingPortfolioConstructionModel to allocate capital based on the latest Insight weights, generating
long or short targets as per the Insight direction and adjusting allocations if total weights exceed 1, ensuring
portfolio weights reflect current market insights and maintains proper risk management.
SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`resolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LongShor t`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Sector Weighting Model

The `SectorWeightingPortfolioConstructionModel` generates target portfolio weights based on the `CompanyReference.IndustryTemplateCode` provided by the US Fundamental dataset . The target percent holdings of each sector is 1/S where S is the number of sectors and the target percent holdings of each security is 1/N where N is the number of securities of each sector. If the insight has a direction of `InsightDirection. Up` , the model generates long targets. If the insight has a direction of `InsightDirection. Down` , the model generates short targets. The model ignores `Insight` objects for Symbols that have no `CompanyReference.IndustryTemplateCode` .

```
C#
// Use SectorWeightingPortfolioConstructionModel to ensure diversified sector exposure and balanced allocation,
aligning portfolio weights with sector insights while managing long and short positions based on insight direction.
SetPortfolioConstruction(new SectorWeightingPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`resolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Accumulative Insight Model

The `AccumulativeInsightPortfolioConstructionModel` generates target portfolio weights based on all the active insights of a security. For each active Insight of direction `InsightDirection. Up` , it increases the position size by a fixed percent. For each active Insight of direction `InsightDirection. Down` , it decreases the position size by a fixed percent. For each active Insight of direction `InsightDirection.Flat` , it moves the position size towards 0 by a fixed percent.

```
C#
// Use AccumulativeInsightPortfolioConstructionModel to adjust portfolio weights based on the cumulative value of all
active insights, increasing position size for insights with UP direction to capitalize on expected upward movements,
while reducing position size with down or flat insights to mitigate potential losses.
SetPortfolioConstruction(new AccumulativeInsightPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalanceFunc`	`Func<DateTime, DateTime?>`	A function that receives the algorithm UTC time and returns the next expected rebalance time. If the function returns `null`, the portfolio doesn't rebalance.	`null`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`
`percent`	`double`	The percentage amount of the portfolio value to allocate to a single insight	0.03 (3%)

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Mean Variance Optimization Model

The `MeanVarianceOptimizationPortfolioConstructionModel` seeks to build a portfolio with the least volatility possible and achieve a target return.

```
C#
// Use MeanVarianceOptimizationPortfolioConstructionModel to determine portfolio weights by optimizing for the best
risk-return trade-off balancing the expected returns against the risk of each security to construct a portfolio
aiming to maximize returns for a given level of risk or minimize risk for a given level of returns.
SetPortfolioConstruction(new MeanVarianceOptimizationPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalanceResolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias.LongShort`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	63
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`
`targetReturn`	`double`	The target portfolio return	0.02 (2%)
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`null`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the MinimumVariancePortfolioOptimizer with upper and lower weights that respect the `portfolioBias` .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Black Litterman Optimization Model

The `BlackLittermanOptimizationPortfolioConstructionModel` receives `Insight` objects from multiple Alphas and combines them into a single portfolio. These multiple sources of Alpha models can be seen as the "investor views" required in the classical model.

```
C#
// Use BlackLittermanOptimizationPortfolioConstructionModel to incorporate market equilibrium portfolio and the
investor views to create an improved portfolio aligning with both market expectations and investor insights.
SetPortfolioConstruction(new BlackLittermanOptimizationPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalanceResolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LongShort`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	63
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`
`riskFreeRate`	`double`	The risk free rate	0.0
`delta`	`double`	The risk aversion coefficient of the market portfolio	2.5
`tau`	`double`	The model parameter indicating the uncertainty of the CAPM prior	0.05
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`null`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the MinimumVariancePortfolioOptimizer with upper and lower weights that respect the `portfolioBias` .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security

when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Mean Reversion Model

The `MeanReversionPortfolioConstructionModel` implements an on-line portfolio selection technique, named "On-Line Moving Average Reversion" (OLMAR). The basic idea is to represent multi-period mean reversion as "Moving Average Reversion" (MAR), which explicitly predicts next price relatives using moving averages and then forms portfolios with online learning techniques.

```
C#
// Use MeanReversionPortfolioConstructionModel to build a portfolio that capitalizes on the expected mean-reversion
of asset prices, adjusting allocations based on deviations from historical averages to potentially enhance returns by
exploiting price reversions.
SetPortfolioConstruction(new MeanReversionPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalanceResolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LongShor t`
`reversionThreshold`	`decimal`	Reversion threshold	1
`windowSize`	`int`	The window size of mean price	20
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Reference:

- Li, B., Hoi, S. C. (2012). On-line portfolio selection with moving average reversion. arXiv preprint arXiv:1206.4626 .

Risk Parity Model

The `RiskParityPortfolioConstructionModel` seeks to build a portfolio with the equal contribution of risk to the total portfolio risk from all assets.

```
C#
// Use RiskParityPortfolioConstructionModel to allocate portfolio weights based on risk contributions, ensuring that
each asset contributes equally to the portfolio's overall risk, aiming for balanced risk exposure and potentially
improved risk-adjusted returns.
SetPortfolioConstruction(new RiskParityPortfolioConstructionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`rebalanceResolution`	`Resolution`	Rebalancing frequency	`Resolution.Daily`
`portfolioBias`	`PortfolioBias`	The bias of the portfolio	`PortfolioBias. LongShort`
`lookback`	`int`	Historical return lookback period	1
`period`	`int`	The time interval of history price to calculate the weight	252
`resolution`	`Resolution`	The resolution of the history price	`Resolution.Daily`
`optimizer`	`IPortfolioOptimizer`	The portfolio optimization algorithm	`null`

This model supports other data types for the rebalancing frequency argument. For more information about the supported types, see Rebalance Frequency . If you don't provide an `optimizer` argument, the default one is the RiskParityPortfolioOptimizer .

This model removes expired insights from the Insight Manager during each rebalance. It also removes all insights for a security when the security is removed from the universe .

For more information about this model, see the class reference and implementation .

Portfolio Construction

Supported Optimizers

Introduction

This page describes the pre-built Portfolio Optimizer models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Portfolio Optimizer model .

Maximum Sharpe Ratio Optimizer

The `MaximumSharpeRatioPortfolioOptimizer` seeks to maximize the portfolio Sharpe Ratio .

```
C#
var optimizer = new MaximumSharpeRatioPortfolioOptimizer();
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lower`	`double`	The lower bounds on portfolio weights	-1
`upper`	`double`	The upper bounds on portfolio weights	1
`riskFreeRate`	`double`	The risk free rate	0

For more information about this model, see the class reference and implementation .

Minimum Variance Optimizer

The `MinimumVariancePortfolioOptimizer` seeks to minimize the portfolio variance and achieve a target return.

```
C#
var optimizer = new MinimumVariancePortfolioOptimizer();
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lower`	`double`	The lower bounds on portfolio weights	-1
`upper`	`double`	The upper bounds on portfolio weights	1
`targetReturn`	`double`	The target portfolio return	0.02 (2%)

For more information about this model, see the class reference and implementation .

Unconstrained Mean Variance Optimizer

The `UnconstrainedMeanVariancePortfolioOptimizer` seeks to find the optimal risk-adjusted portfolio that lies on the efficient frontier.

```C#
var optimizer = new UnconstrainedMeanVariancePortfolioOptimizer();
```

For more information about this model, see the class reference and implementation .

Risk Parity Optimizer

The `RiskParityPortfolioOptimizer` seeks to equalize the individual risk contribution to the total portfolio risk from each asset.

```C#
var optimizer = new RiskParityPortfolioOptimizer();
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`lower`	`double`	The lower bounds on portfolio weights	1e-05
`upper`	`double`	The upper bounds on portfolio weights	`Double.MaxValue`

For more information about this model, see the class reference and implementation .

Algorithm Framework

Risk Management

Risk Management

Key Concepts

Introduction

The Risk Management model seeks to manage risk on the `PortfolioTarget` collection it receives from the Portfolio Construction model before the targets reach the Execution model. There are many creative ways to manage risk. Some examples of risk management include the following:

- *"Trailing Stop Risk Management Model"*
  Create and manage trailing stop-loss orders for open positions.
- *"Option Hedging Risk Management Model"*
  Purchase options to hedge large equity exposures.
- *"Sector Exposure Risk Management Model"*
  Reduce position sizes when overexposed to sectors or individual assets, keeping the portfolio within diversification requirements.
- *"Flash Crash Detection Risk Management Model"*
  Scan for strange market situations that might be precursors to a flash crash and attempt to protect the portfolio when they are detected.

Add Models

To set a Risk Management model, in the `Initialize` method, call the `AddRiskManagement` method.

```
C#
// Add the null risk management model, which doesn't affect the portfolio targets.
AddRiskManagement(new NullRiskManagementModel());
```

To view all the pre-built Risk Management models, see Supported Models .

Multi-Model Algorithms

To add multiple Risk Management models, in the `Initialize` method, call the `AddRiskManagement` method multiple times.

```
C#
// Add multiple Risk Management models to sequentially adjust portfolio targets, with each model refining the targets
passed from the previous model, managing risk across individual securities and sectors.
AddRiskManagement(new MaximumDrawdownPercentPerSecurity());
AddRiskManagement(new MaximumSectorExposureRiskManagementModel());
```

If you add multiple Risk Management models, the original collection of `PortfolioTarget` objects from the Portfolio Construction model is passed to the first Risk Management model. The risk-adjusted targets from the first Risk Management model are

passed to the second Risk Management model. The process continues sequentially until all of the Risk Management models have had an opportunity to adjust the targets.

Model Structure

Risk Management models should extend the `RiskManagementModel` class. Extensions of the `RiskManagementModel` class must implement the `ManageRisk` method, which receives an array of `PortfolioTarget` objects from the Portfolio Construction model at every time step and should return an array of risk-adjusted `PortfolioTarget` objects. The method should only return the adjusted targets, not all of targets. If the method creates a `PortfolioTarget` object to liquidate a security, cancel the security's insights to avoid re-entering the position.

```C#
// Extend the RiskManagementModel class by implementing the ManageRisk method, which receives PortfolioTarget objects
from the Portfolio Construction model and returns only the risk-adjusted targets.
class MyRiskManagementModel : RiskManagementModel
{
    // Adjust the portfolio targets and return them. If no changes emit nothing.
    public override List<PortfolioTarget> ManageRisk(QCAlgorithm algorithm, PortfolioTarget[] targets)
    {
        return new List<PortfolioTarget>();
    }

    // Optional: Be notified when securities change
    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        // Security additions and removals are pushed here.
        // This can be used for setting up algorithm state.
        // changes.AddedSecurities
        // changes.RemovedSecurities
    }
}
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

To view a full example of a `RiskManagementModel` subclass, see the MaximumDrawdownPercentPerSecurity in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Risk Management model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Risk Management model. If you need to save data for individual securities, cast the `Security` object to a `dynamic` object and then save custom members to it .

```
C#
class MyRiskManagementModel : RiskManagementModel{
    private List<Security> _securities = new List<Security>();

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        base.OnSecuritiesChanged(algorithm, changes);
        foreach (var security in changes.AddedSecurities)
        {
            // Store and manage Symbol-specific data
            var dynamicSecurity = security as dynamic;
            dynamicSecurity.Sma = SMA(security.Symbol, 20);

            _securities.Add(security);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            if (_securities.Contains(security))
            {
                algorithm.DeregisterIndicator((security as dynamic).Sma);

                _securities.Remove(security);
            }
        }
    }
}
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `Add` method.

```
C#
_targetsCollection.Add(portfolioTarget);
```

To add a list of `PortfolioTarget` objects, call the `AddRange` method.

```
C#
_targetsCollection.AddRange(portfolioTargets);
```

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `Contains` method.

```
C#
var targetInCollection = _targetsCollection.Contains(portfolioTarget);
```

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `ContainsKey` method.

```
C#
var symbolInCollection = _targetsCollection.ContainsKey(symbol);
```

To get all the Symbol objects, use the `Keys` property.

```
var symbols = _targetsCollection.Keys;
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
var portfolioTarget = _targetsCollection[symbol];
```

To iterate through the `PortfolioTargetCollection` , call the `GetEnumerator` method.

```
var enumerator = _targetsCollection.GetEnumerator();
```

To get all the `PortfolioTarget` objects, use the `Values` property

```
var portfolioTargets = _targetsCollection.Values;
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `OrderByMarginImpact` method.

```
foreach (var target in _targetsCollection.OrderByMarginImpact(algorithm))
{
    // Place order
}
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `Remove` method.

```
removeSuccessful = _targetsCollection.Remove(symbol);
```

To remove all the `PortfolioTarget` objects, call the `Clear` method.

```
_targetsCollection.Clear();
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `ClearFulfilled` method.

```
_targetsCollection.ClearFulfilled(algorithm);
```

Universe Timing Considerations

If the Risk Management model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate some common practices for implementing a risk management model.

Example 1: Take Profit Stop Loss

The following algorithm trades 20-60 EMA crosses on the top 500 liquid US stocks in equal weighting. To minimize risk and capture early profit, we can implement both `MaximumUnrealizedProfitPercentPerSecurity` to take profit and `TrailingStopRiskManagementModel` to stop loss by trailing high price.

```
C#
public class FrameworkRiskManagementAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe of the most liquid stocks since their trend is more capital-supported.
        AddUniverseSelection(new QC500UniverseSelectionModel());
        // Emit insights on EMA cross, indicating the trend changes. We use short-term versus medium-term for more
trade opportunities.
        AddAlpha(new EmaCrossAlphaModel(20, 60, Resolution.Daily));
        // Equal weighting on each insight is needed to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        // Take profit at 10%.
        AddRiskManagement(new MaximumUnrealizedProfitPercentPerSecurity(0.1m));
        // Trailing stop loss at 5%.
        AddRiskManagement(new TrailingStopRiskManagementModel(0.05m));
    }
}
```

Example 2: Tail Value At Risk

The following algorithm implements a custom risk management model that liquidates the position if an asset has PnL lower than the tail value-at-risk (TVaR) throughout the insight to avoid large catastrophic losses. To calculate the TVaR, we create a log return indicator and use the following formula for the calculation: $\textrm{TVaR}_{\alpha} = \mu + \sigma \times \phi[\Phi^{-1}(\alpha)] / (1 - \alpha)$

```
C#
```

```
using Accord.Statistics;
using MathNet.Numerics.Distributions;

public class FrameworkRiskManagementAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 15);
        SetCash(1000000);

        // Add a universe of the most liquid stocks since their trend is more capital-supported.
        AddUniverseSelection(new QC500UniverseSelectionModel());
        // Emit insights all for selected stocks, rebalancing every 2 weeks.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(14)));
        // Equal weighting on each insight is needed to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        // Liquidate on extreme catastrophic event.
        AddRiskManagement(new TailValueAtRiskRiskManagementModel(0.05d, 14d));
    }

    private class TailValueAtRiskRiskManagementModel : RiskManagementModel

Risk Management

Supported Models

Introduction

This page describes the pre-built Risk Management models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Risk Management model .

Null Model

The `NullRiskManagementModel` is the default Risk Management model. It doesn't adjust any of the `PortfolioTarget` objects it receives from the Portfolio Construction model.

```
C#
// Adding the null risk management model doesn't affect the portfolio targets.
AddRiskManagement(new NullRiskManagementModel());
```

For more information about this model, see the class reference and implementation .

Maximum Security Drawdown Model

The `MaximumDrawdownPercentPerSecurity` model monitors the unrealized profit percentage of each security in the portfolio. When the percentage drops below a threshold relative to the opening price, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
C#
// Add risk management model to limit maximum drawdown per security, reducing position size to prevent further
losses.
AddRiskManagement(new MaximumDrawdownPercentPerSecurity());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumDrawdownPercent`	`decimal`	The maximum percentage drawdown allowed for any single security holding	0.05 (5%)

For more information about this model, see the class reference and implementation .

Maximum Portfolio Drawdown Model

The `MaximumDrawdownPercentPortfolio` model monitors the portfolio drawdown . The drawdown can be relative to the starting portfolio value or the maximum portfolio value. When the portfolio value drops below a percentage threshold, the model liquidates the portfolio and cancels all insights in the Insight Manager . To liquidate the portfolio, the model must receive at least 1 `PortfolioTarget` after the drawdown threshold is passed. After the portfolio is liquidated, the model resets. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
// Add risk management model to limit maximum drawdown for the entire portfolio, protecting overall portfolio value
from significant losses.
AddRiskManagement(new MaximumDrawdownPercentPortfolio());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumDrawdownPercent`	`decimal`	Maximum spread accepted comparing to current price in percentage	0.05 (5%)
`isTrailing`	`bool`	If `false` , the drawdown is relative to the starting value of the portfolio. If `true` , the drawdown is relative the last maximum portfolio value	`false`

For more information about this model, see the class reference and implementation .

Maximum Unrealized Profit Model

The `MaximumUnrealizedProfitPercentPerSecurity` model monitors the unrealized profit of each security in the portfolio. When the unrealized profit exceeds a profit threshold, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
// Add risk management model to secure gains by limiting the maximum unrealized profit for each security, locking in
profits before potential reversals.
AddRiskManagement(new MaximumUnrealizedProfitPercentPerSecurity());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumUnrealizedProfitPercent`	`decimal`	The maximum percentage unrealized profit allowed for any single security holding	0.05 (5%)

For more information about this model, see the class reference and implementation .

Maximum Sector Exposure Model

The `MaximumSectorExposureRiskManagementModel` limits the absolute portfolio exposure in a each industry sector to a predefined maximum percentage. If the absolute portfolio exposure exceeds the maximum percentage, the weight of each Equity in the sector is scaled down so the sector doesn't exceed the maximum percentage. This process requires assets that are selected by Morningstar fundamental data . This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
// Add risk management model to limit exposure to any single sector, ensuring diversification and reducing sector-specific risk.
AddRiskManagement(new MaximumSectorExposureRiskManagementModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumSectorExposure`	`decimal`	The maximum exposure for any sector	0.2 (20%)

For more information about this model, see the class reference and implementation .

Trailing Stop Model

The `TrailingStopRiskManagementModel` monitors the drawdown of each security in the portfolio. When the peak-to-trough drawdown of the unrealized profit exceeds a threshold, it liquidates the position and cancels all insights in the Insight Manager that are for the security. This model can operate even when the Portfolio Construction model provides an empty list of `PortfolioTarget` objects.

```
// Add risk management model to implement trailing stops, which adjusts stop-loss levels as the price moves favorably, helping to lock in gains and limit losses.
AddRiskManagement(new TrailingStopRiskManagementModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`maximumDrawdownPercent`	`decimal`	The maximum percentage drawdown allowed for algorithm portfolio compared with the highest unrealized profit	0.05 (5%)

For more information about this model, see the class reference and implementation .

Algorithm Framework

Execution

Execution

Key Concepts

Introduction

The Execution model receives an array of risk-adjusted `PortfolioTarget` objects from the Risk Management model and places trades in the market to satisfy the targets. The Execution model only receives updates to the portfolio target share counts. It doesn't necessarily receive all of the targets at once.

Set Models

To set an Execution model, in the `Initialize` method, call the `SetExecution` method.

```
// Satisify portfolio targets by immediately sending market orders.
SetExecution(new ImmediateExecutionModel());
```

To view all the pre-built Execution models, see Supported Models .

Model Structure

Execution models should extend the `ExecutionModel` class. Extensions of the `ExecutionModel` must implement the `Execute` method, which receives an array of `PortfolioTarget` objects at every time step and is responsible for reaching the target portfolio as efficiently as possible. The Portfolio Construction model creates the `PortfolioTarget` objects, the Risk Management model may adjust them, and then the Execution model places the orders to fulfill them.

```C#
 // Basic Execution Model Scaffolding Structure Example
class MyExecutionModel : ExecutionModel {

   // Fill the supplied portfolio targets efficiently.
   public override void Execute(QCAlgorithm algorithm, IPortfolioTarget[] targets)
   {
      // NOP
   }

   //  Optional: Securities changes event for handling new securities.
   public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
   {
        // Security additions and removals are pushed here.
        // This can be used for setting up algorithm state.
        // changes.AddedSecurities
        // changes.RemovedSecurities
   }

   //  Optional: Order event for handling new order events.
   public override void OnOrderEvent(QCAlgorithm algorithm, OrderEvent orderEvent)
   {
        // Order events are pushed here.
        // This can be used for tracking order status or handling invalid and cancelled orders.
   }
}
```

The `algorithm` argument that the methods receive is an instance of the base `QCAlgorithm` class, not your subclass of it.

The following table describes the properties of the `PortfolioTarget` class that you may access in the Execution model:

Property	Data Type	Description
`Symbol`	`Symbol`	Asset to trade
`Quantity`	`decimal`	Number of units to hold

To view a full example of an `ExecutionModel` subclass, see the ImmediateExecutionModel in the LEAN GitHub repository.

Track Security Changes

The Universe Selection model may select a dynamic universe of assets, so you should not assume a fixed set of assets in the Execution model. When the Universe Selection model adds and removes assets from the universe, it triggers an `OnSecuritiesChanged` event. In the `OnSecuritiesChanged` event handler, you can initialize the security-specific state or load any history required for your Execution model. If you need to save data for individual securities, cast the `Security` object to a `dynamic` object and then save custom members to it .

```
C#
class MyExecutionModel : ExecutionModel{
    private List<Security> _securities = new List<Security>();

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // Store and manage Symbol-specific data
            var dynamicSecurity = security as dynamic;
            dynamicSecurity.Sma = SMA(security.Symbol, 20);

            _securities.Add(security);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            if (_securities.Contains(security))
            {
                algorithm.DeregisterIndicator((security as dynamic).Sma);

                _securities.Remove(security);
            }
        }
    }
}
```

Portfolio Target Collection

The `PortfolioTargetCollection` class is a helper class to manage `PortfolioTarget` objects. The class manages an internal dictionary that has the security `Symbol` as the key and a `PortfolioTarget` as the value.

Add Portfolio Targets

To add a `PortfolioTarget` to the `PortfolioTargetCollection` , call the `Add` method.

```
C#
_targetsCollection.Add(portfolioTarget);
```

To add a list of `PortfolioTarget` objects, call the `AddRange` method.

```
C#
_targetsCollection.AddRange(portfolioTargets);
```

Check Membership

To check if a `PortfolioTarget` exists in the `PortfolioTargetCollection` , call the `Contains` method.

```
C#
var targetInCollection = _targetsCollection.Contains(portfolioTarget);
```

To check if a Symbol exists in the `PortfolioTargetCollection` , call the `ContainsKey` method.

```
C#
var symbolInCollection = _targetsCollection.ContainsKey(symbol);
```

To get all the Symbol objects, use the `Keys` property.

```
var symbols = _targetsCollection.Keys;
```

Access Portfolio Targets

To access the `PortfolioTarget` objects for a Symbol, index the `PortfolioTargetCollection` with the Symbol.

```
var portfolioTarget = _targetsCollection[symbol];
```

To iterate through the `PortfolioTargetCollection` , call the `GetEnumerator` method.

```
var enumerator = _targetsCollection.GetEnumerator();
```

To get all the `PortfolioTarget` objects, use the `Values` property

```
var portfolioTargets = _targetsCollection.Values;
```

Order Portfolio Targets by Margin Impact

To get an enumerable where position reducing orders are executed first and the remaining orders are executed in decreasing order value, call the `OrderByMarginImpact` method.

```
foreach (var target in _targetsCollection.OrderByMarginImpact(algorithm))
{
    // Place order
}
```

This method won't return targets for securities that have no data yet. This method also won't return targets for which the sum of the current holdings and open orders quantity equals the target quantity.

Remove Portfolio Targets

To remove a `PortfolioTarget` from the `PortfolioTargetCollection` , call the `Remove` method.

```
removeSuccessful = _targetsCollection.Remove(symbol);
```

To remove all the `PortfolioTarget` objects, call the `Clear` method.

```
_targetsCollection.Clear();
```

To remove all the `PortfolioTarget` objects that have been fulfilled, call the `ClearFulfilled` method.

```
_targetsCollection.ClearFulfilled(algorithm);
```

Universe Timing Considerations

If the Execution model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate some common practices for implementing the execution model.

Example 1: Iceberg Execution

The following algorithm simulates an account with large capital that equally holds the most liquid stocks. To hide the footprint and avoid a large market impact that might erode the profit margin, we can set up an iceberg execution system, submitting only 10% of the volume of the bid/ask side order book to the order direction.

```C#
public class FrameworkExecutionModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000000);

        // Add a universe of the most liquid stocks since their trend is more capital-supported.
        AddUniverseSelection(new QC500UniverseSelectionModel());
        // Emit insights all for selected stocks.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Equal weighting on each insight is needed to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        // Iceberg ordering to hide traces and avoid market impact.
        // Since quote data will be used, make sure the asset class and resolution are compatible.
        SetExecution(new IcebergExecutionModel(0.1m));
    }

    private class IcebergExecutionModel : ExecutionModel
    {
        private readonly PortfolioTargetCollection _targetsCollection = new PortfolioTargetCollection();
        // The maximum order size taken from the order book in percentage.
        private readonly decimal _maximumOrderQuantityPercentVolume;

        public IcebergExecutionModel(decimal orderPercentVolume = 0.1m)
        {
            _maximumOrderQuantityPercentVolume = orderPercentVolume;
        }

        public override void Execute(QCAlgorithm algorithm, IPortfolioTarget[] targets)
        {
            //Update the complete set of portfolio targets with the new targets
            _targetsCollection.AddRange(targets);

            if (!_targetsCollection.IsEmpty)
            {
                foreach (var target in _targetsCollection.OrderByMarginImpact(algorithm))
                {
                    var symbol = target.Symbol;

                    // Calculate the remaining quantity to be ordered
                    var unorderedQuantity = OrderSizing.GetUnorderedQuantity(algorithm, target);
                    // Adjust order size to respect maximum order size based on a percentage of the current volume
                    var orderSize = GetOrderSizeForPercentVolume(algorithm.Securities[symbol],
_maximumOrderQuantityPercentVolume, unorderedQuantity);

                    if (orderSize != 0)
                    {
                        algorithm.MarketOrder(symbol, orderSize);
                    }
                }

                _targetsCollection.ClearFulfilled(algorithm);
            }
        }

        private static decimal GetOrderSizeForPercentVolume(Security security, decimal maximumPercentCurrentVolume,
decimal desiredOrderSize)
        {
            // Take N% from the order book according to the order direction.
            var maxOrderSize = maximumPercentCurrentVolume * (desiredOrderSize > 0 ? security.BidSize :
security.AskSize);
            var orderSize = Math.Min(maxOrderSize, Math.Abs(desiredOrderSize));

            return Math.Sign(desiredOrderSize) * OrderSizing.AdjustByLotSize(security, orderSize);
        }
    }
}
```

Example 2: More Favorable Than Signal Time

Some algorithms are signaling based on daily close data. However, their orders often emit when the next market opens, making the filling price slip. To avoid this slippage negatively impacting your expectations, we can construct a custom execution model

to place orders only when the price is more favorable than the last close price. Although we did not set a time limit in this example, you may consider doing so.

C#

```
public class FrameworkExecutionModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 1);

        // Add a universe of the most liquid stocks since their trend is more capital-supported.
        AddUniverseSelection(new QC500UniverseSelectionModel());
        // Emit insights all for selected stocks.
        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(7)));
        // Equal weighting on each insight is needed to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        // Only place an order if the price is more favorable than the price at the insight signal.
        SetExecution(new FavorableExecutionModel());
    }

    private class FavorableExecutionModel : ExecutionModel
    {
        private readonly PortfolioTargetCollection _targetsCollection = new PortfolioTargetCollection();
        private Dictionary<Symbol, decimal> _lagPriceBySymbol = new();

        public override void Execute(QCAlgorithm algorithm, IPortfolioTarget[] targets)
        {
            _targetsCollection.AddRange(targets);
            if (!_targetsCollection.IsEmpty)
            {
                foreach (var target in _targetsCollection.OrderByMarginImpact(algorithm))
                {
                    var symbol = target.Symbol;
                    var security = algorithm.Securities[symbol];

                    // Calculate the remaining quantity to be ordered
                    var quantity = OrderSizing.GetUnorderedQuantity(algorithm, target, security, true);

                    if (quantity != 0)
                    {
                        if
(BuyingPowerModelExtensions.AboveMinimumOrderMarginPortfolioPercentage(security.BuyingPowerModel, security, quantity,
                            algorithm.Portfolio, algorithm.Settings.MinimumOrderMarginPortfolioPercentage))
                        {
                            // Cache the price at signal emission to compare if the current price is more favorable.
                            if (!_lagPriceBySymbol.TryGetValue(symbol, out var lastPrice))
                            {
                                var history = algorithm.History<TradeBar>(symbol, 1, Resolution.Daily);
                                _lagPriceBySymbol[symbol] = lastPrice = history.Last().Close;
                            }

                            // Only order if the price is more favorable than the price at signal emission.
                            if ((security.Price <= lastPrice && quantity > 0) || (security.Price >= lastPrice &&
quantity < 0))
                            {
                                algorithm.MarketOrder(security, quantity);
                            }
                        }
                        else if (!PortfolioTarget.MinimumOrderMarginPercentageWarningSent.HasValue)
                        {
                            // will trigger the warning if it has not already been sent
                            PortfolioTarget.MinimumOrderMarginPercentageWarningSent = false;
                        }
                    }
                }

                _targetsCollection.ClearFulfilled(algorithm);
            }
        }
    }
}
```

Execution

Supported Models

Introduction

This page describes the pre-built Execution models in LEAN. The number of models grows over time. To add a model to LEAN, make a pull request to the GitHub repository . If none of these models perform exactly how you want, create a custom Execution model .

Null Model

The `NullExecutionModel` doesn't place any trades.

```
C#
// Set the execution model to NullExecutionModel, which disables execution functionality for debugging or when the
execution logic is not needed for the current strategy.
SetExecution(new NullExecutionModel());
```

For more information about this model, see the class reference and implementation .

Immediate Model

The `ImmediateExecutionModel` is the default Execution model. It uses market orders to immediately fill portfolio targets. It's similar to placing market orders in line with your algorithm logic.

```
C#
// Use ImmediateExecutionModel for executing trades instantly at market price to minimize execution delay. This may
incur extra slippage.
SetExecution(new ImmediateExecutionModel());
```

For more information about this model, see the class reference and implementation .

Spread Model

The `SpreadExecutionModel` executes trades with market orders if the exchange is open and the bid-ask spread is within a threshold percentage. The model only works if the security subscription provides QuoteBar data. The spread percentage is calculated as

$$\frac{a - b}{p}$$

where a is the ask price, b is the bid price, and p is the price.

```
C#
// Use SpreadExecutionModel to manage trade execution based on bid-ask spreads, aiming to optimize trade execution
costs and reduce slippage.
SetExecution(new SpreadExecutionModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`acceptingSpreadPercent`	`decimal`	Maximum spread accepted comparing to current price in percentage	0.005 (0.5%)

For more information about this model, see the class reference and implementation .

Standard Deviation Model

The `StandardDeviationExecutionModel` seeks to fill orders when the price is more than 2 standard deviations lower than the average price over a trailing period. The intent is to find dips in the market to place trades. In strongly trending markets, this procedure can result in delayed trade placement since it might be a while before the next price spike or dip.

```
// Use StandardDeviationExecutionModel to execute trades based on volatility measures, aiming to adapt trade sizes
and timing according to market volatility.
SetExecution(new StandardDeviationExecutionModel());
```

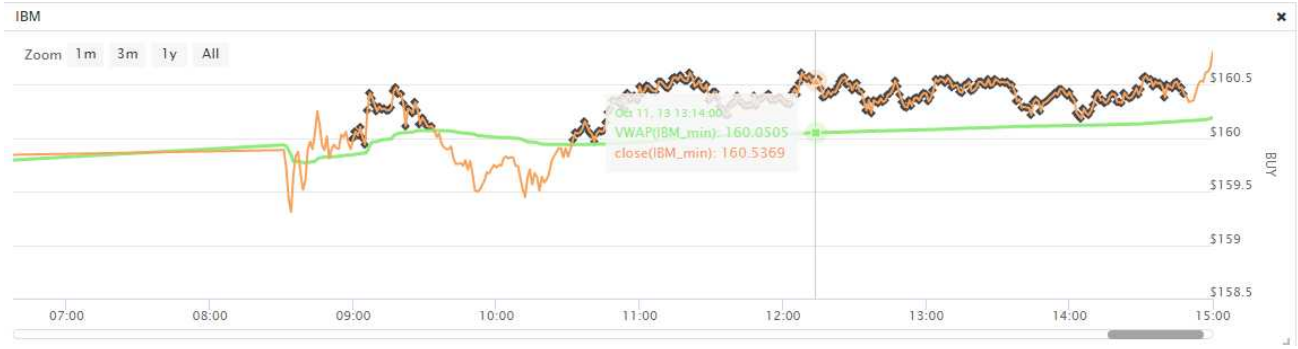
The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`period`	`decimal`	Period of the standard deviation indicator	60
`deviations`	`int`	The number of deviations away from the mean before submitting an order	2
`resolution`	`Resolution`	The resolution of the STD and SMA indicators	`Resolution.Minute`

For more information about this model, see the class reference and implementation .

VWAP Model

The `VolumeWeightedAveragePriceExecutionModel` works to fill your orders at or better than the volume-weighted average price (VWAP) for the trading day. This is a best-effort algorithm, so no guarantee can be made that it will reach the VWAP.



VWAP Execution Model Fill Placements

The model uses market orders and it only works if the security subscription provides intraday data. It sets a maximum order size of 1% of the current bar's volume, but you can update the maximum order size through the `MaximumOrderQuantityPercentVolume` member.

```C#
// Use VolumeWeightedAveragePriceExecutionModel to execute trades based on volume-weighted average price, aiming to
minimize market impact and achieve better execution prices.
SetExecution(new VolumeWeightedAveragePriceExecutionModel());
```

For more information about this model, see the class reference and implementation .

Algorithm Framework

Hybrid Algorithms

Introduction

Classic style algorithms can also use Algorithm Framework modules. This allows you to get the best of both styles of algorithm design, combining easily pluggable modules with the superior control of classic format.

Examples of popular use-cases of a hybrid approach are:

- Using framework universe selection models as the assets to select.
- Using portfolio construction models to decide portfolio allocations.
- Using a risk control model for free portfolio risk monitoring.
- Passing data between modules freely without concerns of the module interface.

Universe Selection

You can add one or more Framework Universe Selection Models to your algorithm and it will operate normally. You can also combine it with the `AddUniverse` method of the classic approach. The following example initializes a classic algorithm with framework universe selection models:

```
C#
// Use a hybrid approach by combining Framework Universe Selection Models with classic methods to leverage both the
modular flexibility of Framework modules and the control of classic design. This allows for better universe
selection, portfolio allocation, and risk management.
public override void Initialize()
{
    UniverseSettings.Asynchronous = true;
    SetUniverseSelection(new ManualUniverseSelectionModel(QuantConnect.Symbol.Create("SPY", SecurityType.Equity,
Market.USA)));
    AddUniverseSelection(new ManualUniverseSelectionModel(QuantConnect.Symbol.Create("AAPL", SecurityType.Equity,
Market.USA)));
    AddUniverse(Universe.Top(5));
}
```

Alpha

You can add one or multiple Alpha models to your classic algorithm and place the orders using `Insight` objects without a Portfolio Construction model. To receive the collection of `Insight` objects in a classic algorithm, implement the `InsightsGenerated` event handler:

```
C#
// Add one or multiple Alpha models to a classic algorithm allowing for direct trading based on generated Insight
objects, bypassing the need for a Portfolio Construction model.
public override void Initialize()
{
    AddAlpha(new EmaCrossAlphaModel());
    // The InsightsGenerated event handler is used to receive and process the collection of insights, facilitating
flexible and dynamic trading strategies.
    InsightsGenerated += OnInsightsGenerated;
}
private void OnInsightsGenerated(IAlgorithm algorithm, GeneratedInsightsCollection insightsCollection)
{
    var insights = insightsCollection.Insights;
}
```

Portfolio Construction

You can add a Portfolio Construction model to your classic algorithm and have it place orders without returning `Insight` objects from an Alpha model. To emit insights without an Alpha model, in the `OnData` method, call the `EmitInsights` method.

The following example uses a Portfolio Construction Framework model with `EmitInsights` method in a classic algorithm:

```C#
// Add a Portfolio Construction model to place orders directly without relying on Alpha-generated insights.
public override void Initialize()
{
    SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
}
// Use the EmitInsights method in the OnData method to provide trading signals for executing trades, ensuring
balanced investment with the chosen Portfolio Construction model.
public override void OnData(Slice slice)
{
 EmitInsights(new Insight("GOOG", TimeSpan.FromMinutes(20), InsightType.Price, InsightDirection.Up));
 EmitInsights(new []{
  new Insight("AAPL", TimeSpan.FromMinutes(20), InsightType.Price, InsightDirection.Up),
  new Insight("MSFT", TimeSpan.FromMinutes(20), InsightType.Price, InsightDirection.Up)
 });
}
```

Risk Management

Some Risk Management Models don't require a Portfolio Construction model to provide `PortfolioTarget` objects, allowing them to directly monitor the portfolio holdings and liquidate positions when neccessary. To see which pre-built Risk Management models don't need the Portfolio Construction model to provide `PortfolioTarget` objects, see Supported Models .

You can add one or more Risk Management Models to your algorithm and it will operate normally. The following example initializes a classic algorithm with framework risk management models:

```C#
// Add Risk Management models to monitor portfolio risk directly, without needing PortfolioTargets from a Portfolio
Construction model. These models can independently manage holdings and trigger liquidations as needed.
public override void Initialize()
{
    AddRiskManagement(new MaximumDrawdownPercentPerSecurity(0.05m));
    AddRiskManagement(new MaximumUnrealizedProfitPercentPerSecurity(0.1m));
}
```

Execution

Execution models can place orders for your strategy instead of placing them manually. LEAN routes PortfolioTarget objects to the `Execute` method of the Execution Model to place orders.

The following example uses a Framework Execution Model in a classic style algorithm:

```C#
// Use SetExecution to place orders via the Execution Model, which routes PortfolioTarget objects to its
// execute method, instead of placing orders manually. This ensures automated and consistent order execution.
public override void Initialize()
{
    // Execute the market order imediately to fill the portfolio targets.
    SetExecution(new ImmediateExecutionModel());
}
```

Universe Timing Considerations

If the Alpha, Portfolio Construction, Risk Management, or Execution model manages some indicators or consolidators for securities in the universe and the universe selection runs during the indicator sampling period or the consolidator aggregation

period, the indicators and consolidators might be missing some data. For example, take the following scenario:

- The security resolution is minute
- You have a consolidator that aggregates the security data into daily bars to update the indicator
- The universe selection runs at noon

In this scenario, you create and warm-up the indicator at noon. Since it runs at noon, the history request that gathers daily data to warm up the indicator won't contain any data from the current day and the consolidator that updates the indicator also won't aggregate any data from before noon. This process doesn't cause issues if the indicator only uses the close price to calculate the indicator value (like the simple moving average indicator) because the first consolidated bar that updates the indicator will have the correct close price. However, if the indicator uses more than just the close price to calculate its value (like the True Range indicator), the open, high, and low values of the first consolidated bar may be incorrect, causing the initial indicator values to be incorrect.

Examples

The following examples demonstrate common practices for implementing hybrid algorithms.

Example 1: Corresponding Alpha

The following algorithm trades two separate logics:

- EMA cross on the 20 most liquid stocks
- Buy and hold the top 20 weighted SPY constituents

To do so, we can save the universe and allow an access point in the corresponding alpha model to filter the signals that are only applicable to the selected equities from each universe.

C#

```
public class FrameworkHybridAlgorithm : QCAlgorithm
{
    public Universe Universe1, Universe2;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe of the most liquid stocks since their trend is more capital-supported to trend EMA cross.
        Universe1 = AddUniverse(LiquidSelection);
        // Emit insights if the trend of selected liquid stocks changes.
        AddAlpha(new CustomEmaCrossAlphaModel(this));

        // Add another universe set to pick the most weighted SPY constituents since they usually have excess return
compared to the rest.
        Universe2 = AddUniverse(Universe.ETF("SPY", Market.USA, UniverseSettings, EtfConstituentFilter));
        // Emit insights for all selected SPY constituents.
        AddAlpha(new CustomConstantAlphaModel(this));

        // Equal weighting on each insight is needed to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    private IEnumerable<Symbol> LiquidSelection(IEnumerable<Fundamental> fundamentals)
    {
        // Select the top 20 liquid equities for EMA cross trading.
        return (from f in fundamentals
            orderby f.DollarVolume descending
            select f.Symbol).Take(20);
    }

    private IEnumerable<Symbol> EtfConstituentFilter(IEnumerable<ETFConstituentUniverse> constituents)
    {
        // Select the top 20 weighted stocks of SPY constituents to hold.
        return (from c in constituents
```

```
            where c.Weight.HasValue
            orderby c.Weight.Value descending
            select c.Symbol).Take(20);
    }

    private class CustomEmaCrossAlphaModel : EmaCrossAlphaModel
    {
        private FrameworkHybridAlgorithm _algorithm;
        private readonly int _fastPeriod, _slowPeriod;
        private readonly Resolution _resolution;

        public CustomEmaCrossAlphaModel(FrameworkHybridAlgorithm algorithm, int fastPeriod = 20, int slowPeriod = 60,
Resolution resolution = Resolution.Daily)
            : base(fastPeriod, slowPeriod, resolution)
        {
            _algorithm = algorithm;
            _fastPeriod = fastPeriod;
            _slowPeriod = slowPeriod;
            _resolution = resolution;
        }

        public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
        {
            foreach (var added in changes.AddedSecurities)
            {
                // Only trade the liquid universe for this alpha model.
                if (_algorithm.Universe1.Selected.Contains(added.Symbol))
                {
                    SymbolData symbolData;
                    if (!SymbolDataBySymbol.TryGetValue(added.Symbol, out symbolData))
                    {
                        SymbolDataBySymbol[added.Symbol] = new SymbolData(added, _fastPeriod, _slowPeriod, algorithm,
_resolution);
                    }
                    else
                    {
                        // A security that was already initialized was re-added, reset the indicators.
                        symbolData.Fast.Reset();
                        symbolData.Slow.Reset();
                    }
                }
            }

            foreach (var removed in changes.RemovedSecurities)
            {
                SymbolData symbolData;
                if (SymbolDataBySymbol.TryGetValue(removed.Symbol, out symbolData))
                {
                    // clean up our consolidators.
                    symbolData.RemoveConsolidators();
                    SymbolDataBySymbol.Remove(removed.Symbol);
                }
            }
        }
    }

    private class CustomConstantAlphaModel : ConstantAlphaModel
    {
        private FrameworkHybridAlgorithm _algorithm;

        public CustomConstantAlphaModel(FrameworkHybridAlgorithm algorithm)
            // Daily insight length due to daily signals.
            : base(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1))
        {
            _algorithm = algorithm;
        }

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice data)
        {
            var insights = base.Update(algorithm, data);
            // Only trade the selected SPY constituents universe for this alpha model.
            return insights.Where(x => _algorithm.Universe2.Selected.Contains(x.Symbol));
        }
    }
}
```

Example 2: Bracket Order On Insight

The following algorithm uses framework universe selection and alpha model to filter the universe and generate insights. However, the portfolio construction model cannot handle bracket orders easily. Hence, we will access the active insights to place bracket orders using the classic implementation, with stop losses at 1% and take profits at 2%.

C#

```
public class FrameworkHybridAlgorithm : QCAlgorithm
{
    private List<Insight> _orderedInsights = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Add a universe of the most liquid stocks since their trend is more capital-supported to trend EMA cross.
        AddUniverse(LiquidSelection);
        // Emit insights if the trend of selected liquid stocks changes.
        AddAlpha(new EmaCrossAlphaModel(20, 60, Resolution.Daily));
    }

    private IEnumerable<Symbol> LiquidSelection(IEnumerable<Fundamental> fundamentals)
    {
        // Select the top 20 liquid equities for EMA cross trading.
        return (from f in fundamentals
            orderby f.DollarVolume descending
            select f.Symbol).Take(20);
    }

    public override void OnData(Slice slice)
    {
        // Exit positions if insight is expired.
        foreach (var insight in new List<Insight>(_orderedInsights))
        {
            // If the insight is expired or profit taken or stop loss
            if (insight.IsExpired(UtcTime) || !Portfolio[insight.Symbol].Invested)
            {
                // Discontinue the insight.
                Insights.Cancel(new[] { insight });
                // Liquidate any positions and any open (bracket) orders.
                Liquidate(insight.Symbol);
                // Remove from the cache.
                _orderedInsights.Remove(insight);
            }
        }

        // Place orders for active insights if not yet ordered.
        var activeInsights = Insights.GetActiveInsights(UtcTime);
        foreach (var insight in activeInsights)
        {
            if (!_orderedInsights.Contains(insight))
            {
                // Position sizing by given weight or equal weighting to dissipate capital risk.
                var size = 0d;
                if (insight.Weight.HasValue)
                {
                    size = insight.Weight.Value;
                }
                else
                {
                    size = 1d / activeInsights.Count;
                }
                SetHoldings(insight.Symbol, size);
                // Add to cache to avoid re-order.
                _orderedInsights.Add(insight);
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            if (orderEvent.Ticket.OrderType == OrderType.Market && Portfolio[orderEvent.Symbol].Quantity != 0)
            {
                // Stop loss order at 1%.
                var stopPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 0.99m : orderEvent.FillPrice *
1.01m;
```

```
                StopMarketOrder(orderEvent.Symbol, -Portfolio[orderEvent.Symbol].Quantity, stopPrice);
                // Take profit order at 2%.
                var takeProfitPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 1.02m :
orderEvent.FillPrice * 0.98m;
                LimitOrder(orderEvent.Symbol, -Portfolio[orderEvent.Symbol].Quantity, takeProfitPrice);
            }
            else if (orderEvent.Ticket.OrderType == OrderType.StopMarket || orderEvent.Ticket.OrderType ==
OrderType.Limit)
            {
                // Cancel any open order if stop loss or take profit order filled.
                Transactions.CancelOpenOrders();
            }
        }
    }
}
```

Algorithm Framework

Insight Manager

Introduction

The `InsightManager` tracks all of the Insight objects in your algorithm. It's an `InsightCollection`, which stores all of your insights in an internal dictionary that has the security `Symbol` as the key and a list of `Insight` objects as the value. You can access the manager anywhere in your algorithm where you have reference to the algorithm class. If you want to use an `InsightCollection` in your algorithm that's seperate from the `InsightManager`, create a new `InsightCollection`.

Check Membership

To check if an insight exists in the `InsightManager`, call the `Contains` method.

```
C#

// Check the algorithms central insight collection (InsightManager) to avoid emitting duplicates, reducing the
processing work.
if (algorithm.Insights.Contains(insight))
{

}
```

To check if the `InsightManager` has an insight for a `Symbol`, call the `ContainsKey` method.

```
C#

// Check the algorithms central insight collection (InsightManager) if there's already been an insight for this
symbol across the other alphas.
if (algorithm.Insights.ContainsKey(symbol))
{

}
```

To check if the `InsightManager` has active insights for a `Symbol` at a specific Coordinated Universal Time (UTC), call the `HasActiveInsights` method.

```
C#

// Check if there are active insights for a specific symbol at the given time to determine if alpha should emit more
insights.
if (algorithm.Insights.HasActiveInsights(symbol, utcTime))
{

}
```

Get Insights

To get the insights for a `Symbol`, index the `InsightManager` with the `Symbol`.

```
C#

if (algorithm.Insights.ContainsKey(symbol))
{
    var insights = algorithm.Insights[symbol];
}
```

To get the insights that pass a filter, call the `GetInsights` method.

```
var insights = algorithm.Insights.GetInsights(insight => insight.Direction == InsightDirection.Up);
```

To iterate through the `InsightManager` , call the `GetEnumerator` method.

```
var enumerator = algorithm.insights.get_enumerator();
```

To get all of the insights that will be active at a certain UTC time, call the `GetActiveInsights` method.

```
var activeInsights = algorithm.Insights.GetActiveInsights(utcTime);
```

Get the Next Expiry Time

To get the next insight expiry time in UTC, call the `GetNextExpiryTime` method.

```
var nextExpiry = algorithm.Insights.GetNextExpiryTime();
```

Remove Insights

Only the Portfolio Construction model should remove insights from the `InsightManager` . It should remove insights when the insights expire and when the corresponding security leaves the universe .

To remove an insight from the `InsightManager` , call the `Remove` method.

```
var removeSuccessful = algorithm.Insights.Remove(insight);
```

To remove all the insights for a set of `Symbol` objects, pass a list of `Symbol` objects the `Clear` method.

```
algorithm.insights.clear(symbols);
```

To remove all the insights that will be expired at a certain UTC time, call the `RemoveExpiredInsights` method.

```
var expiredInsights = algorithm.Insights.RemoveExpiredInsights(utcTime);
```

Cancel Insights

In some cases, you may want to cancel an Insight. For example, if a Risk Management model in your algorithm liquidates a security, it should also cancel all of the active insights for the security. If you don't cancel the insights, the Portfolio Construction model might create a new PortfolioTarget to re-enter the position.

Another example of a situtation where you would want to cancel an Insight is when an Alpha model in your algorithm determines the trading opportunity has pre-maturely ended. For instance, say you want your algorithm to enter a long position in a security when its Relative Strength Index (RSI) moves below 20 and then liquidate the position when the security's RSI moves above 30. If you emit an Insight that has a duration of 30 days when the RSI moves below 20 but the RSI moves above 30 in 10 days, you

should cancel the Insight when the RSI moves above 30.

To cancel insights, call the `Cancel` / `Expire` method with a list of `Insight` objects.

```
algorithm.insights.cancel(insights);
```

To cancel all the insights for some securities, call the `Cancel` / `Expire` method with a list of `Symbol` objects.

```
algorithm.insights.cancel(symbols);
```

When you cancel an active insight, it's `CloseTimeUtc` property is set to one second into the past.

Add Insights to Self-Managed Insight Collections

To add insights to the `InsightManager` , return a list of `Insight` objects from the Update method of your Alpha model or call the `EmitInsights` method. If you manage an `InsightCollection` that's seperate from the `InsightManager` , there are some methods to add `Insight` objects to it.

To add an insight to an `InsightCollection` , call the `Add` method.

```
// You can manually add an Insight to an InsightCollection object to organize, fetch, or cancel insights an alpha has
generated.
_insightCollection.Add(insight);
```

To add a list of insights, call the `AddRange` method.

```
// You can manually add a list of Insights to an InsightCollection object to organize, fetch, or cancel insights an
alpha has generated.
_insightCollection.AddRange(insights);
```

Preserve Insights Between Deployments

Follow these steps to use the Object Store to preserve the algorithm state across live deployments:

1. Create an algorithm that defines a storage key and adds insights to the Insight Manager .

   ```
   public class ObjectStoreChartingAlgorithm : QCAlgorithm
   {
       private string _insightKey;
       public override void Initialize()
       {
           _insightKey = $"{ProjectId}/insights";
           SetUniverseSelection(new ManualUniverseSelectionModel(QuantConnect.Symbol.Create("SPY",
   SecurityType.Equity, Market.USA)));
           SetAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(5), 0.025,
   null));
       }
   }
   ```

2. In the OnEndOfAlgorithm event handler of the algorithm, get the Insight objects and save them in the Object Store as a JSON object.

```
C#
public override void OnEndOfAlgorithm()
{
    var insights = Insights.GetInsights(x => x.IsActive(UtcTime));
    ObjectStore.SaveJson(_insightKey, insights);
}
```

3. At the bottom of the `Initialize` method, read the Insight objects from the Object Store and add them to the Insight Manager .

```
C#
if (ObjectStore.ContainsKey(_insightKey))
{
    var insights = ObjectStore.ReadJson<List<Insight>>(_insightKey);
    Insights.AddRange(insights);
}
```

The following algorithm provides a full example of preserving the Insight state between deployments:

```
C#
public class ObjectStoreInsightsAlgorithm : QCAlgorithm
{
    private string _insightsKey = "insights";

    public override void Initialize()
    {
        UniverseSettings.Resolution = Resolution.Daily;

        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _insightsKey = $"{ProjectId}/{_insightsKey}";

        // Read the file with the insights
        if (ObjectStore.ContainsKey(_insightsKey))
        {
            // Load cached JSON key value pair from object store, then add to algorithm insights.
            var insights = ObjectStore.ReadJson<List<Insight>>(_insightsKey);
            Log($"Read {insights.Count} insight(s) from the Object Store");
            Insights.AddRange(insights);

            // Delete the key to reuse it
            ObjectStore.Delete(_insightsKey);
        }

        SetUniverseSelection(new ManualUniverseSelectionModel(QuantConnect.Symbol.Create("SPY", SecurityType.Equity,
Market.USA)));
        SetAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(5), 0.025, null));
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(Resolution.Daily));
    }

    public override void OnEndOfAlgorithm()
    {
        // Get all active insights.
        var insights = Insights.GetInsights(x => x.IsActive(UtcTime));
        // If we want to save all insights (expired and active), we can use.
        // var insights = Insights.GetInsights(x => true);
        Log($"Save {insights.Count} insight(s) to the Object Store.");
        ObjectStore.SaveJson(_insightsKey, insights);
    }
}
```

Properties

The `InsightManager` has the following properties:

Examples

The following examples demonstrate some common practices for using insight manager.

Example 1: Cancel Insight

If the risk management model only submits the `PortfolioTarget` to liquidate the security, it will be re-ordered immediately due to the active insight. Hence, we also need to add logic to cancel the insight in the `ManageRisk` method of the risk management model. The below example only permits 1-day holding time per each insight through a custom risk management model.

```C#
public class FrameworkInsightManagerAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 11, 15);
        SetCash(1000000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe of the most liquid stocks since their trend is more capital-supported.
        AddUniverseSelection(new QC500UniverseSelectionModel());
        // Emit insights on EMA cross, indicating the trend changes. We use short-term versus medium-term for more
trade opportunities.
        AddAlpha(new EmaCrossAlphaModel(20, 60, Resolution.Daily));
        // Equal weighting on each insight is needed to dissipate capital risk evenly.
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        // Add a risk management model that controls maximum holding time.
        AddRiskManagement(new MaximumHoldingTimeRiskManagementModel(TimeSpan.FromDays(5)));
    }

    private class MaximumHoldingTimeRiskManagementModel : RiskManagementModel
    {
        private TimeSpan _maximumHoldingTime;
        // A dictionary to hold the holding time of each position.
        private Dictionary<Symbol, DateTime> _holdingTime = new();

        public MaximumHoldingTimeRiskManagementModel(TimeSpan maximumHoldingTime)
        {
            _maximumHoldingTime = maximumHoldingTime;
        }

        public override IEnumerable<IPortfolioTarget> ManageRisk(QCAlgorithm algorithm, IPortfolioTarget[] _)
        {
            var targets = new List<PortfolioTarget>();

            foreach (var (symbol, holding) in algorithm.Portfolio)
            {
                if (holding.Invested)
                {
                    if (!_holdingTime.TryGetValue(symbol, out var time))
                    {
                        // For newly open positions, save the entry time.
                        _holdingTime[symbol] = time = algorithm.Time;
                    }
                    else if (algorithm.Time - time > _maximumHoldingTime)
                    {
                        // Liquidate the position if the holding time exceeds the permitted level.
                        targets.Add(new PortfolioTarget(symbol, 0m));
                        // Cancel the insight to avoid repeated re-ordering.
                        algorithm.Insights.Cancel(new[] { symbol });
                        // Remove from dictionary.
                        _holdingTime.Remove(symbol);
                    }
                }
            }

            return targets;
        }
    }
}
```

Charting

Introduction

We provide a powerful charting API that you can use to build many chart types.

Charts

Charts contain a collection of series, which display data on the chart. To add a chart to an algorithm, create a `Chart` object and then call the `AddChart` method.

```C#
var chart = new Chart("<chartName>");
AddChart(chart);
```

The `Chart` constructor expects a name argument. The following chart names are reserved:

- Assets Sales Volume
- Exposure
- Portfolio Margin

Series

A chart series displays data on the chart. To add a series to a chart, create a `Series` object and then call the `AddSeries` method.

```C#
var series = new Series("<seriesName>");
chart.AddSeries(series);
```

Arguments

There are several other headers for the `Series` constructor.

```
Series(name, type)
Series(name, type, index)
Series(name, type, index, unit)
Series(name, type, unit)
Series(name, type, unit, color)
Series(name, type, unit, color, symbol)
```

The following table describes the constructor arguments:

Argument	Data Type	Description
`name`	`string`	Name of the series
`type`	`SeriesType`	Type of the series
`index`	`int`	Index position on the chart of the series
`unit`	`string`	Unit for the series axis
`color`	`Color`	Color of the series
`symbol`	`ScatterMarkerSymbol`	Symbol for the marker in a scatter plot series

The default `Series` is a line chart with a "$" unit on index 0.

Names

The `Series` constructor expects a name argument. If you add a series to one of the default charts, some series names may be reserved. The following table shows the reserved series name for the default charts:

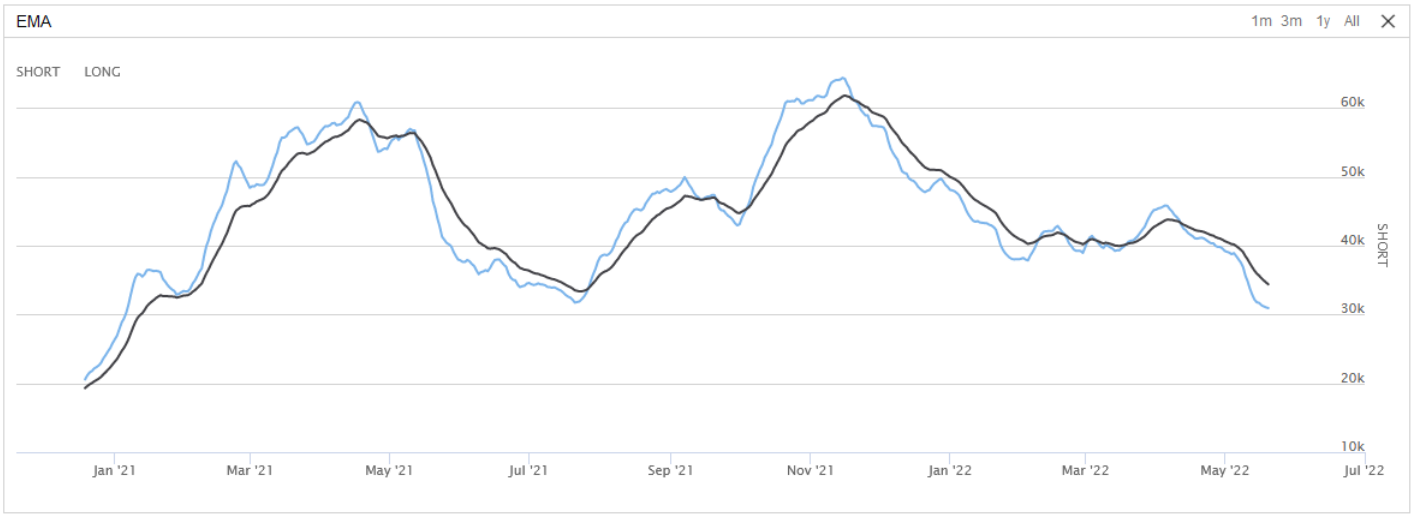
Chart Name	Reserved Series Names
Strategy Equity	Equity, Return
Capacity	Strategy Capacity
Drawdown	Equity Drawdown
Benchmark	Benchmark
Portfolio Turnover	Portfolio Turnover

Types

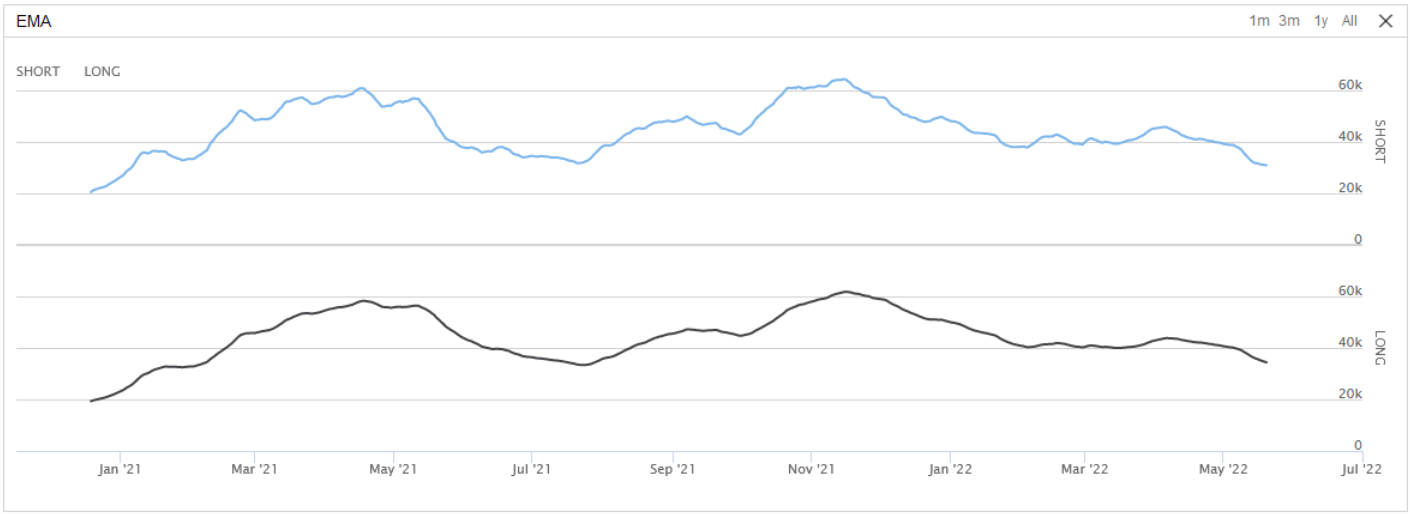
The `SeriesType` enumeration has the following members:

Index

The series index refers to its position in the chart. If all the series are at index 0, they lay on top of each other. If each series has its own index, each series will be separate on the chart. The following image shows an EMA cross chart with both EMA series set to the same index:



The following image shows the same EMA series, but with the short EMA on index 0 and the long EMA on index 1:



Colors

To view the available `Color` options, see the Color Struct Properties in the .NET documentation.

Scatter Marker Symbols

The `ScatterMarkerSymbol` enumeration has the following members:

Candlestick Series

A chart candlestick series displays candlesticks on the chart. To add a candlestick series to a chart, create a `CandlestickSeries` object and then call the `AddSeries` method.

```C#
var candlestickSeries = new CandlestickSeries("<seriesName>");
chart.AddSeries(candlestickSeries);
```

There are several other headers for the `CandlestickSeries` constructor.

```
CandlestickSeries(name)
CandlestickSeries(name, index)
CandlestickSeries(name, index, unit)
CandlestickSeries(name, unit)
```

The following table describes the constructor arguments:

Argument	Data Type	Description
`name`	`string`	Name of the series
`index`	`int`	Index position on the chart of the series
`unit`	`string`	Unit for the series axis

The default `CandlestickSeries` has 0 index and "$" unit.

Plot Series

To add a data point to a chart series, call the `Plot` method. If you haven't already created a chart and series with the names you pass to the `Plot` method, the chart and/or series is automatically created.

```
C#
Plot("<chartName>", "<seriesName>", value);
```

The `value` argument can be an integer or decimal number. If the chart is a time series, the value is added to the chart using the algorithm time as the x-coordinate.

To plot the current value of indicators, call the `Plot` method. The method accepts up to four indicators.

```
C#
// In Initialize
var symbol = AddEquity("SPY");
var smaShort = SMA(symbol, 10);
var smaLong = SMA(symbol, 20);

// In OnData
Plot("<chartName>", smaShort, smaLong)
```

To plot all of the values of some indicators, in the `Initialize` method, call the `PlotIndicator` method. The method plots each indicator value as the indicator updates. The method accepts up to four indicators.

```
C#
var symbol = AddEquity("SPY");
var smaShort = SMA(symbol, 10);
var smaLong = SMA(symbol, 20);
PlotIndicator("<chartName>", smaShort, smaLong)
```

Plot Candlestick

To add a sample of open, high, low, and close values to a candlestick series, call the `Plot` method with the data points. If you haven't already created a chart and series with the names you pass to the `Plot` method, the chart and/or series is automatically created.

```
C#
Plot("<chartName>", "<seriesName>", open, high, low, close);
```

The `open` , `high` , `low` , and `close` arguments can be an integer for decimal number. If the chart is a time series, the values are added to the chart using the algorithm time as the x-coordinate.

To plot the current trade bar, call the `Plot` method with a `TradeBar` argument in the `OnData` method.

```
// In Initialize
var equity = AddEquity("SPY");
var forex = AddForex("EURUSD");

// In OnData
var tradeBar = slice.Bars["SPY"];
var collapsed = slice.QuoteBars["EURUSD"].Collapse();   // Collapses QuoteBar into TradeBar object

Plot("<chartName1>", "<seriesName>", tradeBar)
Plot("<chartName2>", "<seriesName>", collapsed)
```

To plot consolidated bars, call the `Plot` method with a `TradeBar` argument in the consolidation handler.

```
// In Initialize
var equity = AddEquity("SPY");
Consolidate(equity.Symbol, TimeSpan.FromMinutes(10), ConsolidationHandler);

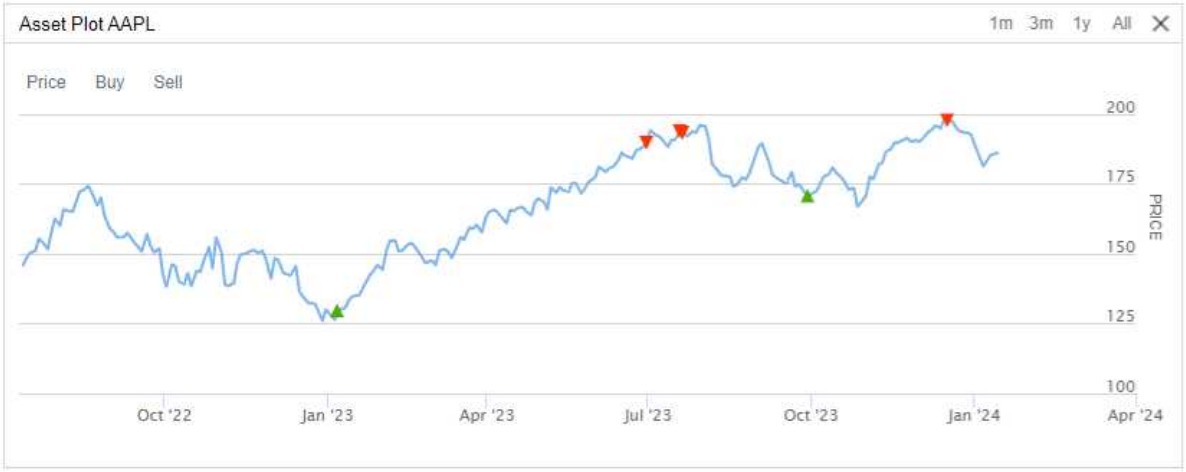
// Define the consolidation handler
void ConsolidationHandler(TradeBar consolidatedBar)
{
    Plot("<chartName>", "<seriesName>", consolidatedBar)
}
```

Plot Asset Data

Asset plots display the trade prices of an asset and the following order events you have for the asset:

Order Event	Icon
Submissions	Gray circle
Updates	Blue circle
Cancellations	Gray square
Fills and partial fills	Green (buys) or red (sells) arrows

The following image shows an example asset plot for AAPL:



The order submission icons aren't visible by default.

For more information about these charts, including how to view them in QC Cloud, see Asset Plots for backtests or live trading .

View Charts

The following table describes where you can access your charts, depending on how to deploy your algorithms:

Location	Algorithm Lab Algorithms	CLI Cloud Algorithms	CLI Local Algorithms
Backtest results page	✓	✓	
Live results page	✓	✓	
/backtests/read endpoint	✓	✓	
/live/read endpoint	✓	✓	
ReadBacktest method	✓	✓	
ReadLiveAlgorithm method	✓	✓	
Local JSON file in your <projectName> / backtests / <timestamp> or <projectName> / live / <timestamp> directory		✓	✓

Quotas

When you run backtests, you must stay within the plotting quotas to avoid errors.

Cloud Quotas

Intensive charting requires hundreds of megabytes of data, which is too much to stream online or display in a web browser. The number of series and the number of data points per series you can plot depends on your organization tier . The following table shows the quotas:

Tier	Max Series	Max Data Points per Series
Free	10	4,000
Quant Researcher	10	8,000
Team	25	16,000
Trading Firm	25	32,000
Institution	100	96,000

If you exceed the series quota, your algorithm stops executing and the following message displays:

Exceeded maximum chart series count, new series will be ignored. Limit is currently set at <quota>.

If you exceed the data points per series quota, the following message displays:

Exceeded maximum points per chart, data skipped

If your plotting needs exceed the preceding quotas, create the plots in the Research Environment instead .

Local Quotas

If you execute local backtests, the charting quotas are set by the `maximum-chart-series` and `maximum-data-points-per-chart-series` configuration settings .

Examples

The following example shows how to plot the daily closing price of SPY with a scatter plot:

```C#
public class ChartingDemoAlgorithm : QCAlgorithm
{
    private ExponentialMovingAverage _emaFast;
    private ExponentialMovingAverage _emaSlow;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.AutomaticIndicatorWarmUp = true;
        var symbol = AddEquity("MSFT", Resolution.Daily).Symbol;
        _emaFast = EMA(symbol, 10);
        _emaSlow = EMA(symbol, 50);
        var chart = new Chart("Price");
        AddChart(chart);
        chart.AddSeries(new Series("CROSS UP", SeriesType.Scatter, "$", Color.Green, ScatterMarkerSymbol.Triangle));
        chart.AddSeries(new Series("CROSS DOWN", SeriesType.Scatter, "$", Color.Red,
ScatterMarkerSymbol.TriangleDown));
        chart.AddSeries(new Series("EMA FAST", SeriesType.Line, "$", Color.Orange));
        chart.AddSeries(new Series("EMA SLOW", SeriesType.Line, "$", Color.Blue));
        chart = new Chart("Volume");
        AddChart(chart);
        chart.AddSeries(new Series("Volume", SeriesType.Bar, "", Color.Gray));
        chart = new Chart("Candlestick");
        AddChart(chart);
        chart.AddSeries(new CandlestickSeries("MSFT", "$"));
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        var data = (TradeBar)Securities[symbol].GetLastData();
        if (data != null)
        {
            Plot("Candlestick", "MSFT", data);
            Plot("Volume", "Volume", data.Volume);
        }
        Plot("Price", "EMA FAST", _emaFast);
        Plot("Price", "EMA SLOW", _emaSlow);
        if (_emaFast > _emaSlow && _emaFast[1] < _emaSlow[1])
            Plot("Price", "CROSS UP", Securities[symbol].Price);
        else if (_emaFast < _emaSlow && _emaFast[1] > _emaSlow[1])
            Plot("Price", "CROSS DOWN", Securities[symbol].Price);
    }
}

Logging

Introduction

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code. Consider adding them in the code block of an `if` statement to signify an error has been caught.

It's good practice to add logging statements to live algorithms so you can understand its behavior and keep records to compare against backtest results. If you don't add logging statements to a live algorithm and the algorithm doesn't trade as you expect, it's difficult to evaluate the underlying problem.

Log Messages

Log statements are added to the log file while your algorithm continues executing. Logging dataset information is not permitted. Use `Log` method statements to debug your backtests and live trading algorithms.

If you execute algorithms in QuantConnect Cloud, log length is capped by organization tier . If your organization hits the daily limit, contact us .

If you log the same content multiple times, only the first instance is added to the log file. To bypass this rate-limit, add a timestamp to your log messages.

For live trading, the log files of each cloud project can store up to 100,000 lines for up to one year. If you log more than 100,000 lines or some lines become older than one year, we remove the oldest lines in the files so your project stays within the quota.

To record the algorithm state when the algorithm stops executing, add log statements to the `OnEndOfAlgorithm` event handler.

```
C#
Log("My log message");
```

Debug Messages

Debug statements are the same as log statements, but `Debug` method statements are orange in the Cloud Terminal. Use these statements when you want to give more attention to a message in the Cloud Terminal. Debug messages can be up to 200 characters in length. If you send multiple debug statements within 1 second, your messages are rate-limited to avoid crashing your browser.

```
C#
Debug("My debug message");
```

Error Messages

Error statements are the same as log statements, but `Error` method statements are displayed in red text in the Cloud Terminal. Use these statements when you want to give the most attention to a message in the Cloud Terminal. Error statements are rate-limited like debug statements.

```
Error("My error message");
```

Quit Messages

Quit statements cause your project to stop running and may log some data to the log file and Cloud Terminal. These statements are orange in the Cloud Terminal. When you call the `Quit` method method, the program continues executing until the end of the method definition. If you want to quit execution immediately, `return` after you call `Quit` method.

```
Quit("My quit message");
```

Get Logs

The following tables describe how to access the logs of your backtests and live algorithms:

Deployment Target	Execution Mode	Access Tools
QuantConnect Cloud	Backtest	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform
QuantConnect Cloud	Live Trading	• Live results page in the Algorithm Lab • Live results page on Local Platform • /live/read/log endpoint
Local	Backtest	• Backtest results page on Local Platform • <organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>-log.txt • lean logs CLI command
Local	Live Trading	• Live results page on Local Platform • <organizationWorkspace> / <projectName> / live / <timeStamp> / / L-<deploymentId>-log.txt • lean logs CLI command

Example

The following examples demonstrate some common practices for logging.

Example 1: On Events And Trading Logic

The following example trades a simple EMA cross trend-following strategy on SPY. We log or debug messages in event handlers and trading logic changes to get information on any event flow.

C#

```
public class LoggingAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 12);
        SetEndDate(2024, 10, 1);
        SetCash(1000000);

        // Request SPY data to trade.
        _spy = AddEquity("SPY").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_spy, 20, Resolution.Daily);

        // Warm up the algorithm for indicator readiness.
        SetWarmUp(20, Resolution.Daily);
    }

    public override void OnWarmupFinished()
    {
        // Signals on warm-up finished.
        Log("Warm up finished");
    }

    public override void OnData(Slice slice)
    {
        if (!IsWarmingUp && slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trend-following strategy using price and EMA.
            // If the price is above EMA, SPY is in an uptrend, and we buy it.
            if (bar.Close > _ema && Portfolio[_spy].IsLong)
            {
                Debug("Trend changes to upwards");
                SetHoldings(_spy, 1m);
            }
            else if (bar.Close < _ema && Portfolio[_spy].IsShort)
            {
                Debug("Trend changes to downwards");
                SetHoldings(_spy, -1m);
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            // Log the order details if being filled.
            Log($"Order filled - Quantity: {orderEvent.Quantity}");
        }
    }
}
```

Statistics

LEAN automatically monitors a set of statistics as your algorithms execute. You can even create custom statistics for further analysis.

Statistics

Algorithm Statistics

Introduction

The `StatisticsResults` object tracks all the statistics of your algorithm. You can access the statistics anywhere in your algorithm where you have a reference to the algorithm class. Some of these statistics are a function of the risk free interest rate and the number of trading days per year .

Properties

The `StatisticsResults` object has the following properties:

Add Statistics

To add custom statistics to the `StatisticsResults` object, call the `SetSummaryStatistic` method with the statistic name and value.

```
C#
SetSummaryStatistic("name", value);
```

Get Values

To get the `StatisticsResults` , use the `Statistics` member of the algorithm class.

```
C#
var sharpe = Statistics.TotalPerformance.PortfolioStatistics.SharpeRatio;
```

To get the value of a custom statistic while your algorithm runs, index the `Summary` member with the statistic name. The values in the `Summary` dictionary are strings, so you may need to cast the value that returns to a different data type.

```
C#
var value = Statistics.Summary["name"];
```

The following table describe other ways to get the statistics after your backtest completes:

Deployment Target	Access Tools
QuantConnect Cloud	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform • ReadBacktest API method • /backtests/read endpoint
Local	• Backtest results page on Local Platform • <organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>.json

Examples

The following examples demonstrate common practices for getting algorithm statistics.

Example 1: Portfolio Statistics

To evaluate the algorithm's best domain or regime, we can log the portfolio statistics daily along the backtest to analyze. To do so, we log the Sharpe Ratio, Beta, and 95% Value-at-Risk at the end of each day, storing them in the object store for assessment later.

C#

```
public class AlgorithmStatisticsAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;
    private List<string> _statistics = new() { "Time,Sharpe,Beta,95VaR" };

    public override void Initialize()
    {
        SetStartDate(2024, 9, 12);
        SetEndDate(2024, 10, 1);
        SetCash(1000000);

        // Request SPY data to trade.
        _spy = AddEquity("SPY").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_spy, 20, Resolution.Daily);
        // Warm-up indicator for immediate readiness.
        WarmUpIndicator(_spy, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trend-following strategy using price above or below EMA.
            // If the price is above EMA, SPY is in an uptrend, and we buy it.
            if (bar.Close > _ema && !Portfolio[_spy].IsLong)
            {
                SetHoldings(_spy, 1m);
            }
            else if (bar.Close < _ema && !Portfolio[_spy].IsShort)
            {
                SetHoldings(_spy, -1m);
            }
        }
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        // Obtain the algorithm statistics interested.
        var sharpe = Statistics.TotalPerformance.PortfolioStatistics.SharpeRatio;
        var b = Statistics.TotalPerformance.PortfolioStatistics.Beta;
        var var = Statistics.TotalPerformance.PortfolioStatistics.ValueAtRisk95;

        // Plot the statistics.
        Plot("Statistics", "Sharpe", sharpe);
        Plot("Statistics", "Beta", b);
        Plot("Statistics", "Value-at-Risk", var);

        // Write to save the statistics.
        _statistics.Add($"{Time:yyyyMMdd},{sharpe},{b},{var}");
    }

    public override void OnEndOfAlgorithm()
    {
        // Save the logged statistics for later access in the object store.
        ObjectStore.Save($"{ProjectId}/algorithm-statistics", string.Join('\n', _statistics));
    }
}
```

Other Examples

Statistics

Runtime Statistics

Introduction

Runtime statistics show the performace of your algorithm at a single moment in time. Some of these statistics are a function of the risk free interest rate and the number of trading days per year .

Default Statistics

The following table describes the default runtime statistics:

Statistic	Description
Equity	The total portfolio value if all of the holdings were sold at current market rates.
Fees	The total quantity of fees paid for all the transactions.
Holdings	The absolute sum of the items in the portfolio.
Net Profit	The dollar-value return across the entire trading period.
PSR	The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark (1).
Return	The rate of return across the entire trading period.
Unrealized	The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread.
Volume	The total value of assets traded for all of an algorithm's transactions.

Add Statistics

To add a custom runtime statistic, call the `SetRuntimeStatistic` method with a `name` and `value` . The `value` argument can be a `string` or a number.

```
SetRuntimeStatistic(name, value);
```

Don't try to set a value for any of the preceding default runtime statistics. LEAN overwrites the value that you try to set.

Get Values

To get the value of a runtime statistic in an algorithm, index the `RuntimeStatistics` member of the algorithm class with the statistic name. The values of the `RuntimeStatistics` dictionary are strings, so you may need to cast the result to a different data type.

```
var value = RuntimeStatistics[name];
```

The following table describe other ways to get the runtime statistics of your backtests and live algorithms:

Deployment Target	Execution Mode	Access Tools
QuantConnect Cloud	Backtest	• Backtest results page in the Algorithm Lab • Backtest results page on Local Platform • ReadBacktest API method • /backtests/read endpoint
QuantConnect Cloud	Live Trading	• Live results page in the Algorithm Lab • Live results page on Local Platform • ReadLiveAlgorithm API method • /live/read endpoint
Local	Backtest	• Backtest results page on Local Platform • <organizationWorkspace> / <projectName> / backtests / <unixTimestamp> / <algorithmId>.json
Local	Live Trading	• Live results page on Local Platform • <organizationWorkspace> / <projectName> / live / <timeStamp> / / L-<deploymentId>.json

Examples

The following examples demonstrate common practices for setting runtime statistics.

Example 1: Display Banner

The following algorithm demonstrates how to put calculated runtime statistics of interest in the top display banner in the backtest interface and plot the data for analysis.

C#

```
public class RuntimeStatisticsAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 12);
        SetEndDate(2024, 10, 1);
        SetCash(1000000);

        // Request SPY data to trade.
        _spy = AddEquity("SPY").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_spy, 20, Resolution.Daily);
        // Warms up indicator for immediate readiness.
        WarmUpIndicator(_spy, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trend-following strategy using price and EMA.
            // If the price is above the EMA, SPY is in an uptrend, and we buy it.
            if (bar.Close > _ema && !Portfolio[_spy].IsLong)
            {
                SetHoldings(_spy, 1m);
            }
            else if (bar.Close < _ema && !Portfolio[_spy].IsShort)
            {
                SetHoldings(_spy, -1m);
            }
        }
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        // Set the 95VaR and fee-to-profit ratio to the display banner.
        var var = Statistics.TotalPerformance.PortfolioStatistics.ValueAtRisk95;
        var feeToProfit = Statistics.TotalPerformance.TradeStatistics.TotalProfitLoss != 0 ?
            Statistics.TotalPerformance.TradeStatistics.TotalFees /
Statistics.TotalPerformance.TradeStatistics.TotalProfitLoss :
            0m;
        SetRuntimeStatistic("95VaR", var);
        SetRuntimeStatistic("Fee-to-Profit", feeToProfit);

        // Plot the calculated statistics.
        Plot("Statistics", "95VaR", var);
        Plot("Statistics", "fee-to-profit", feeToProfit);
    }

    public override void OnEndOfAlgorithm()
    {
        // Log the 95VaR when the algorithm stops
        var valueAtRisk95 = RuntimeStatistics["95VaR"];
        Log($"Final valueAtRisk95={valueAtRisk95}");
    }
}
```

Statistics

Trade Statistics

Introduction

The `TradeBuilder` tracks the trades of your algorithm and calculates some statistics. Some of these statistics are a function of the risk free interest rate and the number of trading days per year . You can adjust how the `TradeBuilder` defines a trade and how it matches offsetting order fills.

Set Trade Builder

To set the `TradeBuilder` , in the `Initialize` method, call the `SetTradeBuilder` method.

```
C#
SetTradeBuilder(new TradeBuilder(groupingMethod, matchingMethod));
```

The following table describes the arguments the `TradeBuilder` constructor accepts:

Argument	Data Type	Description	Default Value
`groupingMethod`	`FillGroupingMethod`	The method used to group order fills into trades	
`matchingMethod`	`FillMatchingMethod`	The method used to match offsetting order fills	

The `FillGroupingMethod` enumeration has the following members:

The `FillMatchingMethod` enumeration has the following members:

Default Behavior

The default `TradeBuilder` uses `FillGroupingMethod.FillToFill` and `FillMatchingMethod.FIFO` .

Check Open Positions

To check if you have a position open for a security as defined by the `FillGroupingMethod` , call the `HasOpenPosition` method.

```
C#
// Check if the trade builder has recorded any active trades (unclosed positions)
// for a security.
var hasOpenPosition = TradeBuilder.HasOpenPosition(_symbol);
```

Get Closed Trades

To get your closed trades, use the `ClosedTrades` property.

```
C#
var trades = TradeBuilder.ClosedTrades;
```

This property returns a list of `Trade` objects, which have the following attributes:

Examples

The following examples demonstrate common practices for using trade statistics.

Example 1: Kelly Criterion Sizing Using Previous Trades

The following algorithm uses the previous trades to update the win probability and expected return of each trade of the EMA cross strategy of SPY, by the concept of Bayes Theorem. The updated figures are used for position sizing through Kelly Criterion.

C#

```
public class TradeStatisticsAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 12);
        SetEndDate(2024, 10, 1);
        SetCash(1000000);

        // Request SPY data to trade.
        _spy = AddEquity("SPY").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_spy, 20, Resolution.Daily);
        // Warm-up indicator for immediate readiness.
        WarmUpIndicator(_spy, _ema, Resolution.Daily);

        // Set up a trade builder to track the trade statistics; we are interested in open-to-close round trade.
        SetTradeBuilder(new TradeBuilder(FillGroupingMethod.FlatToFlat, FillMatchingMethod.FIFO));
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trend-following strategy using price and EMA.
            // If the price is above EMA, SPY is in an uptrend, and we buy it.
            var sign = 0m;
            if (bar.Close > _ema && !Portfolio[_spy].IsLong)
            {
                sign = 1m;
            }
            else if (bar.Close < _ema && !Portfolio[_spy].IsShort)
            {
                sign = -1m;
            }
            else
            {
                return;
            }

            var size = 1m;
            var trades = TradeBuilder.ClosedTrades;

            if (trades.Count > 4)
            {
                // Use the trade builder to obtain the win rate and % return of the last five trades to calculate
position size.
                var lastFiveTrades = trades.OrderBy(x => x.ExitTime).TakeLast(5);
                var probWin = lastFiveTrades.Count(x => x.IsWin) / 5m;
                var winSize = lastFiveTrades.Average(x => x.ProfitLoss / x.EntryPrice);
                // Use the Kelly Criterion to calculate the order size.
                size = probWin - (1 - probWin) / winSize;
            }

            SetHoldings(_spy, sign * size);
        }
    }
}
```

Live Trading

QuantConnect enables you to run your algorithms in live mode with real-time market data. You can use the same algorithm for backtesting and live trading with different brokerages and data providers.

Live Trading

Key Concepts

Introduction

Algorithms should generally work seamlessly shifting from backtesting to live trading with no changes required. In backtesting algorithm events are triggered as fast as possible, whereas in live trading events are triggered in realtime.

Algorithm Portfolio

The live trading algorithm portfolio is loaded from the brokerage holdings, including open orders. When there are unsupported asset types in the portfolio the live trading strategy is stopped as we cannot be sure how to model the asset.

In paper trading the algorithm starts from no portfolio, and attempts to remember the previous portfolio state from the last time the portfolio was deployed.

Your algorithm should not assume it starts from an empty portfolio as you may have holdings from previous deployments.

Stateful Strategies

There is no automatic state management of live strategies in QuantConnect. We recommend algorithms reconstruct state or indicator needs using the WarmUp and History methods.

Once the algorithm has warmed up some objects you can use the Object Store to save the data for the next algorithm restart.

In the event the algorithm is terminated unexpectedly, you should review the live algorithm portfolio at the brokerage to confirm it will behave as expected.

Data Delivery Times

Most data is available at the same time as in backtesting, with the exception of daily data which is often delayed by 4-8 hours (4am - 8am).

US Equities universe selection data is processed at 7-8am ET.

Latency

Live data takes time to travel from the source to your algorithm. The QuantConnect latencies vary depending on the data provider, but for US Equities, we have a latency of 5-40 milliseconds. A much more significant source of latency is the round trip order times from brokers, which can vary from 100ms to 5 seconds. QuantConnect is not intended for high-frequency trading, but we have integrations to high-speed brokers if you need.

Other Brokerages

If we do not support your brokerage reach out to let us and we can attempt to add them to the roadmap. With enough community requests we can build and open-source the brokerage integration.

Live Trading

Brokerages

Introduction

Brokerages provide you with a connection to the market so you can fill trades. To avoid placing invalid orders for execution in live trading, LEAN validates your orders before sending them to the real brokerage. To view all of the integrated brokerages, see Brokerages .

Portfolio

In live trading, LEAN populates the `Portfolio` object with your account holdings and the `Transactions` object with your open positions. If you don't manually subscribe to the assets in your account, LEAN subscribes to them with the lowest resolution of the subscriptions in your algorithm. For example, say you hold AAPL shares in your account and create the following subscriptions in your algorithm:

```
C#
AddEquity("SPY", Resolution.Hour);
AddEquity("MSFT", Resolution.Second);
```

In this case, LEAN subscribes to second-resolution data for AAPL since the lowest resolution in your algorithm is `Resolution.Second` .

Deposits and Withdrawals

You can deposit and withdraw cash from your brokerage account while you run an algorithm that's connected to the account. We sync the algorithm's cash holdings with the cash holdings in your brokerage account every day at 7:45 AM Eastern Time (ET).

Monitor the Brokerage Connection

We notify your algorithm when your brokerage connection disconnects and reconnects.

Lost Connections

If the brokerage connection breaks, we notify your algorithm through the `OnBrokerageDisconnect` event handler.

```
C#
public override void OnBrokerageDisconnect()
{
    Debug("Brokerage connection lost");
}
```

Restored Connections

When the brokerage connection restores after it disconnects, we notify your algorithm through the `OnBrokerageReconnect` event handler.

```
public override void OnBrokerageReconnect()
{
    Debug("Brokerage connection restored");
}
```

When LEAN reconnects with your brokerage, it synchronizes the state of your live orders. For example, say the brokerage fills your limit order during the period of disconnection. When the connection restores, LEAN updates the state of your portfolio and orders to reflect the filled order, but you won't receive an order event .

Example Algorithm

For a full example algorithm that implements the `OnBrokerageDisconnect` and `OnBrokerageReconnect` methods, see the BrokerageActivityEventHandlingAlgorithm in the LEAN GitHub repository.

Monitor Brokerage Messages

When your brokerage sends you a message, we notify your algorithm through the `OnBrokerageMessage` event handler.

```
public override void OnBrokerageMessage(BrokerageMessageEvent messageEvent)
{
    Debug(f"Brokerage message received: {messageEvent.Message}");
}
```

`BrokerageMessageEvent` objects have the following attributes:

For a full example algorithm that implements the `OnBrokerageMessage` method, see the BrokerageActivityEventHandlingAlgorithm in the LEAN GitHub repository.

To handle brokerage messages outside of your algorithm class, create and set a `BrokerageMessageHandler` . For a more information example, see the Reality Modeling > Brokerage Message Handler .

Brokerage Models

Brokerage features and limitations are realistically modelled with Brokerage Models. These reality models set the supported order and asset types for the brokerage. To learn how to set your specific brokerage, see Supported Models .

Examples

The following examples demonstrate common practices for handling live brokerage messages.

Example 1: Pre-Open Order Error

The following algorithm simulate extended market hour trading on Tradier Brokerage . We place a market-on-open order at 7:30am and expect the order cannot submit to the broker since it is not supported, resulting into an error.

C#

```
public class OrderErrorsAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 5);
        // Simulate Tradier brokerage, which does not support the market-on-open orders.
        SetBrokerageModel(BrokerageName.TradierBrokerage, AccountType.Cash);

        // Request extended market hour SPY data for trading.
        _spy = AddEquity("SPY", extendedMarketHours: true).Symbol;

        // Set a scheduled event to trade 2 hours pre-open to place the market-on-open-order.
        Schedule.On(
            DateRules.EveryDay(_spy),
            TimeRules.BeforeMarketOpen(_spy, 120),
            OpenPosition
        );
    }

    private void OpenPosition()
    {
        // Buy on market open will result in an error since Tradier does not support it.
        MarketOnOpenOrder(_spy, 10);
    }

    // It will be triggered on live trading.
    public override void OnBrokerageMessage(BrokerageMessageEvent message)
    {
        if (message.Type == BrokerageMessageType.Error)
        {
            Log($"{Time}: {message.Type}: Message: {message.Message}");
        }
    }
}
```

Live Trading

Data Providers

Introduction

Data providers provide a stream of asset prices and quotes delivered to your trading algorithm during live execution. You need live data provider to inject data into your algorithm so that you can make real-time trading decisions and so that the values of the securities in your portfolio update in real-time. You can source data from QuantConnect, brokerage, or a third-party source. To view the available data providers you can use in QuantConnect cloud, see Datasets . To view the available data providers you can use with local algorithms, see the Data Providers .

Data Providers

You can source data from QuantConnect, your brokerage, or third-party providers. The following table lists the data providers:

Data Provider	Cloud	Local
QuantConnect	✓	
Alpaca	✓	✓
Alpha Vantage		✓
Binance	✓	✓
Bitfinex	✓	✓
Bybit	✓	✓
Charles Schwab	✓	✓
Coinbase	✓	✓
FactSet		✓
Interactive Brokers	✓	✓
IQFeed		✓
Kraken	✓	✓
Polygon	✓	✓
Samco	✓	✓
Theta Data		✓
TradeStation	✓	✓
Terminal Link		✓
Tradier	✓	✓
Zerodha	✓	✓

Bar Building

We aggregate ticks to build bars.

In live trading, bars are built using the exchange timestamps with microsecond accuracy. This microsecond-by-microsecond processing of the ticks can mean that the individual bars between live trading and backtesting can have slightly different ticks. As a result, it's possible for a tick to be counted in different bars between backtesting and live trading, which can lead to bars having slightly different open, high, low, close, and volume values.

Latency

Live data takes time to travel from the source to your algorithm. The QuantConnect latencies vary depending on the data provider, but for US Equities, we have a latency of 5-40 milliseconds. A much more significant source of latency is the round trip order times from brokers, which can vary from 100ms to 5 seconds. QuantConnect is not intended for high-frequency trading, but we have integrations to high-speed brokers if you need.

History Requests

In live trading, if you make a history request for minute data at noon and the history period covers the start of the previous day to the present moment, the data from the previous day will be backtest data. The data of the current day will be live data that we collected throughout the morning. If you make this history request in a backtest, you might get slightly different data for the current day because of post-processing from the data vendor.

In cloud deployments, QuantConnect is the default data provider. If you remove it and use a different data provider, you won't get any price data from QuantConnect. However, we provide the following datasets:

- US Equity Security Master
- US Futures Security Master
- US Equity Option Universe
- US Index Option Universe
- Universe selection datasets
- Non-streaming alternative datasets

Warm Up Periods

LEAN supports an automated fast-forward system called "Warm Up". It simulates winding back the date you deployed your algorithm by a specific time period. In backtests, it changes the start date of your algorithm to an earlier time. In live trading, it fetches data from before your deployment and fast forwards through your strategy up to the present day. Warm Up is a great way to prepare your algorithm and its indicators for trading. You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state.

Live Trading

Trading and Orders

Introduction

LEAN has dozens of methods to create, update, and cancel orders. You can place orders automatically with helper methods or manually through methods on the algorithm API. You can fetch, update, and cancel manual orders with order tickets . As the state of your orders change, LEAN creates events that notify your algorithm.

In backtesting, LEAN simulates order fills with historical data, but you can create your own fill, fee, slippage, and margin models via plugin points. You control how optimistic or pessimistic order fills are with transaction model classes. For more information about these types of models, see Reality Modeling .

In live trading, orders fill asynchronously. We send your order to the API of your brokerage and wait for their response to update the state of your algorithm and portfolio. The timing of live order fills doesn't depend on the resolution of your security subscriptions. When your order fills, the fill price and fee is set by your brokerage. You can add event handlers to your algorithm to monitor the brokerage connection and brokerage messages .

In backtesting, the trade fill timing depends on the resolution of your security subscription. For example, if you subscribe to a security with minute resolution data, the algorithm only receives data in one-minute time slices . As a result, the fill model can only evaluate if the order should fill on a minute-by-minute frequency.

Order Life Cycle

When you call one of the order methods to place an order, LEAN performs pre-order checks to ensure that the order meets some requirements and uses the last known price to check you have enough capital . To see the requirements of each order, see the Requirements section of the documentation for the order types and the Orders section of your brokerage model . If you can place the order, LEAN creates `Order` and OrderTicket objects. The order ticket is sent to your brokerage. As the brokerage processes your order, it returns another order ticket and it's compared against the order to see if the order is satisfied. Orders fill asynchronously in live trading, so if you want to change an order, you must request it with the order ticket. Order changes are not guaranteed since your order may fill by the time brokerage receives the request.

When you create an order ticket, LEAN validates it to avoid sending orders that will be rejected by your brokerage. If the order is invalid, it's status is set to `OrderStatus.Invalid` . Otherwise, LEAN sets the order status to `OrderStatus.New` , sends the order to your brokerage, and waits for the brokerage message. If your brokerage accepts the order, the order status becomes `OrderStatus.Submitted` . Otherwise, it becomes `OrderStatus.Canceled` .

You can update orders until they fill or the brokerage prevents modifications. If you place an order update request, LEAN validates it to avoid sending orders that will be rejected by you brokerage. If the order update is valid, LEAN sends the update request and waits for the brokerage message. If your brokerage accepts the update, the order status becomes `OrderStatus.UpdateSubmitted` . Otherwise, it becomes `OrderStatus.Canceled` .

The brokerage notifies LEAN when you order fills (`OrderStatus.Filled`), partially fills (`OrderStatus.PartiallyFilled`) or is canceled (`OrderStatus.Canceled`). The brokerage can cancel your order before it completely fills. For example, if you place a market on open and the asset price moves before the market open to where you can't afford the quantity of the order, the brokerage rejects your order. The brokerage can also cancel your market on open order after partial fills if there is no shares left

to trade.

Transaction Manager

LEAN doesn't save orders and order tickets across live deployments.

When you deploy your algorithm, LEAN fetches the open orders from your brokerage and populate the algorithm transactions manager (`SecurityTransactionManager`).

Disable Buying Power

You can disable order margin checks and opt to let your brokerage decide to accept or reject the trades. This is helpful in live trading if you have a more permissive brokerage margin allowance that what LEAN models. The default position group buying power models are helpful for Option trading strategies. However, it can be counterproductive if it's not a supported Option strategy . To disable the validations of the default position group buying power model, use the `NullSecurityPositionGroupModel` . To set the `NullSecurityPositionGroupModel` for the portfolio, during initialization , call the `SetPositions` method with the `SecurityPositionGroupModel. Null` argument.

```
C#

Portfolio.SetPositions(SecurityPositionGroupModel.Null);
```

To disable the validations of the default buying power model , use the `NullBuyingPowerModel` . To set the `NullBuyingPowerModel` for a security subscription, call the `SetBuyingPowerModel` method with the `BuyingPowerModel. Null` argument.

```
C#

public override void Initialize()
{
    var equity = AddEquity("SPY");
    // To disable any buying power of the selected security
    equity.SetBuyingPowerModel(BuyingPowerModel.Null);
    // Alias:
    // equity.SetMarginModel(SecurityMarginModel.Null);
}
```

You can also set the `NullBuyingPowerModel` in a security initializer . If your algorithm has a universe, use the security initializer technique. To set the buying power of securities in the security initializer, set the brokerage model , set the security initializer , and then create security subscriptions.

```
C#

public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite the security buying power
        security.SetBuyingPowerModel(BuyingPowerModel.Null);
    }
}
```

Trading and Orders

Financial Advisors

Introduction

Financial Advisor accounts enable certified professionals to use a single trading algorithm to manage several client accounts. Our Interactive Brokers integration enables you to place FA group orders if your IB account code starts with F, FA, or I.

Group Routing

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```
C#
DefaultOrderProperties = new InteractiveBrokersOrderProperties
{
    FaGroup = "TestGroupEQ",
    FaMethod = "Equal",
    Account = "DU123456"
};
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `Portfolio["SPY"].Quantity` is zero.

Allocation Methods

LEAN supports several allocation methods for FA group orders. If you intend to use the same group allocation method for every order, set the `DefaultOrderProperties` of your algorithm, which sets the order properties for all of your orders.

```
C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new InteractiveBrokersOrderProperties()
    {
        FaGroup = "TestGroupEQ",
        FaMethod = "Equal",
        Account = "DU123456"
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);
}
```

To adjust the order properties of an order, change the `DefaultOrderProperties` or pass an order properties object to the order method . The following sections explain the FA group allocation methods.

Equal

This group allocation method distributes shares equally between all accounts in the group. When you use this method, you need to specify an order quantity.

For example, say your Account Group includes four accounts and you place an order to buy 400 shares of a stock. In this case,

each account receives 100 shares. If your Account Group includes six accounts, each account receives 66 shares, and then 1 share is allocated to each account until all are distributed. After you submit the order, your algorithm receives order events to track the order progress. When all the shares are bought, the order status is `OrderStatus.Filled`. If one of the accounts in the group can't afford 10 of the shares it needs to buy, 10 shares are cancelled and you'll only end up buying 390 shares in total.

```
C#
LimitOrder(
    _symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "Equal"
    }
);
```

Net Liquidation Value

This group allocation method distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net liquidation value in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with Net Liquidation values of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```
C#
LimitOrder(_symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "NetLiq"
    }
);
```

Available Equity

This group allocation method distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with available equity of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```
C#
LimitOrder(_symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "AvailableEquity"
    }
);
```

Subscription Requirements

To use FA group orders through our Interactive Brokers integration, you need to connect as a member of a Trading Firm and Institution organization. If you aren't currently on either of these tiers, upgrade your organization.

Live Trading

Reconciliation

Introduction

Algorithms usually perform differently between backtesting and live trading over the same time period. Backtests are simulations where we model reality as close as possible, but the modeling isn't always perfect. To measure the performance differences, we run an out-of-sample (OSS) backtest in parallel to all of your live trading deployments. The live results page displays the live equity curve and the OOS backtest equity curve of your algorithms.

If your algorithm is perfectly reconciled, it has an exact overlap between its live and OOS backtest equity curves. Deviations mean that the performance of your algorithm has differed between the two execution modes. Several factors can contribute to the deviations.

Differences From Data

The data that your algorithm uses can cause differences between backtesting and live trading performance.

Data Providers

QuantConnect provides high-quality historical data for all supported asset classes . However, our live data provider lacks data feeds for equity options, index options, and futures options. If your algorithm trades these asset classes, you must rely on brokerage or third-party data feeds.

Look-Ahead Bias

The Time Frontier minimizes the risk of look-ahead bias in backtests, but it does not completely eliminate the risk of look-ahead bias. For instance, if you use a custom dataset that contains look-ahead bias, your algorithm's live and backtest equity curves

may deviate. To avoid look-ahead bias with custom datasets, set a `Period` on your custom data points so that your algorithm receives the data points after the `Time + Period`.

Discrete Time Steps

In backtests, we inject data into your algorithm at predictable times, according to the data resolution. In live trading, we inject data into your algorithm when new data is available. Therefore, if your algorithm has a condition with a specific time (i.e. time is 9:30:15), the condition may work in backtests but it will always fail in live trading since live data has microsecond precision. To avoid issues, either use a time range in your condition (i.e. 9:30:10 < time < 9:30:20), use a rounded time, or use a Scheduled Event.

Custom Data Emission Times

Custom data is often timestamped to midnight, but the data point may not be available in reality until several days after that point. If your custom dataset is prone to this delay, your backtest may not fetch the same data at the same time or frequency that your live trading algorithm receives the data, leading to deviations between backtesting and live trading. To avoid issues, ensure the timestamps of your custom dataset are the times when the data points would be available in reality.

In backtesting, LEAN and custom data are perfectly synchonized. In live trading, daily and hourly data from a custom data source are not because of the frequency that LEAN checks the data source depends on the `resolution` argument. The following table shows the polling frequency of each resolution:

Resolution	**Update Frequency**
Daily	Every 30 minutes
Hour	Every 30 minutes
Minute	Every minute
Second	Every second
Tick	Constantly checks for new data

Split Adjustment of Indicators

Backtests use adjusted price data by default. Therefore, if you don't change the data normalization mode , the indicators in your backtests are updated with adjusted price data. In contrast, if a split or dividend occurs in live trading, your indicators will temporarily contain price data from before the corporate event and price data from after the corporate event. If this occurs, your indicators will produce different signals in your backtests compared to your live trading deployment. To avoid issues, reset and warm up your indicators when your algorithm receives a corporate event.

Tick Slice Sizes

In backtesting, we collect ticks into slices that span 1 millisecond before injecting them into your algorithm. In live trading, we collect ticks into slices that span up to 70 milliseconds before injecting them into your algorithm. This difference in slice sizes can cause deviations between your algorithm's live and OOS backtest equity curves. To avoid issues, ensure your strategy logic is compatible with both slice sizes.

Opening and Closing Auctions

The opening and closing price of the day is set by very specific opening and closing auction ticks. When a stock like Apple is listed, it’s listed on Nasdaq. The open auction tick on Nasdaq is the price that’s used as the official open of the day. NYSE,

BATS, and other exchanges also have opening auctions, but the only official opening price for Apple is the opening auction on the exchange where it was listed.

We set the opening and closing prices of the first and last bars of the day to the official auction prices. This process is used for second, minute, hour, and daily bars for the 9:30 AM and 4:00 PM Eastern Time (ET) prices. In contrast, other platforms might not be using the correct opening and closing prices.

The official auction prices are usually emitted 2-30 seconds after the market open and close. We do our best to use the official opening and closing prices in the bars we build, but the delay can be so large that there isn't enough time to update the opening and closing price of the bar before it's injected into your algorithms. For example, if you subscribe to second resolution data, we wait until the end of the second for the opening price but most second resolution data won't get the official opening price. If you subscribe to minute resolution data, we wait until the end of the minute for the opening auction price. Most of the time, you'll get the actual opening auction price with minute resolution data, but there are always exceptions. Nasdaq and NYSE can have delays in publishing the opening auction price, but we don't have control over those issues and we have to emit the data on time so that you get the bar you are expecting.

Data Updates

Data issues are incorrect or missing values in a dataset. These issues are generally a result of human error or from mistakes in the data collection process. Data issues can be reported by any QuantConnect member. When data issues are reported and verified, our Data Team works to quickly resolve them. Thanks to the communal efforts of the QuantConnect members, the QuantConnect data is reviewed and fixed by over 250,000 people, giving you a very high-quality source of data.

Data updates change backtest results and, consequently, cause differences between backtesting running with fixed data and live trading. For more information on common data issues, please refer to the data issues documentation .

Differences From Modeling

The modeling that your algorithm uses can cause differences between backtesting and live trading performance.

Reality Modeling Error

We provide brokerage models to model fees, slippage, and order fills in backtests. However, these model predictions may not always match the fees that your live algorithm incurs, leading to deviations between backtesting and live trading. You can adjust the reality models that your algorithm uses to more accurately reflect the specific assets that you're trading. For more information about reality models, see Reality Modeling .

Market Impact

We don't currently model market impact. So, if you are trading large orders, your fill prices can be better during backtesting than live trading, causing deviations between backtesting and live trading. To avoid issues, implement a custom fill model in your backtests that incorporates market impact.

Fills

In backtests, orders fill immediately. In live trading, they are sent to your brokerage and take about half a second to execute. If you fill an order in a backtest with stale data, deviations between backtesting and live trading can occur because the order is filled at a price that is likely different from the real market price. Stale order fills commonly occur in backtests when you create a Scheduled Event with an incompatible data resolution. For instance, if you subscribe to hourly data, place a Scheduled Event for 11:15 AM, and fill an order during the Scheduled Event, the order will fill at a stale price because the data between 11:00 AM and 11:15 AM is missing. To avoid stale fills, only place orders when your algorithm receives price data.

In live trading, your brokerage provides the fill price of your orders. Since the backtesting brokerage models do not know the

price at which live orders are filled, the fill price of backtest orders is based on the best price available in the current backtesting data. Similarly, limit orders can fill at different prices between backtesting and live trading. In backtesting, limit orders fill as soon as the limit price is hit. In live trading, your brokerage may fill the same limit order at a different price or fail to fill the order, depending on the position of your order in their order book.

Borrowing Costs

By default, LEAN doesn't simulate the cost of borrowing shorts in backtests, but you can enable them by setting a margin interest model.

Differences From Brokerage

The brokerage that your algorithm uses can cause differences between backtesting and live trading performance.

Portfolio Allocations on Small Accounts

If you trade a small portfolio, it's difficult to achieve accurate portfolio allocations because shares are usually sold in whole numbers. For instance, you likely can't allocate exactly 10% of your portfolio to a security. You can use fractional shares to achieve accurate portfolio allocations, but not all brokerages support fractional shares. To get the closest results when backtesting and live trading over the same period, ensure both algorithms have the same starting cash balance.

Different Backtest Parameters

If you don't start your backtest and live deployment on the same date with the same holdings, deviations can occur between backtesting and live trading. To avoid issues, ensure your backtest parameters are the same as your live deployment.

Non-deterministic State From Algorithm Restarts

If you stop and redeploy your live trading algorithm, it needs to restart in a stateful way or else deviations can occur between backtesting and live trading. To avoid issues, redeploy your algorithm in a stateful way using the `SetWarmUp` and `History` methods. Furthermore, use the Object Store to save state information between your live trading deployments.

Existing Portfolio Securities

If you deploy your algorithm to live trading with a brokerage account that has existing holdings, your live trading equity curve reflects your existing positions, but the backtesting curve won't. Therefore, if you have existing positions in your brokerage account when you deploy your algorithm to live trading, deviations will occur between backtesting and live trading. To avoid issues, deploy your algorithm to live trading using a separate brokerage account or subaccount that does not have existing positions.

Brokerage Limitations

We provide brokerage models that support specific order types and model your buying power. In backtesting, we simulate your orders with the brokerage model you select. In live trading, we send your orders to your brokerage for execution. If the brokerage model that you use in backtesting is not the same brokerage that you use in live trading, deviations may occur between backtesting and live trading. The deviations can occur if your live brokerage doesn't support the order types that you use or if the backtesting brokerage models your buying power with a different methodology than the real brokerage. To avoid brokerage model issues, set the brokerage model in your backtest to the same brokerage that you use in live trading.

Differences From Third-Party Indicators

The values of our indicators can sometimes produce different results than the indicators on other platforms. There can be several reasons for these discrepancies.

Price Differences

If you find differences in indicator values, compare the prices that are fed into the indicator on each platform. If the input data is slightly different, the indicator values will be different. To test if it's a difference in price data, feed in the data from the third-party platform into our indicators. We validate the indicators against third-party sources and when the values are the same, the indicator values are similar too.

Timestamp Differences

We timestamp our data to the time when the period ends. Many other platforms timestamp to the beginning of the candle.

Implementation Differences

Some indicators can have slightly different default arguments for their implementation. A common difference across platforms is to use a different `MovingAverageType` for the indicators. To view the default arguments for all our indicators, see Supported Indicators . To view the full implementation of our indicators, see the LEAN GitHub repository .

Warm Up Period Differences

Some platforms use all of the historical data to warm up their indicators while LEAN indicators have a fixed number of bars they need to warm up. As a result, indicators with long memory like the Exponential Moving Average can have slightly different values across platforms.

Risk Free Interest Rate Differences

Some indicators, like Sharpe ratios and Sortino ratios , are a function of the risk free interest rate . LEAN provides several different ways to define the interest rate, which can lead to different indicator values compared to other platforms.

Differences From Real-time Scheduled Events

In live trading, Scheduled Events execute in a parallel thread based on a real-time clock. If you set a Scheduled Event to fire at 10:00 AM, it executes at exactly 10:00 AM. In backtesting, Scheduled Events are part of the main algorithm manager loop, so they may not execute exactly when you set them. For example, if your algorithm subscribes to minute resolution US Equity data with regular trading hours and you set a Scheduled Event to occur at 2:00 AM, your Scheduled Event will execute at 9:31 AM when the next bar is fed into your algorithm.

The difference between live trading and backtesting is important to note because it can affect your algorithm's behavior. There are two common scenarios to consider.

Execution Timing and Backtest Timeouts

Take the following scenario:

- You set Scheduled Events for 2:00 AM, 3:00 AM, and 4:00 AM each day.
- Each Scheduled Event takes eight minutes to execute.
- Your algorithm only subscribes to US Equity securities without extended market hours (9:30 AM - 4:00 PM).

In this scenario, the Scheduled Events each fire at the correct time and execute without error in live trading. In backtesting, all of the Scheduled Events execute at 9:31 AM when your algorithm receives the first bar of the trading day. Since all the Scheduled Events take eight minutes to execute, the algorithm tries to execute all the Scheduled Events but reaches the 10-minute timeout and the backtest stops execution.

Live Data Delays

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the

bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute. Take the following scenario:

- You subscribe to minute resolution data
- You set a Scheduled Event for 10:00 AM
- The Scheduled Event checks the current asset price

In live trading, the Scheduled Event executes at exactly 10:00 AM but your algorithm may receive the 9:59-10:00 AM bar at 10:00:00.01 AM. Therefore, when you check the price in the Scheduled Event, the price from the 9:58-9:59 AM bar is the latest price. In backtesting, the Scheduled Event gets the price from the 9:59-10:00 AM bar since your algorithm receives the bar at perfect timing.

Live Trading

Notifications

Introduction

Set up some live trading notifications so that you are notified of market events and your algorithm's performance. QuantConnect Cloud supports email, SMS, webhooks, and Telegram notifications for live trading algorithms. If you run local algorithm with LEAN or the LEAN CLI, the notification services aren't available. To view the number of notification you can send for free in QuantConnect Cloud, see the Live Trading Notification Quotas . Notifications are different from commands because notifications enable you to send information out of your algorithm while commands enable you to manually call methods in your algorithm as it runs.

Email

Email notifications can include up to 10KB of text content in the message body. These notifications can be slow since they go through your email provider. If you don't receive an email notification that you're expecting, check your junk folders.

To send email notifications in your code files, run:

```C#
var message = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511";
Notify.Email(emailAddress: "quant@office.com", subject: "Last Trade", message: message);
```

You can include an attachment and set its name.

```C#
var attachment = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511";
var headers = new Dictionary<string, string> { { "filename", "trades.csv" } };
Notify.Email(address: "quant@office.com", subject: "Last Trade", message: "See attachment", data: attachment,
headers: headers);
```

If you don't provide headers, the attachment name is attachment.txt .

FTP

FTP notifications send files to your FTP server. You can use password and SSH authentication.

To send a file to your FTP server in your code files, run:

```C#
var fileContent = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511";
Notify.Ftp(hostname: "myftpserver.com", username: "admin", password: "12345", filePath: "trades.csv", fileContent:
fileContent, port: 21);
```

To send a file to your SFTP server in your code files, run:

```C#
var fileContent = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511";
Notify.Sftp(hostname: "mysftpserver.com", username: "admin", password: "12345", filePath: "trades.csv", fileContent:
fileContent, port: 21);
```

You can use password authentication over SFTP using SSH keys.

```C#
var fileContent = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511";
Notify.Sftp(hostname: "mysftpserver.com", username: "admin", privateKey: "12345", privateKeyPassphrase: "67890",
filePath: "trades.csv", fileContent: fileContent, port: 21);
```

The `filePath` parameter is path to file on the FTP server. The `port` parameter is optional.

SMS

SMS notifications are the only type of notification that you don't need an internet connection to receive. They can include up to 1,600 characters of text content in the message body.

To send SMS notifications in your code files, run:

```C#
var message = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511";
Notify.Sms(phoneNumber: "+100503016366", message: message);
```

Telegram

Telegram notifications are automated messages to a Telegram group.

To send Telegram notifications in your code files, run:

```C#
var message = "2023-07-13T12:20:00.2033226Z,EURUSD,1.11853,89187,Market,Filled,99758.33511";
Notify.Telegram(id: "-503016366", message: message, token: "1234");
```

The `id` argument is your Telegram group Id. Your group Id is in the URL when you open your group chat in the Telegram web interface. For example, the group Id of web.telegram.org/z/#-503016366 is -503016366.

The `token` optional argument is a token of a bot you must add to your Telegram group. To create a bot, chat with @BotFather and follow its instructions. If you want to use our bot, the username is @quantconnect_notifications_bot.

To add emoticons to your `message` , convert the emoticon character to UTF-32 with the Unicode Converter on the Branah website. For example, the rocket emoji is `0001f680` in UTF-32 format, so use `\U001f680` in your message.

Webhooks

Webhook notifications are an HTTP-POST request to a URL you provide. The request is sent with a timeout of 300s. You can process these notifications on your web server however you want. For instance, you can inject the content of the notifications into your server's database or use it to create other notifications on your own server.

To send webhook notifications in your code files, run:

```C#
var data = "";
var headers = new Dictionary<string, string> { { "Authorization", "Basic XXXXXX" } };
Notify.Web(address: "http://api.myserver.com", data: data, headers: headers);
```

The `data` argument can be any serializable type .

To send a webhook to a Discord server, generate a webhook URL (for instructions, see Intro to Webhooks in the Discord Help

Center) and serialize the data in a dictionary with a `content` key.

```C#
var discordURL = "https://discord.com/api/webhooks/.../...";
Notify.Web(discordURL, JsonSerializer.Serialize(new { content = "Hello world!" }));
```

Receive Notifications

To receive external notification in your algorithm, see Commands .

Terms of Use

The notification system can't be used for data distribution.

Examples

The following examples demonstrate common practices for sending notifications in live algorithms.

Example 1: Pre-Open Order Error

The following algorithm simulate extended market hour trading on Tradier Brokerage . We place a market-on-open order at 7:30am and expect the order cannot submit to the broker since it is not supported, resulting into an error.

```C#
public class OrderErrorsAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 5);
        // Simulate Tradier brokerage, which does not support the market-on-open orders.
        SetBrokerageModel(BrokerageName.TradierBrokerage, AccountType.Cash);

        // Request extended market hour SPY data for trading.
        _spy = AddEquity("SPY", extendedMarketHours: true).Symbol;

        // Set a scheduled event to trade 2 hours pre-open to place the market-on-open-order.
        Schedule.On(
            DateRules.EveryDay(_spy),
            TimeRules.BeforeMarketOpen(_spy, 120),
            OpenPosition
        );
    }

    private void OpenPosition()
    {
        // Buy on market open will result in an error since Tradier does not support it.
        MarketOnOpenOrder(_spy, 10);
    }

    // It will be triggered on live trading.
    public override void OnBrokerageMessage(BrokerageMessageEvent message)
    {
        if (message.Type == BrokerageMessageType.Error)
        {
            Log($"{Time}: {message.Type}: Message: {message.Message}");
        }
    }
}
```

LiveFeaturesAlgorithm.cs C#

Live Trading

Commands

Introduction

Commands enable you to manually call methods in your live algorithm as it runs. You can command live projects to update your algorithm state, place orders, or run any other logic. Commands are different from notifications because notifications enable you to send information *out* of your algorithm while commands enable you to send information *into* your algorithm.

Basic Usage

To receive and handle generic commands in your algorithm, define the `OnCommand` method. This method receives the data you want to inject into your algorithm and returns a boolean that represents if the command was successful.

```C#
public class BasicCommandAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetBenchmark(x => 1); // So the algorithm needs no asset data.
    }

    public override bool? OnCommand(dynamic data)
    {
        Log($"Got command at {Time} with data: {data}");
        return true;
    }
}
```

To invoke the `OnCommand` event handler, send a payload (for example, `{"ticker": "AAPL", "quantity": 1}`) through the QuantConnect REST API or LEAN CLI . The keys of the payload become the members of the `data` object.

Encapsulate Event Handlers

To encapsulate the command handler logic, define isolated classes. Command classes should extend the `Command` class. Extensions of the `Command` class must implement a `Run` method, which receives the payload you send and returns a boolean that represents if the command was successful. To add the command to your algorithm, call the `AddCommand` method.

```C#
public class EncapsulatedCommandAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        AddCommand<MyCommand>();
        SetBenchmark(x => 1); // So the algorithm doesn't need asset data.
    }

    public void DoSomething()
    {
        Log("Something was done!");
    }
}

public class MyCommand : Command
{
    public string Ticker { get; set; }
    public int Quantity { get; set; }
    public Dictionary<string, string> Parameters { get; set; }
    public override bool? Run(IAlgorithm algorithm)
    {
        ((QCAlgorithm)algorithm).Log($"ticker: {Ticker}; quantity: {Quantity}; parameters: {Parameters}");
        ((EncapsulatedCommandAlgorithm)algorithm).DoSomething();
        return true;
    }
}
```

To invoke the `Run` method of the class you define, send a payload with a `$type` key (for example, `{"ticker": "AAPL", "quantity": 1, "$type": "MyCommand"}`). The value of the `$type` key must be the `Command` class you define. The other keys of the payload set the members of the class. If you don't provide a `$type` key, LEAN runs the `OnCommand` method instead of the `Run` method in your custom `Command` class.

Send Command Link

You can create the command in your algorithm and then send yourself an email notification with a link inside it. When you click the link, it then executes the event handler in your algorithm. To create the link, call the `Link` method. The following algorithm demonstrates how send command requests for the `on_command` event handler:

```C#
public class BasicLinkedCommandAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetBenchmark(x => 1); // So the algorithm needs no asset data.
        var link = Link(new {Ticker = "AAPL", Quantity = 1});
        Notify.Email("email@address.com", "Run Command?", $"Click here to run: {link}");
    }

    public override bool? OnCommand(dynamic data)
    {
        Log($"Got command at {Time} with data: {data}");
        return true;
    }
}
```

The following algorithm demonstrates how to send command requests for an event handler you encapsulate in a class:

```C#
public class EncapsulatedAndLinkedCommandAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        AddCommand<MyCommand>();
        SetBenchmark(x => 1); // So the algorithm doesn't need asset data.
        var potentialCommand = new MyCommand
        {
            Ticker = "AAPL",
            Quantity = 1,
            Parameters = new() { {"tag", "Signal X"} }
        };
        var link = Link(potentialCommand);
        Notify.Email("email@address.com", "Run Command?", $"Click here to run: {link}");
    }

}

public class MyCommand : Command
{
    public string Ticker { get; set; }
    public int Quantity { get; set; }
    public Dictionary<string, string> Parameters { get; set; }
    public override bool? Run(IAlgorithm algorithm)
    {
        ((QCAlgorithm)algorithm).Log($"ticker: {Ticker}; quantity: {Quantity}; parameters: {Parameters}");
        return true;
    }
}
```

Broadcast Command

You can create the command in your algorithm and then broadcast it to all live algorithms in your organization, except the source algorithm and commands of unregisted type name. The following algorithm demonstrates how broadcast a command to the `OnCommand` event handler in all your live algorithms:

```C#
public class BasicBroadcastCommandAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetBenchmark(x => 1); // So the algorithm needs no asset data.
        var broadcastResult = BroadcastCommand(new {Ticker = "AAPL", Quantity = 1});
    }

    public override bool? OnCommand(dynamic data)
    {
        Log($"Got command at {Time} with data: {data}");
        return true;
    }
}
```

You can control the command data by encapsulating the event handler in a class. The following algorithm demonstrates how to broadcast a command for an event handler you encapsulate in a class:

```C#
public class EncapsulatedAndBroadcastCommandAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        AddCommand<MyCommand>();
        SetBenchmark(x => 1); // So the algorithm doesn't need asset data.
        var potentialCommand = new MyCommand
        {
            Ticker = "AAPL",
            Quantity = 1,
            Parameters = new() { {"tag", "Signal X"} }
        };
        var broadcastResult = BroadcastCommand(potentialCommand);
    }
}

public class MyCommand : Command
{
    public string Ticker { get; set; }
    public int Quantity { get; set; }
    public Dictionary<string, string> Parameters { get; set; }
    public override bool? Run(IAlgorithm algorithm)
    {
        ((QCAlgorithm)algorithm).Log($"ticker: {Ticker}; quantity: {Quantity}; parameters: {Parameters}");
        return true;
    }
}
```

Send Commands by API

To send a command to your algorithm, send a payload through the QuantConnect REST API or LEAN CLI . LEAN converts the first character in each key of the payload to uppercase before injecting the data into your algorithm. The following script demonstrates how to send a command with the REST API. In this case, it calls the `OnCommand` method.

To get your user Id and API token, see Request API Token .

Broadcast Commands by API

To broadcast a command to your live algorithms, send a payload through the QuantConnect REST API or LEAN CLI . LEAN converts the first character in each key of the payload to uppercase before injecting the data into your algorithm. The following script demonstrates how to broadcast a command to all projects in your organization with the REST API.

To get your user Id, API token, and organization Id, see Request API Token and Get Organization Id .

Examples

The following examples demonstrate common practices for implementing live commands.

Example 1: Grey Box

The following algorithm trades a simple EMA cross strategy on SPY. However, instead of direct ordering by the algorithm as a "black box", it sends an email to ask for clicking a confirmation link before ordering, making each order decision an informed manual decision. The algorithm is called a "grey box".

```C#
public class LiveCommandAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 12);
        SetEndDate(2024, 10, 1);
        SetCash(1000000);

        // Request SPY data to trade.
        _spy = AddEquity("SPY").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_spy, 20, Resolution.Daily);
        // Warm-up indicator for immediate readiness.
        WarmUpIndicator(_spy, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar) && LiveMode)
        {
            // Trend-following strategy using price and EMA.
            // If the price is above EMA, SPY is in an uptrend, and we buy it.
            // We sent a link to our email address and await confirmation.
            string link;
            if (bar.Close > _ema && !Portfolio[_spy].IsLong)
            {
                link = Link(new {Ticker = "SPY", Size = 1});
                Notify.Email("email@address.com", "Trade Confirmation Needed", $"Click here to run: {link}");
            }
            else if (bar.Close < _ema && !Portfolio[_spy].IsShort)
            {
                link = Link(new {Ticker = "SPY", Size = -1});
                Notify.Email("email@address.com", "Trade Confirmation Needed", $"Click here to run: {link}");
            }
        }
    }

    public override bool? OnCommand(dynamic data)
    {
        // If we click the email link to confirm the trade, the algorithm will place the order.
        SetHoldings(data.Ticker, data.Size);
        return true;
    }
}
```

Example 2: Parent-Child Communication

Parent algorithm

The parent algorithm is connected to a brokerage. It receives commands from other algorithms and places market orders based on those commands.

```C#
public class ParentAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Remove benchmark so doesn't need asset data.
        SetBenchmark(x => 1);

        // Seed each asset with it's price to trade right away.
        Settings.SeedInitialPrices = true;
    }

    public override bool? OnCommand(dynamic payload)
    {
        Log($"{Time} - Execute on_command(): {payload}");
        var equity = AddEquity(payload.ticker);

        if (!string.IsNullOrWhiteSpace(payload.email))
        {
            Notify.Email(address: payload.email, subject: $"Order Executed from {payload.source}", message: $"
{equity.symbol}, {payload.quantity}, {payload.source}");
        }

        MarketOrder(equity.symbol, payload.quantity, asynchronous: true, tag: payload.source);
        return true;
    }
}
```

Child algorithm

The child algorithm is connected to a paper trading account. It contains the trading logic and sends commands to the parent algorithm for execution.

```C#
public class ChildAlgorithm : QCAlgorithm
{
    // Set the initials to identify the sender and the cash this algorithm will use.
    private const string _initials = "C1";

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // When an order is filled, we send a command to the parent algorithm with the order details.
        if (orderEvent.Status == OrderStatus.Filled)
        {
            Log($"{Time} - Sending command");
            var response = Send(orderEvent.Symbol.Value, orderEvent.FillQuantity, _initials);
            Log($"{Time} - Command response {response}");
        }
    }

    private string Send(string ticker, decimal quantity, string name)
    {
        if (!LiveMode) return string.Empty;

        // Set the project ID with the ID of your parent algorithm.
        ProjectId = 30123456;
        // Generate the command link with the desired data payload, and execute with download_data.
        var link = Link(new {ticker, quantity, name});
        return link.DownloadData();
    }
}
```

Live Trading

Arbitrage

Introduction

Arbitrage is the practice of taking advantage of a price difference between two or more markets. QuantConnect supports arbitrage strategies by allowing you to run multiple live algorithms deployments simultaneously and communicate between them using commands .

Basic Implementation

You can broadcast a command from and execute the event handler in another project. Add the project ID to the command data to identify the source of the command:

```C#
public class BasicBroadcastCommandAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetBenchmark(x => 0);           // So the algorithm needs no asset data.
        var broadcastResult = BroadcastCommand(new { Sender = ProjectId, Ticker = "AAPL", Quantity = 1 });
    }

    public override bool? OnCommand(dynamic data)
    {
        // Receive the command from the other algorithm
        Log($"Got command at {Time} with data: {data}");
        return true;
    }
}
```

Examples

The following examples demonstrate common practices for implementing arbitrage algorithms.

Example 1: Long-short Bitcoin in two exchanges

The following algorithms trade an arbitrage strategy with BTCUSDT.

Primary algorithm

The primary algorithm trades a simple EMA cross strategy on BTCUSDT in Kraken. It broadcasts a command with the order filled quantity to all live deployments, and logs the command data it receives from the secondary algorithm.

C#

```
public class CryptoArbitrageA : QCAlgorithm
{
    private Symbol _btc;
    private ExponentialMovingAverage _ema;
    // Set a threshold value for the EMA cross.
    private decimal _threshold = 0.005m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetAccountCurrency("USDT", 100000);

        // Set the brokerage model to trade on Kraken.
        SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin);
        // Request BTCUSDT data to trade.
        _btc = AddCrypto("BTCUSDT").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_btc, 22);
        // Warm-up indicator for immediate readiness.
        WarmUpIndicator(_btc, _ema);
        // Trade when the EMA is updated.
        _ema.Updated += Trade;
    }

    private void Trade(object _, IndicatorDataPoint current)
    {
        var ema = current.Value;
        var holdings = Portfolio[_btc];
        var price = holdings.Price;

        // Trend-following strategy using price and EMA.
        // If the price is above EMA, BTC is in an uptrend, and we buy it.
        if (!holdings.IsLong && price > ema * (1m+_threshold))
        {
            SetHoldings(_btc, 1);
        }
        else if (!holdings.IsShort && price < ema * (1m-_threshold))
        {
            SetHoldings(_btc, -1);
        }
    }

    public override bool? OnCommand(dynamic data)
    {
        // The algorithm will log the command data from the secondary algorithm.
        Log($"Got command at {Time} with data: {data}");
        return true;
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // If an order is filled, we call the BroadcastCommand method to send a command to all live deployments.
        // You can add the project ID to the command data to identigy the sender.
        if (!LiveMode || orderEvent.Status != OrderStatus.Filled) return;
        var broadcastResult = BroadcastCommand(new { Sender = ProjectId, Ticker = $"{orderEvent.Symbol.Value}",
Portfolio[orderEvent.Symbol].Quantity });
    }

}
```

Secondary algorithm

The secondary algorithm trades the opposite direction of the primary in Bybit using the command it receives from the primary algorithm. It broadcasts a command with the order filled quantity to all live deployments.

C#

```
public class CryptoArbitrageB : QCAlgorithm
{
    private Symbol _btc;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetAccountCurrency("USDT", 100000);

        // Set the brokerage model to trade on Bybit.
        SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);
        // Request BTCUSDT data to trade.
        _btc = AddCrypto("BTCUSDT").Symbol;
    }

    public override bool? OnCommand(dynamic data)
    {
        // The algorithm will trade the opposite direction of the primary algorithm.
        Log($"Got command at {Time} with data: {data}");
        var quantity = -(Portfolio[_btc].Quantity + (decimal)data.Quantity);
        if (quantity != 0)
            MarketOrder(_btc, quantity, tag:data.ToString());
        return true;
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // If an order is filled, we call the BroadcastCommand method to send a command to all live deployments.
        // You can add the project ID to the command data to identify the sender.
        if (!LiveMode || orderEvent.Status != OrderStatus.Filled) return;
        var broadcastResult = BroadcastCommand(new { Sender = ProjectId, Ticker = $"{orderEvent.Symbol.Value}",
Portfolio[orderEvent.Symbol].Quantity });
    }

}
```

Live Trading

Charting and Logging

Introduction

The live results page shows your algorithm's live trading performance. You can add custom charts and logs to the results page.

Charting

Charts are sampled every one and ten minutes. If you create 1-minute resolution custom charts, the IDE charting will downgrade the granularity and display the 10-minutes sampling after a certain amount of samples. There are not quotas in live trading.

Logging

Algorithms can record string messages ('log statements') to a file for analysis after a backtest is complete, or as a live algorithm is running. These records can assist in debugging logical flow errors in the project code. Consider adding them in the code block of an `if` statement to signify an error has been caught.

It's good practice to add logging statements to live algorithms so you can understand its behavior and keep records to compare against backtest results. If you don't add logging statements to a live algorithm and the algorithm doesn't trade as you expect, it's difficult to evaluate the underlying problem.

If you run algorithms on QuantConnect, you must stay within the log quota . To only log when your algorithm is live, use the `LiveMode` property.

C#

```
if (LiveMode)
{
    Log("My log message");
}
```

Runtime Statistics

Runtime statistics show the performace of your algorithm at a single moment in time.

The following table describes the default runtime statistics:

Statistic	Description
Equity	The total portfolio value if all of the holdings were sold at current market rates.
Fees	The total quantity of fees paid for all the transactions.
Holdings	The absolute sum of the items in the portfolio.
Net Profit	The dollar-value return across the entire trading period.
PSR	The probability that the estimated Sharpe ratio of an algorithm is greater than a benchmark (1).
Return	The rate of return across the entire trading period.
Unrealized	The amount of profit a portfolio would capture if it liquidated all open positions and paid the fees for transacting and crossing the spread.
Volume	The total value of assets traded for all of an algorithm's transactions.

For more information about runtime statistics, see Runtime Statistics .

Examples

The following examples demonstrate some common practices for logging in live algorithm.

Example 1: On Events And Trading Logic

The following example trades a simple EMA cross trend-following strategy on SPY. We log or debug messages in event handlers and trading logic changes to get information on any event flow.

C#

```
public class LoggingAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 12);
        SetEndDate(2024, 10, 1);
        SetCash(1000000);

        // Request SPY data to trade.
        _spy = AddEquity("SPY").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_spy, 20, Resolution.Daily);

        // Warm up the algorithm for indicator readiness.
        SetWarmUp(20, Resolution.Daily);
    }

    public override void OnWarmupFinished()
    {
        // Signals on warm-up finished.
        Log("Warm up finished");
    }

    public override void OnData(Slice slice)
    {
        if (!IsWarmingUp && slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trend-following strategy using price and EMA.
            // If the price is above EMA, SPY is in an uptrend, and we buy it.
            if (bar.Close > _ema && Portfolio[_spy].IsLong)
            {
                Debug("Trend changes to upwards");
                SetHoldings(_spy, 1m);
            }
            else if (bar.Close < _ema && Portfolio[_spy].IsShort)
            {
                Debug("Trend changes to downwards");
                SetHoldings(_spy, -1m);
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            // Log the order details if being filled.
            Log($"Order filled - Quantity: {orderEvent.Quantity}");
        }
    }
}
```

Signal Exports

Key Concepts

Introduction

QuantConnect Signal Exports allows you to transmit the state of an algorithm's trading and portfolio positions to your fund or a third-party service. QuantConnect implements two signal services out of the box: Collective2 and Numerai . To send portfolio targets to your fund, you need to create a custom Signal Export implementation.

Add Providers

To export signals to a signal provider, during initialization , add a signal export provider.

```
C#
SignalExport.AddSignalExportProvider(new CustomSignalExport());
```

You can add multiple signal export providers to a single algorithm.

Send Portfolio Targets

The signal export manager automatically sends signals when your portfolio holdings change to your fund or a third-party service. By default, it waits five seconds after an order is filled to aggregate all the state changes into a single post. Set the `AutomaticExportTimeSpan` property to change the waiting time.

```
C#
SignalExport.AutomaticExportTimeSpan = TimeSpan.FromSeconds(1);
```

To send targets that aren't based on your portfolio holdings, see Manual Exports .

To disable automatic exports, set the `AutomaticExportTimeSpan` property to `null` .

```
C#
SignalExport.AutomaticExportTimeSpan = null;
```

Custom Signal Exports

Signal export providers must implement the `ISignalExportTarget` interface. Extensions of the `ISignalExportTarget` interface must define the `Send` and the `Dispose` methods.

The `Send` receives a `SignalExportTargetParameters` object with a list of `PortfolioTarget` objects you can use to create the API request payload.

The `Dispose` method is called when the algorithm is disposed. You can use this method to release unmanaged resources such as HTTP Clients.

```C#
public class CustomSignalExportExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the custom signal export provider
        AddEquity("SPY");
        SignalExport.AddSignalExportProviders(new CustomSignalExport());
    }

    public override void OnData(Slice slice)
    {
        // Buy the SPY ETF when the algorithm is not invested
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 0.1m);
        }
    }
}

// Define the custom signal export provider
public class CustomSignalExport : ISignalExportTarget
{
    private readonly HttpClient _httpClient = new ();

    public bool Send(SignalExportTargetParameters parameters)
    {
        // Create the request payload using the PortfolioTarget objects in the parameters
        // You can use the PortfolioTarget.Percent to calculate the target quantity
        // from the target percentage
        // The Tag property can be used to send additional information about the target
        // It's only available when you create the PortfolioTarget object with the tag parameter
        // See the Manual Exports documentation for more information
        object SimplePayload(PortfolioTarget target)
        {
            var newTarget = PortfolioTarget.Percent(parameters.Algorithm, target.Symbol, target.Quantity, tag:
target.Tag);
            return new { symbol = newTarget.Symbol.Value, quantity = newTarget.Quantity, tag = newTarget.Tag };
        };

        var message = JsonConvert.SerializeObject(parameters.Targets.Select(SimplePayload));
        using var httpMessage = new StringContent(message, Encoding.UTF8, "application/json");
        // Send the request to your custom endpoint
        var requestUri = "https://your-custom-endpoint.com/api/signal-export";
        using HttpResponseMessage response = _httpClient.PostAsync(requestUri, httpMessage).Result;
        var result = response.Content.ReadFromJsonAsync<RestResponse>().Result;

        // Log the result of the request for debugging purposes
        parameters.Algorithm.Log($"Send #{parameters.Targets.Count} targets. Success: {result.Success}");
        return result.Success;
    }

    public void Dispose() => _httpClient.Dispose();
}
```

Manual Exports

In some cases, you may need to send signals to your fund or a third-party manually. For example, the signal export manager sends signals after a fill event and you need to submit signals when the market is closed or your signals aren't based on your portfolio holdings.

To do this, pass a `PortfolioTarget` object or an array of `PortfolioTarget` objects to the `SetTargetPortfolio` method. The method returns a boolean that represents if the targets were successfully sent to its destination. In this situation, the number you pass to the `PortfolioTarget` constructor represents the portfolio weight. Don't use the `PortfolioTarget.Percent` method.

```C#
var target = new PortfolioTarget(_symbol, weight, tag: "My tag");
var success = SignalExport.SetTargetPortfolio(target);
```

If you use a margin account, you can send your current portfolio holdings by calling the `SetTargetPortfolioFromPortfolio`

method.

```C#
var success = SignalExport.SetTargetPortfolioFromPortfolio();
```

Signal Exports

Collective2

Introduction

Collective2 is a service that connects strategy developers and capital allocators. With our Collective2 integration, you can send trading signals from your live algorithms to Collective2 .

Add Providers

To export signals to Collective2 from your algorithm, during initialization , add a Collective2 signal export provider.

```
SignalExport.AddSignalExportProvider(new Collective2SignalExport(apiKey, systemId, useWhiteLabelApi));
```

The `Collective2SignalExport` constructor accepts the following arguments:

Argument: `apiKey` Your Collective2 API key. To get your API key, see Where can I find my API key? on the Collective2 website. Data Type: `string`
Argument: `systemId` Your Collective2 strategy Id. To get your strategy Id, see How do I find my strategy ID? on the Collective2 website. Data Type: `int`
Argument: `useWhiteLabelApi` Whether to use the white-label API instead of the general one. Data Type: `bool` | Default Value: `false`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our Collective2 integration supports signals for the following asset classes:

- US Equity
- Equity Options
- Forex
- Futures
- Index Options

Send Portfolio Targets

The signal export manager automatically sends signals when your portfolio holdings change to Collective2. By default, it waits five seconds after an order is filled to aggregate all the state changes into a single post. Set the `AutomaticExportTimeSpan` property to change the waiting time.

```
C#
SignalExport.AutomaticExportTimeSpan = TimeSpan.FromSeconds(1);
```

To send targets that aren't based on your portfolio holdings, see Manual Exports .

To disable automatic exports, set the `AutomaticExportTimeSpan` property to `null` .

```
C#
SignalExport.AutomaticExportTimeSpan = null;
```

Signal Exports

Numerai

Introduction

Numerai is a platform where you can earn rewards by uploading unique live trading signals for a universe of US Equities. The regular Numerai Tournament is built around a free dataset they provide , but with Numerai Signals , you can now use any dataset to generate your trading signals. Through our Numerai integration, you can use our rich library of alternative datasets or your own custom datasets to create and automate your Numerai Signal submissions.

Add Providers

To export signals to Numerai from your algorithm, during initialization , add a Numerai signal export provider.

```C#
SignalExport.AddSignalExportProvider(new NumeraiSignalExport(publicId, secretId, modelId, fileName));
```

The `NumeraiSignalExport` constructor accepts the following arguments:

Argument: `publicId`

Your Numerai API key. To create and view your API keys, see the Automation section of your Account page on the Numerai website.

Data Type: `string` | Default Value: `None`

Argument: `secretId`

Your Numerai API secret. You get your API secret when you create a new API key.

Data Type: `string` | Default Value: `None`

Argument: `modelId`

The Id of the Numerai model. Follow these steps to get the model Id:

1. Open the Models page on the Numerai website.
2. In the Models section, click the three dots next to a model.
3. Click Copy Model ID .

Data Type: `string` | Default Value: `""`

Argument: `fileName`

The name for the signal file. If you use a file name that already exists, the new file overwrites the old one.

Data Type: `string` | Default Value: `"predictions.csv"`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our Numerai integration supports signals for US Equities .

Universe Selection

The Numerai Signals stock market universe covers roughly the top 5,000 largest stocks in the world. The universe available on QuantConnect that's the closest match to the Numerai Signals universe is the CRSP US Total Market Index, which represents approximately 100% of the investable US Equity market regularly traded on the New York Stock Exchange and Nasdaq. This Index doesn't contain all of the stocks in the Numerai Signals universe, but you don't need to submit signals for all the stocks in the Numerai Signals universe.

To get the constituents of the CRSP US Total Market Index, add an ETF constituents universe for the Vanguard Total Stock Market ETF, VTI.

```
UniverseSettings.Asynchronous = true;
_etfSymbol = AddEquity("VTI").Symbol;
AddUniverse(Universe.ETF(_etfSymbol));
```

Schedule Submissions

Every Tuesday, Wednesday, Thursday, Friday, and Saturday of the week, a new round is open for you to submit signals. Saturday rounds open at 18:00 UTC, and the submission window is open until Monday 14:30 UTC. Weekday rounds open at 13:00 UTC, and the submission window is open for 1 hour. For more information about the competition rounds, see Rounds in the Numerai documentation.

To schedule your submissions, you can set a Scheduled Event during initialization.

```
Schedule.On(
    DateRules.EveryDay(_etfSymbol),
    TimeRules.At(13, 0, TimeZones.Utc),
    SubmitSignals);
```

Send Portfolio Targets

To send targets, pass a list of `PortfolioTarget` objects to the `SetTargetPortfolio` method. The method returns a boolean that represents if the targets were successfully sent to Numerai Signals. In this situation, the number you pass to the `PortfolioTarget` constructor represents the portfolio weight. Don't use the `PortfolioTarget.Percent` method.

```
var success = SignalExport.SetTargetPortfolio(targets);
```

Signal Requirements

When you submit signals to Numerai, abide by the following rules:

- All signals must have a quantity between 0 and 1 (exclusive)
- You must submit at least 10 different signals per submission
- At least one of the weights in every batch of signals must be unique

Examples

Signal Exports

vBase

Introduction

validityBase enables you to create a globally credible, independently verifiable audit trail for trading track records, models and signals. This ensures anyone viewing your results can confirm that your results are point-in-time, complete, free from cherry-picking and fully out-of-sample.

QuantConnect users can use validityBase to publish live, verifiable, indices of their trading strategies and signals - increasing their credibility with allocators, clients and potential employers, and significantly increasing their commercial value. Integration is simple. With a single function call from your QuantConnect code, you can automatically build an immutable blockchain-backed audit trail for your signals and models.

Add Providers

To export signals to vBase from your algorithm, during initialization , add a vBase signal export provider.

```
C#
SignalExport.AddSignalExportProvider(new VBaseSignalExport(apiKey, collectionName, storeStampedFile = true,
idempotent = false));
```

The `VBaseSignalExport` constructor accepts the following arguments:

Argument: `apiKey` Your vBase API key. You can find it in your profile Account Settings tab. Data Type: `string`
Argument: `collectionName` The name of the vBase collection to which the signals will be sent. You can create and manage collections in the vBase app Collections tab. Think of a collection like a strategy or dataset name. Data Type: `string`
Argument: `storeStampedFile` Whether to store a stamped copy of the signal in vBase. **Important** if this is marked "no", then you will be responsible for maintaining an exact copy of your stamped data. Losing or accidentally modifying stamped outputs will prevent your work from being verifiable. Data Type: `bool` | Default Value: `true`
Argument: `idempotent` Whether to make the signal export idempotent. If true, sending the same signal multiple times will only create one record in vBase. Data Type: `bool` | Default Value: `false`

You can add multiple signal export providers to a single algorithm.

Asset Classes

Our vBase integration supports all asset classes.

Send Portfolio Targets

To send targets, pass a list of `PortfolioTarget` objects to the `SetTargetPortfolio` method. The method returns a boolean value indicating whether the targets were successfully sent to vBase.

What gets stamped? The provider builds a `sym,wt` (symbol-weight) CSV and, under the hood, uses `PortfolioTarget.Percent` to convert your absolute target quantities into portfolio weights. This ensures the stamp reflects the weighted sizing of your positions at the time of export. Default behavior can be customized by overriding the `BuildCsv` method of the `VBaseSignalExport` class.

```C#
var success = SignalExport.SetTargetPortfolio(targets);
```

Strategy Name
CAPM Alpha Ranking Strategy on Dow 30 Companies Applies CAPM model to rank Dow Jones 30 companies.
Combining Mean Reversion and Momentum in Forex Market Combines momentum and mean reversion techniques in the forex markets.
Pairs Trading-Copula vs Cointegration Applies Copula and Cointergration method to pairs trading.
The Dynamic Breakout II Strategy A demonstration of dynamic breakout II strategy.
Dual Thrust Trading Algorithm A demontration of Dual Thrust Intraday strategy.
Can Crude Oil Predict Equity Returns Applies regression method to predict the return from the stock market and compare it to the short-term U.S. T-bill rate.
Intraday Dynamic Pairs Trading using Correlation and Cointegration Approach A high frequency pairs trading algorithm based on cointegration.
The Momentum Strategy Based on the Low Frequency Component of Forex Market Applies high frequency filter to the momentum strategy.

Stock Selection Strategy Based on Fundamental Factors

MorningStar Fundamental factors universe selection algorithm.

Short-Term Reversal Strategy in Stocks

A short term reversal algorithm which gives the opposite signal by analyzing recent period price action.

Fundamental Factor Long Short Strategy

A basic monthly rebalance long short algorithm based on fundamental factors.

Asset Class Trend Following

Selects ETFs over ten-month moving average and assigns an equally weighted allocation.

Source: Quantpedia

Asset Class Momentum

Selects ETFs in different asset classes with the highest momentum and assigns an equally weighted allocation.

Source: Quantpedia

Residual Momentum

Constructs a long/short portfolio based on trailing residual momentum normalized by its standard deviation

Source: Quantpedia

Sector Momentum

Selects ETFs in different sectors with the highest momentum and assigns an equally weighted allocation.

Source: Quantpedia

Overnight Anomaly

Buy SPY ETF at its closing price and sell it at the opening each day.

Source: Quantpedia

Forex Carry Trade

Goes long the currency with the highest central bank interest rate and goes short the currency with the lowest interest rate.

Source: Quantpedia

Volatility Effect in Stocks

Constructs equally weighted portfolios by selecting stocks with the lowest volatility in the past one year.

Source: Quantpedia

Forex Momentum

Goes long currencies with strongest 12 month momentum against USD and goes short currencies with the lowest 12 month momentum against USD.

Source: Quantpedia

Pairs Trading with Stocks

Looks for the security that minimizes the sum of squared deviations and long-short position is opened when pair prices have diverged by multiple of standard deviations.

Source: Quantpedia

Short Term Reversal

Goes long stocks with the lowest return in the previous month and goes short stocks with the greatest return from the previous month.

Source: Quantpedia

Momentum Effect in Stocks

Goes long stocks with the best 12-month momentum in the large-cap universe.

Source: Quantpedia

Momentum Effect in Country Equity Indexes

Goes long stocks with the best 12-month momentum in the country equity indexes ETFs.

Source: Quantpedia

Mean Reversion Effect in Country Equity Indexes

Goes long country equity indexes ETFs with the worst 36-month return and short ETFs with the best 36-month return.

Source: Quantpedia

Liquidity Effect in Stocks

Goes long stocks with the lowest turnover and short on stocks with the highest turnover from the lowest market-cap quartile.

Source: Quantpedia

Volatility Risk Premium Effect

Sells at-the-money straddle with one month until maturity and buys an offsetting 15% out-of-the-money puts each month.

Source: Quantpedia

Momentum Effect in Commodities Futures

Goes long commodity futures with the highest momentum and short on futures with the lowest momentum.

Source: Quantpedia

Small Capitalization Stocks Premium Anomaly

Goes long stocks with the lowest market capitalization and rebalances the portfolio once a year.

Source: Quantpedia

Paired Switching

Goes long asset with better performance over the last period and rebalances portfolio every quarter.

Source: Quantpedia

Term Structure Effect in Commodities

Buys each month the 20% of commodities with the highest roll-returns and shorts the 20% of commodities with the lowest roll-returns and holds the long-short positions for one month.

Source: Quantpedia

Momentum Effect Combined with Term Structure in Commodities

Portfolios are formed based on roll returns and the algorithm goes long and short contracts with the highest and lowest one-month performance.

Source: Quantpedia

Book-to-Market Value Anomaly

Quintile portfolios are formed based on the Book-to-Market ratio and the highest quintile is held for one year.

Source: Quantpedia

Gold Market Timing

Goes long gold when the Fed model shows that the market is undervalued (the earnings yield is higher than the bond yield and their ratio is at least 2).

Source: Quantpedia

Turn of the Month in Equity Indexes

Buys SPY the day before the end of the month and liquidates position on 3rd trading day of new month.

Source: Quantpedia

Momentum - Short Term Reversal Strategy

Goes long stocks with the decreasing return from the winner group and short stocks with the increasing return from the loser group.

Source: Quantpedia

Pairs Trading with Country ETFs

Identifies the price divergence from two highly correlated country ETFs and takes a market neutral position.

Source: Quantpedia

Sentiment and Style Rotation Effect in Stocks

Creates long-short positions of growth and value stocks based on the investment sentiment.

Source: Quantpedia

Asset Growth Effect

Creates long-short positions of stocks based on the annual change of their total assets.

Source: Quantpedia

Momentum and State of Market Filters

Goes long and short stocks with the highest and lowest six-month momentum respectively if the previous 12 months return on the broad market index was positive.

Source: Quantpedia

Accrual Anomaly

Decile portfolios are formed based on balance sheet based accruals and highest decile is shorted while lowest decile is bought for a year.

Source: Quantpedia

Momentum in Mutual Fund Returns

Forms a long-short portfolio of asset management firms based on trailing rate of change and nearness to trailing high.

Source: Quantpedia

Momentum and Style Rotation Effect

Goes long style index ETF with the highest 12-month momentum and short ETF with the lowest 12-month momentum.

Source: Quantpedia

Trading with WTI BRENT Spread

Goes long the spread if the spread is below 20-day moving average and short if the spread is above 20-day moving average.

Source: Quantpedia

Momentum Effect in REITs

Tercile portfolios are formed based on momentum and the best performing portfolio is held.

Source: Quantpedia

Option Expiration Week Effect

Goes long S&P 100 index ETF during option expiration week and stays in cash during other days.

Source: Quantpedia

Earnings Quality Factor

Goes long stocks with high earnings quality and short stocks with low earnings quality based on composite factor score.

Source: Quantpedia

January Effect in Stocks

Invests into small cap stocks at the beginning of each January and stays invested in large cap stocks for rest of the year.

Source: Quantpedia

Momentum and Reversal Combined with Volatility Effect in Stocks

Goes long on stocks from the highest performing quintile from the highest volatility group and short on stocks from the lowest performing quintile from the highest volatility group.

Source: Quantpedia

ROA Effect within Stocks

Goes long on stocks with highest ROA and short stocks with the lowest ROA from each market capitalization group.

Source: Quantpedia

January Barometer

Invested in equity market with ETF only if January return is positive otherwise switch investments to T-Bills.

Source: Quantpedia

Lunar Cycle in Equity Market

Goes long in emerging market index ETF 7 days before the new moon and switch to a short position on emerging market index ETF 7 days before the full moon.

Source: Quantpedia

VIX Predicts Stock Index Returns

Goes long on equity index ETF if the VIX is in the highest percentile short if VIX is in the lowest percentile in the last two-year history.

Source: Quantpedia

Combining Momentum Effect with Volume

Goes long stocks with the highest volume from the top momentum decile and short stocks with the highest volume from the bottom momentum decile.

Source: Quantpedia

Short Term Reversal with Futures

Goes long (short) on futures from the high-volume, low-open interest group with the lowest (greatest) returns in the previous week.

Source: Quantpedia

Pre-holiday Effect

Invests in equity market 2 days preceding holiday days and stays in cash during the other trading days.

Source: Quantpedia

Beta Factors in Stocks

Goes long stocks with the bottom beta and short stocks with the top beta, securities are weighted by the ranked betas.

Source: Quantpedia

Exploiting Term Structure of VIX Futures

Buys or sells the nearest VIX futures based on the daily roll and hedge against the open positions with E-mini S&P500 futures.

Source: Quantpedia

12 Month Cycle in Cross-Section of Stocks Returns

Reviews the returns from last January, going long on the top 10% winners and short the bottom 10%.

Source: Quantpedia

Momentum Effect in Stocks in Small Portfolios

Goes long in the 10 stocks with the highest performance and goes short in the 10 stocks with the lowest performance in the previous one year.

Source: Quantpedia

Value Effect within Countries

Invests in the cheapest 33% of country ETFs according to CAPE ratios.

Source: Quantpedia

Beta Factor in Country Equity Indexes

Goes long on the low-beta portfolio and short on the high-beta portfolio in country indexes ETFs.

Source: Quantpedia

Price to Earnings Anomaly

Invests in stocks with low P/E ratio.

API Reference

The QuantConnect API Reference is a comprehensive technical document that details every class, method, property, and event available in the LEAN algorithmic trading framework. It serves as the definitive source for understanding how to interact with LEAN, helping you quickly look up syntax and explore available features. The LEAN engine is written in C#, but you can create algorithms with either C# or Python since LEAN uses Python.Net to bridge between your Python code and the underlying C# engine. For your convenience, we provide an API Reference for both languages.

Python

C#

Migrations

Migrations

Zipline

The following pages explain how to migrate trading algorithms from Zipline to LEAN:

Initialization

Using Data

Ordering

Logging and Plotting

Quick Reference

Zipline

Initialization

Initializing State

On QuantConnect, algorithm initialization behavior is equivalent to Quantopian's `initialize` method. `Initialize` is the method equivalent, and it is only ran once at the start of the algorithm. It is responsible for initially adding data to the algorithm, adding a universe, setting the brokerage, setting the algorithm's start and end date, etc.

The algorithm structure in QuantConnect differs from Quantopian's as well. On QuantConnect, we create a class that derives from `QCAlgorithm` and define our overrides/algorithm functionality there. An example of an algorithm with initialization is provided.

Quantopian

QuantConnect

On QuantConnect, the `self` parameter is the equivalent of the `context` parameter in Quantopian algorithms. You can use `self` to access algorithm resources, such as the Portfolio, Orders, Order Tickets, Securities, place orders in your algorithm, and much more.

You can read more about algorithm initialization at the Initializion documentation page.

Attaching Pipelines

The functional equivalent of Pipelines on QuantConnect are Universes. Universes can be used to dynamically select assets your algorithm wants to trade or request data from. To add a universe to your algorithm, you can call the `AddUniverse()` method and provide the required Coarse and Fine universe selection functions.

Coarse Universe selection is the first step of universe selection. It provides a means to filter data in a lightweight fashion before proceeding to Fine Universe selection. Coarse universe will allow you to filter assets based off top-level fundamental factors, such as Dollar Volume for the day, if a company has fundamental data, and market of the asset.

Fine Universe selection is the second step of universe selection. It provides fundamental data to your user-defined function, and can be used to filter in greater detail based on an asset's fundamental data, such as earnings, EPS, etc.

An example of coarse and fine universe selection to filter assets in our algorithm is provided. Adding universes can be used as an alternative to using `AddEquity` if you prefer dynamic asset selection.

You can configure universe settings by modifying the existing `UniverseSettings` attribute of the algorithm.

You can read more about universe selection at the Universe documentation page.

Scheduling Functions

Scheduled Events on QuantConnect are the equivalent of `schedule_function()` from Quantopian. Examples are provided comparing the Scheduled Events functionality between QuantConnect and Quantopian.

Quantopian

QuantConnect

You can read more about scheduled events at the Scheduled Events documentation page.

Setting Slippage and Commissions

QuantConnect supports applying slippage and commissions per individual security.

To add a slippage model to a security, we must set the `SlippageModel` property of the `Security` object to our model. A `Security` is returned when data is added to the algorithm. Examples of setting slippage in an algorithm is provided below for both Quantopian and QuantConnect.

Quantopian

QuantConnect

Commissions

To add a fee model (otherwise known as Commissions on Quantopian) to a security, we must set the `FeeModel` property of the `Security` object to our model. Examples are provided below for Quantopian and QuantConnect.

Quantopian

QuantConnect

You can read more about Securities and their attributes at the Securities and Portfolio and Reality Modeling documentation pages.

Manual Asset Lookup

On QuantConnect, we provide the `Symbol` class to reference a security across time with a changing ticker. This is similar to Quantopian's `symbol()` function, which enables the same functionality.

When you add data to your algorithm, a `Security` object is returned. The `Symbol` is accessible from the `Security` as shown below.

To manually create a reference to an old equity, you can use the `Symbol.create()` method.

You can read more about Symbols and Security Identifiers (SID) at the Security Identifiers documentation page.

Zipline

Using Data

Pipeline in Algorithms

As covered in the Initialization section, Pipelines can be replicated using Universe Selection in QuantConnect, albeit with some additional steps in between and a performance impact.

In this section, we will construct and define an equivalent pipeline model using universe selection in QuantConnect. We will filter our data set in Coarse and Fine, and apply an additional filter to historical data with a rolling window.

We first create a skeleton algorithm definition to begin setting up our Pipeline. Note that this algorithm will allow all equities through, which will have a substantial performance impact on our algorithm.

The skeleton algorithm is the equivalent of the Pipeline call below.

The equivalent of `Pipeline(screen=...)` resolves to the filter applied at the Coarse and Fine stages of universe selection. Let's define a filter of stocks with a dollar volume greater than $50000000 USD, as well as a rolling thirty day return greater than 2%. Once we've initially filtered the Symbols in Coarse Universe Selection, let's define a final filter only allowing stocks with EPS greater than 0. Beware of making `History()` calls with many Symbols. It could potentially cause your algorithm to run out of system resources (i.e. RAM) and reduce performance of your algorithm on universe selection.

This class definition is now roughly equivalent to the following `CustomFactor` and Pipeline call in Quantopian, excluding the EPS filtering.

An example of the shape of the DataFrame returned from History is shown below. The DataFrame has a MultiIndex, with `level=0` being the Symbol, and `level=1` being the Time for that point of data. You can index the Symbol/ `level=0` index by using either the SecurityIdentifier string (e.g. `df.loc["AAPL R735QTJ8XC9X"]`) or with the ticker of the Symbol (e.g. `df.loc["AAPL"]`)

		close	high	low	open	volume
symbol	time					
IBM	2019-04-26	138.62	139.82	137.70	139.82	1419038.0
	2019-04-27	139.44	139.89	138.81	139.28	1275702.0
AAPL	2019-04-26	205.24	207.76	205.12	206.84	10105760.0
	2019-04-27	204.29	205.00	202.12	204.83	9984854.0

BarData Lookup

Similar but different, the Quantopian `BarData` object, and the QuantConnect `Slice` object both provide data to the user's algorithm as point-in-time data.

In Quantopian, data is handled via the `handle_data(context, data)` function. In QuantConnect, data is handled via the `OnData(self, slice)` method. Both of these functions accept data whenever new data exists for a given point in time. Although these two functions share the same method signature, the handling of the data is different.

`BarData` vs. `Slice`

`BarData` is the primary mechanism to retrieve the point-in-time data, as well as requesting history for any given securities in Quantopian. The following code retrieves daily historical data from 30 days into the past, as well as getting the most recent data

for AAPL at the current point-in-time.

Quantopian

QuantConnect

`Slice` represents a single point in time, and does not provide the functionality to access historical data itself. To access historical data in an algorithm, use the algorithm's `self.History()` call to request a pandas DataFrame of historical data. In `Slice`, the data that is accessed is not a pandas DataFrame, but rather a single object containing data for a single point in time.

The `TradeBar` class, for example, only contains scalar values of OHLCV, rather than return a DataFrame of OHLCV values. Since the data `Slice` contains is point-in-time, there will be only a single trade/quote bar per Symbol whenever `OnData(self, data)` is called.

QuantConnect provides Quote (NBBO) data for use in your algorithm, otherwise known as a `QuoteBar`. Quote data is only accessible when an algorithm is set to consume Tick, Second, or Minutely data.

You can access Trade (OHLCV) data by accessing the `Bars` attribute of `Slice`. You can access Quote (Bid(OHLCV), Ask(OHLCV)) data by accessing the `QuoteBars` attribute of `Slice`.

Both of the `Bars` and `QuoteBars` attributes are similar to Python dictionaries, and can be used as such. To check to see if there exists a new piece of data for a given security, you can use Python's `in` operator on `Bars` and or `QuoteBars`. You can also choose to iterate on all data received by calling the `Values` attribute of the `Bars` or `QuoteBars` attributes, which will return either a list of `TradeBar` or `QuoteBar` objects.

The `TradeBar` object contains the `Open`, `High`, `Low`, `Close`, `Volume`, `Time`, `EndTime`, and `Symbol` attributes. The `QuoteBar` object contains the following attributes:

- `Bid.Open`, `Bid.High`, `Bid.Low`, `Bid.Close`, `LastBidSize`
- `Ask.Open`, `Ask.High`, `Ask.Low`, `Ask.Close`, `LastAskSize`
- `Time`, `EndTime`, and `Symbol`.

Note that the `Bid` and `Ask` attributes can potentially be `None` if no bid/ask data exists at a given point-in-time.

The example below shows the different ways to access `TradeBar` and `QuoteBar` data, as well as requesting 30 days of AAPL historical data.

Zipline

Ordering

Placing Orders

Both Quantopian and QuantConnect offer several methods for placing orders. Both platforms have `MarketOrder` , `LimitOrder` , `StopOrder` , and `StopLimitOrder` classes to create specific order types, although the `StopOrder` order is named `StopMarketOrder` on our platform. On Quantopian, creating these orders is done by passing a `style` argument to the `order` method.

On QuantConnect, the same orders can be created with

In addition to the order types above, QuantConnect has several other order types available. Refer to our Trading and Orders documentation for a comprehensive list.

Quantopian's `order_optimal_portfolio` method computes the optimal portfolio weights using an objective and constraints, then places the orders to achieve the desired portfolio. For example, the code below uses the Quantopian API to create an equal-weighted dollar-neutral portfolio.

To acheive the same functionality with QuantConnect, we utilize portfolio construction models . For instance, to create an equal-weighted dollar-neutral portfolio, we could define the following portfolio construction model and attach it to the algorithm.

When algorithms require manual control of their orders, both Quantopian and QuantConnect have lower-level ordering methods. Quantopian's `order` method, which places an order for a fixed number of shares, directly maps to our `Order` method. Additionally, Quantopian's `order_target_percent` method places an order to adjust a position to a target percent of the current portfolio value. Here's an example use case of these methods on the Quantopian platform.

On QuantConnect, these same orders can be placed using the `SetHoldings` and `Order` methods.

Quantopian and QuantConnect don't have equivalents for all the ordering techniques, although we can create a workaround for most situations. For instance, Quantopian's `order_percent` method places an order in the specified asset corresponding to the given percent of the current portfolio value.

To accomplish this on QuantConnect, we can determine the weight of the asset in the `Portfolio` , then manually determine the new target percent to pass to `SetHoldings` .

The Porfolio Object

Quantopian's `Portfolio` class provides read-only access to the current portfolio state. The state includes starting cash, current cash, portfolio value, and positions. The `Portfolio` object is accessed through the `context` object, as seen below.

All of this information, and more, is attainable on QuantConnect by using our `Portfolio` object. Listed below is an example of doing so. Although there isn't a property for starting cash, this value can be saved during Initialization to be referenced later.

On Quantopian, by iterating through the `positions` dictionary, we can access information about currently-held positions. This includes the number of shares held, the last traded price & date of the asset, and the position's cost basis.

Since the `Portfolio` on QuantConnect is a `Dictionary<Symbol, SecurityHolding>` , we can get information on current positions by indexing the `Portfolio` object with a `Symbol` or ticker. The `SecurityHolding` object that is returned contains

information related to a single security in the portfolio. For instance, we have

For more information on our `Portfolio` object refer to the Securities and Portfolio documentation.

Zipline

Logging and Plotting

Logging

In QuantConnect, the `self.Debug()` method is the equivalent of the `log.info()` function in Quantopian. Debug output is viewable via the QuantConnect Terminal Console.

Output to the console via `self.Debug()` is rate-limited. If you need long-term storage of your logs and don't want to overflow the console, consider using `self.Log()` instead. An example comparing logging between Quantopian and QuantConnect is shown below.

Quantopian

QuantConnect

Logging via `self.Log()` has daily limits in QuantConnect. On the free tier, users are limited to 10KB of logs per day for your account/organization. To increase this limit, you can upgrade your account to a different tier. Calls to `self.Debug()` will also count towards the 10KB log limit, but are always outputted to the Terminal Console regardless of your daily log limit.

To view pricing and upgrade your account, visit the Organization Pricing page.

You can view the logs generated via `self.Log()` for a backtest by first accessing a backtest, and clicking the "Logs" tab near the bottom of the page. To download the logs, you can click the "Download Logs" link to download a text file containing your backtest's logs.

Plotting

In Quantopian, plotting/charting is done with the `record(series1_name=scalar_value, series2_name=scalar_value, ...)` function. In QuantConnect, plotting is accessible via the `self.plot("chart name", "series name", scalar_value)` method.

Plotting multiple series in one function call is possible in Quantopian. However, in QuantConnect, a separate call is needed for each series requiring an update. All series with the same chart name will appear on the same window/pane. New charts can be created by calling `self.plot()` method with a unique chart name.

An example of plotting in Quantopian vs. QuantConnect is shown below. The QuantConnect code will create two charts, one named "Chart1" with two series of data, and another named "Chart2" with one series of data. Note that you can also use `self.plot("series name", value)` to place the custom series on the same chart as the equity curve.

Quantopian

QuantConnect

For more information on plotting in QuantConnect, visit the Charting documentation page.

Zipline

Quick Reference

User-Implemented Functions

The following table describes functions that are treated specially when defined in the IDE.

Algorithms are required to implement one method: Initialize(self).

An optional scheduled event can be defined to behave like before_trading_start(). OnData() is also optional but is treated especially if defined.

Quantopian	**QuantConnect**
`initialize` (context)	`Initialize` (self)
Required function called once at the start of a backtest.	
`before_trading_start` (context, data)	`self.Schedule.On(self.DateRules.EveryDay(), self.TimeRules.AfterMarketOpen(symbol, 10), self.before_trading_start)`
Optional function called prior to market open on every trading day.	
`handle_data` (context, data)	`OnData` (self, slice)
Optional function called at the end of each market minute.	

Interface Classes

The following table describes classes that are passed to `initialize()` , `handle_data()` , `before_trading_start()` and any scheduled with `schedule_function()` .

In QuantConnect/Lean, the portfolio state and the positions are class attributes of QCAlgorithm, available via self keyword. The scheduled function is parameterless and can algorithms can self.CurrentSlice.

Quantopian	QuantConnect
`quantopian.algorithm.interface.AlgorithmContext`	`QCAlgorithm`
Shared object for storing custom state.	
`quantopian.algorithm.interface.BarData`	`Slice`
Provides methods for accessing minutely and daily price/volume data from Algorithm API functions.	
`quantopian.algorithm.interface.Portfolio`	`self.Portfolio`
Object providing read-only access to current portfolio state.	
`quantopian.algorithm.interface.Positions`	`self.Transactions`
A dict-like object containing the algorithm's current positions.	

The features from the BarData methods are found in the Slice object (current data), History method (past data) and class attribute Securities.

Quantopian	QuantConnect
`quantopian.algorithm.interface.BarData.current`	`Slice[symbol]`
Returns the "current" value of the given fields for the given assets at the current simulation time.	
`quantopian.algorithm.interface.BarData.history`	`self.History(symbols, bar_count)`
Returns a trailing window of length `bar_count` containing data for the given assets, fields, and frequency.	
`quantopian.algorithm.interface.BarData.can_trade`	`self.Securities[symbol].IsTradable`
For the given asset or iterable of assets, returns True if all of the following are true:	
`quantopian.algorithm.interface.BarData.is_stale`	`not Slice[symbol].IsFillForward`
For the given asset or iterable of assets, returns True if the asset is alive and there is no trade data for the current simulation time.	

Pipeline

The following table describes functions used to schedule and retrieve results of Universe selection. For more information on the Universe Selection API, see the Univeres API Reference.

Quantopian	QuantConnect
`quantopian.algorithm.attach_pipeline` (...)	`universe = self.AddUniverse` (...) name = universe.Configuration.Symbol
Register a pipeline to be computed at the start of each day.	
`quantopian.algorithm.pipeline_output` (name)	`self.UniverseManager` [name]
Get results of the pipeline attached by with `name` .	

Scheduling Functions

The following tables describes functions that can be used to schedule functions to run periodically during your algorithm.

Quantopian	QuantConnect
`quantopian.algorithm.schedule_function` (func)	`self.Schedule.On(IDateRule, ITimeRule, func)`
Schedule a function to be called repeatedly in the future.	

Date Rules

The following table contains functions that can be used with the `date_rule` parameter of `schedule_function()` .

Quantopian	QuantConnect
`quantopian.algorithm.date_rules.every_day` ()	`self.DateRules.EveryDay(symbol)`
Create a rule that triggers every day.	
`quantopian.algorithm.date_rules.month_start` ([...])	`self.DateRules.MonthStart(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days after the start of each month.	
`quantopian.algorithm.date_rules.month_end` ([...])	`self.DateRules.MonthEnd(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days before the end of each month.	
`quantopian.algorithm.date_rules.week_start` ([...])	`self.DateRules.WeekStart(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days after the start of each week.	
`quantopian.algorithm.date_rules.week_end` ([...])	`self.DateRules.WeekEnd(symbol, daysOffset)`
Create a rule that triggers a fixed number of trading days before the end of each week.	

Time Rules

The following table contains functions that can be used with the `time_rule` parameter of `schedule_function()` .

Quantopian	QuantConnect
`quantopian.algorithm.time_rules.market_open` ([...])	`self.TimeRules.AfterMarketOpen(symbol, minutes_after_open = 0)`
Create a rule that triggers at a fixed offset from market open.	
`quantopian.algorithm.time_rules.market_close` ([...])	`self.TimeRules.BeforeMarketClose(symbol, minutes_before_close = 0)`
Create a rule that triggers at a fixed offset from market close.	

Ordering

There are several ways to place orders from an algorithm. For most use-cases, we recommend using SetHoldings method which correctly accounts the porfolio buying power model and fees. At the moment, there is no equivalent for `order_optimal_portfolio()` . However a similar behavior can be replicated with a Portfolio Construction Model.

Algorithms that require explicit manual control of their orders can use the lower-level ordering functions.

Placing Orders

Quantopian	QuantConnect
`quantopian.algorithm.order_optimal_portfolio` (...)	`N/A`
Calculate an optimal portfolio and place orders toward that portfolio.	
`quantopian.algorithm.order` (asset, amount[, ...])	`self.Order(symbol, amount)`
Place an order for a fixed number of shares.	
`quantopian.algorithm.order_value` (asset, value)	`N/A`
Place an order for a fixed amount of money.	
`quantopian.algorithm.order_percent` (asset, ...)	`self.SetHoldings(symbol, percent)`
Place an order in the specified asset corresponding to the given percent of the current portfolio value.	
`quantopian.algorithm.order_target` (asset, target)	`N/A`
Place an order to adjust a position to a target number of shares.	
`quantopian.algorithm.order_target_value` (...)	`N/A`
Place an order to adjust a position to a target value.	
`quantopian.algorithm.order_target_percent` (...)	`self.SetHoldings(symbol, percent)`
Place an order to adjust a position to a target percent of the current portfolio value.	

Controlling Order Execution

Quantopian	QuantConnect
`zipline.finance.execution.ExecutionStyle`	`FillModel`
Base class for order execution styles.	
`zipline.finance.execution.MarketOrder` ([exchange])	`self.MarketOrder` (symbol, quantity)
Execution style for orders to be filled at current market price.	
`zipline.finance.execution.LimitOrder` (limit_price)	`self.LimitOrder` (symbol, quantity, limit_price)
Execution style for orders to be filled at a price equal to or better than a specified limit price.	
`zipline.finance.execution.StopOrder` (stop_price)	`self.StopMarketOrder` (symbol, quantity, stop_price)
Execution style representing a market order to be placed if market price reaches a threshold.	
`zipline.finance.execution.StopLimitOrder` (...)	`self.StopLimitOrder` (symbol, quantity, stop_price, limit_price)
Execution style representing a limit order to be placed if market price reaches a threshold.	

Managing Existing Orders

Quantopian	QuantConnect
`quantopian.algorithm.get_order` (order_id)	`self.Transactions.GetOrderById` (order_id)
Lookup an order based on the order Id returned from one of the order functions.	
`quantopian.algorithm.get_open_orders` ([asset])	`self.Transactions.GetOpenOrders` (symbol)
Retrieve all of the current open orders.	
`quantopian.algorithm.cancel_order` (order_param)	`self.Transactions.CancelOpenOrders` (symbol)
Cancel an open order.	

Customizing the Simulation

Slippage

Algorithms can customize the simulation of order fills by calling SetSlippageModel() with a ISlippageModel which is any class that implements GetSlippageApproximation method. Unlike Quantopian, the slippage model is a security attribute, not a global attribute. Different securities can have different slippage models.

The default slippage model on QuantConnect is a constant slippage model with zero slippage percent (no slippage).

Quantopian	QuantConnect
`quantopian.algorithm.set_slippage` ([...])	`self.Securities[symbol].SetSlippageModel(ISlippageModel)`
Set the slippage models for the simulation.	
`zipline.finance.slippage.SlippageModel` ()	`N/A (class must implement GetSlippageApproximation method)`
Abstract base class for slippage models.	
`zipline.finance.slippage.FixedBasisPointsSlippage` ([...])	`ConstantSlippageModel(slippage_percent)`
Model slippage as a fixed percentage difference from historical minutely close price, limiting the size of fills to a fixed percentage of historical minutely volume.	
`zipline.finance.slippage.NoSlippage` ()	`NullSlippageModel.Instance`
A slippage model where all orders fill immediately and completely at the current close price.	
`zipline.finance.slippage.FixedSlippage` ([spread])	`N/A`
Simple model assuming a fixed-size spread for all assets.	
`zipline.finance.slippage.VolumeShareSlippage` ([...])	`N/A`
Model slippage as a quadratic function of percentage of historical volume.	

Commissions

Algorithms can customize the simulation of order fees by calling SetFeeModel() with a IFeeModel which is any class that implements GetOrderFee method. Unlike Quantopian, the fee model is a security attribute, not a global attribute. Different securities can have different fee models.

The default fee model on QuantConnect depends on the security type and the brokerage. For instance, the default fee model for equity is the Interactive Brokers fee model.

Quantopian	QuantConnect
`quantopian.algorithm.set_commission` ([...])	`self.Securities[symbol].SetFeeModel(IFeeModel)`
Sets the commission models for the simulation.	
`zipline.finance.commission.CommissionModel`	`N/A (class must implement GetOrderFee method)`
Abstract base class for commission models.	
`zipline.finance.commission.PerShare` ([cost, ...])	`N/A`
Calculates a commission for a transaction based on a per share cost with an optional minimum cost per trade.	
`zipline.finance.commission.PerTrade` ([cost])	`N/A`
Calculates a commission for a transaction based on a per trade cost.	
`zipline.finance.commission.PerDollar` ([cost])	`N/A`
Model commissions by applying a fixed cost per dollar transacted.	
`zipline.finance.commission.NoCommission`	`FeeModel()`
Model commissions as free.	

Benchmark

The default benchmark is SPY.

Quantopian	QuantConnect
`quantopian.algorithm.set_benchmark` (benchmark)	`self.SetBenchmark` (benchmark)
Set the benchmark asset.
