Example Applications

The EIA dataset enables you to monitor national and international oil production and consumption in you trading strategies. Examples include the following strategies:

- Trading petroleum companies when there is a change in net imports of petroleum products
- Trading country ETFs when there is a change in the country's net import of resources
- Adjusting exposure to vehicle manufacturer stocks when the supply of gasoline is higher/lower than historical levels

Classic Algorithm Example

The following example algorithm buy a petroleum company when net imports of petroleum products are increasing. When the net imports are decreasing, it short sells the company.

C#

```
public class USEnergyDataAlgorithm : QCAlgorithm
{
    private decimal? previousValue;
    private Symbol tradableSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Requesting data, we trade Exxon Mobil Corp (XOM) as the proxy of petroleum investment
        tradableSymbol = AddEquity("XOM", Resolution.Daily).Symbol;
        // Request US weekly net import petroleum products data for trade signal generation
        var USEnergySymbol = AddData<USEnergy>
(USEnergy.Petroleum.UnitedStates.WeeklyNetImportsOfTotalPetroleumProducts).Symbol;

        // Historical data
        var history = History<USEnergy>(USEnergySymbol, 60, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");

        // Get latest value for net imports of petroleum products for trade system readiness
        previousValue = history.Last().Value;
    }

    public override void OnData(Slice slice)
    {
        // Trade based on the current net imports of petroleum products
        var points = slice.Get<USEnergy>();
        decimal? currentValue = null;
        foreach (var point in points.Values)
        {
            currentValue = point.Value;
        }
        if (currentValue == null)
        {
            return;
        }
        Plot("Net Imports", "Petroleum", (double)currentValue);

        // Buy when net imports of petroleum products are increasing, assuming the demand increases that bring up the
petroleum price
        // Hence the inventory and revenue of the proxy increase, supporting the stock price goes up
        if (currentValue > previousValue)
        {
            SetHoldings(tradableSymbol, 1);
        }

        //  Short sell when net imports of petroleum products are decreasing, decreasing demand lowers the petroleum
price and the proxy stock price
        if (currentValue < previousValue)
        {
            SetHoldings(tradableSymbol, -1);
        }

        previousValue = currentValue;
    }
}
```

Framework Algorithm Example

The following example algorithm buy a petroleum company when net imports of petroleum products are increasing. When the net imports are decreasing, it short sells the company.

C#

```
public class USEnergyDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        UniverseSettings.Resolution = Resolution.Daily;
```

```
        UniverseSettings.Resolution = Resolution.Daily;
        // We only trade Exxon Mobil Corp (XOM) as the proxy of petroleum investment
        var symbols = new[] {QuantConnect.Symbol.Create("XOM", SecurityType.Equity, Market.USA)};
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // A custom alpha model that emit trade insights based on US Energy data
        AddAlpha(new USEnergyAlphaModel(this));
        // Equally invest to dissipate non-systematic capital concentration risk on individual stock
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}

public class USEnergyAlphaModel : AlphaModel
{
    private Symbol USEnergySymbol;
    private List<Symbol> tradableSymbols = new List<Symbol>();
    private decimal? previousValue;

    public USEnergyAlphaModel(QCAlgorithm algorithm)
    {
        // Request US weekly net import petroleum products data for trade signal generation
        USEnergySymbol = algorithm.AddData<USEnergy>
(USEnergy.Petroleum.UnitedStates.WeeklyNetImportsOfTotalPetroleumProducts).Symbol;

        // Historical data
        var history = algorithm.History<USEnergy>(USEnergySymbol, 60, Resolution.Daily);
        algorithm.Debug($"We got {history.Count()} items from our history request");
        // Get latest value for net imports of petroleum products for trade system readiness
        previousValue = history.Last().Value;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        // Trade based on the current net imports of petroleum products
        var points = slice.Get<USEnergy>();
        decimal? currentValue = null;
        foreach (var point in points.Values)
        {
            currentValue = point.Value;
        }
        if (currentValue == null)
        {
            return insights;
        }

        foreach (var symbol in tradableSymbols)
        {
            // Buy when net imports of petroleum products are increasing, assuming the demand increases that bring up
the petroleum price
            // Hence the inventory and revenue of the proxy increase, supporting the stock price goes up
            if (currentValue > previousValue)
            {
                insights.Add(Insight.Price(symbol, TimeSpan.FromDays(7),  InsightDirection.Up));
            }

            //  Short sell when net imports of petroleum products are decreasing, decreasing demand lowers the
petroleum price and the proxy stock price
            if (currentValue < previousValue)
            {
                insights.Add(Insight.Price(symbol, TimeSpan.FromDays(7),  InsightDirection.Down));
            }
        }

        previousValue = currentValue;
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            tradableSymbols.Add(security.Symbol);
        }
    }
}
```

Data Point Attributes

The EIA dataset provides `USEnergy` objects, which have the following attributes:

Datasets

ExtractAlpha

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Cross Asset Model

Estimize

Tactical

True Beats

ExtractAlpha

Cross Asset Model

Introduction

The Cross Asset Model by ExtractAlpha provides stock scoring values based on the trading activity in the Options market. Since the Options market has a higher proportion of institutional traders than the Equities market, the Options market is composed of investors who are more informed and information-driven on average. The data covers a dynamic universe of over 3,000 US Equities, starts in July 2005, and is delivered on a daily frequency. This dataset is created by feature engineering on the Options market put-call spread, volatility skewness, and volume.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Cross Asset Model dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Cross Asset Model dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<ExtractAlphaCrossAssetModel>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	July 2005
Asset Coverage	Over 3,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Cross Asset Model data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class ExtractAlphaCrossAssetModelDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<ExtractAlphaCrossAssetModel>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Cross Asset Model data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} score at {slice.Time}: {dataPoint.Score}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<ExtractAlphaCrossAssetModel>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} score at {slice.Time}: {dataPoint.Score}");
    }
}
```

Historical Data

To get historical Cross Asset Model data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<ExtractAlphaCrossAssetModel>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to Cross Asset Model data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Cross Asset Model dataset by ExtractAlpha enables you to utilize Options market information to extract alpha. Examples include the following strategies:

- Predicting price and volatility changes in Equities.
- Signaling arbitrage opportunities between Options and underlying assets.
- Using it as a stock selection indicator.

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, the algorithm forms an equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

C#

```
public class ExtractAlphaCrossAssetModelAlgorithm : QCAlgorithm
{
    private DataDictionary<ExtractAlphaCrossAssetModel> _points = new DataDictionary<ExtractAlphaCrossAssetModel>();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddUniverse(SelectAssets);
        // Add a Scheduled Event to rebalance the portfolio each day.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(DateRules.EveryDay(spy), TimeRules.AfterMarketOpen(spy, 30), Rebalance);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> coarse)
    {
        // Select non-penny stocks with highest dollar volume due to better informed information from more market
activities
        // Only the ones with fundamental data are supported by cross asset model data
        return (from c in coarse
                where c.HasFundamentalData && c.Price > 4
                orderby c.DollarVolume descending
                select c.Symbol).Take(100);
    }

    public override void OnData(Slice slice)
    {
        // Get the current data from the cross asset model.
        var points = slice.Get<ExtractAlphaCrossAssetModel>();
        if (points.Count > 0)
        {
            _points = points;
            //// Demonstrate how to iterate through the data and access its members:
            //foreach(var kvp in points)
            //{
            //    var datasetSymbol = kvp.Key;
            //    var model = kvp.Value;
            //    Quit(
            //        $"{Time} -- " +
            //        $"Asset Symbol: {datasetSymbol.Underlying}; " +
            //        $"Score: {model.Score}"
            //    );
            //}
        }
    }

    public void Rebalance()
    {
        // Long the ones with the highest return estimates based on option trade data
        // Short the lowest return ones
        var sortedByScore = from s in _points.Values
                            where (s.Score != null && Securities[s.Symbol.Underlying].Price != 0)
```

```
                        orderby s.Score
                        select s.Symbol.Underlying;
        var longSymbols = sortedByScore.TakeLast(10);
        var shortSymbols = sortedByScore.Take(10);

        // Liquidate the ones without a strong trading signal
        // Invest equally and dollar-neutral to evenly dissipate capital risk and hedge systematic risk
        var targets = new List<PortfolioTarget>();
        targets.AddRange(longSymbols.Select(symbol => new PortfolioTarget(symbol, 0.05m)));
        targets.AddRange(shortSymbols.Select(symbol => new PortfolioTarget(symbol, -0.05m)));
        SetHoldings(targets, true);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(dynamic security in changes.AddedSecurities)
        {
            // Requesting cross asset model data for trading signal generation
            security.CrossAssetModel = AddData<ExtractAlphaCrossAssetModel>(security.Symbol).Symbol;
            // Historical Data
            var history = History(security.CrossAssetModel, 2, Resolution.Daily);
        }
        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the cross asset model data for this asset when it leaves the universe.
            RemoveSecurity(security.CrossAssetModel);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, the algorithm forms an equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

C#

```
public class ExtractAlphaCrossAssetModelFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddUniverseSelection(new LiquidEquitiesUniverseSelectionModel());
        // Custom alpha model emits insights based on cross asset model data
        AddAlpha(new ExtractAlphaCrossAssetModelAlphaModel());
        // Invest equally and dollar-neutral to evenly dissipate capital risk and hedge systematic risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
    }

    private IEnumerable<Symbol> MyCoarseFilterFunction(IEnumerable<CoarseFundamental> coarse)
    {

        return (from c in coarse
                where c.HasFundamentalData && c.Price > 4
                orderby c.DollarVolume descending
                select c.Symbol).Take(100);
    }
}

public class LiquidEquitiesUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamentals)
    {
        // Select non-penny stocks with highest dollar volume due to better informed information from more market
activities
        // Only the ones with fundamental data are supported by cross asset model data
        return (from f in fundamentals
                where f.HasFundamentalData && f.Price > 4
                orderby f.DollarVolume descending
                select f.Symbol).Take(100);
    }
}
```

```
public class ExtractAlphaCrossAssetModelAlphaModel: AlphaModel
{
    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Get the current data from the cross asset model.
        var points = slice.Get<ExtractAlphaCrossAssetModel>()
            // Drop factors for assets that have no price or score.
            .Where(kvp => algorithm.Securities[kvp.Key.Underlying].Price != 0 && kvp.Value.Score != null);
        // Demonstrate how to iterate through the data and access its members:
        //foreach(var kvp in points)
        //{
        //    var datasetSymbol = kvp.Key;
        //    var model = kvp.Value;
        //    algorithm.Quit(
        //        $"{algorithm.Time} -- " +
        //        $"Asset Symbol: {datasetSymbol.Underlying}; " +
        //        $"Score: {model.Score}"
        //    );
        //}

        // Long the ones with the highest return estimates based on option trade data
        // Short the lowest return ones
        var sortedByScore = points.OrderBy(kvp => kvp.Value.Score).Select(kvp => kvp.Key.Underlying);
        var longSymbols = sortedByScore.TakeLast(10);
        var shortSymbols = sortedByScore.Take(10);

        var insights = new List<Insight>();
        insights.AddRange(longSymbols.Select(symbol => new Insight(symbol, Expiry.EndOfDay, InsightType.Price,
InsightDirection.Up)));
        insights.AddRange(shortSymbols.Select(symbol => new Insight(symbol, Expiry.EndOfDay, InsightType.Price,
InsightDirection.Down)));
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach(dynamic security in changes.AddedSecurities)
        {
            // Requesting cross asset model data for trading signal generation
            security.CrossAssetModel = algorithm.AddData<ExtractAlphaCrossAssetModel>(security.Symbol).Symbol;
            // Historical Data
            var history = algorithm.History(security.CrossAssetModel, 2, Resolution.Daily);
        }
        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the cross asset model data for this asset when it leaves the universe.
            algorithm.RemoveSecurity(security.CrossAssetModel);
        }
    }
}
```

Data Point Attributes

The Cross Asset Model dataset provides `ExtractAlphaCrossAssetModel` objects, which have the following attributes:

ExtractAlpha

Estimize

Introduction

The Estimize dataset by ExtractAlpha estimates the financials of companies, including EPS, and revenues. The data covers over 2,800 US-listed Equities' EPS/Revenue. The data starts in January 2011 and is updated on a daily frequency. The data is sparse, and it doesn't have new updates every day. This dataset is crowdsourced from a community of 100,000+ contributors via the data provider's web platform.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Estimize dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Estimize dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_estimizeConsensusSymbol = AddData<EstimizeConsensus>(_symbol).Symbol;
_estimizeEstimateSymbol = AddData<EstimizeEstimate>(_symbol).Symbol;
_estimizeReleaseSymbol = AddData<EstimizeRelease>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2011
Asset Coverage	2,800 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Estimize data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class ExtractAlphaEstimizeDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _estimizeConsensusSymbol, _estimizeEstimateSymbol, _estimizeReleaseSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _estimizeConsensusSymbol = AddData<EstimizeConsensus>(_symbol).Symbol;
        _estimizeEstimateSymbol = AddData<EstimizeEstimate>(_symbol).Symbol;
        _estimizeReleaseSymbol = AddData<EstimizeRelease>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Estimize data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_estimizeConsensusSymbol))
    {
        var dataPoint = slice[_estimizeConsensusSymbol];
        Log($"{_estimizeConsensusSymbol} mean at {slice.Time}: {dataPoint.Mean}");
    }

    if (slice.ContainsKey(_estimizeEstimateSymbol))
    {
        var dataPoint = slice[_estimizeEstimateSymbol];
        Log($"{_estimizeEstimateSymbol} EPS at {slice.Time}: {dataPoint.Eps}");
    }

    if (slice.ContainsKey(_estimizeReleaseSymbol))
    {
        var dataPoint = slice[_estimizeReleaseSymbol];
        Log($"{_estimizeReleaseSymbol} EPS at {slice.Time}: {dataPoint.Eps}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<EstimizeConsensus>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} mean at {slice.Time}: {dataPoint.Mentions}");
    }

    foreach (var kvp in slice.Get<EstimizeEstimate>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} EPS at {slice.Time}: {dataPoint.Eps}");
    }

    foreach (var kvp in slice.Get<EstimizeRelease>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} EPS at {slice.Time}: {dataPoint.Eps}");
    }
}
```

Historical Data

To get historical Estimize data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// Dataset objects
var concensusHistory = History<EstimizeConsensus>(_estimizeConsensusSymbol, 100, Resolution.Daily);
var estimateHistory = History<EstimizeEstimate>(_estimizeEstimateSymbol, 100, Resolution.Daily);
var releaseHistory = History<EstimizeRelease>(_estimizeReleaseSymbol, 100, Resolution.Daily);

// Slice objects
var history = History(new[]{_estimizeConsensusSymbol,
                            _estimizeEstimateSymbol,
                            _estimizeReleaseSymbol}, 10, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_estimizeConsensusSymbol);
RemoveSecurity(_estimizeEstimateSymbol);
RemoveSecurity(_estimizeReleaseSymbol);
```

If you subscribe to Estimize data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Estimize dataset enables you to estimate the financial data of a company more accurately for alpha. Examples include the following use cases:

- Fundamental estimates for ML regression/classification models
- Arbitrage/Sentiment trading on market “surprise” from ordinary expectations based on the better expectation by the dataset

- Using industry-specific KPIs to predict the returns of individual sectors

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 250 most liquid US Equities. Each morning, the algorithm forms an equal-weighted with the companies that have a new EPS estimate.

C#

```
public class ExtractAlphaEstimizeAlgorithm : QCAlgorithm
{
    // Add a dictionary to hold the latest Consensus data since this dataset is sparse.
    private Dictionary<Symbol, EstimizeConsensus> _consensusBySymbol = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed securities with their last known prices to avoid stale-price trade errors
        Settings.SeedInitialPrices = true;
        // Add a universe of liquid US Equities.
        AddUniverse(SelectAssets);
        // Add a Scheduled Event to rebalance the portfolio each day.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(
            DateRules.EveryDay(spy),
            TimeRules.AfterMarketOpen(spy, 1),
            Rebalance
        );
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> fundamentals)
    {
        // Select the non-penny stocks with the highest dollar volume,
        // since they have more stable price (lower risk) and more
        // informed insights from high market activities
        return fundamentals
            .Where(x => x.HasFundamentalData && x.Price > 4)
            .OrderBy(x => x.DollarVolume)
            .TakeLast(250)
            .Select(x => x.Symbol);
    }

    public override void OnData(Slice slice)
    {
        // Record the latest Consensus data.
        var consensus = slice.Get<EstimizeConsensus>();
        if (consensus.IsNullOrEmpty()) return;
        foreach (var kvp in consensus)
        {
            _consensusBySymbol[kvp.Key.Underlying] = kvp.Value;
        }
    }

    private void Rebalance()
    {
        if (_consensusBySymbol.Count == 0) return;
        // If there has been new Consensus data released since the previous
        // market open, form an equal-weighted portfolio of all the assets
        // that have new Consensus data.
        var symbols = _consensusBySymbol.Keys.Where(symbol => Securities[symbol].Price > 0);
        var targets = symbols.Select(symbol => new PortfolioTarget(symbol, 1m/symbols.Count()));
        SetHoldings(targets.ToList(), true);
        _consensusBySymbol.Clear();
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (dynamic security in changes.AddedSecurities)
        {
            // Requesting data for trading signal generation
            security.Consensus = AddData<EstimizeConsensus>(security.Symbol).Symbol;
            // Historical data
            var history = History<EstimizeConsensus>(security.Consensus, 100, Resolution.Daily);
        }

        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the Consensus data for this asset when it leaves the universe.
            RemoveSecurity(security.Consensus);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 250 most liquid US Equities. Each morning, the algorithm emits insights for the companies that have a new EPS estimate.

C#

```
public class ExtractAlphaEstimizeFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddUniverseSelection(new LiquidEquitiesUniverseSelectionModel());
        // Custom alpha model that emit signal according to Estimize data
        AddAlpha(new ExtractAlphaEstimizeAlphaModel());
        // Invest equally to evenly dissipate capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
    }
}

public class LiquidEquitiesUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamentals)
    {
        // Select the non-penny stocks with the highest dollar volume,
        // since they have more stable price (lower risk) and more
        // informed insights from high market activities
        return fundamentals
            .Where(x => x.HasFundamentalData && x.Price > 4)
            .OrderBy(x => x.DollarVolume)
            .TakeLast(250)
            .Select(x => x.Symbol);
    }
}

public class ExtractAlphaEstimizeAlphaModel: AlphaModel
{
    // Add a dictionary to hold the latest Consensus data since this dataset is sparse.
    private Dictionary<Symbol, EstimizeConsensus> _consensusBySymbol = new();
    private int _day = -1;

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();
        // Record the latest Consensus data.
        var consensus = slice.Get<EstimizeConsensus>();
        if (!consensus.IsNullOrEmpty())
        {
            foreach (var kvp in consensus)
            {
                _consensusBySymbol[kvp.Key.Underlying] = kvp.Value;
            }
        }
        // Wait for the market open to rebalance
        if (_day == algorithm.Time.Day || slice.Bars.Count == 0)
        {
            return insights;
        }
        _day = algorithm.Time.Day;
        // If there has been new Consensus data released since the previous
        // market open, emit insights for all the assets that have new Consensus data.
        if (_consensusBySymbol.Count == 0)
        {
            return insights;
        }
        var symbols = _consensusBySymbol.Keys.Where(symbol => algorithm.Securities[symbol].Price != 0);
        insights.AddRange(symbols.Select(symbol => Insight.Price(symbol, TimeSpan.FromDays(30),
InsightDirection.Up)).ToList());
        _consensusBySymbol.Clear();
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (dynamic security in changes.AddedSecurities)
        {
            // Requesting data for trading signal generation
            security.Consensus = algorithm.AddData<EstimizeConsensus>(security.Symbol).Symbol;
            // Historical data
```

```
            var history = algorithm.History<EstimizeConsensus>(security.Consensus, 100, Resolution.Daily);
        }

        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the Consensus data for this asset when it leaves the universe.
            algorithm.RemoveSecurity(security.Consensus);
        }
    }
}
```

Data Point Attributes

The Estimize dataset provides `EstimizeConsensus` , `EstimizeEstimate` , and `EstimizeRelease` objects.

EstimizeConsensus Attributes

`EstimizeConsensus` objects have the following attributes:

EstimizeEstimate Attributes

EstimizeRelease Attributes

`EstimizeRelease` objects have the following attributes:

ExtractAlpha

Tactical

Introduction

The Tactical dataset by ExtractAlpha is a stock scoring algorithm that captures the technical dynamics of individual US Equities over one to ten trading day horizons. It can assist a longer-horizon investor in timing their entry or exit points or be used in combination with existing systematic or qualitative strategies with similar holding periods.

The data covers a dynamic universe of around 4,700 US Equities per day on average, starts in January 2000, and is delivered on a daily frequency. The Tactical dataset expands upon simple reversal, liquidity, and seasonality factors to identify stocks that are likely to trend or reverse.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Tactical dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the Tactical dataset:

```
C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<ExtractAlphaTacticalModel>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2000
Asset Coverage	5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Tactical data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the

data later in your algorithm.

```
C#
public class ExtractAlphaTacticalModelDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<ExtractAlphaTacticalModel>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Tactical data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} score at {slice.Time}: {dataPoint.Score}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<ExtractAlphaTacticalModel>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} score at {slice.Time}: {dataPoint.Score}");
    }
}
```

Historical Data

To get historical Tactical data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<ExtractAlphaTacticalModel>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
RemoveSecurity(_datasetSymbol);
```

If you subscribe to Tactical data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Tactical dataset enables you to gain insight into short-term stock dynamics for trading. Examples include the following strategies:

- Optimizing entry and exit times in a portfolio construction model.
- Using the raw factor values as technical indicators.
- Inputting the data into machine learning classifier models as trend/reversal labels.

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms an equal-weighted dollar-neutral portfolio of the 10 companies that are most likely to outperform and the 10 that are most likely to underperform.

C#

```
public class ExtractAlphaTacticalModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddUniverse(SelectAssets);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> coarse)
    {
        // Select non-penny stocks with highest dollar volume due to better informed information from more market
activities
        // Only the ones with fundamental data are supported by tactical data
        return (from c in coarse
                where c.HasFundamentalData && c.Price > 4
                orderby c.DollarVolume descending
                select c.Symbol).Take(100);
    }

    public override void OnData(Slice slice)
    {
        // Get the current data from the tactical model.
        var points = slice.Get<ExtractAlphaTacticalModel>()
            // Drop factors for assets that have no price.
            .Where(kvp => Securities[kvp.Key.Underlying].Price != 0);
        //// Demonstrate how to iterate through the data and access its members:
        //foreach(var kvp in points)
        //{

            RemoveSecurity(security.TacticalModel);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms an equal-weighted dollar-neutral portfolio of the 10 companies that are most likely to outperform and the 10 that are most likely to underperform.

C#

```
public class ExtractAlphaTacticalModelFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddUniverseSelection(new LiquidEquitiesUniverseSelectionModel());
        // Custom alpha model to generate trading signal based on tactical data
        AddAlpha(new ExtractAlphaTacticalModelAlphaModel());
        // Invest equally and dollar-neutral to evenly dissipate capital risk and hedge systematic risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
    }
}

public class LiquidEquitiesUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamentals)
    {
        // Select non-penny stocks with highest dollar volume due to better informed information from more market
activities
        // Only the ones with fundamental data are supported by tactical data
        return (from f in fundamentals
                where f.HasFundamentalData && f.Price > 4
                orderby f.DollarVolume descending
                select f.Symbol).Take(100);
    }
}

public class ExtractAlphaTacticalModelAlphaModel: AlphaModel
{
    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Get the current data from the tactical model.
        var points = slice.Get<ExtractAlphaTacticalModel>()
            // Drop factors for assets that have no price or score.
            .Where(kvp => algorithm.Securities[kvp.Key.Underlying].Price != 0);
        //// Demonstrate how to iterate through the data and access its members:
        //foreach(var kvp in points)
        //{
        //    var datasetSymbol = kvp.Key;
        //    var model = kvp.Value;
        //    algorithm.Quit(
        //        $"{algorithm.Time} -- " +
        //        $"Asset Symbol: {datasetSymbol.Underlying}; " +
        //        $"Score: {model.Score}"
        //    );
        //}

        // Long the ones with the highest return estimates riding from tactical strategies
        // Short the lowest that predicted stock price goes down
        var sortedByScore =  points.OrderBy(kvp => kvp.Value.Score)
            .Select(kvp => kvp.Key.Underlying);
        var longSymbols = sortedByScore.TakeLast(10);
        var shortSymbols = sortedByScore.Take(10);

        var insights = new List<Insight>();
        insights.AddRange(longSymbols.Select(symbol => new Insight(symbol, Expiry.EndOfDay, InsightType.Price,
InsightDirection.Up)));
        insights.AddRange(shortSymbols.Select(symbol => new Insight(symbol, Expiry.EndOfDay, InsightType.Price,
InsightDirection.Down)));
        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach(dynamic security in changes.AddedSecurities)
        {
            // Requesting tactical data for trading signal generation
            security.TacticalModel = algorithm.AddData<ExtractAlphaTacticalModel>(security.Symbol).Symbol;
```

```
            // Historical Data
            var history = algorithm.History(security.TacticalModel, 2, Resolution.Daily);
        }
        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the tactical model data for this asset when it leaves the universe.
            algorithm.RemoveSecurity(security.TacticalModel);
        }
    }
}
```

Data Point Attributes

The Tactical dataset provides `ExtractAlphaTacticalModel` objects, which have the following attributes:

ExtractAlpha

True Beats

Introduction

The True Beats dataset by ExtractAlpha provides quantitative predictions of EPS and Revenues for US Equities. The data covers a dynamic universe of around 4,000-5,000 US-listed Equities on a daily average. The data starts in January 2000 and is delivered on a daily frequency. This dataset is created by incorporating the opinions of expert analysts, historical earnings, revenue trends for the company and its peers, and metrics on company earnings management.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the True Beats dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

ExtractAlpha was founded by Vinesh Jha in 2013 with the goal of providing alternative data for investors. ExtractAlpha's rigorously researched data sets and quantitative stock selection models leverage unique sources and analytical techniques, allowing users to gain an investment edge.

Getting Started

The following snippet demonstrates how to request data from the True Beats dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<ExtractAlphaTrueBeats>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2000
Asset Coverage	Over 5,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add True Beats data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class ExtractAlphaTrueBeatsDataAlgorithm: QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<ExtractAlphaTrueBeats>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current True Beats data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} true beat at {slice.Time}: {dataPoint.TrueBeat}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<ExtractAlphaTrueBeats>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} true beat at {slice.Time}: {dataPoint.TrueBeat}");
    }
}
```

Historical Data

To get historical True Beats data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<ExtractAlphaTrueBeats>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to True Beats data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The True Beats dataset enables you to predict EPS and revenue of US-listed Equities for trading. Examples include the following strategies:

- Finding surprise in EPS or revenue for sentiment/arbitrage trading
- Stock or sector selections based on EPS or revenue predictions
- Calculate expected return by valuation models based on EPS or revenue predictions (e.g. Black-Litterman)

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms an equal-weighted dollar-neutral portfolio of the 10 best and 10 worst companies based on their predicted earnings per share.

```C#
public class ExtractAlphaTrueBeatsDataAlgorithm : QCAlgorithm
{
    private DataDictionary<ExtractAlphaTrueBeats> _trueBeats;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 30);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe that runs at the start of each month.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        var dateRule = DateRules.MonthStart(spy);
        UniverseSettings.Schedule.On(dateRule);
        AddUniverse(SelectAssets);
        // Add a Scheduled Event to rebalance the portfolio at the start of each month.
        Schedule.On(dateRule, TimeRules.BeforeMarketClose(spy, 30), Rebalance);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> coarse)
    {
        // Select the stocks with highest dollar volume due to better informed information from more market
activities
        // Only the ones with fundamental data are supported by true beats data
        return (from c in coarse
                where c.HasFundamentalData
                orderby c.DollarVolume descending
                select c.Symbol).Take(100);
    }

    public override void OnData(Slice slice)
    {
        // Get the current data from the true beats dataset.
        var points = slice.Get<ExtractAlphaTrueBeats>();
        if (!points.IsNullOrEmpty())
        {
            _trueBeats = points;
        }
    }

    public void Rebalance()
    {
        var epsPredictionBySymbol = new Dictionary<Symbol, decimal>();
        foreach (var kvp in _trueBeats)
        {
            var datasetSymbol = kvp.Key;
            // Select the subset of TrueBeat objects that have the EPS earnings metric,
            // a value for the fiscal year, and a value for the fiscal quarter.
            var trueBeats = kvp.Value
                .Select(tb => (ExtractAlphaTrueBeat)tb)
                .Where(tb =>
                    tb.EarningsMetric == ExtractAlphaTrueBeatEarningsMetric.EPS &&
                    tb.FiscalPeriod.FiscalQuarter != null
                )
```

```
                .OrderBy(tb => tb.FiscalPeriod.FiscalYear)
                .ThenBy(tb => tb.FiscalPeriod.FiscalQuarter)
                .ToList();
            if (trueBeats.Count == 0)
                continue;
            // Select the TrueBeat object of the closest fiscal quarter.
            epsPredictionBySymbol[datasetSymbol.Underlying] = trueBeats.First().TrueBeat;
        }

        // Long the ones with the highest earning and revenue estimates due to fundamental factor may bring stock
price up
        // Short the lowest that predicted to bring stock price down
        // Invest equally and dollar-neutral to evenly dissipate capital risk and hedge systematic risk
        var sortedByEpsPrediction = epsPredictionBySymbol.OrderBy(kvp => kvp.Value).ToList();
        var shortTargets = sortedByEpsPrediction.Take(10).Select(kvp => new PortfolioTarget(kvp.Key, -0.05m));
        var longTargets = sortedByEpsPrediction.TakeLast(10).Select(kvp => new PortfolioTarget(kvp.Key, 0.05m));
        SetHoldings(longTargets.Concat(shortTargets).ToList(), true);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(dynamic security in changes.AddedSecurities)
        {
            // Requesting true beats data for trading signal generation
            security.TrueBeats = AddData<ExtractAlphaTrueBeats>(security.Symbol).Symbol;
            // Historical Data
            var history = History(security.TrueBeats, 10, Resolution.Daily);
        }
        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the true beats data for this asset when it leaves the universe.
            RemoveSecurity(security.TrueBeats);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms an equal-weighted dollar-neutral portfolio of the 10 best and 10 worst companies based on their predicted earnings per share.

C#

```
public class ExtractAlphaTrueBeatsDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Add a universe that runs at the start of each month.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        var dateRule = DateRules.MonthStart(spy);
        UniverseSettings.Schedule.On(dateRule);
        AddUniverseSelection(new LiquidEquitiesUniverseSelectionModel());
        // Custom alpha model to trade based on true beats data signals
        AddAlpha(new ExtractAlphaTrueBeatsAlphaModel());
        // Invest equally and dollar-neutral to evenly dissipate capital risk and hedge systematic risk

Datasets

FRED

The Research Division of the Federal Reserve bank of St. Louis, MO expands the frontier of economic knowledge by producing high-quality original research in the areas of macroeconomics, money and banking, and applied microeconomics. They contribute to monetary policy discussions by advising the Bank president on a range of topics, especially in preparation for Federal Open Market Committee (FOMC) meetings. The Research Division is in the top 1% of all economics research departments worldwide.

US Federal Reserve (FRED)

FRED

US Federal Reserve (FRED)

Introduction

The Federal Reserve Economic Data (FRED) by the Research Division of the Federal Reserve bank of St. Louis, MO provides various time series relating to macro-economic data. The data covers 560 datasets, starts in January 1999, and is delivered on a daily frequency. The data is created by aggregating daily updates from more than 85 public and proprietary sources.

For more information about the US Federal Reserve (FRED) dataset, including CLI commands and pricing, see the dataset listing
.

About the Provider

The Research Division of the Federal Reserve bank of St. Louis, MO expands the frontier of economic knowledge by producing high-quality original research in the areas of macroeconomics, money and banking, and applied microeconomics. They contribute to monetary policy discussions by advising the Bank president on a range of topics, especially in preparation for Federal Open Market Committee (FOMC) meetings. The Research Division is in the top 1% of all economics research departments worldwide.

Getting Started

The following snippet demonstrates how to request data from the FRED dataset:

```C#
_datasetSymbol = AddData<Fred>("USARECDM", Resolution.Daily).Symbol;
```

QuantConnect provides helpers to find some of the available datasets from FRED:

```C#
_datasetSymbol = AddData<Fred>(Fred.OECDRecessionIndicators.UnitedStatesFromPeakThroughTheTrough,
Resolution.Daily).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1990
Asset Coverage	560 Datasets
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add FRED data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class FredAlternativeDataAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2003, 1, 1);
        SetEndDate(2019, 10, 11);
        SetCash(100000);

        _datasetSymbol = AddData<Fred>(Fred.OECDRecessionIndicators.UnitedStatesFromPeakThroughTheTrough,
Resolution.Daily).Symbol;
    }
}
```

Accessing Data

To get the current FRED data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} value at {slice.Time}: {dataPoint.Value}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<Fred>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} value at {slice.Time}: {dataPoint.Value}");
    }
}
```

Historical Data

To get historical FRED data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<Fred>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to FRED data, call the `RemoveSecurity` method.

```
RemoveSecurity(_datasetSymbol);
```
C#

Supported Datasets

The following lists show the accessor code you need to add each FRED dataset to your algorithm. This list does `not` include all fields from the FRED database. Please refer to FRED website for additional fields.

CBOE

- `Fred.CBOE.VIXOnGoogle` : CBOE Equity VIX on Google (in Index) (`VXGOGCLS`)
- `Fred.CBOE.VXD` : CBOE DJIA Volatility Index (in Index) (`VXDCLS`)
- `Fred.CBOE.VIXOnGoldmanSachs` : CBOE Equity VIX on Goldman Sachs (in Index) (`VXGSCLS`)
- `Fred.CBOE.VIXOnIBM` : CBOE Equity VIX on IBM (in Index) (`VXIBMCLS`)
- `Fred.CBOE.VIXOnAmazon` : CBOE Equity VIX on Amazon (in Index) (`VXAZNCLS`)
- `Fred.CBOE.VXO` : CBOE S&P 100 Volatility Index: VXO (in Index) (`VXOCLS`)
- `Fred.CBOE.VXN` : CBOE NASDAQ 100 Volatility Index (in Index) (`VXNCLS`)
- `Fred.CBOE.TenYearTreasuryNoteVolatilityFutures` : CBOE 10-Year Treasury Note Volatility Futures (in Index) (`VXTYN`)
- `Fred.CBOE.RVX` : CBOE Russell 2000 Volatility Index (in Index) (`RVXCLS`)
- `Fred.CBOE.SP500ThreeMonthVolatilityIndex` : CBOE S&P 500 3-Month Volatility Index (in Index) (`VXVCLS`)
- `Fred.CBOE.VIXOnApple` : CBOE Equity VIX on Apple (in Index) (`VXAPLCLS`)
- `Fred.CBOE.GoldMinersETFVolatilityIndex` : CBOE Gold Miners ETF Volatility Index (in Index) (`VXGDXCLS`)
- `Fred.CBOE.ChinaETFVolatilityIndex` : CBOE China ETF Volatility Index (in Index) (`VXFXICLS`)
- `Fred.CBOE.BrazilETFVolatilityIndex` : CBOE Brazil ETF Volatility Index (in Index) (`VXEWZCLS`)
- `Fred.CBOE.EmergingMarketsETFVolatilityIndex` : CBOE Emerging Markets ETF Volatility Index (in Index) (`VXEEMCLS`)
- `Fred.CBOE.EuroCurrencyETFVolatilityIndex` : CBOE EuroCurrency ETF Volatility Index (in Index) (`EVZCLS`)
- `Fred.CBOE.GoldETFVolatilityIndex` : CBOE Gold ETF Volatility Index (in Index) (`GVZCLS`)
- `Fred.CBOE.CrudeOilETFVolatilityIndex` : CBOE Crude Oil ETF Volatility Index (in Index) (`OVXCLS`)
- `Fred.CBOE.SilverETFVolatilityIndex` : CBOE Silver ETF Volatility Index (in Index) (`VXSLVCLS`)
- `Fred.CBOE.EnergySectorETFVolatilityIndex` : CBOE Energy Sector ETF Volatility Index (in Index) (`VXXLECLS`)
- `Fred.CBOE.VIX` : CBOE Volatility Index: VIX (in Index) (`VIXCLS`)

Central Bank Interventions

- `Fred.CentralBankInterventions.JapaneseBankPurchasesOfDmEuroAgainstJpy` : Japan Intervention: Japanese Bank purchases of DM/Euro against JPY (in 100 Million Yen) (`JPINTDDMEJPY`)
- `Fred.CentralBankInterventions.JapaneseBankPurchasesOfUsdAgainstDm` : Japan Intervention: Japanese Bank purchases of USD against DM (in 100 Million Yen) (`JPINTDEXR`)
- `Fred.CentralBankInterventions.JapaneseBankPurchasesOfUsdAgainstRupiah` : Japan Intervention: Japanese Bank purchases of USD against Rupiah (in 100 Million Yen) (`JPINTDUSDRP`)
- `Fred.CentralBankInterventions.USInterventionInMarketTransactionsInTheJpyUsd` : U.S. Intervention: in Market Transactions in the JPY/USD (Millions of USD) (in Millions of USD) (`USINTDMRKTJPY`)
- `Fred.CentralBankInterventions.USInterventionWithCustomerTransactionsInOtherCurrencies` : U.S. Intervention: With-Customer Transactions in Other Currencies (Millions of USD) (in Millions of USD) (`USINTDCSOTH`)
- `Fred.CentralBankInterventions.USInterventionWithCustomerTransactionsInTheJpyUsd` : U.S. Intervention: With-Customer Transactions in the JPY/USD (Millions of USD) (in Millions of USD) (`USINTDCSJPY`)
- `Fred.CentralBankInterventions.USInterventionWithCustomerTransactionsInTheDemUsdEuro` : U.S. Intervention: With-Customer Transactions in the DEM/USD (Euro since 1999) (Millions of USD) (in Millions of USD) (`USINTDCSDM`)

- Fred.CentralBankInterventions.USInterventionInMarketTransactionsInOtherCurrencies : U.S. Intervention: in Market Transactions in Other Currencies (Millions of USD) (in Millions of USD) (USINTDMRKTOTH)
- Fred.CentralBankInterventions.CentralBankOfTurkeyPurchasesOfUsd : Turkish Intervention: Central Bank of Turkey Purchases of USD (Millions of USD) (in Millions of USD) (TRINTDEXR)
- Fred.CentralBankInterventions.JapaneseBankPurchasesOfUsdAgainstJpy : Japan Intervention: Japanese Bank purchases of USD against JPY (in 100 Million Yen) (JPINTDUSDJPY)
- Fred.CentralBankInterventions.USInterventionInMarketTransactionsInTheDemUsdEuro : U.S. Intervention: in Market Transactions in the DEM/USD (Euro since 1999) (Millions of USD) (in Millions of USD) (USINTDMRKTDM)
- Fred.CentralBankInterventions.SwissNationalBankPurchasesOfDemAgainstChfMillionsOfDem : Swiss Intervention: Swiss National Bank Purchases of DEM against CHF (Millions of DEM) (in Millions of DEM) (CHINTDCHFDM)
- Fred.CentralBankInterventions.SwissNationalBankPurchasesOfUsdAgainstDem : Swiss Intervention: Swiss National Bank Purchases of USD against DEM (Millions of USD) (in Millions of USD) (CHINTDUSDDM)
- Fred.CentralBankInterventions.SwissNationalBankPurchasesOfUsdAgainstJpy : Swiss Intervention: Swiss National Bank Purchases of USD against JPY (Millions of USD) (in Millions of USD) (CHINTDUSDJPY)
- Fred.CentralBankInterventions.SwissNationalBankPurchasesOfUsdAgainstChf : Swiss Intervention: Swiss National Bank Purchases of USD against CHF (Millions of USD) (in Millions of USD) (CHINTDCHFUSD)
- Fred.CentralBankInterventions.BancoDeMexicoPurchaseOnTheUsd : Mexican Intervention: Banco de Mexico Purchase on the USD (in Millions of USD) (MEXINTDUSD)

Commercial Paper

- Fred.CommercialPaper.ThreeMonthAANonfinancialCommercialPaperRate : 3-Month AA Nonfinancial Commercial Paper Rate (in Percent) (DCPN3M)
- Fred.CommercialPaper.OneMonthAANonfinancialCommercialPaperRate : 1-Month AA Nonfinancial Commercial Paper Rate (in Percent) (DCPN30)
- Fred.CommercialPaper.TwoMonthAANonfinancialCommercialPaperRate : 2-Month AA Nonfinancial Commercial Paper Rate (in Percent) (DCPN2M)
- Fred.CommercialPaper.ThreeMonthAAFinancialCommercialPaperRate : 3-Month AA Financial Commercial Paper Rate (in Percent) (DCPF3M)
- Fred.CommercialPaper.TwoMonthAAFinancialCommercialPaperRate : 2-Month AA Financial Commercial Paper Rate (in Percent) (DCPF2M)
- Fred.CommercialPaper.OneMonthAAFinancialCommercialPaperRate : 1-Month AA Financial Commercial Paper Rate (in Percent) (DCPF1M)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween1and4DaysUsedForA2P2Nonfinancial : Number of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Number) (NONFIN14A2P2VOL)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween5and9DaysUsedForA2P2Nonfinancial : Number of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Number) (NONFIN59A2P2VOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween5and9DaysUsedForA2P2Nonfinancial : Total Value of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN59A2P2AMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween41and80DaysUsedForAANonfinancial : Number of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Number) (NONFIN4180AAVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityGreaterThan80DaysUsedForAAAssetBacked : Total Value of

Issues, with a Maturity Greater Than 80 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Millions of Dollars) (ABGT80AAAMT)

- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween41and80DaysUsedForAANonfinancial : Total Value of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN4180AAAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween41and80DaysUsedForA2P2Nonfinancial : Number of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Number) (NONFIN4180A2P2VOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween41and80DaysUsedForA2P2Nonfinancial : Total Value of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN4180A2P2AMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween21and40DaysUsedForAANonfinancial : Number of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Number) (NONFIN2140AAVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween21and40DaysUsedForAANonfinancial : Total Value of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN2140AAAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween21and40DaysUsedForA2P2Nonfinancial : Number of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Number) (NONFIN2140A2P2VOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween21and40DaysUsedForA2P2Nonfinancial : Total Value of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN2140A2P2AMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween1and4DaysUsedForAANonfinancial : Number of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Number) (NONFIN14AAVOL)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween10And20DaysUsedForA2P2Nonfinancial : Number of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Number) (NONFIN1020A2P2VOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween10And20DaysUsedForAANonfinancial : Total Value of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN1020AAAMT)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween21and40DaysUsedForAAAssetBacked : Total Value of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Millions of Dollars) (AB2140AAAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween10And20DaysUsedForAANonfinancial : Number of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Number) (NONFIN1020AAVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween1and4DaysUsedForA2P2Nonfinancial : Total Value of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN14A2P2AMT)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween1and4DaysUsedForAANonfinancial : Total Value of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN14AAAMT)
- Fred.CommercialPaper.TotalValueofCommercialPaperIssueswithaMaturityBetween1and4Days : Total Value of

Commercial Paper Issues with a Maturity Between 1 and 4 Days (in Millions of Dollars) (MKT14MKTAMT)

- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween10And20DaysUsedForA2P2Nonfinancial : Total Value of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN1020A2P2AMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityGreaterThan80DaysUsedForAAFinancial : Number of Issues, with a Maturity Greater Than 80 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Number) (FINGT80AAVOL)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween10And20DaysUsedForAAFinancial : Number of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Number) (FIN1020AAVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween1and4DaysUsedForAAFinancial : Total Value of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Millions of Dollars) (FIN14AAAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween1and4DaysUsedForAAFinancial : Number of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Number) (FIN14AAVOL)
- Fred.CommercialPaper.TotalValueofCommercialPaperIssueswithaMaturityBetween10And20Days : Total Value of Commercial Paper Issues with a Maturity Between 10 and 20 Days (in Millions of Dollars) (MKT1020MKTAMT)
- Fred.CommercialPaper.NumberofCommercialPaperIssueswithaMaturityBetween10And20Days : Number of Commercial Paper Issues with a Maturity Between 10 and 20 Days (in Number) (MKT1020MKTVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween21and40DaysUsedForAAFinancial : Total Value of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Millions of Dollars) (FIN2140AAAMT)
- Fred.CommercialPaper.NumberofCommercialPaperIssueswithaMaturityBetween1and4Days : Number of Commercial Paper Issues with a Maturity Between 1 and 4 Days (in Number) (MKT14MKTVOL)
- Fred.CommercialPaper.TotalValueofIssuersofCommercialPaperwithaMaturityBetween21and40Days : Total Value of Issuers of Commercial Paper with a Maturity Between 21 and 40 Days (in Millions of Dollars) (MKT2140MKTAMT)
- Fred.CommercialPaper.NumberofCommercialPaperIssueswithaMaturityBetween21and40Days : Number of Commercial Paper Issues with a Maturity Between 21 and 40 Days (in Number) (MKT2140MKTVOL)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween21and40DaysUsedForAAFinancial : Number of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Number) (FIN2140AAVOL)
- Fred.CommercialPaper.TotalValueofIssuersofCommercialPaperwithaMaturityBetween41and80Days : Total Value of Issuers of Commercial Paper with a Maturity Between 41 and 80 Days (in Millions of Dollars) (MKT4180MKTAMT)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween5and9DaysUsedForAANonfinancial : Total Value of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFIN59AAAMT)
- Fred.CommercialPaper.NumberofCommercialPaperIssueswithaMaturityBetween41and80Days : Number of Commercial Paper Issues with a Maturity Between 41 and 80 Days (in Number) (MKT4180MKTVOL)
- Fred.CommercialPaper.NumberofCommercialPaperIssueswithaMaturityBetween5and9Days : Number of Commercial Paper Issues with a Maturity Between 5 and 9 Days (in Number) (MKT59MKTVOL)
- Fred.CommercialPaper.TotalValueofIssuersofCommercialPaperwithaMaturityGreaterThan80Days : Total Value of Issuers of Commercial Paper with a Maturity Greater Than 80 Days (in Millions of Dollars) (MKTGT80MKTAMT)
- Fred.CommercialPaper.NumberofCommercialPaperIssueswithaMaturityGreaterThan80Days : Number of Commercial Paper Issues with a Maturity Greater Than 80 Days (in Number) (MKTGT80MKTVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween41and80DaysUsedForAAFinancial : Total Value of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Millions

of Dollars) (FIN4180AAAMT)

- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween41and80DaysUsedForAAFinancial : Number of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Number) (FIN4180AAVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween41and80DaysUsedForAAAssetBacked : Total Value of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Millions of Dollars) (AB4180AAAMT)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween5and9DaysUsedForAAFinancial : Total Value of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Millions of Dollars) (FIN59AAAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween5and9DaysUsedForAAFinancial : Number of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Number) (FIN59AAVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityGreaterThan80DaysUsedForAAFinancial : Total Value of Issues, with a Maturity Greater Than 80 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Millions of Dollars) (FINGT80AAAMT)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween10And20DaysUsedForAAFinancial : Total Value of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the AA Financial Commercial Paper Rates (in Millions of Dollars) (FIN1020AAAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween21and40DaysUsedForAAAssetBacked : Number of Issues, with a Maturity Between 21 and 40 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Number) (AB2140AAVOL)
- Fred.CommercialPaper.TotalValueofIssuersofCommercialPaperwithaMaturityBetween5and9Days : Total Value of Issuers of Commercial Paper with a Maturity Between 5 and 9 Days (in Millions of Dollars) (MKT59MKTAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityGreaterThan80DaysUsedForAAAssetBacked : Number of Issues, with a Maturity Greater Than 80 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Number) (ABGT80AAVOL)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween5and9DaysUsedForAANonfinancial : Number of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Number) (NONFIN59AAVOL)
- Fred.CommercialPaper.FifteenDayAAAssetbackedCommercialPaperInterestRate : 15-Day AA Asset-backed Commercial Paper Interest Rate (in Percent) (RIFSPPAAAD15NB)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween5and9DaysUsedForAAAssetBacked : Total Value of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Millions of Dollars) (AB59AAAMT)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween41and80DaysUsedForAAAssetBacked : Number of Issues, with a Maturity Between 41 and 80 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Number) (AB4180AAVOL)
- Fred.CommercialPaper.FifteenDayA2P2NonfinancialCommercialPaperInterestRate : 15-Day A2/P2 Nonfinancial Commercial Paper Interest Rate (in Percent) (RIFSPPNA2P2D15NB)
- Fred.CommercialPaper.SevenDayA2P2NonfinancialCommercialPaperInterestRate : 7-Day A2/P2 Nonfinancial Commercial Paper Interest Rate (in Percent) (RIFSPPNA2P2D07NB)
- Fred.CommercialPaper.OvernightA2P2NonfinancialCommercialPaperInterestRate : Overnight A2/P2 Nonfinancial Commercial Paper Interest Rate (in Percent) (RIFSPPNA2P2D01NB)
- Fred.CommercialPaper.NinetyDayAAFinancialCommercialPaperInterestRate : 90-Day AA Financial Commercial Paper Interest Rate (in Percent) (RIFSPPFAAD90NB)

- Fred.CommercialPaper.OvernightAAAssetbackedCommercialPaperInterestRate : Overnight AA Asset-backed Commercial Paper Interest Rate (in Percent) (RIFSPPAAAD01NB)
- Fred.CommercialPaper.Three0DayA2P2NonfinancialCommercialPaperInterestRate : 30-Day A2/P2 Nonfinancial Commercial Paper Interest Rate (in Percent) (RIFSPPNA2P2D30NB)
- Fred.CommercialPaper.SixtyDayAAFinancialCommercialPaperInterestRate : 60-Day AA Financial Commercial Paper Interest Rate (in Percent) (RIFSPPFAAD60NB)
- Fred.CommercialPaper.Three0DayAAFinancialCommercialPaperInterestRate : 30-Day AA Financial Commercial Paper Interest Rate (in Percent) (RIFSPPFAAD30NB)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityGreaterThan80DaysUsedForA2P2Nonfinancial : Total Value of Issues, with a Maturity Greater Than 80 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Millions of Dollars) (NONFINGT80A2P2AMT)
- Fred.CommercialPaper.Three0DayAAAssetbackedCommercialPaperInterestRate : 30-Day AA Asset-backed Commercial Paper Interest Rate (in Percent) (RIFSPPAAAD30NB)
- Fred.CommercialPaper.SixtyDayAAAssetbackedCommercialPaperInterestRate : 60-Day AA Asset-backed Commercial Paper Interest Rate (in Percent) (RIFSPPAAAD60NB)
- Fred.CommercialPaper.NinetyDayAAAssetbackedCommercialPaperInterestRate : 90-Day AA Asset-backed Commercial Paper Interest Rate (in Percent) (RIFSPPAAAD90NB)
- Fred.CommercialPaper.FifteenDayAAFinancialCommercialPaperInterestRate : 15-Day AA Financial Commercial Paper Interest Rate (in Percent) (RIFSPPFAAD15NB)
- Fred.CommercialPaper.SevenDayAAFinancialCommercialPaperInterestRate : 7-Day AA Financial Commercial Paper Interest Rate (in Percent) (RIFSPPFAAD07NB)
- Fred.CommercialPaper.SevenDayAAAssetbackedCommercialPaperInterestRate : 7-Day AA Asset-backed Commercial Paper Interest Rate (in Percent) (RIFSPPAAAD07NB)
- Fred.CommercialPaper.OvernightAAFinancialCommercialPaperInterestRate : Overnight AA Financial Commercial Paper Interest Rate (in Percent) (RIFSPPFAAD01NB)
- Fred.CommercialPaper.SixtyDayA2P2NonfinancialCommercialPaperInterestRate : 60-Day A2/P2 Nonfinancial Commercial Paper Interest Rate (in Percent) (RIFSPPNA2P2D60NB)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween5and9DaysUsedForAAAssetBacked : Number of Issues, with a Maturity Between 5 and 9 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Number) (AB59AAVOL)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween1and4DaysUsedForAAAssetBacked : Number of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Number) (AB14AAVOL)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityGreaterThan80DaysUsedForA2P2Nonfinancial : Number of Issues, with a Maturity Greater Than 80 Days, Used in Calculating the A2/P2 Nonfinancial Commercial Paper Rates (in Number) (NONFINGT80A2P2VOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween1and4DaysUsedForAAAssetBacked : Total Value of Issues, with a Maturity Between 1 and 4 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Millions of Dollars) (AB14AAAMT)
- Fred.CommercialPaper.NinetyDayA2P2NonfinancialCommercialPaperInterestRate : 90-Day A2/P2 Nonfinancial Commercial Paper Interest Rate (in Percent) (RIFSPPNA2P2D90NB)
- Fred.CommercialPaper.NumberOfIssuesWithMaturityBetween10And20DaysUsedForAAAssetBacked : Number of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Number) (AB1020AAVOL)
- Fred.CommercialPaper.TotalValueOfIssuesWithMaturityGreaterThan80DaysUsedForAANonfinancial : Total Value of

Issues, with a Maturity Greater Than 80 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Millions of Dollars) (`NONFINGT80AAAMT`)

- `Fred.CommercialPaper.OvernightAANonfinancialCommercialPaperInterestRate` : Overnight AA Nonfinancial Commercial Paper Interest Rate (in Percent) (`RIFSPPNAAD01NB`)
- `Fred.CommercialPaper.TotalValueOfIssuesWithMaturityBetween10And20DaysUsedForAAAssetBacked` : Total Value of Issues, with a Maturity Between 10 and 20 Days, Used in Calculating the AA Asset-Backed Commercial Paper Rates (in Millions of Dollars) (`AB1020AAAMT`)
- `Fred.CommercialPaper.SevenDayAANonfinancialCommercialPaperInterestRate` : 7-Day AA Nonfinancial Commercial Paper Interest Rate (in Percent) (`RIFSPPNAAD07NB`)
- `Fred.CommercialPaper.NinetyDayAANonfinancialCommercialPaperInterestRate` : 90-Day AA Nonfinancial Commercial Paper Interest Rate (in Percent) (`RIFSPPNAAD90NB`)
- `Fred.CommercialPaper.FifteenDayAANonfinancialCommercialPaperInterestRate` : 15-Day AA Nonfinancial Commercial Paper Interest Rate (in Percent) (`RIFSPPNAAD15NB`)
- `Fred.CommercialPaper.Three0DayAANonfinancialCommercialPaperInterestRate` : 30-Day AA Nonfinancial Commercial Paper Interest Rate (in Percent) (`RIFSPPNAAD30NB`)
- `Fred.CommercialPaper.SixtyDayAANonfinancialCommercialPaperInterestRate` : 60-Day AA Nonfinancial Commercial Paper Interest Rate (in Percent) (`RIFSPPNAAD60NB`)
- `Fred.CommercialPaper.NumberOfIssuesWithMaturityGreaterThan80DaysUsedForAANonfinancial` : Number of Issues, with a Maturity Greater Than 80 Days, Used in Calculating the AA Nonfinancial Commercial Paper Rates (in Number) (`NONFINGT80AAVOL`)
- `Fred.CommercialPaper.ThreeMonthCommercialPaperMinusFederalFundsRate` : 3-Month Commercial Paper Minus Federal Funds Rate (in Percent) (`CPFF`)

ICEB of AML

- `Fred.ICEBofAML.AAAAEmergingMarketsCorporatePlusSubIndexTotalReturnIndexValue` : ICE BofAML AAA-A Emerging Markets Corporate Plus Sub-Index Total Return Index Value (in Index) (`BAMLEM1BRRAAA2ACRPITRIV`)
- `Fred.ICEBofAML.AAAAUSEmergingMarketsLiquidCorporatePlusSubIndexTotalReturnIndexValue` : ICE BofAML AAA-A US Emerging Markets Liquid Corporate Plus Sub-Index Total Return Index Value (in Index) (`BAMLEM1RAAA2ALCRPIUSTRIV`)
- `Fred.ICEBofAML.AsiaEmergingMarketsCorporatePlusSubIndexTotalReturnIndexValue` : ICE BofAML Asia Emerging Markets Corporate Plus Sub-Index Total Return Index Value (in Index) (`BAMLEMRACRPIASIATRIV`)

- `Fred.OECDRecessionIndicators.SouthAfricaFromPeakThroughThePeriodPrecedingtheTrough` : OECD based Recession Indicators for South Africa from the Peak through the Period preceding the Trough (in +1 or 0) (`ZAFRECDP`)

Trade Weighted Indexes

- `Fred.TradeWeightedIndexes.MajorCurrenciesGoods` : Trade Weighted U.S. Dollar Index: Major Currencies, Goods (in Index Mar 1973=100) (`DTWEXM`)
- `Fred.TradeWeightedIndexes.OtherImportantTradingPartnersGoods` : Trade Weighted U.S. Dollar Index: Other Important Trading Partners, Goods (in Index Jan 1997=100) (`DTWEXO`)
- `Fred.TradeWeightedIndexes.BroadGoods` : Trade Weighted U.S. Dollar Index: Broad, Goods (in Index Jan 1997=100) (`DTWEXB`)
- `Fred.TradeWeightedIndexes.AdvancedForeignEconomiesGoodsAndServices` : Trade Weighted U.S. Dollar Index: Advanced Foreign Economies, Goods and Services (in Index Jan 2006=100) (`DTWEXAFEGS`)
- `Fred.TradeWeightedIndexes.BroadGoodsAndServices` : Trade Weighted U.S. Dollar Index: Broad, Goods and Services (in Index Jan 2006=100) (`DTWEXBGS`)
- `Fred.TradeWeightedIndexes.EmergingMarketsEconomiesGoodsAndServices` : Trade Weighted U.S. Dollar Index: Emerging Markets Economies, Goods and Services (in Index Jan 2006=100) (`DTWEXEMEGS`)

Example Applications

The FRED dataset enables you to accurately design strategies utilizing macroeconomic indicators. Examples include the

following strategies:

- Trading on macroeconomic factors
- Macroeconomic risk modeling

Classic Algorithm Example

The following example algorithm buys SPY when the FRED Peak to Trough value is 1. Otherwise, it holds cash.

```C#
public class FredAlternativeDataAlgorithm : QCAlgorithm
{
    private Symbol _fredPeakToTrough;
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _spy = AddEquity("SPY", Resolution.Daily).Symbol;

        // Requesting FED US peak-to-trough OECD recession indicators for trade signal generation
        _fredPeakToTrough = AddData<Fred>(Fred.OECDRecessionIndicators.UnitedStatesFromPeakThroughTheTrough).Symbol;

        // Historical data
        var history = History<Fred>(_fredPeakToTrough, 60, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        // Trade with updated FED peak-to-trough indicator
        if (slice.ContainsKey(_fredPeakToTrough) && slice.ContainsKey(_spy))
        {
            var peakToTrough = slice.Get<Fred>(_fredPeakToTrough).Value;

            // Buy SPY if peak to trough value is 0, which is the expansionary period
            if (peakToTrough == 0m && !Portfolio.Invested)
            {
                SetHoldings(_spy, 1);
            }

            // Liquidate holdings if peak to trough value is 1, which is recessionary period
            else if (peakToTrough == 1m && Portfolio.Invested)
            {
                Liquidate(_spy);
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buys SPY when the FRED Peak to Trough value is 1. Otherwise, it holds cash.

```C#
public class FredAlternativeDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Universe contains only SPY as the market representative
        AddUniverseSelection(
            new ManualUniverseSelectionModel(
                QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)
        ));
        // Custom alpha model that use FED data as trade signals
        AddAlpha(new FredAlphaModel(this));
        // Invest equally to evenly diversify the capital concentration risk
```

```
        // Invest equally to evenly dissipate the capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    public class FredAlphaModel : AlphaModel
    {
        private List<Symbol> _symbols = new List<Symbol>();
        private Symbol _fredPeakToTrough;
        private decimal? _fredPeakToTroughValue = null;

        public FredAlphaModel(QCAlgorithm algorithm)
        {
            // Requesting FED US peak-to-trough OECD recession indicators for trade signal generation
            _fredPeakToTrough = algorithm.AddData<Fred>
(Fred.OECDRecessionIndicators.UnitedStatesFromPeakThroughTheTrough, Resolution.Daily).Symbol;

            // Historical data
            var history = algorithm.History<Fred>(_fredPeakToTrough, 60, Resolution.Daily);
            algorithm.Debug($"We got {history.Count()} items from our history request");
            if (history.Count() == 0)
            {
                return;
            }
            _fredPeakToTroughValue = history.Last().Value;
        }

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            // Trade with updated FED peak-to-trough indicator
            if (slice.ContainsKey(_fredPeakToTrough))
            {
                _fredPeakToTroughValue = slice.Get<Fred>(_fredPeakToTrough).Value;
            }

            // Ensure we have a FRED peak to trough value
            if (_fredPeakToTroughValue == null)
            {
                return insights;
            }

            foreach (var symbol in _symbols)
            {
                // Ensure we have data for the security in the current Slice to avoid stale filling
                if (!(slice.ContainsKey(symbol) && slice[symbol] != null))
                {
                    continue;
                }

                // Buy SPY if peak to trough value is 0, which is the expansionary period
                if (_fredPeakToTroughValue == 0m && !algorithm.Portfolio[symbol].Invested)
                {
                    insights.Add(Insight.Price(symbol, TimeSpan.FromDays(365*2),  InsightDirection.Up));
                }
                // Liquidate holdings if peak to trough value is 1, which is recessionary period
                else if (_fredPeakToTroughValue == 1m && algorithm.Portfolio[symbol].Invested)
                {
                    insights.Add(Insight.Price(symbol, TimeSpan.FromDays(365*2),  InsightDirection.Flat));
                }
            }

            return insights;
        }

        public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
        {
            foreach (var security in changes.AddedSecurities)
            {
                _symbols.Add(security.Symbol);
            }

            foreach (var security in changes.RemovedSecurities)
            {
                _symbols.Remove(security.Symbol);
            }
        }
    }
}
```

Data Point Attributes

The FRED dataset provides `Fred` objects, which have the following attributes:

Datasets

Federal Reserve Bank of St Louis

The Federal Reserve Bank of St. Louis, often referred to as the St. Louis Fed, is one of the 12 regional banks that make up the United States Federal Reserve System. It is responsible for the Eighth Federal Reserve District, which includes the states of Arkansas, Illinois, Indiana, Kentucky, Mississippi, Missouri, and Tennessee, as well as portions of eastern Kansas and southern Illinois.

The St. Louis Fed, like other regional banks, participates in the formulation and implementation of monetary policy in the United States. It contributes to the Federal Open Market Committee (FOMC) meetings, where key decisions regarding interest rates and other monetary policy tools are made.

US Interest Rate

Federal Reserve Bank of St Louis

US Interest Rate

Introduction

The US Interest Rate dataset provides the primary credit rate from the Federal Open Market Committee (FOMC). The data starts in January 2003 and is updated on a daily frequency. This dataset is created using information from the FOMC meetings.

For more information about the US Interest Rate dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Federal Reserve Bank of St. Louis, often referred to as the St. Louis Fed, is one of the 12 regional banks that make up the United States Federal Reserve System. It is responsible for the Eighth Federal Reserve District, which includes the states of Arkansas, Illinois, Indiana, Kentucky, Mississippi, Missouri, and Tennessee, as well as portions of eastern Kansas and southern Illinois.

The St. Louis Fed, like other regional banks, participates in the formulation and implementation of monetary policy in the United States. It contributes to the Federal Open Market Committee (FOMC) meetings, where key decisions regarding interest rates and other monetary policy tools are made.

Getting Started

The following snippet demonstrates how to access data from the US Interest Rate dataset:

```C#
var interestRate = RiskFreeInterestRateModel.GetInterestRate(Time);
```

To find the average interest rate between two dates, call the `GetRiskFreeRate` method.

```C#
var avgRiskFreeRate = RiskFreeInterestRateModel.GetRiskFreeRate(Time.AddDays(-365), Time);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2003
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

You don't need any special code to request US Interest Rate data. `QCAlgorithm` automatically subscribes to the data by setting

its default risk free interest rate model .

Accessing Data

To get the current US Interest Rate data, call the `GetInterestRate` method of the `RiskFreeInterestRateModel` object with the current time.

```
C#
var interestRate = RiskFreeInterestRateModel.GetInterestRate(Time);
```

Historical Data

To get the average risk free interest rate for a window of time, call the `GetRiskFreeRate` method with the start date and end date.

```
C#
var riskFreeRate = RiskFreeInterestRateModel.GetRiskFreeRate(Time.AddDays(-365), Time);
```

To get the average risk free interest rate for a set of dates, call the `GetAverageRiskFreeRate` method with the list of dates.

```
C#
var riskFreeRate = RiskFreeInterestRateModel.GetAverageRiskFreeRate(
    new [] {Time, Time.AddDays(-180), Time.AddDays(-365)}
);
```

Example Applications

The US Interest Rate dataset provides an important economic indicator. Examples include the following applications:

- Accurately calculating indicators that are a function of the risk-free rate, like Sharpe ratios.
- Forming a portfolio of assets that have a history of outperforming when the rate is increasing/decreasing.
- Canceling orders in a Risk Management model when the expected return of the asset is less than the risk-free rate.

Classic Algorithm Example

The following example algorithm plots the current interest rate and the last year's average.

```
C#
public class RiskFreeInterestRateModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddEquity("SPY");
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        SetHoldings(symbol, 1);
        // Plot the current interest rate and the 1-year average rate for comparison
        Plot("Interest Rate", "EOD", RiskFreeInterestRateModel.GetInterestRate(Time));
        // Get the average risk free rate of the last year at the current time
        Plot("Interest Rate", "1-year Window", RiskFreeInterestRateModel.GetRiskFreeRate(Time.AddDays(-365), Time));
    }
}
```

Datasets

Kavout

Kavout was created by ex-Googlers and the founding team used to work at Google, Microsoft, Baidu, and financial firms with a proven track record of building many mission-critical machine learning systems where billions of data points were processed in real-time to predict the best outcome for core search ranking, ads monetization, recommendations, and trading platforms.

Their mission is to build machine investing solutions to find alpha with adaptive learning algorithms and to create an edge by assimilating vast quantities of complex data through the latest AI and Machine Learning methods to generate signals to uncover hidden, dynamic, and nonlinear patterns in the financial markets.

Composite Factor Bundle

Kavout

Composite Factor Bundle

Introduction

The Composite Factor Bundle dataset by Kavout provides ensemble scores for popular market factors. Kavout signals are machine-learning enhanced scores that capture the returns of systematic factors such as quality, value, momentum, growth, and low volatility. There are many different anomalies discovered by researchers and practitioners across these factor categories and there is no good common definition of each style across the literature. Kavout creates an ensemble score for each style that gauges the different factors considered in the literature and industry practice.

In this data set, you will find Kavout's proprietary signals for quality, value, momentum, growth, and low volatility, which have been adopted by some of the multi-billion dollar quant funds in New York and London. Each signal is generated by an ensemble model consisting of inputs from hundreds of anomalies. The data is generated on a daily basis and covers all the stocks traded in US major markets such as NYSE and Nasdaq since 2003. You could leverage this abundant set of signals to construct and backtest your strategies.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Composite Factor Bundle dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Kavout was created by ex-Googlers and the founding team used to work at Google, Microsoft, Baidu, and financial firms with a proven track record of building many mission-critical machine learning systems where billions of data points were processed in real-time to predict the best outcome for core search ranking, ads monetization, recommendations, and trading platforms.

Their mission is to build machine investing solutions to find alpha with adaptive learning algorithms and to create an edge by assimilating vast quantities of complex data through the latest AI and Machine Learning methods to generate signals to uncover hidden, dynamic, and nonlinear patterns in the financial markets.

Getting Started

The following snippet demonstrates how to request data from the Composite Factor Bundle dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<KavoutCompositeFactorBundle>(_symbol).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2003
Asset Coverage	8,000 US Equities
Data Density	Regular
Resolution	Daily
Timezone	UTC

Requesting Data

To add Composite Factor Bundle data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
public class KavoutCompositeFactorBundleAlgorithm : QCAlgorithm { private Symbol _symbol, _datasetSym
bol; public override void Initialize() { SetStartDate(2019, 1, 1); SetEndDate(2020, 6, 1); SetCash(10
0000); _symbol = AddEquity("AAPL", Resolution.Daily).Symbol; _datasetSymbol = AddData & lt; KavoutCom
positeFactorBundle & gt; (_symbol).Symbol; } }
```

Accessing Data

To get the current Composite Factor Bundle data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

C#

```
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} momentum at {slice.Time}: {dataPoint.Momentum}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

C#

```
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<KavoutCompositeFactorBundle>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} momentum at {slice.Time}: {dataPoint.Momentum}");
    }
}
```

Historical Data

To get historical Composite Factor Bundle data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
var history = History<KavoutCompositeFactorBundle>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
RemoveSecurity(_datasetSymbol);
```

If you subscribe to Composite Factor Bundle data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Composite Factor Bundle dataset enables you to access the performance of 5 different factors in order to engineer strategies. Examples include the following strategies:

- Performing return-risk optimization based on performance and volatility scoring.
- Weighing stocks based on regression analysis in factor-vector space.

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms a equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

```
public class KavoutCompositeFactorBundleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddUniverse(SelectAssets);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<Fundamental> fundamentals)
    {
        // Filter for the highly traded stocks for more informed data from frequent market activities, which may
translate to more accurate prediction
        // Factors scores are only available for the ones with fundamentals
        return (from f in fundamentals
                where f.HasFundamentalData
                orderby f.DollarVolume descending
                select f.Symbol).Take(100);
    }

    public override void OnData(Slice slice)
    {
        // Get the current data from the Kavout dataset.
        var points = slice.Get<KavoutCompositeFactorBundle>()
            // Drop factors for assets that have no price.
            .Where(kvp => Securities[kvp.Key.Underlying].Price != 0);
        //// Demonstrate how to iterate through the data and access its members:
        //foreach(var kvp in points)
        //{
        //    var datasetSymbol = kvp.Key;
        //    var factors = kvp.Value;
        //    Quit(
        //        $"{Time} -- " +
        //        $"Asset Symbol: {datasetSymbol.Underlying}; " +
        //        $"Growth factor: {factors.Growth}"
```

```
        //    );
        //}

        // Only rebalance when there are new Kavout factors.
        if (points.Count() == 0)
        {
            return;
        }

        // Long the stocks with highest factor scores, which indicate higher return from various factors
        // Short the ones with lowest factor scores for lower return estimates
        var sortedByScore = points.OrderBy(kvp => TotalScore(kvp.Value))
            .Select(kvp => kvp.Key.Underlying);
        var longSymbols = sortedByScore.TakeLast(10);
        var shortSymbols = sortedByScore.Take(10);

        // Invest in equal-size and dollar-neutral to evenly dissipate individual capital risk, avoid non-systematic
risk, and better margin
        var targets = new List<PortfolioTarget>();
        targets.AddRange(longSymbols.Select(symbol => new PortfolioTarget(symbol, 0.05m)));
        targets.AddRange(shortSymbols.Select(symbol => new PortfolioTarget(symbol, -0.05m)));

        SetHoldings(targets, true);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(dynamic security in changes.AddedSecurities)
        {
            // Requesting factor bundle data for trade signal generation
            security.kavoutSymbol = AddData<KavoutCompositeFactorBundle>(security.Symbol).Symbol;

            // Historical Data
            var history = History(security.kavoutSymbol, 60, Resolution.Daily);
        }
        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the factor bundle data for this asset when it leaves the universe.
            RemoveSecurity(security.kavoutSymbol);
        }
    }

    private decimal TotalScore(KavoutCompositeFactorBundle value)
    {
        // Return the total score to integrate overall likelihood to outcompete, take equal weighting for each factor
        return value.Growth + value.ValueFactor + value.Quality + value.Momentum + value.LowVolatility;
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 100 most liquid US Equities. Each day, it then forms a equal-weighted dollar-neutral portfolio of the 10 companies most likely to outperform and the 10 companies most likely to underperform.

C#

```
public class KavoutCompositeFactorBundleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddUniverseSelection(new LiquidEquitiesUniverseSelectionModel());
        // Custom alpha model to emit insights based on factor bundle data
        AddAlpha(new KavoutCompositeFactorBundleAlphaModel());
        // Invest in equal-size and dollar-neutral to evenly dissipate individual capital risk, avoid non-systematic
risk, and better margin
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
        SetExecution(new ImmediateExecutionModel());
    }
}

public class LiquidEquitiesUniverseSelectionModel : FundamentalUniverseSelectionModel
{
```

```
    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamentals)
    {
        // Filter for the highly traded stocks for more informed data from frequent market activities, which may
translate to more accurate prediction
        // Factors scores are only available for the ones with fundamentals
        return (from f in fundamentals
                where f.HasFundamentalData
                orderby f.DollarVolume descending
                select f.Symbol).Take(100);
    }
}

public class KavoutCompositeFactorBundleAlphaModel: AlphaModel
{
    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        // Get the current data from the Kavout dataset.
        var points = slice.Get<KavoutCompositeFactorBundle>()
            // Drop factors for assets that have no price.
            .Where(kvp => algorithm.Securities[kvp.Key.Underlying].Price != 0);
        //// Demonstrate how to iterate through the data and access its members:
        //foreach(var kvp in points)
        //{
        //    var datasetSymbol = kvp.Key;
        //    var factors = kvp.Value;
        //    algorithm.Quit(
        //        $"{algorithm.Time} -- " +
        //        $"Asset Symbol: {datasetSymbol.Underlying}; " +
        //        $"Growth factor: {factors.Growth}"
        //    );
        //}

        // Only rebalance when there are new Kavout factors.
        if (points.Count() == 0)
        {
            return new List<Insight>();
        }

        // Long the stocks with highest factor scores, which indicate higher return from various factors
        // Short the ones with lowest factor scores for lower return estimates
        var sortedByScore = points.OrderBy(kvp => TotalScore(kvp.Value))
            .Select(kvp => kvp.Key.Underlying);
        var longSymbols = sortedByScore.TakeLast(10);
        var shortSymbols = sortedByScore.Take(10);

        var insights = new List<Insight>();
        insights.AddRange(longSymbols.Select(symbol => new Insight(symbol, Expiry.EndOfDay, InsightType.Price,
InsightDirection.Up)));
        insights.AddRange(shortSymbols.Select(symbol => new Insight(symbol, Expiry.EndOfDay, InsightType.Price,
InsightDirection.Down)));

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach(dynamic security in changes.AddedSecurities)
        {
            // Requesting factor bundle data for trade signal generation
            security.kavoutSymbol = algorithm.AddData<KavoutCompositeFactorBundle>(security.Symbol).Symbol;
            // Historical Data
            var history = algorithm.History(security.kavoutSymbol, 10, Resolution.Daily);
        }
        foreach (dynamic security in changes.RemovedSecurities)
        {
            // Remove the factor bundle data for this asset when it leaves the universe.
            algorithm.RemoveSecurity(security.kavoutSymbol);
        }
    }

    private decimal TotalScore(KavoutCompositeFactorBundle value)
    {
        // Return the total score to integrate overall likelihood to outcompete, take equal weighting for each factor
        return value.Growth + value.ValueFactor + value.Quality + value.Momentum + value.LowVolatility;
    }
}
```

Data Point Attributes

The Composite Factor Bundle dataset provides `KavoutCompositeFactorBundle` objects, which have the following attributes:

Datasets

Nasdaq

" Nasdaq " was initially an acronym for the National Association of Securities Dealers Automated Quotations. It was founded in 1971 by the National Association of Securities Dealers (NASD), now known as the Financial Industry Regulatory Authority (FINRA), with the goal to provide financial services and operate stock exchanges.

On Dec. 4th, 2018, Nasdaq announced it had acquired Quandl, Inc. , a leading provider of alternative and core financial data. Quandl was founded by Tammer Kamel in 2012, with goal of making it easy for anyone to find and use high-quality data effectively in their professional decision-making. In 2021, Quandl was replaced by Nasdaq Data Link .

Data Link

Nasdaq

Data Link

Introduction

The Data Link dataset by Nasdaq, previously known as Quandl, is a collection of alternative data sets. It has indexed millions of time-series datasets from over 400 sources, which start in different years. This dataset is delivered on several frequencies, but the free data sets have often a daily frequency.

For more information about the Data Link dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

" Nasdaq " was initially an acronym for the National Association of Securities Dealers Automated Quotations. It was founded in 1971 by the National Association of Securities Dealers (NASD), now known as the Financial Industry Regulatory Authority (FINRA), with the goal to provide financial services and operate stock exchanges.

On Dec. 4th, 2018, Nasdaq announced it had acquired Quandl, Inc. , a leading provider of alternative and core financial data. Quandl was founded by Tammer Kamel in 2012, with goal of making it easy for anyone to find and use high-quality data effectively in their professional decision-making. In 2021, Quandl was replaced by Nasdaq Data Link .

Getting Started

The following snippet demonstrates how to request data from the Data Link dataset:

```C#
// For premium datasets, provide your API Key
// NasdaqDataLink.SetAuthCode(GetParameter("nasdaq-data-link-api-key"));

_bitcoinChainSymbol = AddData<NasdaqDataLink>("QDL/BCHAIN", Resolution.Daily).Symbol;
// This dataset has one data column ("Value")

_bitfinexExchangeRateSymbol = AddData<NasdaqCustomColumns>("QDL/BITFINEX", Resolution.Daily).Symbol;
// This dataset has multiple data columns. Create a subclass to set the default value column.

public class NasdaqCustomColumns : NasdaqDataLink
{
    // Select the column "mid"
    public NasdaqCustomColumns() : base(valueColumnName: "mid") { }
}
```

Our Nasdaq Data Link integration supports any dataset from Nasdaq that has a URL starting with `data.nasdaq.com/data/` . To import a dataset from Data Link, you need to get the dataset code. Follow these steps to get the dataset code:

1. Open the Data Link catalog .
2. *(Optional)* Use the filters on the left side bar to narrow down the catalog results.
3. Click one of the data products.
4. On the data product page, click one of the table names.
5. In the top-right corner of the dataset page, copy the Nasdaq Data Link Code.

Data Summary

The data summary depends on the specific Data Link dataset you use. Follow these steps to view the data summary of a dataset:

1. Open the Data Link catalog .
2. Click one of the data products.
3. On the data product page, click one of the table names.
4. View the data frequency and description in the left sidebar.
5. Above the chart, click `Table` to view the start date, end date, and data point attributes.

Backward Compatibility

QuantConnect/LEAN has supported Quandl since 2015. On January, 12, 2022, we moved the implementation from the LEAN GitHub repository to the Lean.DataSource.NasdaqDataLink GitHub repository . Through this transition, we maintained backward compatibility. All of the preceding code snippets work if you replace `NasdaqDataLink` with `Quandl` .

Requesting Data

To add Data Link data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm. If there is more than one value column in the Data Link dataset, to set the `Value` property of the data objects, create a sublcass of the `NasdaqDataLink` class and set its `ValueColumnName` property to the column name.

```
C#
public class NasdaqDataLinkDataAlgorithm : QCAlgorithm
{
    private Symbol _bitcoinChainSymbol , _bitfinexExchangeRateSymbol ;

    public override void Initialize()
    {
        SetStartDate(2022, 1, 1);
        SetEndDate(2022, 7, 1);
        SetCash(100000);

        // For premium datasets, provide your API Key
        // NasdaqDataLink.SetAuthCode(GetParameter("nasdaq-data-link-api-key"));

        _bitcoinChainSymbol = AddData<NasdaqDataLink>("QDL/BCHAIN", Resolution.Daily).Symbol;
        // This dataset has one data column ("Value")
        // Source : https://data.nasdaq.com/databases/BCHAIN

        _bitfinexExchangeRateSymbol = AddData<NasdaqCustomColumns>("QDL/BITFINEX", Resolution.Daily).Symbol;
        // This dataset has multiple data columns
        // Source: https://data.nasdaq.com/databases/BITFINEX
    }
}

public class NasdaqCustomColumns : NasdaqDataLink
{
    // Select the column "mid"
    public NasdaqCustomColumns() : base(valueColumnName: "mid") { }
}
```

Accessing Data

To get the current Data Link data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

To get the default value of the dataset, use the `Value` property. To get the value of a specific column in the dataset, call the `GetStorageDictionary` method and index the result with the column name.

```
public override void OnData(Slice slice)
{
    if (slice.TryGetValue(_bitcoinChainSymbol, out var point))
    {
        var value = point.Value;
        Log($"{_bitcoinChainSymbol} value at {slice.Time}: {value}");
    }

    if (slice.TryGetValue(_bitfinexExchangeRateSymbol, out var point))
    {
        var value = point.Value;
        var storageDictionary = point.GetStorageDictionary();
        var volume = storageDictionary["volume"];
        Log($"{_bitfinexExchangeRateSymbol} Bitfinex exchange rate at {slice.Time}: {value}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<NasdaqDataLink>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} value at {slice.Time}: {dataPoint.Value}");
    }

    foreach (var kvp in slice.Get<NasdaqCustomColumns>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} value at {slice.Time}: {dataPoint.Value}");
    }
}
```

Historical Data

The process to get historical Data Link data depends on your environment.

In Algorithms

To get historical Data Link data in an algorithm, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
var bitcoinChainHistory = History<NasdaqDataLink>(_bitcoinChainSymbol, 100, Resolution.Daily);
var bitfinexExchangeRateHistory = History<NasdaqDataLink>(_bitfinexExchangeRateSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

In Research Notebooks

To get historical Data Link data in the Research Environment, call the `Download` method with the data URL.

```
var data = qb.Download("https://data.nasdaq.com/api/v3/datatables/QDL/BCHAIN.csv?");
```

To receive a notification when you can use the `History` method in the Research Environment to get data from Data Link, subscribe to Lean.DataSource.NasdaqDataLink GitHub Issue #10 .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#

RemoveSecurity(_bitcoinChainSymbol);
RemoveSecurity(_bitfinexExchangeRateSymbol);
```

Example Applications

The Nasdaq Data Link sources allow you to explore different kinds of data in their database to develop trading strategies. Examples include the following strategies:

- Using alternative data to regress market regime/asset price.
- Backtesting exotic derivatives or private Equity investments.

Classic Algorithm Example

The following example algorithm subscribes to the Bitfinex Crypto Exchange Rate datasets. The algorithm takes a long position in Bitfinex BTCUSD.

```
C#

public class NasdaqImporterAlgorithm : QCAlgorithm
{
    private string nasdaqCode = "QDL/BITFINEX";
    private SimpleMovingAverage sma;

    public override void Initialize()
    {
        // Optional argument - personal token necessary for restricted dataset
        // NasdaqDataLink.SetAuthCode(this.GetParameter("nasdaq-data-link-api-key"));
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(25000);
        // Request nasdaq data link data to trade
        AddData<NasdaqCustomColumns>(nasdaqCode, Resolution.Daily, TimeZones.NewYork);
        // Create SMA indicator that feed with nasdaq data link data, which can be used to determine trend for trend
following trade
        sma = SMA(nasdaqCode, 14);
    }

    public override void OnData(Slice data)
    {
        // OnData event is the primary entry point for your algorithm. Each new data point will be pumped in here.
        if (!Portfolio.HoldStock)
        {
            SetHoldings(nasdaqCode, 1);
            Debug("Purchased " + nasdaqCode + " >> " + Time);
        }

        Plot(nasdaqCode, "PriceSMA", sma.Current.Value);
    }
}

// NasdaqDataLink often doesn't use close columns so need to tell LEAN which is the "value" column.
public class NasdaqCustomColumns : NasdaqDataLink
{
    // Custom nasdaq data type for setting customized value column name.
    // Value column is used for the primary trading calculations and charting.
    public NasdaqCustomColumns() : base("mid")
    {
        ValueColumnName = "mid";
    }
}
```

Framework Algorithm Example

The following example algorithm subscribes to the Bitcoin Chain dataset and Bitfinex Crypto Exchange Rate dataset. The

algorithm takes a long position in Bitfinex BTCUSD.

```C#
public class NasdaqDataLinkFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        /// Requesting Data
        // For premium datasets, provide your API Key
        // NasdaqDataLink.SetAuthCode(GetParameter("nasdaq-data-link-api-key"));

        // Add nasdaq data link data as trading vehicle
        var bitcoinChainSymbol = AddData<NasdaqDataLink>("QDL/BCHAIN", Resolution.Daily).Symbol;

        /// Historical Data
        var history = History<NasdaqDataLink>(bitcoinChainSymbol, 1000, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request for {bitcoinChainSymbol} Nasdaq Data Link");

        // Custom alpha model that emit insights based on updated nasdaq data link data
        AddAlpha(new NasdaqDataLinkAlphaModel(this));

        // Invest equally to evenly dissipate the capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(time => null));
    }
}

public class NasdaqDataLinkAlphaModel : AlphaModel
{
    private Symbol _bitfinexExchangeRateSymbol;

    public NasdaqDataLinkAlphaModel(QCAlgorithm algorithm)
    {
        /// Requesting NASDAQ data link custom data
        _bitfinexExchangeRateSymbol = algorithm.AddData<NasdaqCustomColumns>("QDL/BITFINEX",
Resolution.Daily).Symbol;
        // This dataset has multiple data columns, so create a custom class to set the value column name

        /// Historical Data
        var history = algorithm.History<NasdaqCustomColumns>(_bitfinexExchangeRateSymbol, 100, Resolution.Daily);
        algorithm.Debug($"We got {history.Count()} items from our history request for {_bitfinexExchangeRateSymbol}
Nasdaq Data Link");
    }

    public override List<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        List<Insight> insights = new List<Insight>();

        /// Trade only based on updated NASDAQ data link data
        foreach (var kvp in slice.Get<NasdaqCustomColumns>())
        {
            var datasetSymbol = kvp.Key;
            if (datasetSymbol != _bitfinexExchangeRateSymbol || algorithm.Portfolio[datasetSymbol].Invested)
            {
                continue;
            }
            insights.Add(Insight.Price(datasetSymbol, TimeSpan.FromDays(6*22), InsightDirection.Up));
        }

        return insights;
    }
}

public class NasdaqCustomColumns : NasdaqDataLink
{
    // Select the column "mid".
    public NasdaqCustomColumns() : base(valueColumnName: "mid") { }
}
```

Datasets

Quiver Quantitative

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

WallStreetBets

Quiver Quantitative

CNBC Trading

Introduction

The CNBC Trading dataset by Quiver Quantitative tracks the recommendations made by media personalities on CNBC and their historical performance. The data covers over 1,500 US Equities, starts in December 2020, and is delivered on a daily frequency. This dataset covers recommendations made on Mad Money, Halftime Report, and Fast Money.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the CNBC Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the CNBC Trading dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<QuiverCNBCs>(_symbol).Symbol;

_universe = AddUniverse<QuiverCNBCsUniverse>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	December 25, 2020
Asset Coverage	1,515 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add CNBC Trading data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class QuiverCNBCDataAlgorithm: QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol= AddData<QuiverCNBCs>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current CNBC Trading data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoints = slice[_datasetSymbol];
        foreach (var dataPoint in dataPoints)
        {
            Log($"{_datasetSymbol} direction at {slice.Time}: {dataPoint.Direction}");
        }
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<QuiverCNBCs>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoints = kvp.Value;
        foreach(var dataPoint in dataPoints)
        {
            Log($"{datasetSymbol} direction at {slice.Time}: {dataPoint.Direction}");
        }
    }
}
```

Historical Data

To get historical CNBC Trading data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<QuiverCNBCs>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on CNBC Trading data, call the `AddUniverse` method with the

`QuiverCNBCsUniverse` class and a selection function.

```C#
private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<QuiverCNBCsUniverse>(altCoarse =>
    {
        var cnbcDataBySymbol = new Dictionary<Symbol, List<QuiverCNBCsUniverse>>();

        foreach (var datum in altCoarse.OfType<QuiverCNBCsUniverse>())
        {
            var symbol = datum.Symbol;

            if (!cnbcDataBySymbol.ContainsKey(symbol))
            {
                cnbcDataBySymbol.Add(symbol, new List<QuiverCNBCsUniverse>());
            }
            cnbcDataBySymbol[symbol].Add(datum);
        }

        // define our selection criteria
        return from kvp in cnbcDataBySymbol
            where kvp.Value.Where(x => x.Direction == OrderDirection.Buy) >= 3
            select kvp.Key;
    });
}
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = History(universe, 30, Resolution.Daily);
foreach (var cnbcs in universeHistory)
{
    foreach (QuiverCNBCsUniverse cnbc in cnbcs)
    {
        Log($"{cnbc.Symbol} traders at {cnbc.EndTime}: {cnbc.Traders}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var cnbcs in universeHistory)
{
    foreach (QuiverCNBCsUniverse cnbc in cnbcs)
    {
        Console.WriteLine($"{cnbc.Symbol} traders at {cnbc.EndTime}: {cnbc.Traders}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to CNBC Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative CNBC Trading dataset enables you to create strategies using the latest recommendations made by media personalities on CNBC. Examples include the following strategies:

- Taking short positions in securities that were mentioned by Jim Cramer (CNBC commentator) in the last week
- Trading securities that were most/least discussed across CNBC programs over the last year

Classic Algorithm Example

The following example algorithm buys Apple stock if the net recommendation of media personalities on CNBC for Apple is positive. Otherwise, it holds cash.

```
C#
public class QuiverCNBCsAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;
    private Dictionary<OrderDirection, int> _intByOrderDirection;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _symbol = AddEquity("AAPL").Symbol;
        // Subscribe to CNBC data for AAPL to generate trade signal
        _datasetSymbol = AddData<QuiverCNBCs>(_symbol).Symbol;
        // Define a mapping from OrderDirection to int.
        _intByOrderDirection = new () {
            {OrderDirection.Buy, 1},
            {OrderDirection.Hold, 0},
            {OrderDirection.Sell, -1}
        };

        // history request
        var history = History<QuiverCNBCs>(new[] {_datasetSymbol}, 10, Resolution.Daily);
        Debug($"We got {history.Count()} items from historical data request of {_datasetSymbol}.");
    }

    public override void OnData(Slice slice)
    {
        foreach (var kvp in slice.Get<QuiverCNBCs>())
        {
            // Using mean prediction from CNBC analysts to be the trade signal
            // If the average CNBC insight is upward movement, invest AAPL
            if (kvp.Value.Average(x => _intByOrderDirection[(x as QuiverCNBC).Direction]) > 0)
            {
                SetHoldings(_symbol, 1);
            }
            else
            {
                SetHoldings(_symbol, 0);
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have at least 3 positive opinions from CNBC

sources. Each day, it then forms a equal-weighted portfolio with all the securities in the universe.

```C#
public class QuiverCNBCsDataAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, Symbol> _datasetSymbolBySymbol = new();
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Filter universe based on CNBC data
        AddUniverse<QuiverCNBCsUniverse>(data =>
        {
            var cnbcDataBySymbol = new Dictionary<Symbol, List<QuiverCNBCsUniverse>>();

            foreach (var datum in data.OfType<QuiverCNBCsUniverse>())
            {
                var symbol = datum.Symbol;

                if (!cnbcDataBySymbol.ContainsKey(symbol))
                {
                    cnbcDataBySymbol.Add(symbol, new List<QuiverCNBCsUniverse>());
                }
                cnbcDataBySymbol[symbol].Add(datum);
            }

            // Select the stocks with at least 3 CNBC analysts to suggest buy, reassuring the signal
            return from kvp in cnbcDataBySymbol
                where kvp.Value.Where(x => x.Direction == OrderDirection.Buy).Count() >= 3
                select kvp.Key;
        });

        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));

        // Invest equally to evenly dissipate the capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // Requesting CNBC Data
            var symbol = security.Symbol;
            var datasetSymbol = AddData<QuiverCNBCs>(symbol).Symbol;
            _datasetSymbolBySymbol.Add(symbol, datasetSymbol);

            // History request
            var history = History<QuiverCNBCs>(datasetSymbol, 10, Resolution.Daily);
            Debug($"We get {history.Count()} items in historical data of {datasetSymbol}");
        }

        foreach (var security in changes.RemovedSecurities)
        {
            var symbol = security.Symbol;
            if (_datasetSymbolBySymbol.ContainsKey(symbol))
            {
                // Remove subscription of CNBC data to release computation resources
                _datasetSymbolBySymbol.Remove(symbol, out var datasetSymbol);
                RemoveSecurity(datasetSymbol);
            }
        }
    }
}
```

Research Example

The following example lists US Equities mentioned by Jim Cramer.

C#

```
#r "../QuantConnect.DataSource.QuiverCNBC.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<QuiverCNBCs>(aapl).Symbol;

// Historical data
var history = qb.History<QuiverCNBCs>(symbol, 60, Resolution.Daily);
foreach (var cnbcs in history)
{
    foreach (QuiverCNBC cnbc in cnbcs)
    {
        Console.WriteLine($"{cnbc.Symbol} traders at {cnbc.EndTime}: {cnbc.Traders}");
    }
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return from d in altCoarse.OfType<QuiverCNBCsUniverse>()
        where d.Traders.Contains("Cramer") select d.Symbol;
}
var universe = qb.AddUniverse<QuiverCNBCsUniverse<(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-60), qb.Time);
foreach (var cnbcs in universeHistory)
{
    foreach (QuiverCNBCsUniverse cnbc in cnbcs)
    {
        Console.WriteLine($"{cnbc.Symbol} traders at {cnbc.EndTime}: {cnbc.Traders}");
    }
}
```

Data Point Attributes

The Quiver Quantitative CNBC Trading dataset provides `QuiverCNBCs` , `QuiverCNBC` , and `QuiverCNBCsUniverse` objects.

QuiverCNBCs

`QuiverCNBCs` objects have the following attributes:

QuiverCNBC

`QuiverCNBC` objects have the following attributes:

QuiverCNBCsUniverse

`QuiverCNBCsUniverse` objects have the following attributes:

Quiver Quantitative

Corporate Lobbying

Introduction

The Corporate Lobbying dataset by Quiver Quantitative tracks the lobbying activity of US Equities. The Lobbying Disclosure Act of 1995 requires lobbyists in the United States to disclose information about their activities, such as their clients, which issues they are lobbying on, and how much they are being paid. Quiver Quantiative scrapes this data and maps it to stock tickers to track which companies are spending money for legislative influence.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Corporate Lobbying dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the Corporate Lobbying dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<QuiverLobbyings>(_symbol).Symbol;

_universe = AddUniverse<QuiverLobbyingUniverse>(UniverseSelectionFilter);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 4, 1999
Asset Coverage	1,418 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Corporate Lobbying data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class QuiverLobbyingDataAlgorithm: QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        var symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol= AddData<QuiverLobbyings>(symbol).Symbol;
    }
}
```

Accessing Data

To get the current Corporate Lobbying data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoints = slice[_datasetSymbol];
        foreach (var dataPoint in dataPoints)
        {
            Log($"{_datasetSymbol} amount at {slice.Time}: {dataPoint.Amount}");
        }
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<QuiverLobbyings>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoints = kvp.Value;
        foreach(var dataPoint in dataPoints)
        {
            Log($"{datasetSymbol} amount at {slice.Time}: {dataPoint.Amount}");
        }
    }
}
```

Historical Data

To get historical Corporate Lobbying data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<QuiverLobbyings>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Corporate Lobbying data, call the `AddUniverse` method with the

`QuiverLobbyingUniverse` class and a selection function.

```
C#
private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<QuiverLobbyingUniverse>("QuiverLobbyingUniverse", Resolution.Daily, altCoarse =>
    {
        var lobbyDataBySymbol = new Dictionary<Symbol, List<QuiverLobbyingUniverse>>();

        foreach (var datum in altCoarse.OfType<QuiverLobbyingUniverse>())
        {
            var symbol = datum.Symbol;

            if (!lobbyDataBySymbol.ContainsKey(symbol))
            {
                lobbyDataBySymbol.Add(symbol, new List<QuiverLobbyingUniverse>());
            }
            lobbyDataBySymbol[symbol].Add(datum);
        }

        return from kvp in lobbyDataBySymbol
               where kvp.Value.Sum(x => x.Amount) >= 100000
               select kvp.Key;
    })
};
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
C#
var universeHistory = History(universe, 30, Resolution.Daily);
foreach (var lobbyings in universeHistory)
{
    foreach (QuiverLobbyingUniverse lobbying in lobbyings)
    {
        Log($"{lobbying.Symbol} issue at {lobbying.EndTime}: {lobbying.Issue}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var lobbyings in universeHistory)
{
    foreach (QuiverLobbyingUniverse lobbying in lobbyings)
    {
        Consolte.WriteLine($"{lobbying.Symbol} issue at {lobbying.EndTime}: {lobbying.Issue}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to Corporate Lobbying data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Corporate Lobbying dataset enables you to create strategies using the latest information on lobbying activity. Examples include the following strategies:

- Trading securities that have spent the most on lobbying over the last quarter
- Trading securities that have had the biggest change in lobbying spend for privacy legislation over the last year

Classic Algorithm Example

The following example algorithm tracks the lobbying activity of Apple. When the company initiates a lobbying activity worth more than $50K, the algorithm buys Apple stock. When the company initiates a lobbying activity worth less than $10K, the algorithm short sells Apple stock.

```
C#
public class QuiverLobbyingAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _symbol = AddEquity("AAPL").Symbol;
        // Subscribe to lobbying data for AAPL to generate trade signal
        _datasetSymbol = AddData<QuiverLobbyings>(_symbol).Symbol;

        // history request
        var history = History<QuiverLobbyings>(new[] {_datasetSymbol}, 10, Resolution.Daily);
        Debug($"We got {history.Count()} items from historical data request of {_datasetSymbol}.");
    }

    public override void OnData(Slice slice)
    {
        // Trade only base on lobbying data
        foreach (var kvp in slice.Get<QuiverLobbyings>())
        {
            var lobbyings = kvp.Value;
            // Buy if over 50000 lobbying amount, suggesting a favored political prospect and sentiment
            if (lobbyings.Any(lobbying => ((QuiverLobbying) lobbying).Amount >= 50000m))
            {
                SetHoldings(_symbol, 1);
            }
            // Sell if below 10000 lobbying amount, suggesting a less favorable political prospect and sentiment
            else if (lobbyings.Any(lobbying => ((QuiverLobbying) lobbying).Amount <= 10000m))
            {
                SetHoldings(_symbol, -1);
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have at least $100K worth of new lobbying activity. Each day, it then forms an equal-weighted portfolio with all of the securities in the universe.

C#

```
public class QuiverLobbyingDataAlgorithm : QCAlgorithm
{
    // To hold the lobbying dataset symbol for managing subscription
    private Dictionary<Symbol, Symbol> _datasetSymbolBySymbol = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Filter universe based on the lobbying data
        AddUniverse<QuiverLobbyingUniverse>( data =>
        {
            var lobbyDataBySymbol = new Dictionary<Symbol, List<QuiverLobbyingUniverse>>();

            foreach (var datum in data.OfType<QuiverLobbyingUniverse>())
            {
                var symbol = datum.Symbol;

                if (!lobbyDataBySymbol.ContainsKey(symbol))
                {
                    lobbyDataBySymbol.Add(symbol, new List<QuiverLobbyingUniverse>());
                }
                lobbyDataBySymbol[symbol].Add(datum);
            }

            // Select and invest all stocks with lobbying amount above 100000, suggesting a more favorable political
prospect and sentiment
            return from kvp in lobbyDataBySymbol
                where kvp.Value.Sum(x => x.Amount) >= 100000m
                select kvp.Key;
        });

        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));

        // Invest equally to evenly dissipate the capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // Requesting lobbying data for trading
            var symbol = security.Symbol;
            var datasetSymbol = AddData<QuiverLobbyings>(symbol).Symbol;
            _datasetSymbolBySymbol .Add(symbol, datasetSymbol);
            // History request
            var history = History<QuiverLobbyings>(datasetSymbol, 10, Resolution.Daily);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            var symbol = security.Symbol;
            if (_datasetSymbolBySymbol .ContainsKey(symbol))
            {
                // Remove lobbying data subscription to release computation resources
                _datasetSymbolBySymbol .Remove(symbol, out var datasetSymbol);
                RemoveSecurity(datasetSymbol);
            }
        }
    }
}
```

Research Example

The following example lists US Equities that have brought health related issues.

```C#
#r "../QuantConnect.DataSource.QuiverLobbying.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<QuiverLobbyings>(aapl).Symbol;

// Historical data
var history = qb.History<QuiverLobbyings>(symbol, 60, Resolution.Daily);
foreach (var lobbyings in history)
{
    foreach (QuiverLobbying lobbying in lobbyings)
    {
        Console.WriteLine($"{lobbying.Symbol} issue at {lobbying.EndTime}: {lobbying.Issue}");
    }
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return from d in altCoarse.OfType<QuiverLobbyingUniverse>()
        where d.Issue.ToLower().Contains("health") select d.Symbol;
}
var universe = qb.AddUniverse(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-60), qb.Time);
foreach (var lobbyings in universeHistory)
{
    foreach (QuiverLobbyingUniverse lobbying in lobbyings)
    {
        Console.WriteLine($"{lobbying.Symbol} issue at {lobbying.EndTime}: {lobbying.Issue}");
    }
}
```

Insider Trading

Introduction

Corporate insiders are required to disclose purchases or sales of their own stock within two business days of when they occur. Using these disclosures, we collect data on insider trading activity, which can give hints on whether executives are bullish or bearish on their own companies. Here is a blog that we did on this dataset: https://www.quiverquant.com/blog/081121

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Insider Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the Insider Trading dataset:

```
C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<QuiverInsiderTrading>(aapl).Symbol;
_universe = AddUniverse<QuiverInsiderTradingUniverse>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	25 April 2014
Asset Coverage	4994 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add Insider Trading data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```C#
public class QuiverInsiderTradingDataAlgorithm: QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        var symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol= AddData<QuiverInsiderTrading>(symbol).Symbol;
    }
}
```

Accessing Data

To get the current Insider Trading data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoints = slice[_datasetSymbol];
        foreach (QuiverInsiderTrading dataPoint in dataPoints)
        {
            Log($"{_datasetSymbol} shares at {slice.Time}: {dataPoint.Shares}");
        }
    }
}
```

Note that `dataPoints` is a list of `QuiverInsiderTrading` object since we can have several trades per symbol in a day. You need to iterate `dataPoints` to access the data.

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<QuiverInsiderTrading>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoints = kvp.Value;
        foreach(QuiverInsiderTrading dataPoint in dataPoints)
        {
            Log($"{datasetSymbol} shares at {slice.Time}: {dataPoint.Shares}");
        }
    }
}
```

Historical Data

To get historical Insider Trading data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
var history = History<QuiverInsiderTrading>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Insider Trading data, call the `AddUniverse` method with the `QuiverInsiderTradingUniverse` class and a selection function.

```
C#
public class InsiderTradingUniverseAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2023, 1, 1);
        _universe = AddUniverse<QuiverInsiderTradingUniverse>(SelectAssets);
    }

    private IEnumerable<Symbol> SelectAssets(IEnumerable<BaseData> altCoarse)
    {
        var dollarVolumeBySymbol = new Dictionary<Symbol, decimal?>();
        foreach (QuiverInsiderTradingUniverse data in altCoarse)
        {
            if (data.PricePerShare == 0m || data.PricePerShare == null)
            {
                continue;
            }
            if (!dollarVolumeBySymbol.ContainsKey(data.Symbol))
            {
                dollarVolumeBySymbol[data.Symbol] = 0;
            }
            dollarVolumeBySymbol[data.Symbol] += data.Shares * data.PricePerShare;
        }
        return dollarVolumeBySymbol
            .OrderByDescending(kvp => kvp.Value)
            .Take(10)
            .Select(kvp => kvp.Key);
    }
}
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
C#
var universeHistory = History(universe, 30, Resolution.Daily);
foreach (var insiders in universeHistory)
{
    foreach (QuiverInsiderTradingUniverse insider in insiders)
    {
        Log($"{insider.Symbol} volume at {insider.EndTime}: {insider.Shares * insider.PricePerShare}");
    }
}}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var insiders in universeHistory)
{
    foreach (QuiverInsiderTradingUniverse insider in insiders)
    {
        Console.WriteLine($"{insider.Symbol} volume at {insider.EndTime}: {insider.Shares * insider.PricePerShare}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to Insider Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative Insider Trading dataset enables researchers to create strategies using the latest information on insider trading activity. Examples include:

- Taking a short position in securities that have had the most insider selling over the last 5 days
- Buying any security that has had over $100,000 worth of shares purchased by insiders in the last month

Classic Algorithm Example

In this example, we would 100% long AAPL if there was any insider buying event. Otherwise, we liquidate it.

C#

```
public class QuiverInsiderTradingAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _symbol = AddEquity("AAPL").Symbol;
        // Subscribe to insider trade data for AAPL to generate trade signal
        _datasetSymbol = AddData<QuiverInsiderTrading>(_symbol).Symbol;

        // history request
        var history = History<QuiverInsiderTrading>(new[] {_datasetSymbol}, 10, Resolution.Daily);
        Debug($"We got {history.Count()} items from historical data request of {_datasetSymbol}.");
    }

    public override void OnData(Slice slice)
    {
        // Trade only base on insider trade data
        foreach (var kvp in slice.Get<QuiverInsiderTrading>())
        {
            foreach (QuiverInsiderTrading insiderTrade in kvp.Value)
            {
                // Any buy insider trade will result in buying, assuming insider have confidence in stock price with
more informed information and projection
                if (insiderTrade.Shares > 0)
                {
                    SetHoldings(_symbol, 1);
                }
                // Any sell insider trade will result in liquidation, assuming insiders believe the stock price has
reached maximum or poor future confidence
                else
                {
                    Liquidate(_symbol);
                }
            }
        }
    }
}
```

Framework Algorithm Example

In this example, we long a equal-sized portfolio with equities that having insider trading for over $100000 USD in the previous day.

C#

```
public class QuiverInsiderTradingDataAlgorithm : QCAlgorithm
{
    // To hold the insider trade dataset symbol for managing subscription
    private Dictionary<Symbol, Symbol> _dataSymbols = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Filter universe using insider trade data
        AddUniverse<QuiverInsiderTradingUniverse>(data =>
        {
            var symbolData = new Dictionary<Symbol, List<QuiverInsiderTradingUniverse>>();

            foreach (var datum in data.OfType<QuiverInsiderTradingUniverse>())
            {
                var symbol = datum.Symbol;

                if (!symbolData.ContainsKey(symbol))
                {
                    symbolData.Add(symbol, new List<QuiverInsiderTradingUniverse>());
                }
                symbolData[symbol].Add(datum);
            }

            // Select the ones with insider trading dollar amount above 100k, assuming insider have confidence in
stock price with more informed information and projection
            return from kvp in symbolData
                where kvp.Value.Sum(x => x.Shares * x.PricePerShare) >= 100000
                select kvp.Key;
        });

        AddAlpha(new ConstantAlphaModel(InsightType.Price, InsightDirection.Up, TimeSpan.FromDays(1)));

        // Invest equally to evenly dissipate the capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // Requesting insider trade data for trading
            var symbol = security.Symbol;
            var datasetSymbol = AddData<QuiverInsiderTrading>(symbol).Symbol;
            _dataSymbols.Add(symbol, datasetSymbol);
            // History request
            var history = History<QuiverInsiderTrading>(datasetSymbol, 10, Resolution.Daily);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            var symbol = security.Symbol;
            if (_dataSymbols.ContainsKey(symbol))
            {
                // Remove insider trade data subscription to release computation resources
                _dataSymbols.Remove(symbol, out var datasetSymbol);
                RemoveSecurity(datasetSymbol);
            }
        }
    }
}
```

Research Example

The following example lists US Equities having insider trading for over $10,000,000.

C#

```
#r "../QuantConnect.DataSource.QuiverInsiderTrading.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<QuiverInsiderTrading>(aapl).Symbol;

// Historical data
var history = qb.History<QuiverInsiderTrading>(symbol, 60, Resolution.Daily);
foreach (var insiders in history)
{
    foreach (QuiverInsiderTrading insider in insiders)
    {
        Console.WriteLine($"{insider.Symbol} shares at {insider.EndTime}: {insider.Shares}");
    }
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return from d in altCoarse.OfType<QuiverInsiderTradingUniverse>()
        where d.Shares * d.PricePerShare >= 10000000 select d.Symbol;
}
var universe = qb.AddUniverse<QuiverInsiderTradingUniverse>(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-5), qb.Time);
foreach (var insiders in universeHistory)
{
    foreach (QuiverInsiderTradingUniverse insider in insiders)
    {
        Console.WriteLine($"{insider.Symbol} volume at {insider.EndTime}: {insider.Shares * insider.PricePerShare}");
    }
}
```

Data Point Attributes

The Insider Trading dataset provides `QuiverInsiderTrading` and `QuiverInsiderTradingUniverse` object.

QuiverInsiderTrading

`QuiverInsiderTrading` objects have the following attributes:

QuiverInsiderTradingUniverse

`QuiverInsiderTradingUniverse` objects have the following attributes:

Quiver Quantitative

US Congress Trading

Introduction

The US Congress Trading dataset by Quiver Quantitative tracks US Equity trades made by members of Congress in the Senate and the House of Representatives. The data covers 1,800 US Equities, starts in January 2016, and is delivered on a daily frequency. This dataset is created by scraping SEC reports.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Congress Trading dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the US Congress Trading dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<QuiverCongress>(_symbol).Symbol;

_universe = AddUniverse<QuiverQuantCongresssUniverse>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2016
Asset Coverage	1,800 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add US Congress Trading data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class QuiverCongressDataAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        var symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<QuiverCongress>(symbol).Symbol;
    }
}
```

Accessing Data

To get the current US Congress Trading data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoints = slice[_datasetSymbol];
        foreach (var dataPoint in dataPoints)
        {
            Log($"{_datasetSymbol} transaction amount at {slice.Time}: {dataPoint.Amount}");
        }
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<QuiverCongress>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} transaction amount at {slice.Time}: {dataPoint.Amount}");
    }
}
```

Historical Data

To get historical US Congress Trading data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<QuiverCongress>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on US Congress Trading data, call the `AddUniverse` method with the `QuiverQuantCongressUniverse` class and a selection function.

```
C#
private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<QuiverQuantCongresssUniverse>(altCoarse =>
    {
        return from d in altCoarse.OfType<QuiverCongressDataPoint>()
            where d.Amount > 200000 && d.Transaction == OrderDirection.Buy
            select d.Symbol;
    })
};
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
C#
var universeHistory = History(_universe, 30, Resolution.Daily);
foreach (var trade in universeHistory.SelectMany(x => x).OfType<QuiverCongressDataPoint>())
{
    Log($"{trade.Symbol} amount at {trade.EndTime}: {trade.Amount} {trade.Representative}");
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var trade in universeHistory.SelectMany(x => x).OfType<QuiverCongressDataPoint>())
{
    Console.WriteLine($"{trade.Symbol} amount at {trade.EndTime}: {trade.Amount} {trade.Representative}");
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to US Congress Trading data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The US Congress Trading dataset enables you to take immediate action on trades made by informed Members of Congress. Examples include the following strategies:

- Following the trades of specific representatives on the premise that the representatives are more informed
- Assigning a long/short-bias to securities on a daily frequency based on how Members of Congress are trading them

Classic Algorithm Example

The following example algorithm follows the net bias of the trades made by Members of Congress each day. When Members of Congress are net buyers, the algorithm buys. When they are net sellers, the algorithm short sells.

```
C#
public class QuiverCongressDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Requesting data per underlying data to subscribe to updated congress members' trade information
        var aapl = AddEquity("AAPL", Resolution.Daily).Symbol;
        var quiverCongressSymbol = AddData<QuiverCongress>(aapl).Symbol;

        // Historical data
        var history = History<QuiverCongress>(quiverCongressSymbol, 60, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        var congressBySymbol = slice.Get<QuiverCongress>();

        // Determine net direction of Congress trades for each security to estimate the sentiment direction due to
political factor
        var netQuantityBySymbol = new Dictionary<Symbol, decimal>();
        foreach (var (s, points) in congressBySymbol)
        {
            var symbol = s.Underlying;
            if (!netQuantityBySymbol.ContainsKey(symbol))
            {
                netQuantityBySymbol[symbol] = 0m;
            }
            // Voting weight is by order size
            foreach(QuiverCongressDataPoint point in points)
            {
                netQuantityBySymbol[symbol] += (point.Transaction == OrderDirection.Buy ? 1 : -1) * (point.Amount ??
0m);
            }
        }

        foreach (var (symbol, netQuantity) in netQuantityBySymbol)
        {
            if (netQuantity == 0)
            {
                Liquidate(symbol);
                continue;
            }
            // Buy when Congress members have bought, short otherwise
            SetHoldings(symbol, netQuantity > 0 ? 1 : -1);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm follows the net bias of the trades made by Members of Congress each day. When Members of Congress are net buyers, the algorithm buys. When they are net sellers, the algorithm short sells.

```
C#
public class QuiverCongressDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
```

```
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Filter according to QuiverCongress data
        AddUniverse<QuiverQuantCongressUniverse>("QuiverQuantCongresssUniverse", Resolution.Daily, altCoarse =>
        {
            // Only include the ones with large size buy, since they are estimated to be materially confident to go
up
            return from d in altCoarse.OfType<QuiverCongressDataPoint>()
                where d.Amount > 10000 && d.Transaction == OrderDirection.Buy
                select d.Symbol;
        });
        AddAlpha(new CongressAlphaModel());
        SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel(time => null));
        AddRiskManagement(new NullRiskManagementModel());
        SetExecution(new ImmediateExecutionModel());
    }
}

public class CongressAlphaModel : AlphaModel
{
    private Dictionary<Symbol, SymbolData> _symbolDataBySymbol = new ();
    private Dictionary<Symbol, Insight> _insightBySymbol = new ();

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var congressBySymbol = slice.Get<QuiverCongress>();
        if (congressBySymbol.Count > 0)
        {
            _insightBySymbol.Clear();
            // Determine net direction of Congress trades for each security to estimate the sentiment direction due
to political factor
            var netQuantityBySymbol = new Dictionary<Symbol, decimal>();
            foreach (var (s, points) in congressBySymbol)
            {
                var symbol = s.Underlying;
                if (!netQuantityBySymbol.ContainsKey(symbol))
                {
                    netQuantityBySymbol[symbol] = 0m;
                }
                // Voting weight is by order size
                foreach(QuiverCongressDataPoint point in points)
                {
                    netQuantityBySymbol[symbol] += (point.Transaction == OrderDirection.Buy ? 1 : -1) *
(point.Amount ?? 0m);
                }
            }

            foreach (var (symbol, netQuantity) in netQuantityBySymbol)
            {
                // Buy when Congress members have bought, as they may have advance information to be confident to the
return direction
                InsightDirection direction;
                if (netQuantity > 0 && !algorithm.Portfolio[symbol].IsLong)
                {
                    direction = InsightDirection.Up;
                }
                // Short sell when Congress members have sold
                else if (netQuantity < 0 && !algorithm.Portfolio[symbol].IsShort)
                {
                    direction = InsightDirection.Down;
                }
                else
                {
                    continue;
                }
                _insightBySymbol[symbol] = Insight.Price(symbol, TimeSpan.FromDays(7), direction, weight: 0.5);
            }
        }
        return _insightBySymbol.Keys
            .ToList() // snapshot keys
            .Where(symbol => algorithm.Securities[symbol].Price != 0m)
            .Select(symbol => {
                var val = _insightBySymbol[symbol]; // capture value
                _insightBySymbol.Remove(symbol);    // remove
                return val;
            })
            .ToList();
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
```

```
    {
        foreach (var security in changes.AddedSecurities)
        {
            var symbol = security.Symbol;
            _symbolDataBySymbol.Add(symbol, new SymbolData(algorithm, symbol));
        }

        foreach (var security in changes.RemovedSecurities)
        {
            var symbol = security.Symbol;
            if (_symbolDataBySymbol.ContainsKey(symbol))
            {
                _symbolDataBySymbol[symbol].dispose();
                _symbolDataBySymbol.Remove(symbol);
            }
        }
    }
}

public class SymbolData
{
    private Symbol _quiverCongressSymbol;
    private QCAlgorithm _algorithm;

    public SymbolData(QCAlgorithm algorithm, Symbol symbol)
    {
        _algorithm = algorithm;

        // Requesting data per underlying data to subscribe to updated congress members' trade information
        _quiverCongressSymbol = algorithm.AddData<QuiverCongress>(symbol).Symbol;

        // Historical data
        var history = algorithm.History<QuiverCongress>(_quiverCongressSymbol, 60, Resolution.Daily);
        algorithm.Debug($"We got {history.Count()} items from our history request for {symbol} Quiver Congress
data");
    }

    public void dispose()
    {
        // Unsubscribe from Quiver Congress feed for this security to release computational resources
        _algorithm.RemoveSecurity(_quiverCongressSymbol);
    }
}
```

Research Example

The following example lists trades made by Members of Congress daily as buyers.

```C#
#r "../QuantConnect.DataSource.QuiverQuantCongressTrading.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Add QuiverCongress
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var quiverCongressSymbol = qb.AddData<QuiverCongress>(aapl).Symbol;

// Historical data
var history = qb.History<QuiverCongress>(quiverCongressSymbol, 60, Resolution.Daily);
foreach (var trade in history.SelectMany(x => x).OfType<QuiverCongressDataPoint>())
{
    Console.WriteLine($"{trade.EndTime} {trade.Symbol.Value} {trade.Representative} {trade.Amount}");
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable>BaseData> altCoarse)
{
    return from d in altCoarse.OfType<QuiverCongressDataPoint>()
        where d.Transaction == OrderDirection.Buy select d.Symbol;
}
var universe = qb.AddUniverse>QuiverQuantCongressUniverse>(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-60), qb.Time);
foreach (var trade in universeHistory.SelectMany(x => x).OfType<QuiverCongressDataPoint>())
{
    Console.WriteLine($"{trade.EndTime} {trade.Symbol.Value} {trade.Representative} {trade.Amount}");
}
```

Data Point Attributes

The US Congress Trading dataset provides `QuiverCongressDataPoint` , `QuiverCongress` , and `QuiverQuantCongressUniverse` objects.

QuiverCongressDataPoint Attributes

`QuiverCongressDataPoint` object has the following attributes:

QuiverCongress Attributes

`QuiverCongress` object has the following attributes:

QuiverQuantCongressUniverse Attributes

`QuiverQuantCongressUniverse` object has the following attributes:

Quiver Quantitative

US Government Contracts

Introduction

The US Government Contracts dataset by Quiver Quantitative tracks the transactions of government contracts with publicly traded companies. The data covers over 700 US Equities, starts in October 2019, and is delivered on a daily frequency. Quiver Quantitative creates this dataset by using the API for USASpending.gov , which has the official open data source of federal spending information. The rows in this dataset only show new contracts, not payments or modifications to existing contracts. The dollar amounts are based on the total dollars obligated from each contract.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Government Contracts dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the US Government Contracts dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<QuiverGovernmentContract>(_symbol).Symbol;

_universe = AddUniverse<QuiverGovernmentContractUniverse>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	October 15, 2019
Asset Coverage	748 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add US Government Contracts data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so

you can access the data later in your algorithm.

```
C#
public class QuiverGovernmentContractDataAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        var symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol= AddData<QuiverGovernmentContract>(symbol).Symbol;
    }
}
```

Accessing Data

To get the current US Government Contract data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoints = slice[_datasetSymbol];
        foreach (var dataPoint in dataPoints)
        {
            Log($"{_datasetSymbol} amount at {slice.Time}: {dataPoint.Amount}");
        }
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<QuiverGovernmentContract>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoints = kvp.Value;
        foreach(var dataPoint in dataPoints)
        {
            Log($"{datasetSymbol} amount at {slice.Time}: {dataPoint.Amount}");
        }
    }
}
```

Historical Data

To get historical US Government Contracts data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<QuiverGovernmentContract>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on US Government Contract data, call the `AddUniverse` method with the `QuiverGovernmentContractUniverse` class and a selection function.

```C#
private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<QuiverGovernmentContractUniverse>(altCoarse =>
    {
        var govContractDataBySymbol = new Dictionary<Symbol, List<QuiverGovernmentContractUniverse>>();

        foreach (var datum in altCoarse.OfType<QuiverGovernmentContractUniverse>())
        {
            var symbol = datum.Symbol;

            if (!govContractDataBySymbol.ContainsKey(symbol))
            {
                govContractDataBySymbol.Add(symbol, new List<QuiverGovernmentContractUniverse>());
            }
            govContractDataBySymbol[symbol].Add(datum);
        }

        return from kvp in govContractDataBySymbol
            where kvp.Value.Count >= 3 && kvp.Value.Sum(x => x.Amount) > 50000m
            select kvp.Key;
    });
}
```

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = History(universe, 30, Resolution.Daily);
foreach (var contracts in universeHistory)
{
    foreach (QuiverGovernmentContractUniverse contract in contracts)
    {
        Log($"{contract.Symbol} amount at {contract.EndTime}: {contract.Amount}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
foreach (var contracts in universeHistory)
{
    foreach (QuiverGovernmentContractUniverse contract in contracts)
    {
        Console.WriteLine($"{contract.Symbol} amount at {contract.EndTime}: {contract.Amount}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to US Government Contracts data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Quiver Quantitative US Government Contracts dataset enables you to create strategies using the latest information on government contracts activity. Examples include the following strategies:

- Buying securities that have received the most new government contract awards over the last month
- Trading securities that have had the biggest change in government contracts awards over the last year

Classic Algorithm Example

The following example algorithm buys Apple stock when they receive a new government contract worth over 50*K*. *Iftheyreceiveanewcontractworthunder*10K, the algorithm short sells Apple.

```
C#
public class QuiverGovernmentContractAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _symbol = AddEquity("AAPL").Symbol;
        // Subscribe to government contract data for AAPL to generate trade signal
        _datasetSymbol = AddData<QuiverGovernmentContract>(_symbol).Symbol;

        // history request
        var history = History<QuiverGovernmentContract>(new[] {_datasetSymbol}, 10, Resolution.Daily);
        Debug($"We got {history.Count()} items from historical data request of {_datasetSymbol}.");
    }

    public override void OnData(Slice slice)
    {
        // Trade only base on government contract data
        foreach (var kvp in slice.Get<QuiverGovernmentContract>())
        {
            // Buy if over 50000 government contract amount, suggesting a large income
            if (kvp.Value.Any(x => (int) (x as QuiverGovernmentContract).Amount > 50000m))
            {
                SetHoldings(_symbol, 1);
            }
            // Sell if below 10000 government contract amount, suggesting a smaller than usual income
            else if (kvp.Value.Any(x => (int) (x as QuiverGovernmentContract).Amount < 10000m))
            {
                SetHoldings(_symbol, -1);
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities that have just received a government contract worth at least $5K. Each day, it then forms an equal-weighted dollar-neutral portfolio with the 10 companies that received the largest contracts and the 10 companies that received the smallest contracts.

```
C#
```

```
public class QuiverGovernmentContractFrameworkAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        // Filter universe using government contract data
        AddUniverse<QuiverGovernmentContractUniverse>(data =>
        {
            var govContractDataBySymbol = new Dictionary<Symbol, List<QuiverGovernmentContractUniverse>>();

            foreach (var datum in data.OfType<QuiverGovernmentContractUniverse>())
            {
                var symbol = datum.Symbol;

                if (!govContractDataBySymbol.ContainsKey(symbol))
                {
                    govContractDataBySymbol.Add(symbol, new List<QuiverGovernmentContractUniverse>());
                }
                govContractDataBySymbol[symbol].Add(datum);
            }

            // Only select the stocks with over 5000 government contracts, which is considered material information
            return from kvp in govContractDataBySymbol
                where kvp.Value.Sum(x => x.Amount) > 5000m
                select kvp.Key;
        });

        // Custom alpha model that emit insights based on updated government contract data
        AddAlpha(new QuiverGovernmentContractAlphaModel());

        // Invest equally to evenly dissipate the capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());

        SetExecution(new ImmediateExecutionModel());
    }
}

public class QuiverGovernmentContractAlphaModel: AlphaModel
{
    // A variable to control the rebalancing time
    private DateTime _time;
    // To hold the government contract dataset symbol for managing subscription
    private Dictionary<Symbol, Symbol> _datasetSymbolBySymbol = new();

    public QuiverGovernmentContractAlphaModel()
    {
        _time = DateTime.MinValue;
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        if (_time > algorithm.Time) return new List<Insight>();

        // Trade signal only based on government contract data
        var dataPoints = slice.Get<QuiverGovernmentContract>();

        if (dataPoints.IsNullOrEmpty()) return new List<Insight>();

        // To aggregate all data per symbol for analysis
        var govContracts = dataPoints
            .Where(kvp => algorithm.Securities[kvp.Key.Underlying].Price != 0)
            .ToDictionary(kvp => kvp.Key, kvp => kvp.Value.Sum(x => ((QuiverGovernmentContract)x).Amount));

        // Long the top 10 highest government contract amount, predicting a higher expected income and return
        // Short the lowest 10 government contract amount, predicting a lower expected income and return
        var sortedByGovContract = from kvp in govContracts
                        orderby kvp.Value descending
                        select kvp.Key.Underlying;
        var longSymbols = sortedByGovContract.Take(10).ToList();
        var shortSymbols = sortedByGovContract.TakeLast(10).ToList();

        var insights = new List<Insight>();
        insights.AddRange(longSymbols.Select(symbol =>
            new Insight(symbol, Expiry.EndOfDay, InsightType.Price, InsightDirection.Up)));
        insights.AddRange(shortSymbols.Select(symbol =>
            new Insight(symbol, Expiry.EndOfDay, InsightType.Price, InsightDirection.Down)));
```

```
        _time = Expiry.EndOfDay(algorithm.Time);

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // Requesting government contract data for trade signal generation
            var symbol = security.Symbol;
            var datasetSymbol = algorithm.AddData<QuiverGovernmentContract>(symbol).Symbol;
            _datasetSymbolBySymbol.Add(symbol, datasetSymbol);
            // History request
            var history = algorithm.History<QuiverGovernmentContract>(datasetSymbol, 10, Resolution.Daily);
        }

        foreach (var security in changes.RemovedSecurities)
        {
            var symbol = security.Symbol;
            if (_datasetSymbolBySymbol.ContainsKey(symbol))
            {
                // Remove government contract data subscription to release computation resources
                _datasetSymbolBySymbol.Remove(symbol, out var datasetSymbol);
                algorithm.RemoveSecurity(datasetSymbol);
            }
        }
    }
}
```

Research Example

The following example lists all US Equities with Government contracts in the past year.

C#

```
#r "../QuantConnect.DataSource.QuiverGovernmentContracts.dll"
using QuantConnect.DataSource;

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<QuiverGovernmentContract>(aapl).Symbol;

// Historical data
var history = qb.History<QuiverGovernmentContract>(symbol, 360, Resolution.Daily);
foreach (var contracts in history)
{
    foreach (QuiverGovernmentContract contract in contracts)
    {
        Console.WriteLine($"{contract.Symbol} amount at {contract.EndTime}: {contract.Amount}");
    }
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return from d in altCoarse.OfType<QuiverGovernmentContractUniverse>()
        select d.Symbol;
}
var universe = qb.AddUniverse<QuiverGovernmentContractUniverse<(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-360), qb.Time);
foreach (var contracts in universeHistory)
{
    foreach (QuiverGovernmentContractUniverse contract in contracts)
    {
        Console.WriteLine($"{contract.Symbol} amount at {contract.EndTime}: {contract.Amount}");
    }
}
```

Data Point Attributes

The US Government Contracts dataset provides `QuiverGovernmentContract` and `QuiverGovernmentContractUniverse` objects.

QuiverGovernmentContract

`QuiverGovernmentContract` objects have the following attributes:

QuiverGovernmentContractUniverse

`QuiverGovernmentContractUniverse` objects have the following attributes:

Quiver Quantitative

WallStreetBets

Introduction

The WallStreetBets dataset by Quiver Quantitative tracks daily mentions of different equities on Reddit's popular WallStreetBets forum. The data covers 6,000 Equities, starts in August 2018, and is delivered on a daily frequency. The dataset is created by scraping the daily discussion threads on r/WallStreetBets and parsing the comments for ticker mentions.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the WallStreetBets dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Quiver Quantitative was founded by two college students in February 2020 with the goal of bridging the information gap between Wall Street and non-professional investors. Quiver allows retail investors to tap into the power of big data and have access to actionable, easy to interpret data that hasn't already been dissected by Wall Street.

Getting Started

The following snippet demonstrates how to request data from the WallStreetBets dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_datasetSymbol = AddData<QuiverWallStreetBets>(_symbol).Symbol;

_universe = AddUniverse<QuiverWallStreetBetsUniverse>(UniverseSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	August 2018
Asset Coverage	6,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add WallStreetBets data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class QuiverWallStreetBetsDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);
        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _datasetSymbol = AddData<QuiverWallStreetBets>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current WallStreetBets data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoints = slice[_datasetSymbol];
        foreach (var dataPoint in dataPoints)
        {
            Log($"{_datasetSymbol} mentions at {slice.Time}: {dataPoint.Mentions}");
        }
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<QuiverWallStreetBets>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoints = kvp.Value;
        foreach (var dataPoint in dataPoints)
        {
            Log($"{datasetSymbol} mentions at {slice.Time}: {dataPoint.Mentions}");
        }
    }
}
```

Historical Data

To get historical WallStreetBets data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<QuiverWallStreetBets>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on WallStreetBets data, call the `AddUniverse` method with the

`QuiverWallStreetBetsUniverse` class and a selection function.

```
C#

private Universe _universe;
public override void Initialize()
{
    _universe = AddUniverse<QuiverWallStreetBetsUniverse>(altCoarse =>
    {
        return from d in altCoarse.OfType<QuiverWallStreetBetsUniverse>()
            where d.Mentions > 10 && d.Rank > 10 select d.Symbol;
    });
}
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
C#

var universeHistory = History(_universe, 30, Resolution.Daily);
foreach (var bets in universeHistory)
{
    foreach (QuiverWallStreetBetsUniverse bet in bets)
    {
        Log($"{bet.Symbol} mentions at {bet.EndTime}: {bet.Mentions}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```
C#

var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-30), qb.Time);
{
    foreach (QuiverWallStreetBetsUniverse bet in bets)
    {
        Log($"{bet.Symbol} rank at {bet.EndTime}: {bet.Rank}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#

RemoveSecurity(_datasetSymbol);
```

If you subscribe to WallStreetBets data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The WallStreetBets dataset enables you to create strategies using the latest activity on the WallStreetBets daily discussion thread. Examples include the following strategies:

- Trading any security that is being mentioned
- Trading securities that are receiving more/less mentions than they were previously
- Trading the security that is being mentioned the most/least for the day

Classic Algorithm Example

The following example algorithm creates a dynamic universe of US Equities based on daily WallStreetBets data. When a security is mentioned on r/WallStreetBets more than five times in a day, the algorithm buys the security. When a security is mentioned five time in a day or less, the algorithm short sells the security.

```C#
public class QuiverWallStreetBetsDataAlgorithm : QCAlgorithm
{
    private Universe _universe;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        UniverseSettings.Resolution = Resolution.Daily;
        // Filter using wall street bet insights
        _universe = AddUniverse<QuiverWallStreetBetsUniverse>(altCoarse =>
        {
            // Select the ones with popularity (mentions) of better-than-others performance (rank)
            return from d in altCoarse.OfType<QuiverWallStreetBetsUniverse>()
                    where d.Mentions > 10 && d.Rank < 100
                    select d.Symbol;
        });
    }

    public override void OnData(Slice slice)
    {
        var points = slice.Get<QuiverWallStreetBets>();
        foreach (var point in points.Values)
        {
            var symbol = point.Symbol.Underlying;
            var security = Securities[symbol];
            if (!security.IsTradable)
            {
                continue;
            }

            // Buy if the stock was mentioned more than 5 times in the WallStreetBets daily discussion, which
translate into high popularity of rise
            if (point.Mentions > 5 && !security.Holdings.IsLong)
            {
                MarketOrder(symbol, 1);
            }
            // Otherwise, short sell
            else if (point.Mentions <= 5 && !security.Holdings.IsShort)
            {
                MarketOrder(symbol, -1);
            }
        }
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach(var added in changes.AddedSecurities)
        {
            // Requesting wall street bet data to obtain the trader's insights
            var quiverWSBSymbol = AddData<QuiverWallStreetBets>(added.Symbol).Symbol;
            // Historical data
            var history = History<QuiverWallStreetBets>(quiverWSBSymbol, 60, Resolution.Daily);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of US Equities based on daily WallStreetBets data. When a security is mentioned on r/WallStreetBets more than five times in a day, the algorithm buys the security. When a security is mentioned five time in a day or less, the algorithm short sells the security.

```C#
public class QuiverWallStreetBetsDataAlgorithm : QCAlgorithm
{
    private Universe _universe;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
```

```
        UniverseSettings.Resolution = Resolution.Daily;

Research Example

The following example lists low-ranking US Equities that are mentioned more than ten times on r/WallStreetBets.

C#

```
#r "../QuantConnect.DataSource.QuiverWallStreetBets.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var aapl = qb.AddEquity("AAPL", Resolution.Daily).Symbol;
var symbol = qb.AddData<QuiverWallStreetBets>(aapl).Symbol;

// Historical data
var history = qb.History<QuiverWallStreetBets>(symbol, 60, Resolution.Daily);
foreach (var bet in history.OfType<QuiverWallStreetBets>())
{
    Console.WriteLine($"{bet.Symbol} rank at {bet.EndTime}: {bet.Rank}");
}

// Add Universe Selection
IEnumerable<Symbol> UniverseSelection(IEnumerable<BaseData> altCoarse)
{
    return from d in altCoarse.OfType<QuiverWallStreetBetsUniverse>()
        where d.Mentions > 10 && d.Rank < 100 select d.Symbol;
}
var universe = qb.AddUniverse<QuiverWallStreetBetsUniverse>(UniverseSelection);

// Historical Universe data
var universeHistory = qb.UniverseHistory(universe, qb.Time.AddDays(-60), qb.Time);
foreach (var bets in universeHistory)
{
    foreach (QuiverWallStreetBetsUniverse bet in bets)
    {
        Console.WriteLine($"{bet.Symbol} rank at {bet.EndTime}: {bet.Rank}");
    }
}
```

Datasets

RegAlytics

RegAlytics was founded by Mary Kopczynski, Aaron Heisler, Alexander Appugliese, and Werner Pauliks in 2019 with the goal of significantly reducing the time and cost required to mitigate regulatory risk. RegAlytics provides access to accurate and clean regulatory data from all global regulators in all sectors that is enriched by regulatory experts for risk and compliance teams everywhere. Please come to RegAlytics directly if you would like data on other sectors or countries!

US Regulatory Alerts - Financial Sector

RegAlytics

US Regulatory Alerts - Financial Sector

Introduction

The US Regulatory Alerts dataset by RegAlytics tracks changes from over 8,000 globally governing bodies. The data covers over 2.5 million alerts, starts from January 2020, and is delivered on a daily basis. This dataset is created by sourcing information from over 8,000 regulators and using proprietary technology to gather and structure the regulatory data. Once prepared, the data is thoroughly reviewed by RegAlytics' team of regulatory experts and delivered each morning by 8AM for industry use.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the US Regulatory Alerts - Financial Sector dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

RegAlytics was founded by Mary Kopczynski, Aaron Heisler, Alexander Appugliese, and Werner Pauliks in 2019 with the goal of significantly reducing the time and cost required to mitigate regulatory risk. RegAlytics provides access to accurate and clean regulatory data from all global regulators in all sectors that is enriched by regulatory experts for risk and compliance teams everywhere. Please come to RegAlytics directly if you would like data on other sectors or countries!

Getting Started

The following snippet demonstrates how to request data from the US Regulatory Alerts - Financial Sector dataset:

```C#
_datasetSymbol = AddData<RegalyticsRegulatoryArticles>("REG").Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2020
Coverage	2,500,000 Alerts
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add US Regulatory Alerts data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can

access the data later in your algorithm.

```
C#
public class RegalyticsDataAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        _datasetSymbol = AddData<RegalyticsRegulatoryArticles>("REG").Symbol;
    }
}
```

Accessing Data

To get the current US Regulatory Alerts data, index the current `Slice` with the dataset `Symbol` . `Slice` objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoints = slice[_datasetSymbol];
        foreach (var dataPoint in dataPoints)
        {
            Log($"{_datasetSymbol} title at {slice.Time}: {dataPoint.Title}");
        }
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    var data = slice.Get<RegalyticsRegulatoryArticles>();
    if (!data.IsNullOrEmpty())
    {
        foreach (var articles in data.Values)
        {
            Log($"{Time} {articles.ToString()}");
            foreach (RegalyticsRegulatoryArticle article in articles)
            {
                Log($"{_datasetSymbol} article title at {slice.Time}: {article.Title}");
            }
        }
    }
}
```

Historical Data

To get historical US Regulatory Alerts data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<RegalyticsRegulatoryArticles>(_datasetSymbol, 100, Resolution.Daily);
```

Remove Subscriptions

To remove your subscription to US Regulatory Alerts data, call the `RemoveSecurity` method.

```
RemoveSecurity(_datasetSymbol);
```

Example Applications

This regulatory dataset enables you to accurately design strategies while mitigating regulatory risk. Examples include the following strategies:

- Temporarily increasing/decreasing exposure to securities when new regulations are announced
- Parsing the content of regulatory announcements to determine market or sector impact
- Country rotation based on regulatory alert sentiment

Classic Algorithm Example

The following example algorithm sells short 100% SPY if any predetermined negative sentimental phrase was present in any of the previous day's regulatory articles. Otherwise, it buys and hold 100% SPY.

```
public class RegalyticsDataAlgorithm : QCAlgorithm
{
    // Pre-defined list of negative sentiment phrases as indicator for short selling, since these words will decrease
confident in equity performance
    private readonly string[] _negativeSentimentPhrases = new [] {"emergency rule", "proposed rule change",
"development of rulemaking"};
    private Symbol _symbol, _regalyticsSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        _symbol = AddEquity("SPY", extendedMarketHours: true).Symbol;

        // Requesting data to receive updated regulatory news for timely short selling
        _regalyticsSymbol = AddData<RegalyticsRegulatoryArticles>("REG").Symbol;

        // Historical data for past articles
        var history = History<RegalyticsRegulatoryArticles>(_regalyticsSymbol, 7, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        // Only trade on regulatory news data
        var data = slice.Get<RegalyticsRegulatoryArticles>();
        if (data.IsNullOrEmpty())
        {
            return;
        }
        // If any of the negative phrases appeared in regulatory news, we expect a market drop for the day
        var detectedNegativity = false;
        foreach (var articles in data.Values)
        {
            if (detectedNegativity) break;
            detectedNegativity = _negativeSentimentPhrases
                .Any(p => articles.Any(x => ((RegalyticsRegulatoryArticle) x).Title.ToLower().Contains(p)));
        }
        Transactions.CancelOpenOrders();
        var quantity = CalculateOrderQuantity(_symbol, detectedNegativity ? -1d : 1d);
        if (quantity == 0) return;
        MarketOrder(_symbol, quantity);
    }
}
```

Framework Algorithm Example

The following example algorithm buys and holds the S&P 500 ETF, SPY. To reduce regulatory risk, it liquidates your holdings for 2 days following regulatory announcements regarding new rules.

C#

```
public class RegalyticsDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        UniverseSettings.Resolution = Resolution.Daily;
        //  Trade SPY as the proxy of the whole equity market movement on the regulatory news
        AddUniverseSelection(
            new ManualUniverseSelectionModel(
                QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)
        ));

        AddAlpha(new RegAnalyticsAlphaModel(this));

        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(time => null));

        AddRiskManagement(new NullRiskManagementModel());

        SetExecution(new ImmediateExecutionModel());
    }

    public class RegAnalyticsAlphaModel : AlphaModel
    {
        private List<Symbol> _symbols = new List<Symbol>();
        private Symbol _regalyticsSymbol;
        private DateTime _lastNewsDate = DateTime.MinValue;
        private InsightDirection _targetDirection = InsightDirection.Up;
        // Pre-defined list of negative sentiment phrases as indicator for short selling, since these words will
decrease confident in equity performance
        private string[] _negativeSentimentPhrases = new string[] {"emergency rule", "proposed rule change",
"development of rulemaking"};
        // Assuming the negative impact of the regulatory news will last for 2 days
        private TimeSpan _newsAffectDuration = TimeSpan.FromDays(2);

        public RegAnalyticsAlphaModel(QCAlgorithm algorithm)
        {
            // Requesting data to receive updated regulatory news for timely short selling
            _regalyticsSymbol = algorithm.AddData<RegalyticsRegulatoryArticles>("REG").Symbol;

            // Historical data for past articles
            var history = algorithm.History<RegalyticsRegulatoryArticles>(_regalyticsSymbol, 14, Resolution.Daily);
            algorithm.Debug($"We got {history.Count()} items from our history request");
        }

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            // Only trade on regulatory news data
            if (slice.ContainsKey(_regalyticsSymbol) && slice[_regalyticsSymbol] != null)
            {
                var articles = slice[_regalyticsSymbol];
                foreach (RegalyticsRegulatoryArticle article in articles)
                {
                    var title = article.Title.ToLower();
                    // If any of the negative phrases appeared in regulatory news, we expect a market drop for the
day
                    // Signal an exit from the market when regulatory articles with negative sentiment are released
                    if (_negativeSentimentPhrases.Any(x => title.Contains(x)))
                    {
                        _targetDirection = InsightDirection.Flat;
                        _lastNewsDate = slice.Time;
                    }
                }
            }

            // Signal an entry if we've waited long enough for the market to digest the negative news
            if (_lastNewsDate + _newsAffectDuration < slice.Time)
            {
                _targetDirection = InsightDirection.Up;
```

```
                _targetDirection = InsightDirection.Up;
            }

            foreach (var symbol in _symbols)
            {
                // Ensure we have security data in the current Slice to avoid stale fill
                if (!(slice.ContainsKey(symbol) && slice[symbol] != null))
                {
                    continue;
                }

                if (_targetDirection == InsightDirection.Up && !algorithm.Portfolio[symbol].Invested)
                {
                    insights.Add(Insight.Price(symbol, TimeSpan.FromDays(90), InsightDirection.Up));
                }
                else if (_targetDirection == InsightDirection.Flat && algorithm.Portfolio[symbol].Invested)
                {
                    insights.Add(Insight.Price(symbol, _newsAffectDuration, InsightDirection.Flat));
                }
            }
            return insights;
        }

        public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
        {
            foreach (var security in changes.AddedSecurities)
            {
                _symbols.Add(security.Symbol);
            }

            foreach (var security in changes.RemovedSecurities)
            {
                _symbols.Remove(security.Symbol);
            }
        }
    }
}
```

Data Point Attributes

The US Regulatory Alerts dataset provides `RegalyticsRegulatoryArticle` and `RegalyticsRegulatoryArticles` objects.

RegalyticsRegulatoryArticle

`RegalyticsRegulatoryArticle` objects have the following attributes:

RegalyticsRegulatoryArticles

`RegalyticsRegulatoryArticles` objects have the following attributes:

Datasets

Securities and Exchange Commission

The mission of the U.S. Securities and Exchange Commission is to protect investors, maintain fair, orderly, and efficient markets, and facilitate capital formation. The SEC oversees the key participants in the securities world, including securities exchanges, securities brokers and dealers, investment advisors, and mutual funds. The SEC is concerned primarily with promoting the disclosure of important market-related information, maintaining fair dealing, and protecting against fraud.

US SEC Filings

Securities and Exchange Commission

US SEC Filings

Introduction

The US SEC Filings dataset provides the quarterly financial earning reports that the United States Securities and Exchange Commission (SEC) requires from publicly traded companies in the US. The data covers 15,000 US Equities, starts in January 1998, and is delivered on a daily frequency. The data is sourced from the SEC's Electronic Data Gathering, Analysis, and Retrieval (EDGAR) system. QuantConnect downloads and formats the Quarterly Financial Reports (10-Q) and Annual Financial Report (8-K) filings of companies into a format for easy consumption by LEAN.

For more information about the US SEC Filings dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The mission of the U.S. Securities and Exchange Commission is to protect investors, maintain fair, orderly, and efficient markets, and facilitate capital formation. The SEC oversees the key participants in the securities world, including securities exchanges, securities brokers and dealers, investment advisors, and mutual funds. The SEC is concerned primarily with promoting the disclosure of important market-related information, maintaining fair dealing, and protecting against fraud.

Getting Started

The following snippet demonstrates how to request data from the US SEC Filings dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
_report8KSymbol = AddData<SECReport8K>(_symbol, Resolution.Daily).Symbol;
_report10KSymbol = AddData<SECReport10K>(_symbol, Resolution.Daily).Symbol;
_report10QSymbol = AddData<SECReport10Q>(_symbol, Resolution.Daily).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1998
Asset Coverage	15,000 US Equities
Data Density	Sparse
Resolution	Daily
Timezone	UTC

Requesting Data

To add US SEC Filings data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class SECReportAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _report8KSymbol, _report10KSymbol, _report10QSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2019, 8, 21);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        _report8KSymbol = AddData<SECReport8K>(_symbol, Resolution.Daily).Symbol;
        _report10KSymbol = AddData<SECReport10K>(_symbol, Resolution.Daily).Symbol;
        _report10QSymbol = AddData<SECReport10Q>(_symbol, Resolution.Daily).Symbol;
    }
}
```

Accessing Data

To get the current US SEC Filings data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_report8KSymbol))
    {
        var dataPoint = slice[_report8KSymbol];
        Log($"{_report8KSymbol} report count at {slice.Time}: {data_point.Report.Documents.Count}");
    }

    if (slice.ContainsKey(_report10KSymbol))
    {
        var dataPoint = slice[_report10KSymbol];
        Log($"{_report10KSymbol} report count at {slice.Time}: {data_point.Report.Documents.Count}");
    }

    if (slice.ContainsKey(_report10QSymbol))
    {
        var dataPoint = slice[_report10QSymbol];
        Log($"{_report10QSymbol} report count at {slice.Time}: {data_point.Report.Documents.Count}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<SECReport8K>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} report count at {slice.Time}: {dataPoint.Report.Documents.Count}");
    }

    foreach (var kvp in slice.Get<SECReport10K>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} report count at {slice.Time}: {dataPoint.Report.Documents.Count}");
    }

    foreach (var kvp in slice.Get<SECReport10Q>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} report count at {slice.Time}: {dataPoint.Report.Documents.Count}");
    }
}
```

Historical Data

To get historical US SEC Filings data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
// Dataset objects
var report8KHistory = History<SECReport8K>(_report8KSymbol, 100, Resolution.Daily);
var report10KHistory = History<SECReport10K>(_report10KSymbol, 100, Resolution.Daily);
var report10QHistory = History<SECReport10Q>(_report10QSymbol, 100, Resolution.Daily);

// Slice objects
var history = History(new[] {_report8KSymbol, _report10KSymbol, _report10QSymbol}, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_report8KSymbol);
RemoveSecurity(_report10KSymbol);
RemoveSecurity(_report10QSymbol);
```

If you subscribe to US SEC Filings data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The US SEC Filings dataset enables you to create strategies using information from SEC reports. Examples include the following strategies:

- Extracting information about corporate earnings from the documents for further analysis
- Applying sentiment analysis to the text content of the documents (for example, keyword scoring and ranking)

Classic Algorithm Example

The following example algorithm creates a dynamic universe of the 10 most liquid US Equities. It then buys the securities that have an 8K report with more than 20,000 characters and forms an equal-weighted portfolio. Instead of trading based on how long the report is, you could use sentiment analysis by scoring keywords.

```C#
public class SECReport8KAlgorithm : QCAlgorithm
{
    private Dictionary<Symbol, Symbol> _datasetSymbolBySymbol = new Dictionary<Symbol, Symbol>();
    private List<Symbol> _longSymbols = new List<Symbol>();
    private bool _rebalance = false;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        UniverseSettings.Resolution = Resolution.Daily;
        AddUniverse(CoarseSelector);

        // Request underlying equity data.
        var ibm = AddEquity("IBM", Resolution.Daily).Symbol;
        // Add SEC report 10-Q data for the underlying IBM asset for trade signal generation
        var earningsFiling = AddData<SECReport10Q>(ibm, Resolution.Daily).Symbol;
        // Request 120 days of history with the SECReport10Q IBM custom data Symbol.
        var history = History<SECReport10Q>(earningsFiling, 120, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public IEnumerable<Symbol> CoarseSelector(IEnumerable<CoarseFundamental> coarse)
    {
        // Select the top 10 traded companies with fundamental data, since the market activities can better reflect
the fundamental factor efficiently
        return coarse.Where(x => x.HasFundamentalData)
            .OrderByDescending(x => x.DollarVolume)
            .Take(10).Select(x => x.Symbol);
    }

    public override void OnData(Slice slice)
    {
        // Trade from SEC data
        foreach (var report in slice.Get<SECReport8K>().Values)
        {
            var underlyingSymbol = report.Symbol.Underlying;
            // Skip the Symbol if it's no longer in the universe (insuffucient popularity to reach market efficiency
of fundamental factor)
            if (!_datasetSymbolBySymbol.ContainsKey(underlyingSymbol))
            {
                if (_longSymbols.Contains(underlyingSymbol))
                {
                    _rebalance = true;
                    _longSymbols.Remove(underlyingSymbol);
                }
                continue;
            }

            // Long the stocks with SEC report over 20000 text length, suggesting excessive insights or future
projections are highlighted
            var reportTextLength = report.Report.Documents.Select(x => x.Text.Length).Sum();
            if (reportTextLength > 20000)
            {
                if (!_longSymbols.Contains(underlyingSymbol))
                {
                    _rebalance = true;
                    _longSymbols.Add(underlyingSymbol);
                }
            }
            else if (_longSymbols.Contains(underlyingSymbol))
            {
                _rebalance = true;
                _longSymbols.Remove(underlyingSymbol);
            }
        }

        if (!_rebalance)
        {
            return;
```

```
        }
        _rebalance = false;

        // Invest equally to evenly dissipate the capital concentration risk
        var portfolioTargets = new List<PortfolioTarget>();
        var equalWeighting = _longSymbols.Count > 0 ? 1.0m / _longSymbols.Count : 0m;
        foreach (var kvp in Portfolio)
        {
            var symbol = kvp.Key;
            var securityHolding = kvp.Value;
            var weight = 0m;
            if (_longSymbols.Contains(symbol))
            {
                weight = equalWeighting;
            }
            else if (!securityHolding.Invested)
            {
                continue;
            }
            portfolioTargets.Add(new PortfolioTarget(symbol, weight));
        }
        SetHoldings(portfolioTargets);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            // If added to universe, adds SECReport8K for trade signal generation
            _datasetSymbolBySymbol[security.Symbol] = AddData<SECReport8K>(security.Symbol).Symbol;
        }

        foreach (var security in changes.RemovedSecurities)
        {
            Symbol reportSymbol;
            if (_datasetSymbolBySymbol.TryGetValue(security.Symbol, out reportSymbol))
            {
                // Remove SEC data subscription to release computation resources
                RemoveSecurity(reportSymbol);
                _datasetSymbolBySymbol.Remove(security.Symbol);
            }
        }
    }
}
```

Framework Algorithm Example

The following example algorithm creates a dynamic universe of the 10 most liquid US Equities. It then buys the securities that have an 8K report with more than 20,000 characters and forms an equal-weighted portfolio. Instead of trading based on how long the report is, you could use sentiment analysis by scoring keywords.

C#

```
public class SECReport8KAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        // Seed the price of each asset with its last known price to avoid trading errors.
        Settings.SeedInitialPrices = true;
        UniverseSettings.Resolution = Resolution.Daily;
        // Filter for the most liquid stocks for trading due to high market activities for efficient pricing from
fundamental factor
        AddUniverseSelection(new MostLiquidFundamentalUniverseSelectionModel());
        // Custom alpha model that generates insights from SEC data
        AddAlpha(new SECReport8KAlphaModel());
        // Invest equally to evenly dissipate the capital concentration risk
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel(time => null));
    }
}

class MostLiquidFundamentalUniverseSelectionModel : FundamentalUniverseSelectionModel
{
    public override IEnumerable<Symbol> Select(QCAlgorithm algorithm, IEnumerable<Fundamental> fundamental)
    {
```

```
        {
            // Select the top 10 traded companies with fundamental data, since the market activities can better reflect
the fundamental factor efficiently
            return fundamental
                .OrderByDescending(f => f.DollarVolume)
                .Take(10)
                .Select(f => f.Symbol);
        }
    }

    public class SECReport8KAlphaModel : AlphaModel
    {
        private readonly Dictionary<Symbol, Symbol> _datasetSymbolBySymbol = [];

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            // Trade only based on SEC data
            foreach (var report in slice.Get<SECReport8K>().Values)
            {
                var underlyingSymbol = report.Symbol.Underlying;
                if (!_datasetSymbolBySymbol.ContainsKey(underlyingSymbol))
                {
                    continue;
                }

                // Long the stocks with SEC report over 20000 text length, suggesting excessive insights or future
projections are highlighted
                var reportTextLength = report.Report.Documents.Select(x => x.Text.Length).Sum();
                InsightDirection direction;
                if (reportTextLength > 20000)
                {
                    direction = InsightDirection.Up;
                }
                else if (algorithm.Portfolio[underlyingSymbol].Invested)
                {
                    direction = InsightDirection.Flat;
                }
                else
                {
                    continue;
                }
                insights.Add(Insight.Price(underlyingSymbol, TimeSpan.FromDays(30), direction));
            }

            return insights;
        }

        public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
        {
            foreach (var symbol in changes.AddedSecurities.Select(x => x.Symbol))
            {
                // If added to universe, adds SECReport8K for trade signal generation
                _datasetSymbolBySymbol[symbol] = algorithm.AddData<SECReport8K>(symbol).Symbol;
            }

            foreach (var symbol in changes.RemovedSecurities.Select(x => x.Symbol))
            {
                // Remove SEC data subscription to release computation resources
                if (_datasetSymbolBySymbol.TryGetValue(symbol, out Symbol reportSymbol))
                {
                    algorithm.RemoveSecurity(reportSymbol);
                    _datasetSymbolBySymbol.Remove(symbol);
                }
            }
        }
    }
```

Data Point Attributes

The US SEC Filings dataset provides `SECReport8K` , `SECReport10K` , and `SECReport10Q` objects.

Report 8K Attributes

`SECReport8K` objects have the following attributes:

Report 10K Attributes

`SECReport10K` objects have the following attributes:

Report 10Q Attributes

`SECReport10Q` objects have the following attributes:

Datasets

Smart Insider

Smart Insider was founded by Michael Tindale in 2016 with the goal of forming the most progressive insider data vendor in the field. Smart Insider provides access to buyback intention and transactions for quantitative researchers. In addition to their Corporate Buybacks dataset, Smart Insider provides data on stock trades made by US politicians and thousands of high net worth individuals around the globe.

Corporate Buybacks

Smart Insider

Corporate Buybacks

Introduction

The Corporate Buybacks dataset by Smart Insider tracks US Equities share buyback programs. The data covers 3,000 US Equities, starts in May 2015, and is delivered on a second frequency. This dataset is created by analyzing daily buyback announcements and by using secondary data sources to ensure records are accurate and complete.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Corporate Buybacks dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Smart Insider was founded by Michael Tindale in 2016 with the goal of forming the most progressive insider data vendor in the field. Smart Insider provides access to buyback intention and transactions for quantitative researchers. In addition to their Corporate Buybacks dataset, Smart Insider provides data on stock trades made by US politicians and thousands of high net worth individuals around the globe.

Getting Started

The following snippet demonstrates how to request data from the Corporate Buybacks dataset:

```C#
_symbol = AddEquity("AAPL", Resolution.Minute).Symbol;
_intentionSymbol = AddData<SmartInsiderIntention>(_symbol).Symbol;
_transactionSymbol = AddData<SmartInsiderTransaction>(_symbol).Symbol;

_intentionUniverse = AddUniverse<SmartInsiderIntentionUniverse>(IntentionSelection);
_transactionUniverse = AddUniverse<SmartInsiderTransactionUniverse>(TransactionSelection);
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	May 2015
Asset Coverage	3,000 US Equities
Data Density	Sparse
Resolution	Second
Timezone	New York

Requesting Data

To add Corporate Buybacks data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can

access the data later in your algorithm.

```
C#
public class CorporateBuybacksDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _intentionSymbol, _transactionSymbol;

    public override void Initialize()
    {
        SetStartDate(2016, 1, 1);
        SetEndDate(2021, 1, 1);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Minute).Symbol;
        _intentionSymbol = AddData<SmartInsiderIntention>(_symbol).Symbol;
        _transactionSymbol = AddData<SmartInsiderTransaction>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Corporate Buybacks data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_intentionSymbol))
    {
        var dataPoint = slice[_intentionSymbol];
        Log($"{_intentionSymbol} intention amount at {slice.Time}: {dataPoint.Amount}");
    }

    if (slice.ContainsKey(_transactionSymbol))
    {
        var dataPoint = slice[_transactionSymbol];
        Log($"{_transactionSymbol} transaction amount at {slice.Time}: {dataPoint.Amount}");
    }
}
```

To iterate through all of the dataset objects in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<SmartInsiderIntention>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} intention amount at {slice.Time}: {dataPoint.Amount}");
    }

    foreach (var kvp in slice.Get<SmartInsiderTransaction>())
    {
        var datasetSymbol = kvp.Key;
        var dataPoint = kvp.Value;
        Log($"{datasetSymbol} transaction amount at {slice.Time}: {dataPoint.Amount}");
    }
}
```

Historical Data

To get historical Corporate Buybacks data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
// Dataset objects
var intentionHistory = History<SmartInsiderIntention>(_intentionSymbol, 100, Resolution.Daily);
var transactionHistory = History<SmartInsiderTransaction>(_transactionSymbol, 100, Resolution.Daily);

// Slice objects
var history = History(new[] {_intentionSymbol, _transactionSymbol}, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Universe Selection

To select a dynamic universe of US Equities based on Corporate Buybacks data, call the `AddUniverse` method with the `SmartInsiderIntentionUniverse` class or the `SmartInsiderTransactionUniverse` and a selection function.

```
private Universe _intentionUniverse;
private Universe _transactionUniverse;
public override void Initialize()
{
    _intentionUniverse = AddUniverse<SmartInsiderIntentionUniverse>(altCoarse =>
    {
        return from d in altCoarse.OfType<SmartInsiderIntentionUniverse>()
            where d.Percentage > 0.005m && d.USDMarketCap > 100000000m
            select d.Symbol;
    });
    _transactionUniverse = AddUniverse<SmartInsiderTransactionUniverse>(altCoarse =>
    {
        return from d in altCoarse.OfType<SmartInsiderTransactionUniverse>()
            where d.BuybackPercentage > 0.005m && d.USDMarketCap > 100000000m
            select d.Symbol;
    });
}
```

For more information about dynamic universes, see Universes .

Universe History

You can get historical universe data in an algorithm and in the Research Environment.

Historical Universe Data in Algorithms

To get historical universe data in an algorithm, call the `History` method with the `Universe` object and the lookback period. If there is no data in the period you request, the history result is empty.

```
var intentionUniverseHistory = History(_intentionUniverse, 30, Resolution.Daily);
foreach (var intentions in intentionUniverseHistory)
{
    foreach (SmartInsiderIntentionUniverse intention in intentions)
    {
        Log($"{intention.Symbol.Value} amount at {intention.EndTime}: {intention.AmountValue}");
    }
}

var transactionUniverseHistory = History(_transactionUniverse, 30, Resolution.Daily);
foreach (var transactions in transactionHistory)
{
    foreach (SmartInsiderTransactionUniverse transaction in transactions)
    {
        Log($"{transaction.Symbol.Value} amount at {transaction.EndTime}: {transaction.Amount}");
    }
}
```

Historical Universe Data in Research

To get historical universe data in research, call the `UniverseHistory` method with the `Universe` object, a start date, and an end date. This method returns the filtered universe. If there is no data in the period you request, the history result is empty.

```C#
var intentionUniverseHistory = qb.UniverseHistory(intentionUniverse, qb.Time.AddDays(-30), qb.Time);
foreach (var intentions in intentionUniverseHistory)
{
    foreach (SmartInsiderIntentionUniverse intention in intentions)
    {
        Console.WriteLine($"{intention.Symbol.Value} amount at {intention.EndTime}: {intention.AmountValue}");
    }
}

var transactionUniverseHistory = qb.UniverseHistory(transactionUniverse, qb.Time.AddDays(-30), qb.Time);
foreach (var transactions in transactionHistory)
{
    foreach (SmartInsiderTransactionUniverse transaction in transactions)
    {
        Console.WriteLine($"{transaction.Symbol.Value} amount at {transaction.EndTime}: {transaction.Amount}");
    }
}
```

You can call the `History` method in Research.

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_intentionSymbol);
RemoveSecurity(_transactionSymbol);
```

If you subscribe to Corporate Buybacks data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Corporate Buybacks dataset enables you to design strategies using information on company buyback programs. Examples include the following strategies:

- Buying securities when the company announces an upcoming share buyback on the premise that the reduction in supply (shares outstanding) will drive up the remaining shares' price
- Buying securities when the company executes an upcoming share buyback on the premise that the reduction in supply (shares outstanding) will drive up the remaining shares' price

Classic Algorithm Example

The following example algorithm buys Apple stock when there is a buyback intention or transaction and then it sells the stock 3 days later:

```C#
public class CorporateBuybacksDataAlgorithm : QCAlgorithm
{
    private Symbol _aapl;
    private Symbol _smartInsiderIntention;
    private Symbol _smartInsiderTransaction;
    private DateTime _entryTime;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _aapl = AddEquity("AAPL", Resolution.Minute).Symbol;

        // Requesting insider trade intention news and actual trades to estimate the return, since insiders may have
better information of the future confidence
        _smartInsiderIntention = AddData<SmartInsiderIntention>(_aapl).Symbol;
        _smartInsiderTransaction = AddData<SmartInsiderTransaction>(_aapl).Symbol;

        // Historical data
        var intentionHistory = History<SmartInsiderIntention>(_smartInsiderIntention, 365, Resolution.Daily);
        Debug($"We got {intentionHistory.Count()} items from our history request for intentions");

        var transactionHistory = History<SmartInsiderTransaction>(_smartInsiderTransaction, 365, Resolution.Daily);
        Debug($"We got {transactionHistory.Count()} items from our history request for transactions");
    }

    public override void OnData(Slice slice)
    {
        // Buy Apple whenever we receive a buyback intention or transaction notification, given the insiders may have
confidence in the future to buy more
        // This news may stimulate market popularity
        if (slice.ContainsKey(_smartInsiderIntention) || slice.ContainsKey(_smartInsiderTransaction))
        {
            SetHoldings(_aapl, 1);
            _entryTime = Time;
        }

        // Liquidate holdings 3 days after the latest entry
        // The market popularity and possible overbrought is cooled
        if (Portfolio.Invested && Time >= _entryTime + TimeSpan.FromDays(3))
        {
            Liquidate();
        }
    }
}
```

Framework Algorithm Example

The following example algorithm buys Apple stock when there is a buyback intention or transaction and then it sells the stock 3 days later:

```C#
public class CorporateBuybacksDataAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Only interest in AAPL's insider trades information
        var symbols = new[] {QuantConnect.Symbol.Create("AAPL", SecurityType.Equity, Market.USA)};
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        AddAlpha(new CorporateBuybacksAlphaModel());
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    public class CorporateBuybacksAlphaModel : AlphaModel
    {
        private Symbol _aapl;
        private Symbol _smartInsiderIntention;
        private Symbol _smartInsiderTransaction;

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            // Buy Apple whenever we receive a buyback intention or transaction notification, given the insiders may
have confidence in the future to buy more
            // This news may stimulate market popularity, so we hold for 3 days
            if (slice.ContainsKey(_smartInsiderIntention) || slice.ContainsKey(_smartInsiderTransaction))
            {
                insights.Add(Insight.Price(_aapl, TimeSpan.FromDays(3),  InsightDirection.Up));
            }
            return insights;
        }

        public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
        {
            foreach (var security in changes.AddedSecurities)
            {
                _aapl = security.Symbol;

                // Requesting insider trade intention news and actual trades to estimate the return, since insiders
may have better information of the future confidence
                _smartInsiderIntention = algorithm.AddData<SmartInsiderIntention>(_aapl).Symbol;
                _smartInsiderTransaction = algorithm.AddData<SmartInsiderTransaction>(_aapl).Symbol;

                // Historical data
                var intentionHistory = algorithm.History<SmartInsiderIntention>(_smartInsiderIntention, 365,
Resolution.Daily);
                algorithm.Debug($"We got {intentionHistory.Count()} items from our history request for intentions");

                var transactionHistory = algorithm.History<SmartInsiderTransaction>(_smartInsiderTransaction, 365,
Resolution.Daily);
                algorithm.Debug($"We got {transactionHistory.Count()} items from our history request for
transactions");
            }
        }
    }
}
```

Research Example

The following example lists US Equities with the highest buyback amount.

C#

```
#r "../QuantConnect.DataSource.SmartInsiderIntentionsTransactions.dll"
using QuantConnect.DataSource;

var qb = new QuantBook();

// Requesting data
var symbol = qb.AddEquity("AAPL").Symbol;
var intentionSymbol = qb.AddData<SmartInsiderIntention>(symbol).Symbol;
var transactionSymbol = qb.AddData<SmartInsiderTransaction>(symbol).Symbol;

// Historical data for SmartInsiderIntention
var intentionHistory = qb.History<SmartInsiderIntention>(symbol, 300, Resolution.Daily);
foreach (SmartInsiderIntention intention in intentionHistory)
{
    Console.WriteLine($"{intention.NoteText} at {intention.EndTime}");
}

// Historical data for SmartInsiderTransaction
var transactionHistory = qb.History<SmartInsiderTransaction>(symbol, 300, Resolution.Daily);
foreach (SmartInsiderTransaction transaction in transactionHistory)
{
    Console.WriteLine($"{transaction.NoteText} at {transaction.EndTime}");
}

// Add Universe Selection for SmartInsiderIntention
IEnumerable<Symbol> IntentionSelection(IEnumerable<BaseData> altCoarse)
{
    return (from d in altCoarse.OfType<SmartInsiderIntentionUniverse>()
        where d.AmountValue.HasValue
        orderby d.AmountValue descending select d.Symbol).Take(10);
}
var intentionUniverse = qb.AddUniverse<SmartInsiderIntentionUniverse>(IntentionSelection);

// Historical Universe data
var intentionUniverseHistory = qb.UniverseHistory(intentionUniverse, qb.Time.AddDays(-10), qb.Time);
foreach (var intentions in intentionUniverseHistory)
{
    foreach (SmartInsiderIntentionUniverse intention in intentions)
    {
        Console.WriteLine($"{intention.Symbol.Value} amount at {intention.EndTime}: {intention.AmountValue}");
    }
}

// Add Universe Selection for SmartInsiderTransaction
IEnumerable<Symbol> TransactionSelection(IEnumerable<BaseData> altCoarse)
{
    return (from d in altCoarse.OfType<SmartInsiderTransactionUniverse>()
        where d.Amount.HasValue
        orderby d.Amount descending select d.Symbol).Take(10);
}
var transactionUniverse = qb.AddUniverse<SmartInsiderTransactionUniverse>(TransactionSelection);

// Historical Universe data
var transactionHistory = qb.UniverseHistory(transactionUniverse, qb.Time.AddDays(-10), qb.Time);
foreach (var transactions in transactionHistory)
{
    foreach (SmartInsiderTransactionUniverse transaction in transactions)
    {
        Console.WriteLine($"{transaction.Symbol.Value} amount at {transaction.EndTime}: {transaction.Amount}");
    }
}
```

Data Point Attributes

The Corporate Buybacks dataset provides `SmartInsiderIntention`, `SmartInsiderIntentionUniverse`, `SmartInsiderTransaction`, and `SmartInsiderTransactionUniverse` objects.

SmartInsiderIntention Attributes

`SmartInsiderIntention` objects have the following attributes:

Datasets

Tiingo

Tiingo was founded by Rishi Singh in 2014. Tiingo goes beyond traditional news sources and focuses on finding rich, quality content written by knowledgeable writers. Their proprietary algorithms scan unstructured, non-traditional news and other information sources while tagging companies, topics, and assets. This refined system is backed by over ten years of research and development, and is written by former institutional quant traders. Because of this dedicated approach, Tiingo's News API is a trusted tool used by quant funds, hedge funds, pension funds, social media companies, and tech companies around the world.

Tiingo News Feed

Tiingo

Tiingo News Feed

Introduction

The Tiingo News Feed dataset by Tiingo tracks US Equity news releases. The data covers 10,000 US Equities, starts in January 2014, and is delivered on a second frequency. This dataset is creating by Tiingo integrating over 120 different news providers into their platform.

This dataset depends on the US Equity Security Master dataset because the US Equity Security Master dataset contains information on splits, dividends, and symbol changes.

For more information about the Tiingo News Feed dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

Tiingo was founded by Rishi Singh in 2014. Tiingo goes beyond traditional news sources and focuses on finding rich, quality content written by knowledgeable writers. Their proprietary algorithms scan unstructured, non-traditional news and other information sources while tagging companies, topics, and assets. This refined system is backed by over ten years of research and development, and is written by former institutional quant traders. Because of this dedicated approach, Tiingo's News API is a trusted tool used by quant funds, hedge funds, pension funds, social media companies, and tech companies around the world.

Getting Started

The following snippet demonstrates how to request data from the Tiingo News Feed dataset:

```C#
_aapl = AddEquity("AAPL", Resolution.Minute).Symbol;
_datasetSymbol = AddData<TiingoNews>(_aapl).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 2014
Asset Coverage	10,000 US Equities
Data Density	Sparse
Resolution	Second
Timezone	UTC

Requesting Data

To add Tiingo News Feed data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```
C#
public class TiingoNewsDataAlgorithm : QCAlgorithm
{
    private Symbol _symbol, _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2021, 1, 1);
        SetEndDate(2021, 6, 1);
        SetCash(100000);

        _symbol = AddEquity("AAPL", Resolution.Minute).Symbol;
        _datasetSymbol = AddData<TiingoNews>(_symbol).Symbol;
    }
}
```

Accessing Data

To get the current Tiingo News Feed data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```
C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var article = slice[_datasetSymbol];
        Log($"{_datasetSymbol} article description at {slice.Time}: {article.Description}");
    }
}
```

To iterate through all of the articles in the current `Slice` , call the `Get` method.

```
C#
public override void OnData(Slice slice)
{
    foreach (var kvp in slice.Get<TiingoNews>())
    {
        var datasetSymbol = kvp.Key;
        var article = kvp.Value;
        Log($"{datasetSymbol} article description at {slice.Time}: {article.Description}");
    }
}
```

Historical Data

To get historical Tiingo News Feed data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```
C#
var history = History<TiingoNews>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove a subscription, call the `RemoveSecurity` method.

```
C#
RemoveSecurity(_datasetSymbol);
```

If you subscribe to Tiingo News Feed data for assets in a dynamic universe, remove the dataset subscription when the asset leaves your universe. To view a common design pattern, see Track Security Changes .

Example Applications

The Tiingo News Feed enables you to accurately design strategies harnessing news articles on the companies you're trading. Examples include the following strategies:

- Creating a dictionary of sentiment scores for various words and assigning a sentiment score to the content of each news release
- Calculating the sentiment of news releases with Natural Language Processing (NLP)
- Trading securities when their news releases are tagged by Tiingo with current buzzwords
- Detecting impactful news in ETF constituents

Classic Algorithm Example

The following example algorithm assigns a sentiment score to each news article that's released for Apple. When the sentiment score is positive, the algorithm buys Apple stock. When the sentiment score is negative, it short sells Apple stock.

```C#
public class TiingoNewsDataAlgorithm : QCAlgorithm
{
    private Symbol _aapl;
    private Symbol _tiingoSymbol;
    private int _currentHoldings = 0;
    private int _targetHoldings = 0;
    // Custom word-score map to assign score for each word in article
    private Dictionary<string, int> _wordScores = new Dictionary<string, int>(){
        {"good", 1}, {"great", 1}, {"best", 1}, {"growth", 1},
        {"bad", -1}, {"terrible", -1}, {"worst", -1}, {"loss", -1}
    };

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Requesting Tiingo news data to obtain the updated news articles to calculate the sentiment score
        _aapl = AddEquity("AAPL", Resolution.Minute).Symbol;
        _tiingoSymbol = AddData<TiingoNews>(_aapl).Symbol;

        // Historical data
        var history = History<TiingoNews>(_tiingoSymbol, 14, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        if (slice.ContainsKey(_tiingoSymbol))
        {
            // Assign a sentiment score to the news article
            var titleWords = slice[_tiingoSymbol].Description.ToLower();
            var score = 0;
            foreach (KeyValuePair<string, int> entry in _wordScores)
            {
                if (titleWords.Contains(entry.Key))
                {
                    score += entry.Value;
                }
            }

            // Buy if aggregated sentiment score shows positive sentiment, sell vice versa
            if (score > 0)
            {
                _targetHoldings = 1;
            }
            else if (score < 0)
            {
                _targetHoldings = -1;
            }
        }

        // Buy or short sell if the sentiment has changed from our current holdings
        if (slice.ContainsKey(_aapl) && _currentHoldings != _targetHoldings)
        {
            SetHoldings(_aapl, _targetHoldings);
            _currentHoldings = _targetHoldings;
        }
    }
}
```

Framework Algorithm Example

The following example algorithm assigns a sentiment score to each news article that's released for Apple. When the sentiment score is positive, the algorithm buys Apple stock. When the sentiment score is negative, it short sells Apple stock. The algorithm holds positions for 14 days.

```C#
public class TiingoNewsDataAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
```

```
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var symbols = new[] {QuantConnect.Symbol.Create("AAPL", SecurityType.Equity, Market.USA)};
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        AddAlpha(new TiingoNewsAlphaModel());
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }

    public class TiingoNewsAlphaModel : AlphaModel
    {
        private Symbol _aapl;
        private Symbol _tiingoSymbol;
        private int _currentHoldings = 0;
        private int _targetHoldings = 0;
        // Custom word-score map to assign score for each word in article
        private Dictionary<string, int> _wordScores = new Dictionary<string, int>(){
            {"good", 1}, {"great", 1}, {"best", 1}, {"growth", 1},
            {"bad", -1}, {"terrible", -1}, {"worst", -1}, {"loss", -1}
        };

        public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
        {
            var insights = new List<Insight>();

            if (slice.ContainsKey(_tiingoSymbol))
            {
                // Assign a sentiment score to the news article by the word-score map
                var titleWords = slice[_tiingoSymbol].Description.ToLower();
                var score = 0;
                foreach (KeyValuePair<string, int> entry in _wordScores)
                {
                    if (titleWords.Contains(entry.Key))
                    {
                        score += entry.Value;
                    }
                }

                // Buy if aggregated sentiment score shows positive sentiment, sell vice versa
                if (score > 0)
                {
                    _targetHoldings = 1;
                }
                else if (score < 0)
                {
                    _targetHoldings = -1;
                }
            }

            // Buy or short sell if the sentiment has changed from our current holdings
            if (slice.ContainsKey(_aapl) && _currentHoldings != _targetHoldings)
            {
                _currentHoldings = _targetHoldings;
                var direction = _targetHoldings == 1 ? InsightDirection.Up : InsightDirection.Down;
                insights.Add(Insight.Price(_aapl, TimeSpan.FromDays(14), direction));
            }

            return insights;
        }

        public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
        {
            foreach (var security in changes.AddedSecurities)
            {
                _aapl = security.Symbol;

                // Requesting Tiingo news data to obtain the updated news articles to calculate the sentiment score
                _tiingoSymbol = algorithm.AddData<TiingoNews>(_aapl).Symbol;

                // Historical data
                var history = algorithm.History<TiingoNews>(_tiingoSymbol, 14, Resolution.Daily);
                algorithm.Debug($"We got {history.Count()} items from our history request");
            }
        }
    }
}
```

Data Point Attributes

The Tiingo News Feed dataset provides `TiingoNews` objects, which have the following attributes:

Datasets

Treasury Department

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

US Treasury Yield Curve

Treasury Department

US Treasury Yield Curve

Introduction

The US Treasury Yield Curve datasets tracks the yield curve rate from the US Department of the Treasury. The data starts in January 1990 and is delivered on a daily frequency. This dataset is calculated from composites of indicative, bid-side market quotations (not actual transactions) obtained by the Federal Reserve Bank of New York at or near 3:30 PM Eastern Time (ET) each trading day.

For more information about the US Treasury Yield Curve dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

The Treasury Department is the executive agency responsible for promoting economic prosperity and ensuring the financial security of the United States. The Department is responsible for a wide range of activities such as advising the President on economic and financial issues, encouraging sustainable economic growth, and fostering improved governance in financial institutions. The Department of the Treasury operates and maintains systems that are critical to the nation's financial infrastructure, such as the production of coin and currency, the disbursement of payments to the American public, revenue collection, and the borrowing of funds necessary to run the federal government.

Getting Started

The following snippet demonstrates how to request data from the US Treasury Yield Curve dataset:

```C#
_datasetSymbol = AddData<USTreasuryYieldCurveRate>("USTYCR").Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	January 1990
Coverage	1 Dataset
Data Density	Sparse
Resolution	Daily
Timezone	New York

Requesting Data

To add US Treasury Yield Curve data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```C#
public class USTreasuryYieldCurveDataAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2019, 1, 1);
        SetEndDate(2020, 6, 1);
        SetCash(100000);

        _datasetSymbol = AddData<USTreasuryYieldCurveRate>("USTYCR").Symbol;
    }
}
```

Accessing Data

To get the current US Treasury Yield Curve data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} one month value at {slice.Time}: {dataPoint.OneMonth}");
    }
}
```

Historical Data

To get historical US Treasury Yield Curve data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
var history = History<USTreasuryYieldCurveRate>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to US Treasury Yield Curve data, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The US Treasury Yield Curve dataset enables you to monitor the yields of bonds with numerous maturities in your strategies. Examples include the following strategies:

- Short selling SPY when the yield curve inverts
- Buying short-term Treasuries and short selling long-term Treasuries when the yield curve becomes steeper (aka curve steepener trade)

Classic Algorithm Example

The following example algorithm short sells SPY for two years when the yield curve inverts:

```C#
public class USTreasuryDataAlgorithm : QCAlgorithm
{
    private Symbol _spySymbol;
    private Symbol _yieldCurveSymbol;
    private DateTime _lastInversion = DateTime.MinValue;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Request SPY as the market representative for trading
        _spySymbol = AddEquity("SPY", Resolution.Hour).Symbol;

        // Requesting yield curve data for trade signal generation (inversion)
        _yieldCurveSymbol = AddData<USTreasuryYieldCurveRate>("USTYCR").Symbol;

        // Historical data
        var history = History<USTreasuryYieldCurveRate>(_yieldCurveSymbol, 60, Resolution.Daily);
        Debug($"We got {history.Count()} items from our history request");
    }

    public override void OnData(Slice slice)
    {
        // Trade only based on updated yield curve data
        if (!slice.TryGetValue(_yieldCurveSymbol, out var rates))
        {
            return;
        }

        // Only advance if a year has gone by, since the inversion signal indicates longer term market regime that
will not revert in a short period
        if (Time - _lastInversion < TimeSpan.FromDays(365))
        {
            return;
        }

        // Normally, 10y yield should be greater than 2y yield due to default risk accumulation
        // But if an inversion occurs, it means the market expects a recession in short term such that the near-
expiry bond is more likely to default
        // if there is a yield curve inversion after not having one for a year, short sell SPY for two years for the
expected down market
        if (!Portfolio.Invested && rates.TwoYear > rates.TenYear)
        {
            Debug($"{Time} - Yield curve inversion! Shorting the market for two years");
            SetHoldings(_spySymbol, -0.5);
                _lastInversion = Time;
            return;
        }

        // If two years have passed, liquidate our position in SPY assuming the market starts resilience
        if (Time - _lastInversion >= TimeSpan.FromDays(365 * 2))
        {
            Liquidate(_spySymbol);
        }
    }
}
```

Framework Algorithm Example

The following example algorithm short sells SPY for two years when the yield curve inverts:

C#

```
public class USTreasuryYieldCurveDataAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        UniverseSettings.Resolution = Resolution.Hour;
        // Universe only have SPY as the market representative for trading
        var symbols = new[] {QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)};
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // Custom alpha model that emit insight according to US Treasury data
        AddAlpha(new USTreasuryAlphaModel(this));
        // Use insight weighting PCM to limit the size of investment, reduce the fluctuation of the portfolio value
        SetPortfolioConstruction(new InsightWeightingPortfolioConstructionModel((time) => null));
    }
}

public class USTreasuryAlphaModel : AlphaModel
{
    private Symbol? _spySymbol = null;
    private Symbol _yieldCurveSymbol;
    private DateTime _lastInversion = DateTime.MinValue;

    public USTreasuryAlphaModel(QCAlgorithm algorithm)
    {
        // Requesting yield curve data for trade signal generation (inversion)
        _yieldCurveSymbol = algorithm.AddData<USTreasuryYieldCurveRate>("USTYCR").Symbol;

        // Historical data
        var history = algorithm.History<USTreasuryYieldCurveRate>(_yieldCurveSymbol, 60, Resolution.Daily);
        algorithm.Debug($"We got {history.Count()} items from our history request");
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        // Trade only based on updated yield curve data
        if (!slice.TryGetValue(_yieldCurveSymbol, out var rates) || _spySymbol == null)
        {
            return insights;
        }

        // Only advance if a year has gone by, since the inversion signal indicates longer term market regime that
will not revert in a short period
        if (slice.Time - _lastInversion < TimeSpan.FromDays(365))
        {
            return insights;
        }

        // Normally, 10y yield should be greater than 2y yield due to default risk accumulation
        // But if an inversion occurs, it means the market expects a recession in short term such that the near-
expiry bond is more likely to default
        // if there is a yield curve inversion after not having one for a year, short sell SPY for two years for the
expected down market
        if (!algorithm.Portfolio.Invested && rates.TwoYear > rates.TenYear)
        {
            algorithm.Debug($"{slice.Time} - Yield curve inversion! Shorting the market for two years");
            _lastInversion = slice.Time;
            insights.Add(Insight.Price(_spySymbol, slice.Time + TimeSpan.FromDays(2*365), InsightDirection.Down,
null, null, null, 0.5));
        }

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            _spySymbol = security.Symbol;
        }
    }
}
```

Data Point Attributes

The US Treasury Yield Curve dataset provides `USTreasuryYieldCurveRate` objects, which have the following attributes:

Datasets

VIX Central

VIX Central was founded by Eli Mintz in 2012 with goal of displaying historical VIX term structures in a simple and intuitive interface. VIX Central provides access to real-time and historical VIX data for individual investors.

VIX Central Contango

VIX Central

VIX Central Contango

Introduction

The VIX Central Contango dataset by VIX Central tracks VIX Futures (VX) contango data. The data covers 12 Futures contracts closest to expiry/maturity, starts in June 2010, and is delivered on a daily frequency. The dataset is created by QuantConnect downloading data from VIX Central website, which collects and analyses VIX and VX (VIX Futures) data.

Contango and Backwardation are terms used to describe if participants in the Futures market are overpaying or underpaying relative to the "spot" price of the underlying commodity when trading a Futures contract ("spot" price is the price of the actual commodity/asset at a given moment in time). Contango and backwardation can be used to determine forward-looking expectations of the commodity's spot price by the time the Future has expired/matured and is set to be delivered by participants of the Futures market. As Futures near their expiration/maturity date, contango and backwardation curves tend to converge on the spot price of the commodity at the time of expiration.

For more information about the VIX Central Contango dataset, including CLI commands and pricing, see the dataset listing .

About the Provider

VIX Central was founded by Eli Mintz in 2012 with goal of displaying historical VIX term structures in a simple and intuitive interface. VIX Central provides access to real-time and historical VIX data for individual investors.

Getting Started

The following snippet demonstrates how to request data from the VIX Central Contango dataset:

```
C#
_datasetSymbol = AddData<VIXCentralContango>("VIX", Resolution.Daily).Symbol;
```

Data Summary

The following table describes the dataset properties:

Property	Value
Start Date	June 2010
Asset Coverage	1 Futures Chain with 12 contracts
Data Density	Regular
Resolution	Daily
Timezone	New York

Requesting Data

To add VIX Central Contango data to your algorithm, call the `AddData` method. Save a reference to the dataset `Symbol` so you can access the data later in your algorithm.

```C#
public class VixCentralContangoAlgorithm : QCAlgorithm
{
    private Symbol _datasetSymbol;

    public override void Initialize()
    {
        SetStartDate(2014, 1, 1);
        SetEndDate(2018, 1, 1);
        SetCash(25000);

        _datasetSymbol = AddData<VIXCentralContango>("VX", Resolution.Daily).Symbol;
    }
}
```

Accessing Data

To get the current VIX Central Contango data, index the current `Slice` with the dataset `Symbol` . Slice objects deliver unique events to your algorithm as they happen, but the `Slice` may not contain data for your dataset at every time step. To avoid issues, check if the `Slice` contains the data you want before you index it.

```C#
public override void OnData(Slice slice)
{
    if (slice.ContainsKey(_datasetSymbol))
    {
        var dataPoint = slice[_datasetSymbol];
        Log($"{_datasetSymbol} front month at {slice.Time}: {dataPoint.FrontMonth}");
    }
}
```

Historical Data

To get historical VIX Central Contango data, call the `History` method with the dataset `Symbol` . If there is no data in the period you request, the history result is empty.

```C#
var history = History<VIXCentralContango>(_datasetSymbol, 100, Resolution.Daily);
```

For more information about historical data, see History Requests .

Remove Subscriptions

To remove your subscription to VIX Central Contango data, call the `RemoveSecurity` method.

```C#
RemoveSecurity(_datasetSymbol);
```

Example Applications

The VIX Central Contango dataset enables you to explore VIX Future contracts pricing data. Examples include the following strategies:

- Determining forward-looking expectations by Futures market participants of the underlying commodity's spot price by the time of expiration/maturity
- Creating cash-and-carry arbitrage strategies by trading the spread/convergence of the contango/backwardation curves as a Future nears expiration/maturity

Classic Algorithm Design

The following example algorithm buys SPY when the percentage change between contract F2 and F1 (`Contango_F2_Minus_F1`) is positive. Otherwise, it remains in cash.

```
C#
public class VixCentralContangoAlgorithm : QCAlgorithm
{
    private Symbol _spy, _contango;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(25000);
        // SPY as market representative for macroeconomy indicator trading
        _spy = AddEquity("SPY", Resolution.Daily).Symbol;
        // Request VIX Contango data for trade signal generation
        _contango = AddData<VIXCentralContango>("VX", Resolution.Daily).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Trade base on the updated VIX contango data
        if (!slice.ContainsKey(_contango))
        {
            return;
        }
        var contangoData = slice.Get<VIXCentralContango>(_contango);
        var ratio = contangoData?.Contango_F2_Minus_F1 ?? 0;

        // Bet the market will go up if F2 - F1 price percentage change is positive, meaning the near-term market
volatility is expected to be low
        if (!Portfolio.Invested && ratio > 0)
        {
            SetHoldings(_spy, 1);
        }
        // Liqudiate otherwise to avoid excessive market volatility
        else if(ratio < 0)
        {
            Liquidate();
        }
    }
}
```

Framework Algorithm Design

The following example algorithm buys SPY when the percentage change between contract F2 and F1 (`Contango_F2_Minus_F1`) is positive. Otherwise, it remains in cash.

```
C#
public class VixCentralContangoAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(25000);

        UniverseSettings.Resolution = Resolution.Daily;
        // Include SPY as market representative for macroeconomy indicator trading
        var symbols = new[] {QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA)};
        AddUniverseSelection(new ManualUniverseSelectionModel(symbols));
        // Custom alpha model that emit insights base on VIX contango data
        AddAlpha(new ContangoAlphaModel(this));
        // Equal weighting investment to evenly dissipate the capital concentration risk on non-systematic risky
event
        SetPortfolioConstruction(new EqualWeightingPortfolioConstructionModel());
    }
}

public class ContangoAlphaModel : AlphaModel
{
    private Symbol _contango;
    private List<Symbol> _symbols;
```

```
    public ContangoAlphaModel(QCAlgorithm algorithm)
    {
        _symbols = new List<Symbol>();
        // Request VIX Contango data for trade signal generation
        _contango = algorithm.AddData<VIXCentralContango>("VX", Resolution.Daily).Symbol;

        // Historical data
        var history = algorithm.History<VIXCentralContango>(_contango, 60, Resolution.Daily);
        algorithm.Debug($"We got {history.Count()} items from our history request");
    }

    public override IEnumerable<Insight> Update(QCAlgorithm algorithm, Slice slice)
    {
        var insights = new List<Insight>();

        // Trade base on the updated VIX contango data
        if (!slice.ContainsKey(_contango))
        {
            return insights;
        }
        var contangoData = slice.Get<VIXCentralContango>(_contango);
        var ratio = contangoData?.Contango_F2_Minus_F1 ?? 0;

        // Bet the market will go up if F2 - F1 price percentage change is positive, meaning the near-term market
volatility is expected to be low
        if (!algorithm.Portfolio.Invested && ratio > 0)
        {
            foreach (var symbol in _symbols)
            {
                insights.Add(Insight.Price(symbol, Expiry.OneMonth, InsightDirection.Up));
            }
        }
        // Liqudiate otherwise to avoid excessive market volatility
        else if (ratio < 0)
        {
            foreach (var symbol in _symbols)
            {
                insights.Add(Insight.Price(symbol, Expiry.OneMonth, InsightDirection.Flat));
            }
        }

        return insights;
    }

    public override void OnSecuritiesChanged(QCAlgorithm algorithm, SecurityChanges changes)
    {
        foreach (var symbol in changes.RemovedSecurities.Select(x=> x.Symbol))
        {
            _symbols.Remove(symbol);
        }
        _symbols.AddRange(changes.AddedSecurities.Select(x=> x.Symbol));
    }
}
```

Data Point Attributes

The VIX Central Contango dataset provides `VIXCentralContango` objects, which have the following attributes:

Importing Data

Importing Data

Key Concepts

Introduction

Custom data is your own external data that's not from the Dataset Market. You can use custom data to inform trading decisions and to simulate trades on unsupported securities. To get custom data into your algorithms, you download the entire file at once or read it line-by-line with a custom data reader. If you use a custom data reader, LEAN sends the data to the `OnData` method in your algorithm.

File Providers

The most common file providers to use are the Object Store , Dropbox, GitHub, and Google Sheets.

Object Store

The Object Store is the fastest file provider. If you import files from remote providers, you will be restricted by their rate limits and your download speed.

Dropbox

If you store your custom data in Dropbox, you need to create a link to the file and add `?dl=1` to the end of the file URL. To create file links, see How to share files or folders in the Dropbox documentation. The `?dl=1` parameter lets you download the direct file link, not the HTML page of the file.

GitHub

If you store your custom data in GitHub, you can use public or private repositories. When you download the data, use the raw file (for example, https://raw.githubusercontent.com/<organization>/<repo>/<path>). For instructions on accessing the raw file, see Viewing or copying the raw file content in the GitHub documentation.

Google Sheets

If you store your custom data in Google Sheets, you need to create a link to the file. To create file links, see Make Google Docs, Sheets, Slides & Forms public in the Google Docs documentation. Choose the CSV format to find `/pub?gid={SHEET_ID}&single=true&output=csv` parameter on the end of the link. Google Sheets don't support exporting data in JSON format.

Stream Custom Data

To receive your custom data in the `OnData` method, create a custom type and then create a data subscription. The custom data type tells LEAN where to get your data and how to read it.

All custom data types must extend the `BaseData` class and override the `GetSource` and `Reader` methods

```C#
public class MyCustomDataType : BaseData
{
    public override DateTime EndTime { get; set; }
    public decimal Property1 { get; set; } = 0;

    public override SubscriptionDataSource GetSource(
        SubscriptionDataConfig config,
        DateTime date,
        bool isLive)
    {
        return new SubscriptionDataSource("<sourceURL>", SubscriptionTransportMedium.RemoteFile);
    }

    public override BaseData Reader(
        SubscriptionDataConfig config,
        string line,
        DateTime date,
        bool isLive)
    {
        if (string.IsNullOrWhiteSpace(line.Trim()) || char.IsDigit(line[0]))
        {
            return null;
        }

        var data = line.Split(',');
        return new MyCustomDataType()
        {
            Time = DateTime.ParseExact(data[0], "yyyyMMdd", CultureInfo.InvariantCulture),
            EndTime = Time.AddDays(1),
            Symbol = config.Symbol,
            Value = data[1].IfNotNullOrEmpty(
                s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture)),
            Property1 = data[2].IfNotNullOrEmpty(
                s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture))
        };
    }
}
```

For more information about custom data types, see Streaming Data .

Download Bulk Data

The `Download` method downloads the content served from a local file or URL and then returns it as a string.

```C#
var content = Download("<filePathOrURL>");
```

For more information about bulk downloads, see Bulk Downloads .

File Quotas

There are no limits to the number of files you can load from the Object Store during a single backtest or Research Environment session in QuantConnect Cloud.

The following table shows the number of remote files you can download during a single backtest or Research Environment session in QuantConnect Cloud:

Organization Tier	File Quota
Free	25
Quant Researcher	100
Team	250
Trading Firm	1,000
Institutional	Unlimited

Remote files can be up to 200 MB in size and can have names up to 200 characters long.

Rate Limits

We do not impose a rate limit on file downloads but often external providers do. Dropbox caps download speeds to 10 kb/s after 3-4 download requests. To ensure your algorithms run fast, only use a small number of small custom data files or use the Object Store.

Timeouts

In cloud algorithms, the download methods have a 10-second timeout period. If the methods don't download the data within 10 seconds, LEAN throws an error.

Importing Data

Streaming Data

Streaming Data

Key Concepts

Introduction

There are two techniques to import data into your algorithm. You can either manually import the entire file or stream the file line-by-line into your algorithm's `OnData` event. This page explores streaming a file's contents into your algorithm line-by-line. The data you import can be from a remote server or the Object Store .

Data Formats

Common data formats are CSV , JSON , XML , and ZIP but you can use any file type that can be read over the internet. For Excel files, double check the raw data format for parsing in the data reader, since data will be formatted for convenient visualization in Excel application view. To avoid confusion of data format, save the spreadsheet as a CSV file and open it in a text editor to confirm the raw data format.

If you import from a remote file provider , each request has a one-second overhead, so package your custom data to minimize requests. Bundle dates together where possible to speed up execution. The Object Store file provider gives you the fastest execution because you don't need to download the files on every execution.

Point-In-Time Tickers

Tickers are a string shortcode representation for an asset. Some examples of popular tickers include "AAPL" for Apple Corporation and "IBM" for International Business Machines Corporation. These tickers often change when the company rebrands or they undergo a merger or reverse merger.

The ticker of an asset is not the same as the `Symbol` . `Symbol` objects are permanent and track the underlying entity. When a company rebrands or changes its name, the `Symbol` object remains constant, giving algorithms a way to reliably track assets over time.

Tickers are also often reused by different brokerages. For example Coinbase, a leading US Crypto Brokerage lists the "BTCUSD" ticker for trading. Its competitor, Bitfinex, also lists "BTCUSD". You can trade both tickers with LEAN. `Symbol` objects allow LEAN to identify which market you reference in your algorithms.

To create a `Symbol` object for a point-in-time ticker, call the `GenerateEquity` method to create the security identifier and then call the `Symbol` constructor. For example, Heliogen, Inc. changed their ticker from ATHN to HLGN on December 31, 2021. To convert the ATHN ticker to the Equity `Symbol` , type:

```C#
// Generate an Equity security identifier for a ticker and then create a symbol with it.
var ticker = "ATHN";
var securityID = SecurityIdentifier.GenerateEquity(ticker, Market.USA, mappingResolveDate:new DateTime(2021, 12, 1));
var symbol = new Symbol(securityID, ticker);
```

In the preceding code snippet, the `mappingResolveDate` must be a date when the point-in-time ticker was trading.

For examples of point-in-time tickers in custom data types, refer to the CSV Format Example and JSON Format Example .

Set Data Sources

The `GetSource` method in your custom data class instructs LEAN where to find the data.

```C#
public class MyCustomDataType : BaseData
{
    public override SubscriptionDataSource GetSource(
        SubscriptionDataConfig config,
        DateTime date,
        bool isLiveMode)
    {
        if (isLiveMode)
        {
            return new SubscriptionDataSource("https://www.bitstamp.net/api/ticker/",
SubscriptionTransportMedium.Rest);
        }

        var source = $"http://my-ftp-server.com/{config.Symbol.Value}/{date:yyyyMMdd}.csv";
        return new SubscriptionDataSource(source, SubscriptionTransportMedium.RemoteFile);

        /*
        // Example of loading from the Object Store:
        return new SubscriptionDataSource(Bitstamp.KEY,
            SubscriptionTransportMedium.ObjectStore);

        // Example of loading a remote zip file:
        return new SubscriptionDataSource(
            "https://cdn.quantconnect.com/uploads/multi_csv_zipped_file.zip",
            SubscriptionTransportMedium.RemoteFile,
            FileFormat.ZipEntryName);

        // Example of loading a remote zip file and accessing a CSV file inside it:
        return new SubscriptionDataSource(
            "https://cdn.quantconnect.com/uploads/multi_csv_zipped_file.zip#csv_file_10.csv",
            SubscriptionTransportMedium.RemoteFile,
            FileFormat.ZipEntryName);
        */
    }
}
```

The following table describes the arguments the `GetSource` method accepts:

Argument	Data Type	Description
`config`	`SubscriptionDataConfig`	The subscription configuration
`date`	`DateTime`	Date of this source file
`isLiveMode`	`bool`	`true` if algorithm is running in live mode

You can use these arguments to create `SubscriptionDataSource` objects representing different locations and formats. The following table describes the arguments the `SubscriptionDataSource` accepts:

Argument	Data Type	Description	Default Value
`source`	`string`	Data source location	
`transportMedium`	`SubscriptionTransportMedium`	The transport medium to be used to retrieve data from the source	
`format`	`FileFormat`	The format of the data within the source	`FileFormat.Csv`
`headers`	`IEnumerable<KeyValuePair<string, string>>`	The headers to be used for this source. In cloud algorithms, each of the key-value pairs can consist of up to 1,000 characters.	`null`

The `FileFormat` enumeration has the following members:

The `SubscriptionTransportMedium` enumeration has the following members:

Member	Description	Example
`LocalFile`	The data comes from disk	Lean.DataSource.CBOE
`RemoteFile`	The data is downloaded from a remote source	`Custom Securities Examples`
`Rest`	The data comes from a rest call that is polled and returns a single line/data point of information	`LiveMode` case of Demonstration Algorithm
`ObjectStore`	The data comes from the object store	Example of Custom Data

Parse Custom Data

The `Reader` method of your custom data class takes one line of data from the source location and parses it into one of your custom objects. You can add as many properties to your custom data objects as you need, but the following table describes the properties you must set. When there is no useable data in a line, the method should return `null` . LEAN repeatedly calls the `Reader` method until the date/time advances or it reaches the end of the file.

Property	Description
`Symbol`	You can set this property to `config. Symbol` .
`Time`	The time when the data sample starts.
`EndTime`	The time when the data sample ends and when LEAN should add the sample to a Slice .
`Value`	The default data point value (`decimal`).

The following table describes the arguments the `Reader` method accepts:

Argument	Data Type	Description
`config`	`SubscriptionDataConfig`	The subscription configuration
`line`	`string`	Content from the requested data source
`date`	`DateTime`	Date of this source file
`isLiveMode`	`bool`	`true` if algorithm is running in live mode

You can use these arguments to create `BaseData` objects from different sources.

```C#
public class MyCustomDataType : BaseData
{
    public override BaseData Reader(
        SubscriptionDataConfig config,
        string line,
        DateTime date,
        bool isLiveMode)
    {
        if (string.IsNullOrWhiteSpace(line.Trim()))
        {
            return null;
        }

        if (isLiveMode)
        {
            var custom = JsonConvert.DeserializeObject<MyCustomDataType>(line);
            custom.EndTime = DateTime.UtcNow.ConvertFromUtc(config.ExchangeTimeZone);
            return custom;
        }

        if (!char.IsDigit(line[0]))
        {
            return null;
        }

        var data = line.Split(',');
        return new MyCustomDataType()
        {
            Time = DateTime.ParseExact(data[0], "yyyyMMdd", CultureInfo.InvariantCulture),
            EndTime = Time.AddDays(1),
            Symbol = config.Symbol,
            Value = data[1].IfNotNullOrEmpty(
                s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture)),
        };
    }
}
```

Unsorted Data

By default, LEAN expects the data in chronological order. If the data is unsorted, set the `Sort` property of the `SubscriptionDataSource` object to `true` .

```C#
public class MyCustomDataType : BaseData
{
    public override SubscriptionDataSource GetSource(
        SubscriptionDataConfig config,
        DateTime date,
        bool isLiveMode)
    {
        var source = $"http://my-ftp-server.com/{config.Symbol.Value}/{date:yyyyMMdd}.csv";
        return new SubscriptionDataSource(source, SubscriptionTransportMedium.RemoteFile)
        {
            Sort = true
        };
    }
}
```

LEAN uses `EndTime` property of your custom data to sort it.

Object Store

The Object Store file provider gives you the fastest execution because you don't need to download the files on every execution. To upload the data files into the Object Store, use the Algorithm Lab , CLI , or Research Environment . To then pull the data from the Object Store into an algorithm, set the custom data source to read from the file in Object Store and parse the data in the `Reader` method.

```C#
public class MyCustomDataType : BaseData
{
    public override SubscriptionDataSource GetSource(
        SubscriptionDataConfig config,
        DateTime date,
        bool isLiveMode)
    {
        return new SubscriptionDataSource("<YourCSVKey>", SubscriptionTransportMedium.ObjectStore, FileFormat.Csv);
        // return new SubscriptionDataSource("<YourJSONKey>", SubscriptionTransportMedium.ObjectStore,
FileFormat.UnfoldingCollection);
    }
}
```

Set Properties

To set the Symbol Properties of the custom data, provide a `SymbolProperties` object when you subscribe to the dataset. The ticker you pass to the `SymbolProperties` constructor and the `AddData` `add_data` method must be the same.

To set the Exchange Hours of the custom data, provide a `SecurityExchangeHours` object when you subscribe to the dataset. The default hours are for the market to be open 24/7.

```C#
var ticker = "ABC";
var properties = new SymbolProperties("description", "USD", 1, 0.01, 0.01, ticker);
var hours = MarketHoursDatabase.GetEntry(Market.USA, "SPY", SecurityType.Equity).ExchangeHours;
AddData<CustomData>(ticker, properties, hours);
```

Live Trading Considerations

In live trading, we pass custom data to your algorithm as soon as it arrives. The time it arrives may not align with the time of other slices . Design your algorithm to handle unsychronized data so that you don't run into issues.

Demonstration Algorithm

The following example algorithm implements a custom data source for the Bitstamp API.

```C#
```

```c#
using Newtonsoft.Json;

public class CustomDataBitstampAlgorithm : QCAlgorithm
{
    private Symbol _customDataSymbol;

    public override void Initialize()
    {
        SetStartDate(2020, 9, 1);
        SetEndDate(2020, 12, 31);
        // Define the symbol and "type" of our custom data.
        _customDataSymbol = AddData<Bitstamp>("BTC", Resolution.Daily).Symbol;
        // Get some historical data.
        var history = History<Bitstamp>(_customDataSymbol, 200, Resolution.Daily);
    }

    // Get the data of the current day.
    public void OnData(Bitstamp data)
    {
        Plot(_customDataSymbol, "Price", data.Close);
    }

    public class Bitstamp : BaseData
    {
        public int Timestamp = 0;
        public decimal Open = 0, High = 0, Low = 0, Close = 0, Bid = 0, Ask = 0, WeightedPrice = 0, VolumeBTC = 0,
VolumeUSD = 0;

        public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool
isLiveMode)
        {
            if (isLiveMode)
            {
                return new SubscriptionDataSource("https://www.bitstamp.net/api/ticker/",
SubscriptionTransportMedium.Rest);
            }
            var source =
"https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-data/bitstampusd.csv";
            return new SubscriptionDataSource(source, SubscriptionTransportMedium.RemoteFile);
        }

        public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
        {
            if (string.IsNullOrWhiteSpace(line.Trim()))
            {
                return null;
            }
            var coin = new Bitstamp() {Symbol = config.Symbol};
            // In live trading, parse the JSON file.
            if (isLiveMode)
            {
                //Example Line Format:
                //{"high": "441.00", "last": "421.86", "timestamp": "1411606877", "bid": "421.96", "vwap": "428.58",
"volume": "14120.40683975", "low": "418.83", "ask": "421.99"}
                coin = JsonConvert.DeserializeObject<Bitstamp>(line);
                coin.EndTime = DateTime.UtcNow.ConvertFromUtc(config.ExchangeTimeZone);
                coin.Time = coin.EndTime.AddDays(-1);
                coin.Value = coin.Close;
                return coin;
            }

            // In backtests, parse the CSV file.
            //Example Line Format:
            //Date      Open   High    Low     Close   Volume (BTC)    Volume (Currency)   Weighted Price
            //2011-09-13 5.8    6.0     5.65    5.97    58.37138238,    346.0973893944      5.929230648356
            if (!char.IsDigit(line[0]))
            {
                return null;
            }
            var data = line.Split(',');
            // If value is zero, return null.
            coin.Value = data[4].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            if (coin.Value == 0)
            {
                return null;
            }
            coin.Time = DateTime.Parse(data[0], CultureInfo.InvariantCulture);
            coin.EndTime = coin.Time.AddDays(1);
            coin.Open = data[1].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
```

```
CultureInfo.InvariantCulture));
            coin.High = data[2].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.Low = data[3].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.VolumeBTC = data[5].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.VolumeUSD = data[6].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.WeightedPrice = data[7].IfNotNullOrEmpty(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            coin.Close = coin.Value;
            return coin;
        }
    }
}
```

Streaming Data

Custom Securities

Custom Securities

Key Concepts

Introduction

To receive your custom data in the `OnData` method instead of in a bulk download, create a custom type and then create a data subscription. The custom data type tells LEAN where to get your data and how to read it. All custom data types must extend from `BaseData` and override the `Reader` and `GetSource` methods.

Unlike custom data, native QC data gets the full benefit of security modeling like splits and dividends. Custom data is ignorant of everything about the actual market. Things like market hours, delistings, and mergers don't work with custom data.

Create Subscriptions

After you define the custom data class, in the `Initialize` method of your algorithm, call the `AddData` method. This method gives LEAN the type factory to create the objects, the name of the data, and the resolution at which to poll the data source for updates.

```C#
public class MyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        _symbol = AddData<MyCustomDataType>("<name>", Resolution.Daily).Symbol;
    }
}
```

The `resolution` argument should match the resolution of your custom dataset. The lowest reasonable resolution is every minute. Anything more frequent than every minute is very slow to execute. The frequency that LEAN checks the data source depends on the `resolution` argument. The following table shows the polling frequency of each resolution:

Resolution	Update Frequency
Daily	Every 30 minutes
Hour	Every 30 minutes
Minute	Every minute
Second	Every second
Tick	Constantly checks for new data

There are several other signatures for the `AddData` method.

```
AddData<T>(ticker, resolution);
AddData<T>(ticker, resolution, fillForward, leverage);
AddData<T>(ticker, resolution, timeZone, fillForward, leverage);
AddData<T>(ticker, properties, exchangeHours, resolution, fillForward, leverage);
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `OnData` method. To collect the custom data, use the `Symbol` or name of your custom data subscription. You can access the `Value` and custom properties of your custom data class from the `Slice` . To access the custom properties, use the custom attribute .

C#

```
public class MyAlgorithm : QCAlgorithm
{
    public override void OnData(Slice slice)
    {
        if (slice.ContainsKey(_symbol))
        {
            var customData = slice[_symbol];
            var value = customData.Value;
            var property1 = customData.Property1;
        }
    }

    // You can also get the data directly with OnData(<dataClass>) method
    public void OnData(MyCustomDataType slice)
    {
        var value = slice.Value;
        var property1 = slice.Property1;
    }
}
```

Debugging

In backtests, you can use the IDE debugging capabilities to inspect the variables to understand the internal state of the custom data implementation. For more information about backtest debugging, see the Debugging documentation for Cloud Platform , Local Platform , or the CLI .

In live trading, consider adding logging statements to help with debugging since the debugger isn't available. To log information from inside your custom data class, set a class member that references the algorithm.

```C#
public class MyCustomDataTypeAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        MyCustomDataType.ALGORITHM = this;
        var symbol = AddData<MyCustomDataType>("<name>", Resolution.Daily).Symbol;
    }
}

public class MyCustomDataType : BaseData
{
    public static QCAlgorithm ALGORITHM;

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        if (!char.IsDigit(line.Trim()[0]))
        {
            // Display the line with the header
            ALGORITHM.Debug($"HEADER: {line}");
            return null;
        }
        var data = line.Split(',');
        return new MyCustomDataType()
        {
            Time = DateTime.ParseExact(data[0], "yyyyMMdd", CultureInfo.InvariantCulture),
            EndTime = Time.AddDays(1),
            Symbol = config.Symbol,
            Value = data[1].IfNotNullOrEmpty(
                s => decimal.Parse(s, NumberStyles.Any, CultureInfo.InvariantCulture)),
        };
    }
}
```

Set the Benchmark

To set your custom data source as the benchmark, in the `Initialize` method, call the `SetBenchmark` method with the `Symbol` of your custom data subscription.

```C#
var symbol = AddData<MyCustomDataType>("<name>", Resolution.Daily).Symbol;
SetBenchmark(symbol);
```

Avoid Look-Ahead Bias

Look-ahead bias occurs when you make decisions with information that wouldn't be available until some time in the future. In backtesting, look-ahead bias occurs when you receive data earlier than it would actually be available in reality. If look-ahead bias seeps into your algorithm, it will perform differently between live trading and backtesting.

To avoid look-ahead bias, set the timestamp of data points to the time when the data would actually be available. A lot of external sources apply timestamps to data differently than we do. For instance, on some platforms, daily bars are displayed with the date that they opened. We display daily bars with the date they closed. If you set the `EndTime` to the start of the bar, you'll receive the bar earlier in backtests than you would in live trading.

Time Modeling

Data types classes in LEAN inherit from the `BaseData` class that defines the `Time` and `EndTime` properties. These properties represent the time period of which the data was built. If the data type occurs in a singular point in time, they have no period, so `Time` and `EndTime` are the same. Regardless of the period, LEAN uses the time when the data sample ends, `EndTime` , to add the sample to a `Slice` .

Historical Data

To get a list of historical data points for a custom dataset, call the `History< customDatasetClass >` method with the dataset `Symbol` . For more information about historical data, see Data Points .

Market Hours

The default market hours for custom securities is to be always open. To set the market hours, pass an `exchangeHours` argument to the `AddData` method.

```
C#
var symbol = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
var symbolProperties = SymbolPropertiesDatabase.GetSymbolProperties(symbol.ID.Market, symbol, SecurityType.Equity,
"USD");
var securityExchangeHours = MarketHoursDatabase.GetExchangeHours(symbol.ID.Market, symbol, SecurityType.Equity);
var security = AddData<CustomType>(symbol, symbolProperties, securityExchangeHours, Resolution.Hour);
```

Custom Securities

CSV Format Example

Introduction

This page explains how to import custom data of a single security sourced in CSV format.

Data Format

The following snippet shows an example CSV file:

```
Date,Open,High,Low,Close,SharesTraded,Tur11er(Rs.Cr)
1997-01-01,905.2,941.4,905.2,939.55,38948210,978.21
1997-01-02,941.95,944,925.05,927.05,49118380,1150.42
1997-01-03,924.3,932.6,919.55,931.65,35263845,866.74
...
2014-07-24,7796.25,7835.65,7771.65,7830.6,117608370,6271.45
2014-07-25,7828.2,7840.95,7748.6,7790.45,153936037,7827.61
2014-07-28,7792.9,7799.9,7722.65,7748.7,116534670,6107.78
```

The data in the file must be in chronological order.

Define Custom Types

To define a custom data type, inherit the `BaseData` class and override the GetSource and Reader methods.

C#

```
public class MyCustomDataType : BaseData
{
    public decimal Open;
    public decimal High;
    public decimal Low;
    public decimal Close;

    public override SubscriptionDataSource GetSource(
        SubscriptionDataConfig config,
        DateTime date,
        bool isLiveMode)
    {
        if (!isLiveMode)
        {
            return new SubscriptionDataSource("<CustomDataKey>", SubscriptionTransportMedium.ObjectStore,
FileFormat.Csv);
        }
        return new
SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/csv-data-example.csv", SubscriptionTransportMedium.RemoteFile);
    }

    public override BaseData Reader(
        SubscriptionDataConfig config,
        string line,
        DateTime date,
        bool isLiveMode)
    {
        if (string.IsNullOrWhiteSpace(line.Trim()))
        {
            return null;
        }

        var index = new MyCustomDataType();

        try
        {
            var data = line.Split(',');
            index.Symbol = config.Symbol;
            index.Time = DateTime.Parse(data[0], CultureInfo.InvariantCulture);
            index.EndTime = index.Time.AddDays(1);
            index.Open = data[1].IfNotNullOrEmpty<decimal>(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            index.High = data[2].IfNotNullOrEmpty<decimal>(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            index.Low = data[3].IfNotNullOrEmpty<decimal>(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            index.Close = data[4].IfNotNullOrEmpty<decimal>(s => decimal.Parse(s, NumberStyles.Any,
CultureInfo.InvariantCulture));
            index.Value = index.Close;
        }
        catch
        {
        }
        return index;
    }
}
```

Create Subscriptions

To create a subscription for the custom type, in the `Initialize` method, call the `AddData` method. The `AddData` method returns a `Security` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```C#
public class MyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        _symbol = AddData<MyCustomDataType>("MyCustomDataType", Resolution.Daily).Symbol;
    }
}
```

The `AddData` method creates a subscription for a single custom data asset and adds it to your user-defined universe.

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `OnData` method. To collect the custom data, use the `Symbol` or name of your custom data subscription. You can access the `Value` and custom properties of your custom data class from the `Slice` . To access the custom properties, use the custom attribute .

```C#
public class MyAlgorithm : QCAlgorithm
{
    public override void OnData(Slice slice)
    {
        if (slice.ContainsKey(_symbol))
        {
            var customData = slice[_symbol];
            var close = customData.Close;
        }
    }

    // You can also get the data directly with OnData(<dataClass>) method
    public void OnData(MyCustomDataType customData)
    {
        var close = customData.Close;
    }
}
```

JSON Format Example

Introduction

This page explains how to import custom data of a single security sourced in JSON format.

Data Format

The following code snippet shows an example JSON file

```
[
    {
      "Date": "1997-01-01",
      "Open": 905.2,
      "High": 941.4,
      "Low": 905.2,
      "Close": 939.55,
      "SharesTraded": 38948210,
      "Tur11er(Rs.Cr)": 978.21
    },
    {
      "Date": "1997-01-02",
      "Open": 941.95,
      "High": 944,
      "Low": 925.05,
      "Close": 927.05,
      "SharesTraded": 49118380,
      "Tur11er(Rs.Cr)": 1150.42
    },
    ...
    {
      "Date": "2014-07-25",
      "Open": 7828.2,
      "High": 7840.95,
      "Low": 7748.6,
      "Close": 7790.45,
      "SharesTraded": 153936037,
      "Tur11er(Rs.Cr)": 7827.61
    },
    {
      "Date": "2014-07-28",
      "Open": 7792.9,
      "High": 7799.9,
      "Low": 7722.65,
      "Close": 7748.7,
      "SharesTraded": 116534670,
      "Tur11er(Rs.Cr)": 6107.78
    }
]
```

The data in the file must be in chronological order.

Define Custom Types

To define a custom data type, inherit the `BaseData` class and override the GetSource and Reader methods.

If you need to create multiple objects in your `Reader` method from a single `line` , follow these steps:

1. In the `GetSource` method, pass `FileFormat.UnfoldingCollection` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `Reader` method, order the objects by their timestamp and then return a

`BaseDataCollection(endTime, config.Symbol, objects)` where `objects` is a list of your custom data objects.

```
C#
using Newtonsoft.Json;

public class MyCustomDataType : BaseData
{
    public string Date;
    public decimal Open = 0, High = 0, Low = 0, Close = 0;
    public override DateTime EndTime => Time.AddDays(1);

    public override SubscriptionDataSource GetSource(
        SubscriptionDataConfig config,
        DateTime date,
        bool isLiveMode)
    {
        if (!isLive)
        {
            return new SubscriptionDataSource("<customDataKey>", SubscriptionTransportMedium.ObjectStore,
FileFormat.UnfoldingCollection);
        }
        return new
SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/unfolding-collection-example.json", SubscriptionTransportMedium.RemoteFile, FileFormat.UnfoldingCollection);
    }

    public override BaseData Reader(
        SubscriptionDataConfig config,
        string line,
        DateTime date,
        bool isLiveMode)
    {
        if (string.IsNullOrWhiteSpace(line.Trim()))
        {
            return null;
        }

        var objects = JsonConvert.DeserializeObject<List<MyCustomDataType>>(line).Select(index =>
        {
            index.Symbol = config.Symbol;
            index.Time = DateTime.Parse(x.Date, CultureInfo.InvariantCulture);
            index.Value = x.Close;
            return index;
        }).ToList();

        return new BaseDataCollection(objects.Last().EndTime, config.Symbol, objects);
    }
}
```

Create Subscriptions

To create a subscription for the custom type, in the `Initialize` method, call the `AddData` method. The `AddData` method returns a `Security` object, which contains a `Symbol` . Save a reference to the `Symbol` so you can use it in `OnData` to access the security data in the `Slice` .

```
C#
public class MyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        _symbol = AddData<MyCustomDataType>("MyCustomDataType", Resolution.Daily).Symbol;
    }
}
```

The `AddData` method creates a subscription for a single custom data asset and adds it to your user-defined universe.

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points in the `Slice` it passes to your algorithm's `OnData` method. To collect the custom data, use the `Symbol` or name of your custom data subscription. You can access the `Value` and custom properties of your custom data class from the `Slice` . To access the custom properties, use the custom attribute .

```C#
public class MyAlgorithm : QCAlgorithm
{
    public override void OnData(Slice slice)
    {
        if (slice.ContainsKey(_symbol))
        {
            var customData = slice[_symbol];
            var close = customData.Close;
        }
    }

    // You can also get the data directly with OnData(<dataClass>) method
    public void OnData(MyCustomDataType customData)
    {
        var close = customData.Close;
    }
}
```

Custom Universes

Custom Universes

Key Concepts

Introduction

A custom universe lets you select a basket of assets from a custom dataset.

Initialize Universes

To add a custom universe to your algorithm, in the `Initialize` method, pass your universe type and a selector function to the `AddUniverse` method.

```
C#
AddUniverse<MyCustomUniverseDataClass>(SelectorFunction);
```

Receive Custom Data

The universe selector function receives a list of your custom objects and must return a list of `Symbol` objects. In the selector function definition, you can use any of the properties of your custom data type. The `Symbol` objects that you return from the selector function set the constituents of the universe.

```
C#
public class MyCustomUniverseAlgorithm : QCAlgorithm
{
 private IEnumerable<Symbol> SelectorFunction(IEnumerable<BaseData> data)
 {
        return (from singleStockData in data.OfType<MyCustomUniverseDataClass>()
               where singleStockData.CustomAttribute1 > 0
               orderby singleStockData.CustomAttribute2 descending
               select singleStockData.Symbol).Take(5);
    }
}
```

Historical Data

To get historical data for a custom data universe , call the `History` method with the `Universe` object. For more information about historical data, see Universes .

Custom Universes

CSV Format Example

Introduction

This page explains how to import custom data for universe selection sourced in CSV format.

Data Format

You must create a file with data in CSV format. Ensure the data in the file is in chronological order.

```
20170704,SPY,QQQ,FB,AAPL,IWM
20170706,QQQ,AAPL,IWM,FB,GOOGL
20170707,IWM,AAPL,FB,BAC,GOOGL
...
20170729,SPY,QQQ,FB,AAPL,IWM
20170801,QQQ,FB,AAPL,IWM,GOOGL
20170802,QQQ,IWM,FB,BAC,GOOGL
```

Define Custom Types

To define a custom data type, inherit the `BaseData` class and override the GetSource and Reader methods.

```
C#
public class StockDataSource : BaseData
{
    public List<Symbol> Symbols { get; set; } = [];
    public override DateTime EndTime => Time.AddDays(1);
    public string Line { get; set; }

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        if (!isLiveMode)
        {
            return new SubscriptionDataSource("csv-universe-example.csv", SubscriptionTransportMedium.ObjectStore,
FileFormat.Csv);
        }
        return new
SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/csv-universe-example.csv", SubscriptionTransportMedium.RemoteFile, FileFormat.Csv);
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        var csv = line.Split(',');
        var stocks = new StockDataSource { Symbol = config.Symbol, Line = line };

        try
        {
            stocks.Time = isLiveMode
                ? DateTime.UtcNow.ConvertFromUtc(config.DataTimeZone)
                : DateTime.ParseExact(csv[0], "yyyyMMdd", null);

            stocks.Symbols.AddRange(csv.Skip(1).Select(ticker =>
            {
                // The tickers are point-in-time. We generate its security identifier for a given date
                // Then we create a Symbol where the Value is the ticker
                var sid = SecurityIdentifier.GenerateEquity(ticker, Market.USA, mappingResolveDate: stocks.Time);
                return new Symbol(sid, ticker);
            }));
        }
        catch { }
        return stocks;
}
```

Initialize Universe

To perform a universe selection with custom data, in the `Initialize` method, call the `AddUniverse` method.

```
C#
public class MyAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        AddUniverse<StockDataSource>(FilterFunction);
    }
}
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points into a `IEnumerable<StockDataSource>` object it passes to your algorithm's filter function. Your filter function needs to return a list of `Symbol` or `string` object. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```
C#
public class MyAlgorithm : QCAlgorithm
{
    private IEnumerable<Symbol> FilterFunction(IEnumerable<BaseData> data)
    {
        var stockDataSource = data.OfType<StockDataSource>();
        return stockDataSource.SelectMany(x => x.Symbols);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        Debug(changes.ToString());
    }
}
```

Demonstration Algorithms

Custom Universes

JSON Format Example

Introduction

This page explains how to import custom data for universe selection sourced in JSON format.

Data Format

You must create a file with data in JSON format. Ensure the data in the file is in chronological order.

```
[
    {
      "Date": "20170704",
      "Symbols": ["SPY", "QQQ", "FB", "AAPL", "IWM"]
    },
    {
      "Date": "20170706",
      "Symbols": ["QQQ", "AAPL", "IWM", "FB", "GOOGL"]
    },
    ...
    {
      "Date": "20170801",
      "Symbols": ["QQQ", "FB", "AAPL", "IWM", "GOOGL"]
    },
    {
      "Date": "20170802",
      "Symbols": ["QQQ", "IWM", "FB", "BAC", "GOOGL"]
    }
]
```

Define Custom Types

To define a custom data type, inherit the `BaseData` class and override the GetSource and Reader methods.

If you need to create multiple objects in your `Reader` method from a single `line` , follow these steps:

1. In the `GetSource` method, pass `FileFormat.UnfoldingCollection` as the third argument to the `SubscriptionDataSource` constructor.
2. In the `Reader` method, order the objects by their timestamp and then return a `BaseDataCollection(endTime, config.Symbol, objects)` where `objects` is a list of your custom data objects.

```C#
using Newtonsoft.Json;
using Newtonsoft.Json.Linq;

public class StockDataSource : BaseData
{
    public List<Symbol> Symbols { get; set; } = [];
    public override DateTime EndTime => Time.AddDays(1);
    public string Line { get; set; }

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        if (!isLiveMode)
        {
             return new SubscriptionDataSource("universe-example.json", SubscriptionTransportMedium.ObjectStore,
FileFormat.UnfoldingCollection);
        }
        return new
SubscriptionDataSource("https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-
data/universe-example.json", SubscriptionTransportMedium.RemoteFile, FileFormat.UnfoldingCollection);
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        List<StockDataSource> objects = [];
        foreach(var obj in JsonConvert.DeserializeObject(line) as JArray)
        {
            var stocks = new StockDataSource()
            {
                Time = isLiveMode
                    ? DateTime.UtcNow.ConvertFromUtc(config.DataTimeZone)
                    : DateTime.ParseExact(obj["Date"].Value<string>(), "yyyyMMdd", null),
                Line = JsonConvert.SerializeObject(obj)
            };

            stocks.Symbols.AddRange(obj["Symbols"].Values<string>().Select(ticker =>
            {
                // The tickers are point-in-time. We generate its security identifier for a given date
                // Then we create a Symbol where the Value is the ticker
                var sid = SecurityIdentifier.GenerateEquity(ticker, Market.USA, mappingResolveDate: stocks.Time);
                return new Symbol(sid, ticker);
            }));

            objects.Add(stocks);
        }

        return new BaseDataCollection(objects.Last().EndTime, config.Symbol, objects);
    }
}
```

Initialize Universe

To perform a universe selection with custom data, in the `Initialize` method, call the `AddUniverse` method.

```C#
public class MyAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        AddUniverse<StockDataSource>(FilterFunction);
    }
}
```

Receive Custom Data

As your data reader reads your custom data file, LEAN adds the data points into a `IEnumerable<StockDataSource>` object it passes to your algorithm's filter function. Your filter function needs to return a list of `Symbol` or `string` object. LEAN automatically subscribes to these new assets and adds them to your algorithm.

```
C#
public class MyAlgorithm : QCAlgorithm
{
    private IEnumerable<Symbol> FilterFunction(IEnumerable<BaseData> data)
    {
        var stockDataSource = data.OfType<StockDataSource>();
        return stockDataSource.SelectMany(x => x.Symbols);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        Debug(changes.ToString());
    }
}
```

Importing Data

Bulk Downloads

Introduction

There are two techniques to import data into your algorithm. You can either manually import the entire file or stream the file line-by-line into your algorithm's `OnData` event. This page explores importing an entire file for manual use.

Instead of downloading the file from a remote file provider, you can upload the file to the Object Store (with the Algorithm Lab or with the CLI) for faster execution.

Recommended Use Cases

The batch import technique is outside of the LEAN's awareness or control, so it can't enforce good practices. However, the batch import technique is good for the loading the following datasets:

- Loading data into the Object Store
- Trained AI Models
- Well-defined historical price datasets
- Parameters and setting imports such as `Symbol` lists

Download Files

The `Download` method downloads the content served from a local file or URL and then returns it as a string.

Basic Usage

```C#
var file = Download("<filePathOrURL>");
```

Download Method Arguments

The `Download` method can accept header settings, a username, and a password for authentication.

Argument	Data Type	Description	Default Value
`address`	`string`	A string containing the URI to download	
`headers`	`IEnumerable<KeyValuePair<string, string>>`	Defines header values to add to the request	`Enumerable.Empty<KeyValuePair<string, string>>()`
`userName`	`string`	The user name associated with the credentials	`null`
`password`	`string`	The password for the user name associated with the credentials	`null`

Download Request Headers

```
var headers = new Dictionary { { "1", "1" } };
Download(address, headers);
Download(address, headers, userName, password);
```

Save Files

When you download a remote file, save it into the Object Store so that you don't have to download the file again. If you need to import the file multiple times, it's faster to import it from the Object Store rather than repeatedly downloading the file from the remote file provider.

Transport Binary Data

Follow these steps to transport binary files:

1. Add the following imports to your local program:
2. Serialize your object.
3. Save the string representation of your object to one of the supported sources .
4. Download the remote file into your project.
5. Restore the object.

Examples

The following examples demonstrate common practices for bulk downloading data.

Example 1: Download Machine Learning Model

The following algorithm makes use of a Scikit-Learn machine learning model to predict SPY price changes and place orders according to the prediction. To obtain the model, we either retrieve it from the Object Store if there exists any or download it from a Dropbox link using the `download` method.

Consolidating Data

Consolidating Data

Getting Started

Introduction

Consolidating data allows you to create bars of any length from smaller bars. Consolidation is commonly used to combine one-minute price bars into longer bars such as 10-20 minute bars. Consolidated bars are helpful because price movement over a longer period can sometimes contain less noise and bars of exotic length are less researched than standard bars, so they may present more opportunities to capture alpha.

To consolidate data, create a `Consolidator` object and register it for data. The built-in consolidators make it easy to create consolidated bars without introducing bugs. In the following sections, we will introduce the different types of consolidators and show you how to shape data into any form.

Basic Usage

The following code snippet demonstrates a simple consolidator that aggregates 1-minute bars into 10-minutes bars:

```
C#
```

```
// Add some class members
private Symbol _symbol;
private TradeBarConsolidator _consolidator;

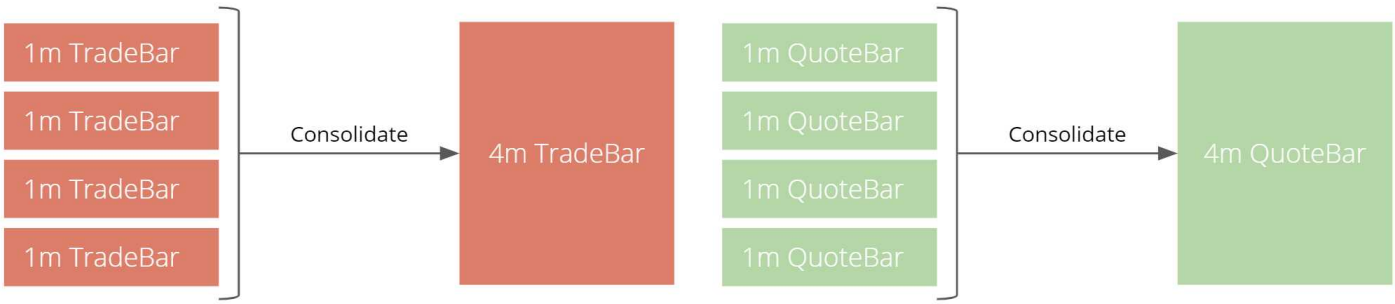
// In Initialize, subscribe to a security, create the consolidator, and register it for automatic updates
_symbol = AddEquity("SPY", Resolution.Minute).Symbol;
_consolidator = Consolidate(_symbol, TimeSpan.FromMinutes(10), ConsolidationHandler);

// Define the consolidation handler
void ConsolidationHandler(TradeBar consolidatedBar)
{

}
```

Data Shapes and Sizes

Consolidators usually produce output data that is the same format as the input data. They aggregate small `TradeBar` objects into a large `TradeBar` , small `QuoteBar` objects into a large `QuoteBar` , and `Tick` objects into either a `TradeBar` or `QuoteBar` .



Many asset classes in QuantConnect have data for both trades and quotes. By default, consolidators aggregate data into

`TradeBar` objects. Forex data is the only exception, which consolidators aggregate into `QuoteBar` objects since Forex data doesn't have `TradeBar` objects.

Consolidator Types

There are many different types of consolidators you can create. The process to create and update the consolidator depends on the input data format, output data format, and the consolidation technique.

Time Period Consolidators

Time period consolidators aggregate data based on a period of time like a number of seconds, minutes, or days. If a time period consolidator aggregates data over multiple days, the multi-day aggregation cycle starts and repeats based on the time stamp of the first data point you use to update the consolidator.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Calendar Consolidators

Calendar consolidators aggregate data based on specific periods of time like a weekly basis, quarterly basis, or any schedule with specific start and end times. In contrast to time period consolidators, the bars that calendar consolidators produce always end on the same schedule, regardless of the first data point the consolidator receives.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Count Consolidators

Count consolidators aggregate data based on a number of bars or ticks. This type of consolidator aggregates n samples together, regardless of the time period the samples cover. Managing count consolidators is similiar to managing time period consolidators , except you create count consolidators with an integer argument instead of a time-based argument.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Mixed-Mode Consolidators

Mixed-mode consolidators are a combination of count consolidators and time period consolidators. This type of consolidator aggregates n samples together or aggregates samples over a specific time period, whichever happens first.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	TradeBarConsolidator
`QuoteBar`	`QuoteBar`	QuoteBarConsolidator
`Tick`	`TradeBar`	TickConsolidator
`Tick`	`QuoteBar`	TickQuoteBarConsolidator

Renko Consolidators

Most Renko consolidators aggregate bars based on a fixed price movement. The `RenkoConsolidator` produces Renko bars by their traditional definition. In the case of a $1 bar size, the `RenkoConsolidator` produces bars that have a body spanning 1.*Theopeningpriceofthefirstbarissettotheclosest*1 multiple of the first trade. When the price moves by at least 1, *thefirstbarcloses*. *Ifabarisarisingbar*, *thefollowingbarcloseswhenthepricemoves*1 above the closing price of the previous bar or 1*belowtheopeningpriceofthepreviousbar*. *Ifabarisafallingbar*, *thefollowingbarcloseswhenthepricemoves*1 below the closing price of the previous bar or $1 above the opening price of the previous bar. If the price jumps multiple dollars in a single tick, the `RenkoConsolidator` produces multiple $1 bars in a single time step.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	RenkoConsolidator
`QuoteBar`	`QuoteBar`	RenkoConsolidator
`Tick`	`TradeBar`	RenkoConsolidator
`Tick`	`QuoteBar`	RenkoConsolidator

Classic Renko Consolidators

Most Renko consolidators aggregate bars based on a fixed price movement. The `ClassicRenkoConsolidator` produces a different type of Renko bars than the `RenkoConsolidator` . A `ClassicRenkoConsolidator` with a bar size of

1*producesanewbarthatspans*1 every time an asset closes $1 away from the close of the previous bar. If the price jumps multiple dollars in a single tick, the `ClassicRenkoConsolidator` only produces one bar per time step where the open of each bar matches the close of the previous bar.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	ClassicRenkoConsolidator
`QuoteBar`	`QuoteBar`	ClassicRenkoConsolidator
`Tick`	`TradeBar`	ClassicRenkoConsolidator
`Tick`	`QuoteBar`	ClassicRenkoConsolidator

Volume Renko Consolidators

Volume Renko consolidators aggregate bars based on a fixed trading volume. These types of bars are commonly known as volume bars. A `VolumeRenkoConsolidator` with a bar size of 10,000 produces a new bar every time 10,000 units of the security trades in the market. If the trading volume of a single time step exceeds two step sizes (i.e. >20,000), the `VolumeRenkoConsolidator` produces multiple bars in a single time step.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	VolumeRenkoConsolidator
`Tick`	`TradeBar`	VolumeRenkoConsolidator

Range Consolidators

Most Range consolidators aggregate bars based on a fixed price movement. It is very much like a Renko Bar, but instead of consolidating a fix movement from the opening price, a Range Bar would fix the range of the whole bar, i.e. High - Low. A new bar is formed when the range of the whole bar reached a preset value, thus it completely neglects the time effect and focuses on the variance/information carried by the price movement.

The following table shows which consolidator type to use based on the data format of the input and output:

Input	Output	Class Type
`TradeBar`	`TradeBar`	RangeConsolidator
`QuoteBar`	`QuoteBar`	RangeConsolidator
`Tick`	`TradeBar`	RangeConsolidator
`Tick`	`QuoteBar`	RangeConsolidator

Sequential Consolidators

Sequential consolidators wire two internal consolidators together such that the output of the first consolidator is the input to the

second consolidator and the output of the second consolidator is the output of the sequential consolidator.

For more information about sequential consolidators, see Combining Consolidators .

Execution Sequence

The algorithm manager calls events in the following order:

1. Scheduled Events
2. Consolidation event handlers
3. `OnData` event handler

This event flow is important to note. For instance, if your consolidation handlers or `OnData` event handler appends data to a `RollingWindow` and you use that `RollingWindow` in your Scheduled Event, when the Scheduled Event executes, the `RollingWindow` won't contain the most recent data.

The consolidators are called in the order that they are updated. If you register them for automatic updates, they are updated in the order that you register them.

Plot Consolidated Data

To plot consolidated bars, call the `Plot` method with a `TradeBar` argument in the consolidation handler.

```
C#

// In Initialize
var equity = AddEquity("SPY");
Consolidate(equity.Symbol, TimeSpan.FromMinutes(10), ConsolidationHandler);

// Define the consolidation handler
void ConsolidationHandler(TradeBar consolidatedBar)
{
    Plot("<chartName>", "<seriesName>", consolidatedBar)
}
```

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
C#

_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```
C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Quick Start Lesson 4: How do I use Consolidators? C#

Consolidating Data

Consolidator Types

Consolidator Types

Time Period Consolidators

Introduction

Time period consolidators aggregate data based on a period of time like a number of seconds, minutes, or days. If a time period consolidator aggregates data over multiple days, the multi-day aggregation cycle starts and repeats based on the time stamp of the first data point you use to update the consolidator.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `TimeSpan` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `TimeSpan` Periods

     ```
     C#
     _consolidator = new TradeBarConsolidator(TimeSpan.FromDays(1));
     // Aliases:
     // _consolidator = CreateConsolidator(TimeSpan.FromDays(1), typeof(TradeBar));
     // _consolidator = ResolveConsolidator(_symbol, TimeSpan.FromDays(1));
     ```

     The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `startTime` parameter of the TradeBarConsolidator type constructor to define a custom start time.

     ```
     C#
     _consolidator = new TradeBarConsolidator(TimeSpan.FromDays(1),
         startTime: new TimeSpan(9, 30, 0));
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

```
_consolidator = TradeBarConsolidator.FromResolution(Resolution.Daily);
// Alias:
// _consolidator = ResolveConsolidator(_symbol, Resolution.Daily);
```

If the security subscription in your algorithm provides `TradeBar` and `QuoteBar` data, `ResolveConsolidator` returns a `TradeBarConsolidator` .

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the TradeBarConsolidator type constructor to `TimeSpan(9, 30, 0)`

2. Add an event handler to the consolidator.

```
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
void ConsolidationHandler(object sender, TradeBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  SubscriptionManager.AddConsolidator(_symbol, _consolidator);
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To

manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var tradeBar = slice.Bars[_symbol];
    _consolidator.Update(tradeBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
foreach (var tradeBar in history)
{
    _consolidator.Update(tradeBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `TimeSpan` or `Resolution` object:

- `TimeSpan` Periods

  ```
  _consolidator = Consolidate(_symbol, TimeSpan.FromDays(1), ConsolidationHandler);
  ```

- `Resolution` Periods

  ```
  _consolidator = Consolidate(_symbol, Resolution.Daily, ConsolidationHandler);
  ```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
void ConsolidationHandler(TradeBar consolidatedBar)
{

}
```

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `TimeSpan` or `Resolution` object. The consolidator time

period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

- `TimeSpan` Periods

```
C#
_consolidator = new QuoteBarConsolidator(TimeSpan.FromDays(1));
// Aliases:
// _consolidator = CreateConsolidator(TimeSpan.FromDays(1), typeof(QuoteBar));
// _consolidator = ResolveConsolidator(_symbol, TimeSpan.FromDays(1));
```

The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

Use the `startTime` parameter of the QuoteBarConsolidator type constructor to define a custom start time.

```
C#
_consolidator = new QuoteBarConsolidator(TimeSpan.FromDays(1),
    startTime: new TimeSpan(9, 30, 0));
```

- `Resolution` Periods

The `Resolution` enumeration has the following members:

```
C#
_consolidator = ResolveConsolidator(_symbol, Resolution.Daily);
```

If the security subscription in your algorithm provides `TradeBar` and `QuoteBar` data, `ResolveConsolidator` returns a `TradeBarConsolidator` .

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the QuoteBarConsolidator type constructor to `TimeSpan(9, 30, 0)`

2. Add an event handler to the consolidator.

```
C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#

     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     C#

     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var quoteBar = slice.QuoteBars[_symbol];
         _consolidator.Update(quoteBar);
     }

     // Example 2: Update the consolidator with data from a history request
     var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
     foreach (var quoteBar in history)
     {
         _consolidator.Update(quoteBar);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#

   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `TimeSpan` or `Resolution` object:

- `TimeSpan` Periods

```C#
_consolidator = Consolidate<QuoteBar>(_symbol, TimeSpan.FromDays(1), TickType.Quote, ConsolidationHandler);
```

- `Resolution` Periods

```C#
_consolidator = Consolidate<QuoteBar>(_symbol, Resolution.Daily, TickType.Quote, ConsolidationHandler);
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```C#
void ConsolidationHandler(QuoteBar consolidatedBar)
{

}
```

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `TimeSpan` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `TimeSpan` Periods

     ```C#
     _consolidator = new TickConsolidator(TimeSpan.FromMilliseconds(100));
     // Aliases:
     // _consolidator = CreateConsolidator(TimeSpan.FromMilliseconds(100), typeof(Tick));
     // _consolidator = ResolveConsolidator(_symbol, TimeSpan.FromMilliseconds(100));
     ```

     The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `startTime` parameter of the TickConsolidator type constructor to define a custom start time.

     ```C#
     _consolidator = new TickConsolidator(TimeSpan.FromMilliseconds(100),
         startTime: new TimeSpan(9, 30, 0));
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

     ```C#
     _consolidator = ResolveConsolidator(_symbol, Resolution.Second);
     ```

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open.

For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the TickConsolidator type constructor to `TimeSpan(9, 30, 0)`

2. Add an event handler to the consolidator.

```
C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, TradeBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```C#
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `TimeSpan` or `Resolution` object:

- `TimeSpan` Periods

  ```C#
  _consolidator = Consolidate(_symbol, TimeSpan.FromMilliseconds(100), ConsolidationHandler);
  ```

- `Resolution` Periods

  ```C#
  _consolidator = Consolidate(_symbol, Resolution.Second, ConsolidationHandler);
  ```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```C#
void ConsolidationHandler(TradeBar consolidatedBar)
{

}
```

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `TimeSpan` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute

bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

- `TimeSpan` Periods

  ```
  C#

  _consolidator = new TickQuoteBarConsolidator(TimeSpan.FromMilliseconds(100));
  // Aliases:
  // _consolidator = CreateConsolidator(TimeSpan.FromMilliseconds(100), typeof(Tick), TickType.Quote);
  // _consolidator = ResolveConsolidator(_symbol, TimeSpan.FromMilliseconds(100), typeof(QuoteBar));
  ```

  The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

  Use the `startTime` parameter of the TickQuoteBarConsolidator type constructor to define a custom start time.

  ```
  C#

  _consolidator = new TickQuoteBarConsolidator(TimeSpan.FromMilliseconds(100),
      startTime: new TimeSpan(9, 30, 0));
  ```

- `Resolution` Periods

  The `Resolution` enumeration has the following members:

  ```
  C#

  _consolidator = ResolveConsolidator(_symbol, Resolution.Second);
  ```

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the TickQuoteBarConsolidator type constructor to `TimeSpan(9, 30, 0)`

2. Add an event handler to the consolidator.

   ```
   C#

   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#

   void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the consolidated bar closes based on the data time zone . If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily

consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#

     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     C#

     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var ticks = slice.Ticks[_symbol];
         foreach (var tick in ticks)
         {
          _consolidator.Update(tick);
         }
     }

     // Example 2: Update the consolidator with data from a history request
     var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
     foreach (var tick in ticks)
     {
         _consolidator.Update(tick);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#

   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `TimeSpan` or `Resolution` object:

- `TimeSpan` Periods

  ```
  C#

  _consolidator = Consolidate<QuoteBar>(_symbol, TimeSpan.FromMilliseconds(100), TickType.Quote,
  ConsolidationHandler);
  ```

- `Resolution` Periods

```
C#
_consolidator = Consolidate<QuoteBar>(_symbol, Resolution.Second, TickType.Quote, ConsolidationHandler);
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
C#
void ConsolidationHandler(QuoteBar consolidatedBar)
{

}
```

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on a period of time:

1. Create the consolidator.

   To set the time period for the consolidator, you can use either a `TimeSpan` or `Resolution` object. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   - `TimeSpan` Periods

     ```
     C#
     _consolidator = new DynamicDataConsolidator(TimeSpan.FromDays(1));
     // Aliases:
     // _consolidator = CreateConsolidator(TimeSpan.FromDays(1), typeof(<dataType>));
     // _consolidator = ResolveConsolidator(_symbol, TimeSpan.FromDays(1));
     ```

     The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

     Use the `startTime` parameter of the DynamicDataConsolidator type constructor to define a custom start time.

     ```
     C#
     _consolidator = new DynamicDataConsolidator(TimeSpan.FromDays(1),
         startTime: new TimeSpan(9, 30, 0));
     ```

   - `Resolution` Periods

     The `Resolution` enumeration has the following members:

     ```
     C#
     _consolidator = ResolveConsolidator(_symbol, Resolution.Daily);
     ```

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the DynamicDataConsolidator type constructor to `TimeSpan(9, 30, 0)`

2. Add an event handler to the consolidator.

```C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```C#
void ConsolidationHandler(object sender, <dataType> consolidatedBar)
{

}
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```C#
  SubscriptionManager.AddConsolidator(_symbol, _consolidator);
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```C#
  // Example 1: Update the consolidator with data from the Slice object
  public override void OnData(Slice slice)
  {
      if slice.ContainsKey(_symbol)
      {
          _consolidator.Update(slice[_symbol]);
      }
  }

  // Example 2: Update the consolidator with data from a history request
  var history = History<<dataType>>(_symbol, 30, Resolution.Daily);
  foreach (var data in history)
  {
      _consolidator.Update(data);
  }
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the

consolidator when the security leaves the universe.

```
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create period consolidators and register them for automatic updates. With just one line of code, you can create data in any time period based on a `TimeSpan` or `Resolution` object:

- `TimeSpan` Periods

```
_consolidator = Consolidate(_symbol, TimeSpan.FromDays(1), ConsolidationHandler);
```

- `Resolution` Periods

```
_consolidator = Consolidate(_symbol, Resolution.Daily, ConsolidationHandler);
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
void ConsolidationHandler(<dataType> consolidatedBar)
{

}
```

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Examples

The following examples demonstrate common practices for implementing time-period consolidators.

Example 1: RSI-MACD Trading

The following algorithm utilizes a 5-minute trade bar consolidator to feed the smoothed trade bar to an RSI indicator and a 15-minute quote bar consolidator to feed the smoothed quote bar to a MACD indicator, generating trade entry signals during an uptrend and oversold conditions while exiting when the trend turns down.

C#

```
public class TimePeriodConsolidatorAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Create RSI and MACD indicators for trade signal generation.
    private RelativeStrengthIndex _rsi = new(14);
    private MovingAverageConvergenceDivergence _macd = new(12, 26, 9);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data to feed to indicators and trade.
        _spy = AddEquity("SPY").Symbol;

        // Create a 5-minute trade bar consolidator to feed the smoothed bar to the RSI indicator for the price
action entry signal.
        var rsiConsolidator = new TradeBarConsolidator(TimeSpan.FromMinutes(5));
        // Create a 15-minute quote bar consolidator to feed the smoothed bar to the MACD consolidator for trend
entry/exit signal.
        var macdConsolidator = new QuoteBarConsolidator(TimeSpan.FromMinutes(15));

        // Subscribe the consolidators to SPY data to automatically update the indicators.
        RegisterIndicator(_spy, _rsi, rsiConsolidator);
        RegisterIndicator(_spy, _macd, macdConsolidator);

        // Warm up the indicators by updating the consolidators with historical data.
        var tradeBars = History<TradeBar>(_spy, 5 * _rsi.WarmUpPeriod, Resolution.Minute);
        foreach (var bar in tradeBars)
        {
            rsiConsolidator.Update(bar);
        }
        var quoteBars = History<QuoteBar>(_spy, 15 * _macd.WarmUpPeriod, Resolution.Minute);
        foreach (var bar in quoteBars)
        {
            macdConsolidator.Update(bar);
        }
    }

    public override void OnData(Slice slice)
    {
        // Entry rule: To maximize return, the MACD histogram must be positive (positive trend) and the RSI must be
below 30 (oversold).
        if (_rsi < 30 && _macd.Histogram > 0 && !Portfolio[_spy].IsLong)
        {
            SetHoldings(_spy, 0.5m);
        }
        // Exit rule: MACD histogram is below 0 (negative trend)
        else if (_macd.Histogram < 0 && Portfolio[_spy].IsLong)
        {
            Liquidate(_spy);
        }
    }
}
```

Example 2: Create Daily `QuoteBar` Objects That Start at 5 PM

The following algorithm consolidates minute resolution Forex data into daily `QuoteBar` objects that open and close at 5 PM Eastern Time.

C#

```
public class CustomStartTimeConsolidatorExampleAlgorithm : QCAlgorithm
{
    private Forex _pair;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add the USDJPY Forex pair.
        _pair = AddForex("USDJPY");
        // Create an EMA indicator for the pair.
        var ema = new ExponentialMovingAverage(10);
        _pair.Set("Ema", ema);
        // Create a QuoteBar consolidator with a custom start time.
        var consolidator = new QuoteBarConsolidator(TimeSpan.FromDays(1), TimeSpan.FromHours(17));
        // Attach a consolidation handler that will receive the consolidated bars.
        consolidator.DataConsolidated += ConsolidationHandler;
        // Subscribe the consolidator for automatic updates with the prices of the pair.
        SubscriptionManager.AddConsolidator(_pair.Symbol, consolidator);
        // Register the indicator for automatic updates with the consolidated bars.
        RegisterIndicator<IndicatorDataPoint>(_pair.Symbol, ema, consolidator);
        // Warm up the consolidator and indicator.
        var history = History<QuoteBar>(_pair.Symbol, 29000, Resolution.Minute);
        foreach (var bar in history)
        {
            consolidator.Update(bar);
        }
    }

    private void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
    {
        // Wait until the indicator is ready and the algorithm is running.
        var ema = _pair.Get<ExponentialMovingAverage>("Ema");
        if (!ema.IsReady || IsWarmingUp)
        {
            return;
        }
        // Plot the closing price and the EMA.
        Plot(consolidatedBar.Symbol.Value, "Close", consolidatedBar.Close);
        Plot(consolidatedBar.Symbol.Value, "EMA", ema.Current.Value);

        if (!_pair.Holdings.IsLong && consolidatedBar.Close > ema)
        {
            SetHoldings(_pair.Symbol, 1);
        }
        if (consolidatedBar.Close < ema)
        {
            Liquidate();
        }
    }
}
```

Consolidator Types

Calendar Consolidators

Introduction

Calendar consolidators aggregate data based on specific periods of time like a weekly basis, quarterly basis, or any schedule with specific start and end times. In contrast to time period consolidators, the bars that calendar consolidators produce always end on the same schedule, regardless of the first data point the consolidator receives.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

     ```
     C#
     _consolidator = new TradeBarConsolidator(Calendar.Weekly);
     // Alias:
     // _consolidator = CreateConsolidator(Calendar.Weekly, typeof(TradeBar));
     ```

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `DateTime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```C#
_consolidator = new TradeBarConsolidator(datetime => {
    var period = TimeSpan.FromDays(7);

    var timeSpan = new TimeSpan(17, 0, 0);
    var newDateTime = datetime.Date + timeSpan;
    var delta = 1 + (int)newDateTime.DayOfWeek;
    if (delta > 6)
    {
        delta = 0;
    }
    var start = newDateTime.AddDays(-delta);

    return new CalendarInfo(start, period);
});
```

2. Add an event handler to the consolidator.

```C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```C#
void ConsolidationHandler(object sender, TradeBar consolidatedBar)
{

}
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with

data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var tradeBar = slice.Bars[_symbol];
    _consolidator.Update(tradeBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
foreach (var tradeBar in history)
{
    _consolidator.Update(tradeBar);
}
```

C#

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   C#

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
_consolidator = Consolidate(_symbol, Calendar.Weekly, ConsolidationHandler);
```

C#

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
void ConsolidationHandler(TradeBar consolidatedBar)
{

}
```

C#

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

```
C#
_consolidator = new QuoteBarConsolidator(Calendar.Weekly);
// Alias:
// _consolidator = CreateConsolidator(Calendar.Weekly, typeof(QuoteBar));
```

- Custom Periods

  If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `DateTime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
C#
_consolidator = new QuoteBarConsolidator(datetime => {
    var period = TimeSpan.FromDays(7);

    var timeSpan = new TimeSpan(17, 0, 0);
    var newDateTime = datetime.Date + timeSpan;
    var delta = 1 + (int)newDateTime.DayOfWeek;
    if (delta > 6)
    {
        delta = 0;
    }
    var start = newDateTime.AddDays(-delta);

    return new CalendarInfo(start, period);
});
```

2. Add an event handler to the consolidator.

```
C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler`, not `ConsolidationHandler()`.

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
{

}
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     C#
     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var quoteBar = slice.QuoteBars[_symbol];
         _consolidator.Update(quoteBar);
     }

     // Example 2: Update the consolidator with data from a history request
     var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
     foreach (var quoteBar in history)
     {
         _consolidator.Update(quoteBar);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
_consolidator = Consolidate<QuoteBar>(_symbol, Calendar.Weekly, TickType.Quote, ConsolidationHandler);
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
void ConsolidationHandler(QuoteBar consolidatedBar)
{

}
```

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

     ```
     _consolidator = new TickConsolidator(Calendar.Weekly);
     // Alias:
     // _consolidator = CreateConsolidator(Calendar.Weekly, typeof(Tick));
     ```

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `DateTime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
C#
_consolidator = new TickConsolidator(datetime => {
    var period = TimeSpan.FromDays(7);

    var timeSpan = new TimeSpan(17, 0, 0);
    var newDateTime = datetime.Date + timeSpan;
    var delta = 1 + (int)newDateTime.DayOfWeek;
    if (delta > 6)
    {
        delta = 0;
    }
    var start = newDateTime.AddDays(-delta);

    return new CalendarInfo(start, period);
});
```

2. Add an event handler to the consolidator.

```
C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, TradeBar consolidatedBar)
{

}
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data

from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
_consolidator = Consolidate(_symbol, Calendar.Weekly, ConsolidationHandler);
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
void ConsolidationHandler(TradeBar consolidatedBar)
{

}
```

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

```
C#
_consolidator = new TickQuoteBarConsolidator(Calendar.Weekly);
// Alias:
// _consolidator = CreateConsolidator(Calendar.Weekly, typeof(Tick), TickType.Quote);
```

- Custom Periods

  If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `DateTime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```
C#
_consolidator = new TickQuoteBarConsolidator(datetime => {
    var period = TimeSpan.FromDays(7);

    var timeSpan = new TimeSpan(17, 0, 0);
    var newDateTime = datetime.Date + timeSpan;
    var delta = 1 + (int)newDateTime.DayOfWeek;
    if (delta > 6)
    {
        delta = 0;
    }
    var start = newDateTime.AddDays(-delta);

    return new CalendarInfo(start, period);
});
```

2. Add an event handler to the consolidator.

```
C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler`, not `ConsolidationHandler()`.

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
{

}
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     C#
     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var ticks = slice.Ticks[_symbol];
         foreach (var tick in ticks)
         {
          _consolidator.Update(tick);
         }
     }

     // Example 2: Update the consolidator with data from a history request
     var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
     foreach (var tick in ticks)
     {
         _consolidator.Update(tick);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
C#
_consolidator = Consolidate<QuoteBar>(_symbol, Calendar.Weekly, TickType.Quote, ConsolidationHandler);
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
C#
void ConsolidationHandler(QuoteBar consolidatedBar)
{

}
```

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on custom start and end periods:

1. Create the consolidator.

   To set the time period for the consolidator, you can use the built-in `CalendarInfo` objects or create your own. The following list describes each technique:

   - Standard Periods

     The following table describes the helper methods that the `Calendar` class provides to create the built-in `CalendarInfo` objects:

Method	Description
`Calendar.Weekly`	Computes the start of week (previous Monday) of the given date/time
`Calendar.Monthly`	Computes the start of month (1st of the current month) of the given date/time
`Calendar.Quarterly`	Computes the start of quarter (1st of the starting month of the current quarter) of the given date/time
`Calendar.Yearly`	Computes the start of year (1st of the current year) of the given date/time

     ```
     C#
     _consolidator = new DynamicDataConsolidator(Calendar.Weekly);
     // Alias:
     // _consolidator = CreateConsolidator(Calendar.Weekly, typeof(<dataType>));
     ```

   - Custom Periods

     If you need something more specific than the preceding time periods, define a method to set the start time and period of the consolidated bars. The method should receive a `DateTime` object that's based in the data time zone and should return a `CalendarInfo` object, which contains the start time of the bar in the data time zone and the duration of the consolidation period. The following example demonstrates how to create a custom consolidator for weekly bars:

```C#
_consolidator = new DynamicDataConsolidator(datetime => {
    var period = TimeSpan.FromDays(7);

    var timeSpan = new TimeSpan(17, 0, 0);
    var newDateTime = datetime.Date + timeSpan;
    var delta = 1 + (int)newDateTime.DayOfWeek;
    if (delta > 6)
    {
        delta = 0;
    }
    var start = newDateTime.AddDays(-delta);

    return new CalendarInfo(start, period);
});
```

2. Add an event handler to the consolidator.

```C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```C#
void ConsolidationHandler(object sender, <dataType> consolidatedBar)
{

}
```

If you use a custom consolidation period method, LEAN passes the consolidated bar to the consolidation handler when the consolidation period ends. The `Time` and `EndTime` properties of the consolidated bar reflect the data time zone, but the `Time` property of the algorithm still reflects the algorithm time zone .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

```C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator

with data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    if slice.ContainsKey(_symbol)
    {
        _consolidator.Update(slice[_symbol]);
    }
}

// Example 2: Update the consolidator with data from a history request
var history = History<<dataType>>(_symbol, 30, Resolution.Daily);
foreach (var data in history)
{
    _consolidator.Update(data);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

You can also use the `Consolidate` helper method to create calendar consolidators and register them for automatic updates.

```
_consolidator = Consolidate(_symbol, Calendar.Weekly, ConsolidationHandler);
```

If you use the `Consolidate` helper method, the consolidation handler doesn't receive an `object` argument.

```
void ConsolidationHandler(<dataType> consolidatedBar)
{

}
```

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Examples

The following examples demonstrate some common practices for calendar consolidators.

Example 1: Daily Futures Bars

Daily bars from the CME and Yahoo Finance represent the price action from 5 PM Central Time (CT) to 4 PM CT on the following day. In contrast, the regular daily resolution bars on QuantConnect represent the price action from 12 AM Eastern Time (ET) to 12 AM ET the following day. To create daily bars that represent the same period of time as the daily bars from the CME, the following algorithm consolidates minute bars (during regular and extended market hours) into daily bars that span from 5 PM CT to 4 PM CT on the following day. The algorithm then uses these consolidated daily bars to place take profit and stop loss orders as a function of the daily Average True Range .

```C#
public class CalendarConsolidatorExampleAlgorithm : QCAlgorithm
{
    private Future _future;
    private decimal _takeProfitPrice, _stopLossPrice;
    // Create an ATR indicator to set take profit and stop loss levels.
    private AverageTrueRange _atr = new(10);
    // Create a day tracker to avoid over-trading.
    private int _day = -1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add ES Futures data and configure the continuous contract settings
        // so you can update the ATR with a smooth feed of prices.
        _future = AddFuture(
            Futures.Indices.SP500EMini,
            extendedMarketHours: true,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            dataMappingMode: DataMappingMode.OpenInterest,
            contractDepthOffset: 0
        );
        // Create a calendar consolidator to generate daily ES Futures bars
        // since market starts at 6pm EST to 5pm EST next day.
        var consolidator = new TradeBarConsolidator(FutureTradingHour);
        consolidator.DataConsolidated += OnConsolidated;
        // Warm up the consolidator and ATR indicator.
        var history = History<TradeBar>(_future.Symbol, 14500, Resolution.Minute);
        foreach (var bar in history)
        {
            consolidator.Update(bar);
        }
        // Subscribe the consolidator for automatic updates with ES data.
```

```
        SubscriptionManager.AddConsolidator(_future.Symbol, consolidator);
    }

    private CalendarInfo FutureTradingHour(DateTime datetime)
    {
        // Set the open time of the bar to be 6 PM EST.
        var start = datetime.Date.AddHours(datetime.Hour < 18 ? -6 : 18);
        // Set the close time of the bar to be 5 PM EST the next day, which is 23 hours later.
        return new CalendarInfo(start, TimeSpan.FromHours(23));
    }

    private void OnConsolidated(object sender, TradeBar bar)
    {
        // Update the ATR indicator since we want the daily ATR to set the stop price.
        _atr.Update(bar);
        // Set the daily take profit and stop price levels as a function of the previous
        // close price and the ATR.
        _takeProfitPrice = bar.Close + _atr * 2m;
        _stopLossPrice = bar.Close - _atr * 2m;
    }

    public override void OnData(Slice slice)
    {
        // Liquidate the current contract in the continuous contract series
        // when it's about to expire.
        if (slice.SymbolChangedEvents.TryGetValue(_future.Symbol, out var changedEvent))
        {
            Liquidate(changedEvent.OldSymbol);
        }

        // If we're not invested, buy the current contract in the continuous contract series.
        if (!Portfolio.Invested && Securities[_future.Mapped].Price != 0 && _day != slice.Time.Day)
        {
            MarketOrder(_future.Mapped, 1);
        }
        // If we're already invested, check if we've hit the TP/SL level.
        else if (Portfolio.Invested && slice.Bars.TryGetValue(_future.Symbol, out var bar))
        {
            // Check if the current price is above profit taker or below stop loss.
            if (bar.Close > _takeProfitPrice || bar.Close < _stopLossPrice)
            {
                // Exit the position.
                Liquidate();
            }
        }
        // Update the daily tracker so we only update our position once per day.
        _day = slice.Time.Day;
    }
}
```

Example 2: Create Daily `QuoteBar` Objects That Start at 5 PM

The following algorithm consolidates minute resolution Forex data into daily `QuoteBar` objects that open and close at 5 PM Eastern Time.

C#

```
public class CalendarConsolidatorExampleAlgorithm : QCAlgorithm
{
    private dynamic _pair;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add the USDJPY Forex pair.
        _pair = AddForex("USDJPY");
        // Create an EMA indicator for the pair.
        _pair.Ema = new ExponentialMovingAverage(10);
        // Create a QuoteBar consolidator with a custom consolidation period.
        var consolidator = new QuoteBarConsolidator(DailyForexConsolidationPeriod);
        // Attach a consolidation handler that will receive the consolidated bars.
        consolidator.DataConsolidated += ConsolidationHandler;
        // Subscribe the consolidator for automatic updates with the prices of the pair.
        SubscriptionManager.AddConsolidator(_pair.Symbol, consolidator);
        // Register the indicator for automatic updates with the consolidated bars.
        RegisterIndicator<IndicatorDataPoint>(_pair.Symbol, _pair.Ema, consolidator);
        // Warm up the consolidator and indicator.
        var history = History<QuoteBar>(_pair.Symbol, 29000, Resolution.Minute);
        foreach (var bar in history)
        {
            consolidator.Update(bar);
        }
    }

    // Define the consolidation period.
    private CalendarInfo DailyForexConsolidationPeriod(DateTime dt)
    {
        // Set the start of the bar to be 5 PM ET.
        var start = dt.Date;
        if (dt.Hour < 17)
        {
            start = start.AddHours(-7);
        }
        else
        {
            start = start.AddHours(17);
        }
        // Set the end of the bar to be 5 PM ET the next day.
        return new CalendarInfo(start, TimeSpan.FromDays(1));
    }

    private void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
    {
        // Wait until the indicator is ready and the algorithm is running.
        if (!_pair.Ema.IsReady || IsWarmingUp)
        {
            return;
        }
        // Plot the closing price and the EMA.
        Plot(consolidatedBar.Symbol.ToString(), "Close", consolidatedBar.Close);
        Plot(consolidatedBar.Symbol.ToString(), "EMA", _pair.Ema.Current.Value);
    }
}
```

For a version of this algorithm with Time Period Consolidators, see Time Period Consolidators > Examples .

Example 3: Monthly Candlesticks

The following algorithm consolidates minute-resolution data into monthly `TradeBar` objects and then plots them as candlesticks .

C#

```
public class CalendarConsolidatorExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add an asset.
        var symbol = AddEquity("SPY").Symbol;
        // Create a consolidator that produces monthly TradeBar objects.
        // This is the stardard way:
        //var consolidator = new TradeBarConsolidator(Calendar.Monthly);
        // However, you can acomplish the same thing with a custom period:
        var consolidator = new TradeBarConsolidator(CustomMonthly);
        // Add a consolidation handler that plots the monthly bars as candlesticks.
        consolidator.DataConsolidated += (_, bar) => Plot(
            "Monthly Candlestick", symbol.Value, bar.Open, bar.High, bar.Low, bar.Close
        );
        // Register the consolidator for automatic updates.
        SubscriptionManager.AddConsolidator(symbol, consolidator);
    }

    public CalendarInfo CustomMonthly(DateTime dt)
    {
        // Set the start time to the beginning of the month.
        var start = dt.AddDays(1 - dt.Day).Date;
        // Set the end time to the beginning of next month.
        var end = start.AddMonths(1);
        return new CalendarInfo(start, (end - start));
    }
}
```

Consolidator Types

Count Consolidators

Introduction

Count consolidators aggregate data based on a number of bars or ticks. This type of consolidator aggregates n samples together, regardless of the time period the samples cover. Managing count consolidators is similiar to managing time period consolidators , except you create count consolidators with an integer argument instead of a time-based argument.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   C#
   _consolidator = new TradeBarConsolidator(10);
   ```

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, TradeBar consolidatedBar)
   {

   }
   ```

   When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  // Example 1: Update the consolidator with data from the Slice object
  public override void OnData(Slice slice)
  {
      var tradeBar = slice.Bars[_symbol];
      _consolidator.Update(tradeBar);
  }

  // Example 2: Update the consolidator with data from a history request
  var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
  foreach (var tradeBar in history)
  {
      _consolidator.Update(tradeBar);
  }
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   _consolidator = new QuoteBarConsolidator(10);
   ```

2. Add an event handler to the consolidator.

   ```
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself.

Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
{

}
```

When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var quoteBar = slice.QuoteBars[_symbol];
    _consolidator.Update(quoteBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
foreach (var quoteBar in history)
{
    _consolidator.Update(quoteBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
C#
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   C#
   _consolidator = new TickConsolidator(10);
   ```

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, TradeBar consolidatedBar)
   {

   }
   ```

   When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   _consolidator = new TickQuoteBarConsolidator(10);
   ```

2. Add an event handler to the consolidator.

   ```
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler`, not `ConsolidationHandler()`.

3. Define the consolidation handler.

```
void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
{

}
```

When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var ticks = slice.Ticks[_symbol];
         foreach (var tick in ticks)
         {
          _consolidator.Update(tick);
         }
     }

     // Example 2: Update the consolidator with data from a history request
     var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
     foreach (var tick in ticks)
     {
         _consolidator.Update(tick);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Other Data

`<dataType>` consolidators aggregate various types of data objects into `<dataType>` objects of the same size or larger. If you

consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a `<dataType>` consolidator based on a number of samples:

1. Create the consolidator.

   To create a count consolidator, pass the number of samples to the consolidator constructor.

   ```
   C#
   _consolidator = new DynamicDataConsolidator(10);
   ```

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, <dataType> consolidatedBar)
   {

   }
   ```

   When the consolidator receives the n -th data point, it passes the consolidated bar to the event handler.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    if slice.ContainsKey(_symbol)
    {
        _consolidator.Update(slice[_symbol]);
    }
}

// Example 2: Update the consolidator with data from a history request
var history = History<<dataType>>(_symbol, 30, Resolution.Daily);
foreach (var data in history)
{
    _consolidator.Update(data);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Examples

The following examples demonstrate common practices for implementing count consolidator.

Example 1: Tick Count Consolidator

```C#
public class CountConsolidatorAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Create EMA indicators for trade signal generation.
    private ExponentialMovingAverage _ema = new(14);
    // The _day variable controls trade daily when open.
    private int _day = -1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 4);
        SetEndDate(2024, 9, 5);

        // Request SPY data to feed to indicators and trade.
        _spy = AddEquity("SPY", Resolution.Tick).Symbol;

        // Create a 10000 trade tick consolidator to feed the "volume" bar to the EMA indicator for trend entry/exit
signal.
        var tickConsolidator = new TickConsolidator(10000);

        // Subscribe the consolidators to SPY data to automatically update the indicators.
        RegisterIndicator(_spy, _ema, tickConsolidator);

        SetWarmUp(120);
    }

    public override void OnData(Slice slice)
    {
        if (_ema.IsReady && slice.Ticks.TryGetValue(_spy, out var ticks) && slice.Time.Day != _day)
        {
            // Obtain the latest quote price from the latest tick.
            var lastTick = ticks.MaxBy(x => x.EndTime);

            // Trade the trend by EMA crosses.
            if (lastTick.Price > _ema && !Portfolio[_spy].IsLong)
            {
                SetHoldings(_spy, 0.5m);
            }
            else if (lastTick.Price < _ema && !Portfolio[_spy].IsShort)
            {
                SetHoldings(_spy, -0.5m);
            }

            _day = slice.Time.Day;
        }
    }
}
```

Mixed-Mode Consolidators

Introduction

Mixed-mode consolidators are a combination of count consolidators and time period consolidators. This type of consolidator aggregates n samples together or aggregates samples over a specific time period, whichever happens first.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `TradeBar` objects of the same size or larger. Follow these steps to create and manage a `TradeBar` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `TimeSpan` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   C#
   _consolidator = new TradeBarConsolidator(10, TimeSpan.FromDays(1));
   ```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the =$consolidatorClassName?> type constructor to `TimeSpan(=$this->timeSpanStartTime?>)`

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, TradeBar consolidatedBar)
   {

   }
   ```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting .

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#

     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     C#

     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var tradeBar = slice.Bars[_symbol];
         _consolidator.Update(tradeBar);
     }

     // Example 2: Update the consolidator with data from a history request
     var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
     foreach (var tradeBar in history)
     {
         _consolidator.Update(tradeBar);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#

   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `QuoteBar` objects of the same size or larger. Follow these steps to create and manage a `QuoteBar` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

To create a mixed-mode consolidator, pass a `TimeSpan` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

```
C#
_consolidator = new QuoteBarConsolidator(10, TimeSpan.FromDays(1));
```

The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the =$consolidatorClassName?> type constructor to `TimeSpan(=$this->timeSpanStartTime?>)`

2. Add an event handler to the consolidator.

```
C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to minute resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to minute resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  C#
  SubscriptionManager.AddConsolidator(_symbol, _consolidator);
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  C#

  // Example 1: Update the consolidator with data from the Slice object
  public override void OnData(Slice slice)
  {
      var quoteBar = slice.QuoteBars[_symbol];
      _consolidator.Update(quoteBar);
  }

  // Example 2: Update the consolidator with data from a history request
  var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
  foreach (var quoteBar in history)
  {
      _consolidator.Update(quoteBar);
  }
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#

   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `TradeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `TimeSpan` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   C#

   _consolidator = new TickConsolidator(10, TimeSpan.FromMilliseconds(100));
   ```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the =$consolidatorClassName?> type constructor to `TimeSpan(=$this->timeSpanStartTime?>)`

2. Add an event handler to the consolidator.

```
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler`, not `ConsolidationHandler()`.

3. Define the consolidation handler.

```
void ConsolidationHandler(object sender, TradeBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period, you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request.

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `QuoteBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a `TimeSpan` object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   _consolidator = new TickQuoteBarConsolidator(10, TimeSpan.FromMilliseconds(100));
   ```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the `startTime` parameter of the =$consolidatorClassName?> type constructor to `TimeSpan(=$this->timeSpanStartTime?>)`

2. Add an event handler to the consolidator.

   ```
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating

consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#

void ConsolidationHandler(object sender, QuoteBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first. If you subscribe to tick resolution data for Bitcoin and create an hourly consolidator, you receive consolidated bars at the top of each hour. However, if you subscribe to tick resolution data for the regular trading hours of US Equities and create a daily consolidator, you receive consolidated bars at market close or midnight, depending on your `DailyPreciseEndTime` setting .

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#

SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
C#

// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Other Data

<dataType> consolidators aggregate various types of data objects into <dataType> objects of the same size or larger. If you consolidate custom data or alternative datasets, check the definition of the data class to see its data type. Follow these steps to create and manage a <dataType> consolidator based on a period of time or a number of samples, whichever occurs first:

1. Create the consolidator.

   To create a mixed-mode consolidator, pass a TimeSpan object and an integer to the consolidator constructor. The consolidator time period must be greater than or equal to the resolution of the security subscription. For instance, you can aggregate minute bars into 10-minute bars, but you can't aggregate hour bars into 10-minute bars.

   ```
   _consolidator = new DynamicDataConsolidator(10, TimeSpan.FromDays(1));
   ```

   The time period is relative to the data time zone , not the algorithm time zone . If you consolidate Crypto data into daily bars, the event handler receives the consolidated bars at midnight 12:00 AM Coordinated Universal Time (UTC), regardless of the algorithm time zone.

   If you consolidate on an hourly basis, the consolidator ends at the top of the hour, not every hour after the market open. For US Equities, that's 10 AM Eastern Time (ET), not 10:30 AM ET. To change this behavior, set the startTime parameter of the =$consolidatorClassName?> type constructor to TimeSpan(=$this->timeSpanStartTime?>)

2. Add an event handler to the consolidator.

   ```
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis () at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be ConsolidationHandler , not ConsolidationHandler() .

3. Define the consolidation handler.

   ```
   void ConsolidationHandler(object sender, <dataType> consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the consolidated bar closes based on the data time zone or the number of samples, whichever occurs first.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the data subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#

     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `<dataType>` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     C#

     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         if slice.ContainsKey(_symbol)
         {
             _consolidator.Update(slice[_symbol]);
         }
     }

     // Example 2: Update the consolidator with data from a history request
     var history = History<<dataType>>(_symbol, 30, Resolution.Daily);
     foreach (var data in history)
     {
         _consolidator.Update(data);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#

   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
C#

_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method

and then warm it up with `ScaledRaw` data from a history request .

```C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Examples

The following examples demonstrate common practices for implementing mixed-mode consolidators.

Example 1: Opening Range Breakout

The following algorithm demonstrates an opening range breakout strategy for BJK (a Gaming ETF). We create a 15-count/30-minute trade bar as the opening range for signal generation. If the close price at 10 am is higher than the high price of the aggregated opening bar, we long BJK and exit by a 2% trailing stop loss.

C#

```
public class MixedModeConsolidatorAlgorithm : QCAlgorithm
{
    private Symbol _equity;
    private TradeBarConsolidator _consolidator;
    private decimal _highPrice = 0m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request CARZ data to feed to the consolidators and trade.
        _equity = AddEquity("CARZ", Resolution.Minute).Symbol;

        // Create a 10-count-or-20-minute trade bar consolidator to create the opening range for trade signal
generation.
        // CARZ is a less liquid ETF, so we use a mixed-mode consolidator.
        _consolidator = new TradeBarConsolidator(10, TimeSpan.FromMinutes(20));

        // Subscribe the consolidators to CARZ data for automatic updating.
        SubscriptionManager.AddConsolidator(_equity, _consolidator);

        // We check if the entry condition is attained 30 minutes after the market opens.
        Schedule.On(
            DateRules.EveryDay(_equity),
            TimeRules.AfterMarketOpen(_equity, 30),
            Entry
        );

        SetWarmUp(1);
    }

    private void Entry()
    {
        // Check if the entry condition is met: the current price is higher than the high price of the open range.
        var current = Securities[_equity].Close;
        if (current > (_consolidator.Consolidated as TradeBar).High)
        {
            MarketOrder(_equity, 20);
            // Cache the current price for trailing stop loss need.
            _highPrice = current;
        }
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_equity, out var bar) && Portfolio.Invested)
        {
            // Update the high price if the current high is higher to update the trailing stop price.
            if (bar.High > _highPrice)
            {
                _highPrice = bar.High;
            }

            // Exit position if the trailing stop loss is hit.
            if (bar.Close < _highPrice * 0.98m)
            {
                Liquidate();
                _highPrice = 0m;
            }
        }
    }
}
```

Consolidator Types

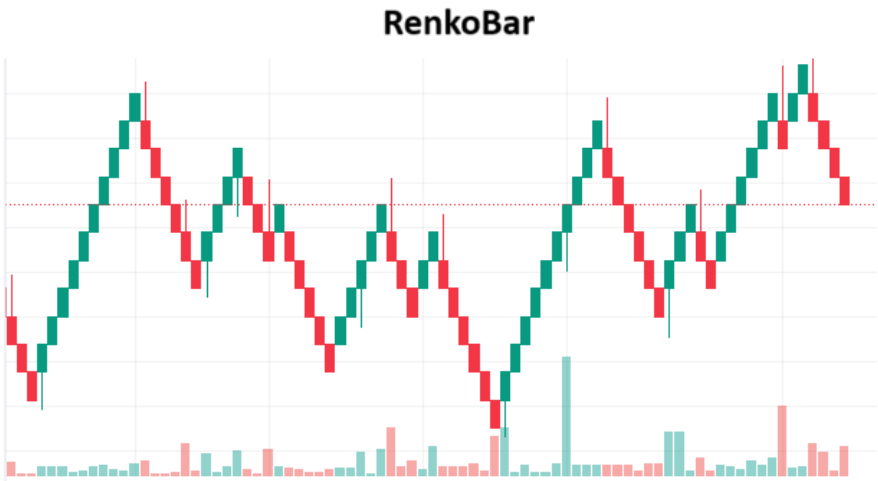
Renko Consolidators

Renko Consolidators

Renko Consolidators

Introduction

Most Renko consolidators aggregate bars based on a fixed price movement. The `RenkoConsolidator` produces Renko bars by their traditional definition. In the case of a $1 bar size, the `RenkoConsolidator` produces bars that have a body spanning 1.*Theopeningpriceofthefirstbarissettotheclosest*1 multiple of the first trade. When the price moves by at least 1, *thefirstbarcloses*. *Ifabarisarisingbar*, *thefollowingbarcloseswhenthepricemoves*1 above the closing price of the previous bar or 1*belowtheopeningpriceofthepreviousbar*. *Ifabarisafallingbar*, *thefollowingbarcloseswhenthepricemoves*1 below the closing price of the previous bar or $1 above the opening price of the previous bar. If the price jumps multiple dollars in a single tick, the `RenkoConsolidator` produces multiple $1 bars in a single time step.



Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   // Create a Renko consolidator that emits a bar when the price moves $1
   _consolidator = new RenkoConsolidator(1m);
   ```

   C#

2. Add an event handler to the consolidator.

```
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler`, not `ConsolidationHandler()`.

3. Define the consolidation handler.

```
void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period, you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request.

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var tradeBar = slice.Bars[_symbol];
    _consolidator.Update(tradeBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
foreach (var tradeBar in history)
{
    _consolidator.Update(tradeBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   // Create a Renko consolidator that emits a bar when the price moves $1
   _consolidator = new RenkoConsolidator(1m);
   ```

2. Add an event handler to the consolidator.

   ```
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler`, not `ConsolidationHandler()`.

3. Define the consolidation handler.

   ```
   void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  C#

  // Example 1: Update the consolidator with data from the Slice object
  public override void OnData(Slice slice)
  {
      var quoteBar = slice.QuoteBars[_symbol];
      _consolidator.Update(quoteBar);
  }

  // Example 2: Update the consolidator with data from a history request
  var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
  foreach (var quoteBar in history)
  {
      _consolidator.Update(quoteBar);
  }
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#

   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   C#

   // Create a Renko consolidator that emits a bar when the price moves $1
   _consolidator = new RenkoConsolidator(1m);
   ```

2. Add an event handler to the consolidator.

   ```
   C#

   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
C#
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RenkoBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the traditional Renko bar rules:

1. Create the consolidator.

   To create a Renko consolidator, pass the bar size to the `RenkoConsolidator` constructor.

   ```
   C#
   // Create a Renko consolidator that emits a bar when the price moves $1
   _consolidator = new RenkoConsolidator(1m);
   ```

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the price movement forms a new Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```C#
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```C#
_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Renko Consolidators

Classic Renko Consolidators

Introduction

Most Renko consolidators aggregate bars based on a fixed price movement. The `ClassicRenkoConsolidator` produces a different type of Renko bars than the `RenkoConsolidator` . A `ClassicRenkoConsolidator` with a bar size of 1*producesanewbarthatspans*1 every time an asset closes $1 away from the close of the previous bar. If the price jumps multiple dollars in a single tick, the `ClassicRenkoConsolidator` only produces one bar per time step where the open of each bar matches the close of the previous bar.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   C#
   // Create a Classic Renko consolidator that emits a bar when the price moves $1
   _consolidator = new ClassicRenkoConsolidator(1m);
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
   - It ignores the volume of the input data
   - It enforces the open and close of each bar to be a multiple of the bar size

   To build the Renko bars with a different property than the `Value` of the `IBaseData` object, provide a `selector` argument. The `selector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   C#
   _consolidator = new ClassicRenkoConsolidator(1m, data => (data as TradeBar).High);
   ```

   To add a non-zero `Volume` property to the Renko bars, provide a `volumeSelector` argument. The `volumeSelector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   C#
   _consolidator = new ClassicRenkoConsolidator(1m, null, data => (data as TradeBar).Volume);
   ```

   To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

```
_consolidator = new ClassicRenkoConsolidator(1m, evenBars: false);
```

2. Add an event handler to the consolidator.

```
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  SubscriptionManager.AddConsolidator(_symbol, _consolidator);
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var tradeBar = slice.Bars[_symbol];
    _consolidator.Update(tradeBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
foreach (var tradeBar in history)
{
    _consolidator.Update(tradeBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RenkoBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   // Create a Classic Renko consolidator that emits a bar when the price moves $1
   _consolidator = new ClassicRenkoConsolidator(1m);
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
   - It ignores the volume of the input data
   - It enforces the open and close of each bar to be a multiple of the bar size

   The following arguments enable you to create Renko bars that aggregate the excess liquidity on the bid.

   ```
   _consolidator = new ClassicRenkoConsolidator(10, null,
       data => (data as QuoteBar).LastBidSize - (data as QuoteBar).LastAskSize);
   ```

   To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

```
_consolidator = new ClassicRenkoConsolidator(1m, evenBars: false);
```

2. Add an event handler to the consolidator.

```
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  SubscriptionManager.AddConsolidator(_symbol, _consolidator);
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var quoteBar = slice.QuoteBars[_symbol];
    _consolidator.Update(quoteBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
foreach (var quoteBar in history)
{
    _consolidator.Update(quoteBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```C#
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```C#
   // Create a Classic Renko consolidator that emits a bar when the price moves $1
   _consolidator = new ClassicRenkoConsolidator(1m);
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
   - It ignores the volume of the input data
   - It enforces the open and close of each bar to be a multiple of the bar size

   To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

   ```C#
   _consolidator = new ClassicRenkoConsolidator(1m, evenBars: false);
   ```

2. Add an event handler to the consolidator.

   ```C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RenkoBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the preceding Renko bar rules:

1. Create the consolidator.

   To create a classic Renko consolidator, pass the bar size to the `ClassicRenkoConsolidator` constructor.

   ```
   // Create a Classic Renko consolidator that emits a bar when the price moves $1
   _consolidator = new ClassicRenkoConsolidator(1m);
   ```

   The `ClassicRenkoConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Renko bars
   - It ignores the volume of the input data
   - It enforces the open and close of each bar to be a multiple of the bar size

   To relax the requirement that the open and close of the Renko bars must be a multiple of bar size, disable the `evenBars` argument. If you disable `evenBars` , the open value of the first Renko bar is set to the first value from the `selector` . The following opening and closing Renko bar values are all multiples of the first value from the `selector`

   ```
   _consolidator = new ClassicRenkoConsolidator(1m, evenBars: false);
   ```

2. Add an event handler to the consolidator.

   ```
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   void ConsolidationHandler(object sender, RenkoBar consolidatedBar)
   {

   }
   ```

The consolidation event handler receives bars when the price movement forms a new classic Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#

     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     C#

     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var ticks = slice.Ticks[_symbol];
         foreach (var tick in ticks)
         {
          _consolidator.Update(tick);
         }
     }

     // Example 2: Update the consolidator with data from a history request
     var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
     foreach (var tick in ticks)
     {
         _consolidator.Update(tick);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#

   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
C#

_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators

when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```
C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Examples

The following examples demonstrate some common practices for implementing classic renko consolidator.

Example 1: 10 Dollar Bar Range SMA Cross

The following algorithm creates a dollar bar for SPY. Then, for each 10-dollar bar, we find their range (high - low) and feed to an SMA indicator, such that we obtain a trend indicator of the range of SPY. We trade VXX as the proxy of the SPY volatility based on the trend of the range SMA.

C#

```
public class ClassicRenkoBarConsolidatorAlgorithm : QCAlgorithm
{
    private Symbol _spy, _vxx;
    private ClassicRenkoConsolidator _consolidator;
    private SimpleMovingAverage _sma = new(10);
    private decimal _high = 0m, _low = 10000m;
    private int _count = 0;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data to feed the consolidators and indicators for trade signal generation.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;
        // Request VXX data for trading.
        _vxx = AddEquity("VXX", Resolution.Minute).Symbol;

        // Create a dollar bar of SPY to track the volatility.
        _consolidator = new ClassicRenkoConsolidator(1);
        _consolidator.DataConsolidated += OnConsolidated;

        // Subscribe the consolidators to SPY data for automatic updating.
        SubscriptionManager.AddConsolidator(_spy, _consolidator);

        _sma.Window.Size = 2;
        SetWarmUp(100);
    }

    private void OnConsolidated(object sender, TradeBar bar)
    {
        // Update the SPY range of the current batch.
        _high = Math.Max(_high, bar.High);
        _low = Math.Min(_low, bar.Low);
        _count++;

        // Update SMA of SPY range of the last 10 Renko bars.
        if (_count >= 10)
        {
            _sma.Update(bar.EndTime, _high - _low);
            // Reset high and low.
            _high = 0m;
            _low = 10000m;
            _count = 0;
        }
    }

    public override void OnData(Slice slice)
    {
        if (_sma.IsReady)
        {
            // If the range trend is increasing, buy VXX as a proxy for the increase in volatility.
            if (_sma > _sma.Previous && !Portfolio[_vxx].IsLong)
            {
                SetHoldings(_vxx, 0.5m);
            }
            // If the range trend is decreasing, sell VXX as a proxy for decreasing volatility.
            else if (_sma < _sma.Previous && !Portfolio[_vxx].IsShort)
            {
                SetHoldings(_vxx, -0.5m);
            }
        }
    }
}
```

Renko Consolidators

Volume Renko Consolidators

Introduction

Volume Renko consolidators aggregate bars based on a fixed trading volume. These types of bars are commonly known as volume bars. A `VolumeRenkoConsolidator` with a bar size of 10,000 produces a new bar every time 10,000 units of the security trades in the market. If the trading volume of a single time step exceeds two step sizes (i.e. >20,000), the `VolumeRenkoConsolidator` produces multiple bars in a single time step.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `VolumeRenkoBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on custom set volume traded:

1. Create the consolidator.

   To create a Volume Renko consolidator, pass the bar size to the `VolumeRenkoConsolidator` constructor.

   ```
   C#
   // Create a Volume Renko consolidator that emits a bar every time 10,000 units trade
   _consolidator = new VolumeRenkoConsolidator(10000m);
   ```

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, VolumeRenkoBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the trading volume forms a new Volume Renko bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var tradeBar = slice.Bars[_symbol];
    _consolidator.Update(tradeBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
foreach (var tradeBar in history)
{
    _consolidator.Update(tradeBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `VolumeRenkoBar` objects. Follow these steps to create and manage a `Tick` consolidator based on custom set volume traded:

1. Create the consolidator.

To create a Volume Renko consolidator, pass the bar size to the `VolumeRenkoConsolidator` constructor.

```
// Create a Volume Renko consolidator that emits a bar every time 10,000 units trade
_consolidator = new VolumeRenkoConsolidator(10000m);
```

2. Add an event handler to the consolidator.

```
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler`, not `ConsolidationHandler()`.

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, VolumeRenkoBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the trading volume forms a new Volume Renko bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period, you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request.

```
C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Examples

The following examples demonstrate common practices for implementing volume renko consolidator.

Example 1: Bollinger Bands From Volume Renko Bar

The following algorithm uses 100,000-share volume Renko bars to spot mean reversal opportunities on SPY with Bollinger Bands. Equal volume bars could provide more equal information in each bar, so the standard deviation and trade opportunities are more credible.

C#

```
public class VolumeRenkoBarConsolidatorAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private VolumeRenkoConsolidator _consolidator;
    // We use a Bollinger band to signal mean reversal opportunities.
    private BollingerBands _bbands = new(20, 2, MovingAverageType.Exponential);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data to feed for the consolidators, indicators, and trade signal generation.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // Create a 100,000-share bar of SPY to obtain a more equally-informed bar.
        _consolidator = new VolumeRenkoConsolidator(100000m);

        // Subscribe the consolidators to SPY data to automatically update the indicator.
        RegisterIndicator(_spy, _bbands, _consolidator);

        // Warm up the indicator for immediate use.
        SetWarmUp(20);
    }

    public override void OnData(Slice slice)
    {
        if (!IsWarmingUp && _bbands.IsReady && slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trade the mean reversal by short-selling SPY if the current price exceeds the upper threshold.
            if (bar.Close > _bbands.UpperBand && !Portfolio[_spy].IsShort)
            {
                SetHoldings(_spy, -0.5m);
            }
            // Trade the mean reversal by buying SPY if the current price is below the lower threshold.
            else if (bar.Close < _bbands.LowerBand && !Portfolio[_spy].IsLong)
            {
                SetHoldings(_spy, 0.5m);
            }
            // Exit position if the price is mean-reverted that crosses the EMA reference.
            else if ((Portfolio[_spy].Quantity > 0 && bar.Close > _bbands.MiddleBand) ||
                (Portfolio[_spy].Quantity < 0 && bar.Close < _bbands.MiddleBand))
            {
                Liquidate(_spy);
            }
        }
    }
}
```

Consolidator Types

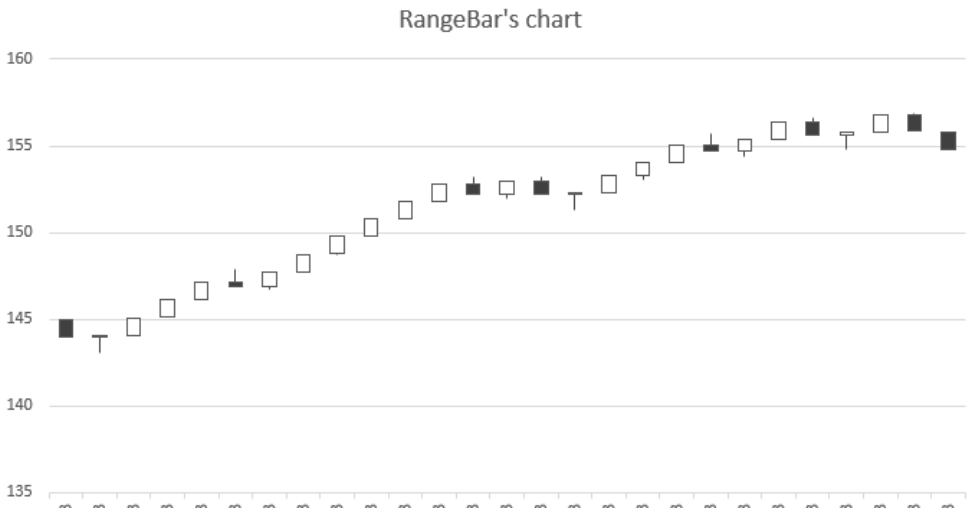
Range Consolidators

Range Consolidators

Range Consolidators

Introduction

Most Range consolidators aggregate bars based on a fixed price movement. It is very much like a Renko Bar, but instead of consolidating a fix movement from the opening price, a Range Bar would fix the range of the whole bar, i.e. High - Low. A new bar is formed when the range of the whole bar reached a preset value, thus it completely neglects the time effect and focuses on the variance/information carried by the price movement.



Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RangeBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the preset range of price movement:

1. Create the consolidator.

   To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

   ```
   // Create a Range consolidator that emits a bar when the high and low differs $1
   _consolidator = new RangeConsolidator(1m);
   ```

2. Add an event handler to the consolidator.

   ```
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, RangeBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var tradeBar = slice.Bars[_symbol];
    _consolidator.Update(tradeBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
foreach (var tradeBar in history)
{
    _consolidator.Update(tradeBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
C#
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow

down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RangeBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the preset range of price movement:

1. Create the consolidator.

   To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

   ```
   C#

   // Create a Range consolidator that emits a bar when the high and low differs $1
   _consolidator = new RangeConsolidator(1m);
   ```

2. Add an event handler to the consolidator.

   ```
   C#

   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#

   void ConsolidationHandler(object sender, RangeBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#

     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with

data from the Slice object in the `OnData` method or with data from a history request .

```
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var quoteBar = slice.QuoteBars[_symbol];
    _consolidator.Update(quoteBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
foreach (var quoteBar in history)
{
    _consolidator.Update(quoteBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RangeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the preset range of price movement:

1. Create the consolidator.

   To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

```
// Create a Range consolidator that emits a bar when the high and low differs $1
_consolidator = new RangeConsolidator(1m);
```

2. Add an event handler to the consolidator.

```
_consolidator.DataConsolidated += ConsolidationHandler;
```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
void ConsolidationHandler(object sender, RangeBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

     ```
     // Example 1: Update the consolidator with data from the Slice object
     public override void OnData(Slice slice)
     {
         var ticks = slice.Ticks[_symbol];
         foreach (var tick in ticks)
         {
          _consolidator.Update(tick);
         }
     }

     // Example 2: Update the consolidator with data from a history request
     var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
     foreach (var tick in ticks)
     {
         _consolidator.Update(tick);
     }
     ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RangeBar` objects. Follow these steps to create

and manage a `Tick` quote bar consolidator based on the preset range of price movement:

1. Create the consolidator.

   To create a Range consolidator, pass the bar size to the `RangeConsolidator` constructor.

   ```
   C#
   // Create a Range consolidator that emits a bar when the high and low differs $1
   _consolidator = new RangeConsolidator(1m);
   ```

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, RangeBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the price movement forms a new Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

     To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

     ```
     C#
     SubscriptionManager.AddConsolidator(_symbol, _consolidator);
     ```

   - Manual Updates

     Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var ticks = slice.Ticks[_symbol];
    foreach (var tick in ticks)
    {
     _consolidator.Update(tick);
    }
}

// Example 2: Update the consolidator with data from a history request
var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
foreach (var tick in ticks)
{
    _consolidator.Update(tick);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```C#
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```C#
_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Range Consolidators

Classic Range Consolidators

Introduction

Most Range consolidators aggregate bars based on a fixed price range movement. The `ClassicRangeConsolidator` produces a different type of Range bars than the `RangeConsolidator` . A `ClassicRangeConsolidator` with a bar size of 1*producesanewbarthatspans*1 every time an asset's price range moves $1. If the price jumps multiple dollars in a single tick, the `ClassicRangeConsolidator` only produces one bar per time step where the open of each bar matches the close of the previous bar.

Consolidate Trade Bars

`TradeBar` consolidators aggregate `TradeBar` objects into `RangeBar` objects. Follow these steps to create and manage a `TradeBar` consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

   ```
   C#
   // Create a Classic Range consolidator that emits a bar when the price range moves $1
   _consolidator = new ClassicRangeConsolidator(1m);
   ```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

   To build the Range bars with a different property than the `Value` of the `IBaseData` object, provide a `selector` argument. The `selector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   C#
   _consolidator = new ClassicRangeConsolidator(1m, data => (data as TradeBar).High);
   ```

   To add a non-zero `Volume` property to the Range bars, provide a `volumeSelector` argument. The `volumeSelector` should be a function that receives the `IBaseData` object and returns a decimal value.

   ```
   C#
   _consolidator = new ClassicRangeConsolidator(1m, null, data => (data as TradeBar).Volume);
   ```

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating

consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, RangeBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `TradeBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var tradeBar = slice.Bars[_symbol];
    _consolidator.Update(tradeBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<TradeBar>(_symbol, 30, Resolution.Minute);
foreach (var tradeBar in history)
{
    _consolidator.Update(tradeBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
C#
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions,

see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Bars

`QuoteBar` consolidators aggregate `QuoteBar` objects into `RangeBar` objects. Follow these steps to create and manage a `QuoteBar` consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

   ```
   C#

   // Create a Classic Range consolidator that emits a bar when the price range moves $1
   _consolidator = new ClassicRangeConsolidator(1m);
   ```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

   The following arguments enable you to create Range bars that aggregate the excessive bid-ask spread on the asset. It can help market-making algorithms to track wider spread opportunities.

   ```
   C#

   _consolidator = new ClassicRangeConsolidator(10, null,
       data => (data as QuoteBar).LastBidSize - (data as QuoteBar).LastAskSize);
   ```

2. Add an event handler to the consolidator.

   ```
   C#

   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#

   void ConsolidationHandler(object sender, RangeBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

   - Automatic Updates

To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

```
C#
SubscriptionManager.AddConsolidator(_symbol, _consolidator);
```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `QuoteBar` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

```
C#
// Example 1: Update the consolidator with data from the Slice object
public override void OnData(Slice slice)
{
    var quoteBar = slice.QuoteBars[_symbol];
    _consolidator.Update(quoteBar);
}

// Example 2: Update the consolidator with data from a history request
var history = History<QuoteBar>(_symbol, 30, Resolution.Minute);
foreach (var quoteBar in history)
{
    _consolidator.Update(quoteBar);
}
```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
C#
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Trade Ticks

`Tick` consolidators aggregate `Tick` objects into `RangeBar` objects. Follow these steps to create and manage a `Tick` consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

```
C#
// Create a Classic Range consolidator that emits a bar when the price range moves $1
_consolidator = new ClassicRangeConsolidator(1m);
```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

2. Add an event handler to the consolidator.

```
C#
_consolidator.DataConsolidated += ConsolidationHandler;
```

LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

```
C#
void ConsolidationHandler(object sender, RangeBar consolidatedBar)
{

}
```

The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  C#
  SubscriptionManager.AddConsolidator(_symbol, _consolidator);
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  C#
  // Example 1: Update the consolidator with data from the Slice object
  public override void OnData(Slice slice)
  {
      var ticks = slice.Ticks[_symbol];
      foreach (var tick in ticks)
      {
       _consolidator.Update(tick);
      }
  }

  // Example 2: Update the consolidator with data from a history request
  var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
  foreach (var tick in ticks)
  {
      _consolidator.Update(tick);
  }
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

```
C#
SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
```

If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Consolidate Quote Ticks

`Tick` quote bar consolidators aggregate `Tick` objects that represent quotes into `RangeBar` objects. Follow these steps to create and manage a `Tick` quote bar consolidator based on the preceding Range bar rules:

1. Create the consolidator.

   To create a classic Range consolidator, pass the bar size to the `ClassicRangeConsolidator` constructor.

   ```
   C#
   // Create a Classic Range consolidator that emits a bar when the price range moves $1
   _consolidator = new ClassicRangeConsolidator(1m);
   ```

   The `ClassicRangeConsolidator` has the following default behavior:

   - It uses the `Value` property of the `IBaseData` object it receives to build the Range bars
   - It ignores the volume of the input data
   - It enforces the high and low of each bar to be a multiple of the bar size

2. Add an event handler to the consolidator.

   ```
   C#
   _consolidator.DataConsolidated += ConsolidationHandler;
   ```

   LEAN passes consolidated bars to the consolidator event handler in your algorithm. The most common error when creating consolidators is to put parenthesis `()` at the end of your method name when setting the event handler of the consolidator. If you use parenthesis, the method executes and the result is passed as the event handler instead of the method itself. Remember to pass the name of your method to the event system. Specifically, it should be `ConsolidationHandler` , not `ConsolidationHandler()` .

3. Define the consolidation handler.

   ```
   C#
   void ConsolidationHandler(object sender, RangeBar consolidatedBar)
   {

   }
   ```

   The consolidation event handler receives bars when the price movement forms a new classic Range bar.

4. Update the consolidator.

   You can automatically or manually update the consolidator.

- Automatic Updates

  To automatically update a consolidator with data from the security subscription, call the `AddConsolidator` method of the Subscription Manager.

  ```
  C#
  SubscriptionManager.AddConsolidator(_symbol, _consolidator);
  ```

- Manual Updates

  Manual updates let you control when the consolidator updates and what data you use to update it. If you need to warm up a consolidator with data outside of the warm-up period , you can manually update the consolidator. To manually update a consolidator, call its `Update` method with a `Tick` object. You can update the consolidator with data from the Slice object in the `OnData` method or with data from a history request .

  ```
  C#
  // Example 1: Update the consolidator with data from the Slice object
  public override void OnData(Slice slice)
  {
      var ticks = slice.Ticks[_symbol];
      foreach (var tick in ticks)
      {
       _consolidator.Update(tick);
      }
  }

  // Example 2: Update the consolidator with data from a history request
  var ticks = History<Tick>(_symbol, TimeSpan.FromMinutes(3), Resolution.Tick);
  foreach (var tick in ticks)
  {
      _consolidator.Update(tick);
  }
  ```

5. If you create consolidators for securities in a dynamic universe and register them for automatic updates, remove the consolidator when the security leaves the universe.

   ```
   C#
   SubscriptionManager.RemoveConsolidator(_symbol, _consolidator);
   ```

   If you have a dynamic universe and don't remove consolidators, they compound internally, causing your algorithm to slow down and eventually die once it runs out of RAM. For an example of removing consolidators from universe subscriptions, see the GasAndCrudeOilEnergyCorrelationAlpha in the LEAN GitHub repository.

Reset Consolidators

To reset a consolidator, call its `Reset` method.

```
C#
_consolidator.Reset();
```

If you are live trading Equities or backtesting Equities without the adjusted data normalization mode , reset your consolidators when splits and dividends occur. When a split or dividend occurs while the consolidator is in the process of building a bar, the open, high, and low may reflect prices from before the split or dividend. To avoid issues, call the consolidator's `Reset` method and then warm it up with `ScaledRaw` data from a history request .

```
C#
public override void OnData(Slice data)
{
    // When a split or dividend occurs...
    if ((data.Splits.ContainsKey(_symbol) && data.Splits[_symbol].Type == SplitType.SplitOccurred) ||
        data.Dividends.ContainsKey(_symbol))
    {
        // If the consolidator is working on a bar...
        if (_consolidator.WorkingData != null)
        {
            // Get adjusted prices for the time period of the working bar.
            var history = History<TradeBar>(_symbol, _consolidator.WorkingData.Time, Time, dataNormalizationMode:
DataNormalizationMode.ScaledRaw);
            // Reset the consolidator.
            _consolidator.Reset();
            // Warm-up the consolidator with the adjusted price data.
            foreach (var bar in history)
            {
                _consolidator.Update(bar);
            }
        }
    }
}
```

Examples

ClassicRangeConsolidatorAlgorithm.cs C#

Consolidator Types

Combining Consolidators

Introduction

Sequential consolidators wire two internal consolidators together such that the output of the first consolidator is the input to the second consolidator and the output of the second consolidator is the output of the sequential consolidator.

Create Consolidators

To create a sequential consolidator, create two consolidators and then pass them to the `SequentialConsolidator` constructor.

```C#
// This first consolidator produces a consolidated bar after a day passes
var oneDayConsolidator = new TradeBarConsolidator(TimeSpan.FromDays(1));

// This second consolidators produces a consolidated bar after it sees 3 samples
var threeCountConsolidator = new TradeBarConsolidator(3);

// This sequential consolidator aggregates three 1-day bars together
_consolidator = new SequentialConsolidator(oneDayConsolidator, threeCountConsolidator);
```

For more information about each type of consolidator, see Consolidator Types .

Consolidating Data

Consolidator History

Introduction

This page explains how to save and access historical consolidated bars.

Save Consolidated Bars

To access historical bars that were passed to your consolidation handler, save the bars as you receive them. You can use a RollingWindow to save the consolidated bars and easily access them later on in your algorithm.

```C#
// Create a class member to store the RollingWindow
_window = new RollingWindow<TradeBar>(2);

// In the consolidation handler, add consolidated bars to the RollingWindow
private void ConsolidationHandler(object sender, TradeBar consolidatedBar)
{
    _window.Add(consolidatedBar);
}
```

Get Historical Bars

If you save consolidated bars in a `RollingWindow`, you can access them by indexing the `RollingWindow`. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

```C#
var mostRecentBar = _window[0];
var previousBar = _window[1];
var oldestBar = _window[-1];
```

To get the consolidated bar that was most recently removed from the `RollingWindow`, use the `MostRecentlyRemoved` property.

```C#
var removedBar = _window.MostRecentlyRemoved;
```

Examples

The following examples demonstrate some common practices for consolidator history.

Example 1: Price Action

The following algorithm trades breakout price action on the SPY five-minute trade bar. To do so, we must create a five-minute trade bar consolidator and a rolling window to hold 3 trade bars to check if the trade conditions are fulfilled.

C#

```
public class ConsolidatorHistoryAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // To hold 3 consolidated trade bars to identify a breakout pattern.
    private RollingWindow<TradeBar> _windows = new(3);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // The breakout is based on a 5-minute consolidated trade bar.
        var consolidator = new TradeBarConsolidator(TimeSpan.FromMinutes(5));
        // Subscribe for automatically updating the consolidator with SPY data.
        SubscriptionManager.AddConsolidator(_spy, consolidator);
        // Add a consolidator handler to check that the breakout condition is fulfilled and traded.
        consolidator.DataConsolidated += OnConsolidated;

        SetWarmUp(TimeSpan.FromDays(1));
    }

    private void OnConsolidated(object sender, TradeBar bar)
    {
        _windows.Add(bar);

        if (!IsWarmingUp && _windows.IsReady)
        {
            // Buy if the breakout price action is fulfilled.
            // 1. Increasing price trend.
            // 2. The last 3 bars are green.
            // 3. The 3rd and 2nd last bars range is decreasing.
            // 4. The last bar exceeds the 2nd last bar by double the 2nd last bar's range.
            var secondLastRange = _windows[1].Close - _windows[1].Open;
            if (bar.Close > _windows[1].Close && _windows[1].Close > _windows[2].Close &&
            _windows[2].Close > _windows[2].Open && _windows[1].Close > _windows[1].Open && _windows[0].Close >
_windows[0].Open &&
            _windows[2].Close - _windows[2].Open > secondLastRange && bar.Close > _windows[1].Close + 2 *
secondLastRange)
            {
                SetHoldings(_spy, 0.5m);
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            if (orderEvent.Ticket.OrderType == OrderType.Market)
            {
                // Stop loss order at 1%.
                var stopPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 0.99m : orderEvent.FillPrice *
1.01m;
                StopMarketOrder(_spy, -Portfolio[_spy].Quantity, stopPrice);
                // Take profit order at 2%.
                var takeProfitPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 1.02m :
orderEvent.FillPrice * 0.98m;
                LimitOrder(_spy, -Portfolio[_spy].Quantity, takeProfitPrice);
            }
            else if (orderEvent.Ticket.OrderType == OrderType.StopMarket || orderEvent.Ticket.OrderType ==
OrderType.Limit)
            {
                // Cancel any open order if stop loss or take profit order filled.
                Transactions.CancelOpenOrders();
            }
        }
    }
}
```

Consolidating Data

Updating Indicators

Introduction

You can use consolidators to automatically update indicators in your algorithms. The consolidators can update your indicators at each time step or with aggregated bars. By default, LEAN updates data point indicators with the close price of the consolidated bars, but you can change it to a custom data field.

Standard Indicator Periods

If your algorithm has a static universe, you can create automatic indicators in just one line of code. When you create an automatic indicator, LEAN creates a consolidator, hooks it up for automatic updates, and then updates the indicator with the consolidated bars.

```C#
// Consolidate minute SPY data into 14-bar daily indicators
var ema = EMA("SPY", 14, Resolution.Daily);
var sma = SMA("SPY", 14, Resolution.Daily);
```

If your algorithm has a dynamic universe, create a manual indicator and then create a time period consolidator that updates the indicator at each time step. Keep a reference to the consolidator so you can remove it when your algorithm removes the security from the universe.

```C#
public override void Initialize()
{
    _ema = new ExponentialMovingAverage(14);
    _consolidator = new TradeBarConsolidator(1);
    _consolidator.DataConsolidated += OnDataConsolidated;
    SubscriptionManager.AddConsolidator(_symbol, _consolidator);
}

// Define consolidator handler function as a class method
public void OnDataConsolidated(object sender, TradeBar bar)
{
    _ema.Update(bar.EndTime, bar.Close);
}
```

Custom Indicator Periods

It's common to update indicators with price data that spans a normal time period like one minute or one day. It's less common to update an indicator with exotic time periods (for example, a 7-minute consolidated bar), so these types of indicators may provide more opportunities for alpha. To update indicators with exotic data, create a manual indicator and then call the `RegisterIndicator` method. The `RegisterIndicator` method wires up the indicator for automatic updates at the time interval you provide.

```C#
// Calculate the SMA with 10 7-minute bars
var symbol = AddEquity("SPY", Resolution.Minute).Symbol;
var indicator = new SimpleMovingAverage(10);
RegisterIndicator(symbol, indicator, TimeSpan.FromMinutes(7));
```

The RegisterIndicator method can accept a TimeSpan , Resolution , or an unregistered consolidator. If you apply the indicator to a security in a dynamic universe, provide a consolidator so that you can remove it when your algorithm removes the security from the universe.

```C#
// TimeSpan
RegisterIndicator(symbol, indicator, TimeSpan.FromMinutes(7));

// Resolution
RegisterIndicator(symbol, indicator, Resolution.Hour);

// Consolidator
_consolidator = new TradeBarConsolidator(35);
RegisterIndicator(symbol, indicator, _consolidator);
```

Custom Indicator Values

Data point indicators use only a single price data in their calculations. By default, those indicators use the closing price. For assets with TradeBar data, that price is the TradeBar close price. For assets with QuoteBar data, that price is the mid-price of the bid closing price and the ask closing price. To create an indicator with the other fields like the Open , High , Low , or Close , provide a selector argument to the RegisterIndicator method.

```C#
// Define a 10-period RSI with indicator the constructor
_rsi = new RelativeStrengthIndex(10, MovingAverageType.Simple);

// Register the daily High price data to automatically update the indicator
RegisterIndicator(symbol, _rsi, Resolution.Daily, Field.High);
```

The RegisterIndicator method can accept a TimeSpan , Resolution , or an unregistered consolidator. If you apply the indicator to a security in a dynamic universe, provide a consolidator so that you can remove it when your algorithm removes the security from the universe.

The Field class has the following selector properties:

To create a custom selector , define a function that calculates the value.

```C#
RegisterIndicator(_symbol, _rsi,  Resolution.Daily, x =>
{
    var bar = x as IBaseDataBar;
    return (bar.Low + bar.High) / 2;
});
```

Examples

The following examples demonstrate common practices for updating indicators using consolidators.

Example 1: Hammer Pattern With 5-Minute Consolidator

The following algorithm trades Hammer and Inverted Hammer candlestick patterns. The candles are constructed with five-minute SPY trade bars consolidated by a five-minute TradeBarConsolidator , while automatically updating with the RegisterIndicator method. Both patterns are bullish, so we buy SPY if the pattern is signaled.

C#

```
using QuantConnect.Indicators.CandlestickPatterns;
public class ConsolidatorUpdatingIndicatorsAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private Hammer _hammer = new();
    private InvertedHammer _invertedHammer = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // The candlestick patterns are based on a 5-minute consolidated trade bar.
        var consolidator = new TradeBarConsolidator(TimeSpan.FromMinutes(5));
        // Subscribe to update the indicators with the 5-minute consolidator automatically.
        RegisterIndicator(_spy, _hammer, consolidator);
        RegisterIndicator(_spy, _invertedHammer, consolidator);
        // Add event handler on candlestick indicators updated to trade the pattern.
        _hammer.Updated += OnUpdated;
        _invertedHammer.Updated += OnUpdated;

        SetWarmUp(1);
    }

    private void OnUpdated(object sender, IndicatorDataPoint point)
    {
        // Both the hammer and inverted Ham patterns indicate bullish movement, so we buy SPY.
        if (point.Value == 1 && !Portfolio[_spy].IsLong)
        {
            SetHoldings(_spy, 0.5m);
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            if (orderEvent.Ticket.OrderType == OrderType.Market)
            {
                // Stop loss order at 1%.
                var stopPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 0.99m : orderEvent.FillPrice *
1.01m;
                StopMarketOrder(_spy, -Portfolio[_spy].Quantity, stopPrice);
                // Take profit order at 2%.
                var takeProfitPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 1.02m :
orderEvent.FillPrice * 0.98m;
                LimitOrder(_spy, -Portfolio[_spy].Quantity, takeProfitPrice);
            }
            else if (orderEvent.Ticket.OrderType == OrderType.StopMarket || orderEvent.Ticket.OrderType ==
OrderType.Limit)
            {
                // Cancel any open order if stop loss or take profit order filled.
                Transactions.CancelOpenOrders();
            }
        }
    }
}
```

Historical Data

Historical Data

Getting Started

Introduction

There are two ways to request historical data in your algorithms: direct historical data requests and indirect algorithm warm up .

History Requests

History requests return all of the data you request as a single object. Follow these steps to get some historical data:

1. Create a new project.

   Projects contain files to run backtests, launch research notebooks, perform parameter optimizations, and deploy live trading strategies. You need to create projects in order to create strategies and share your work with other members.

   The process to create a new project depends on if you use the Cloud Platform , Local Platform , or CLI .

2. In the `Initialize` method, add an asset .

   The `Initialize` method is the entry point of your algorithm where you define a series of settings, including security subscriptions, starting cash balances, and warm-up periods. LEAN only calls the `Initialize` method one time, at the start of your algorithm.

   ```
   C#
   var spy = AddEquity("SPY");
   ```

3. Call the `History` method with the asset's Symbol and a lookback period.

   `Symbol` objects are a way to identify or "finger-print" tradable assets so that no further database look-up is required. All QuantConnect and LEAN Algorithm API methods use `Symbol` objects to identify assets.

   ```
   C#
   var history = History(spy.Symbol, 5, Resolution.Daily);
   ```

Warm Up Periods

Warm-up simulates winding back the clock from the time you deploy the algorithm. In a backest, this is the start date of your algorithm. In live trading, it's the current date. Follow these steps to add a warm-up period to the start of your algorithm:

1. Create a new project.

   The process to create a new project depends on if you use the Cloud Platform , Local Platform , or CLI .

2. In the `Initialize` method, set the backtest dates and add an asset .

```
SetStartDate(2024, 12, 1);
SetEndDate(2024, 12, 2);
AddEquity("SPY", Resolution.Daily);
```

3. In the `Initialize` method, call the `SetWarmUp` method with the warm-up duration.

```
SetWarmUp(10, Resolution.Daily);
```

4. In the `OnData` method, log the time and warm-up state .

```
Log($"IsWarmingUp at {Time}: {IsWarmingUp}");
```

```
Algorithm starting warm up...
IsWarmingUp at 11/22/2024 4:00:00 PM: True
IsWarmingUp at 11/25/2024 4:00:00 PM: True
IsWarmingUp at 11/26/2024 4:00:00 PM: True
IsWarmingUp at 11/27/2024 4:00:00 PM: True
IsWarmingUp at 11/29/2024 1:00:00 PM: True
Algorithm finished warming up.
IsWarmingUp at 12/2/2024 4:00:00 PM: False
```

For more information about warm-up, see Warm Up Periods .

Examples

The following examples demonstrate some common practices for historical data.

Example 1: Simple Moving Average

The following example demonstrates weekly-resampled historical data to calculate the 50-week Simple Moving Average to implement an SMA-cross strategy.

C#

```
public class HistoricalDataAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private TradeBarConsolidator _consolidator;
    private RollingWindow<decimal> _window = new(50);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        // Request SPY data for historical data call and trading.
        _spy = AddEquity("SPY").Symbol;
        // Set up a consolidator to resample historical data to weekly.
        _consolidator = new TradeBarConsolidator(Calendar.Weekly);
        _consolidator.DataConsolidated += (_, updated) => _window.Add(updated.Close);

        // Set a scheduled event to trade SPY with a weekly SMA signal.
        Schedule.On(DateRules.WeekStart(_spy), TimeRules.AfterMarketOpen(_spy, 1), Trade);
    }

    private void Trade()
    {
        // Historical data call to calculate signal.
        var history = History<TradeBar>(_spy, 252, Resolution.Daily);
        // Obtain the weekly close price to calculate the weekly EMA.
        foreach (var bar in history)
        {
            _consolidator.Update(bar);
        }
        // Calculate the current 50-week SMA as a trading signal.
        var sma50 = _window.Average();

        // Trade the SMA cross strategy.
        var price = history.Last().Close;
        if (price > sma50 && !Portfolio[_spy].IsLong)
        {
            SetHoldings(_spy, 1m);
        }
        else if (price < sma50 && !Portfolio[_spy].IsShort)
        {
            SetHoldings(_spy, -1m);
        }
    }
}
```

Historical Data

History Requests

Introduction

There are two ways to request historical data in your algorithms: direct historical data requests and indirect algorithm warm up . You can use a direct historical data request at any time throughout your algorithm. It returns all of the data you request as a single object.

Trailing Data Samples

To get historical data for a trailing time period, call `History` method with an an integer and a `Resolution` . For example, if you pass an asset `Symbol` , 5, and `Resolution.Minute` as the arguments, it returns the data of the asset during the most recent 5 minutes in the asset's market hours . These trailing minute bars can cross multiple trading days.

C#

```
public class TrailingDataSamplesHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("SPY").Symbol;
        // Get the minute-resolution TradeBar data of the asset over the trailing 5 minutes.
        var history = History<TradeBar>(symbol, 5, Resolution.Minute);
    }
}
```

If you don't pass a `Resolution` , it defaults to the resolution of the security subscription. The following example returns 3 days of data for QQQ and 3 minutes of data for SPY:

C#

```
public class TrailingDataSamplesForMulitpleAssetsHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 20);
        SetEndDate(2024, 12, 31);
        // Add two assets with different resolutions.
        var spy = AddEquity("SPY", Resolution.Minute).Symbol;
        var qqq = AddEquity("QQQ", Resolution.Daily).Symbol;
        // Get the trailing 3 bars of data for each asset.
        var history = History<TradeBar>(new[] { spy, qqq }, 3);
    }
}
```

If there is no data for the time period you request, the result has fewer samples. For instance, say an illiquid asset has no trading activity during the last 15 minutes of the trading day and you request the 10 most recent minute bars at market close, 4 PM Eastern Standard Time (ET). In this case, you won't get any data because LEAN will try to fetch data from 3:50 PM ET to 4 PM ET since the market was open during that time , but there were no trades for the asset. For more information about missing data points, see Missing Data Points .

Trailing Time Periods

To get historical data for a trailing time period, pass a `TimeSpan` to the `History` method. The days of the `TimeSpan` represent

calendar days.

```
C#
public class TrailingTimePeriodHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("SPY").Symbol;
        // Get the minute-resolution TradeBar data of the asset over the trailing 3 days.
        var history = History<TradeBar>(symbol, TimeSpan.FromDays(3), Resolution.Minute);
    }
}
```

If there is no data in the time period, the result is empty. For more information about missing data points, see Missing Data Points .

Date Ranges

To get historical data for a specific date range, call `History` method with start and end `DateTime` objects. The `DateTime` objects you provide are based in the algorithm time zone .

```
C#
public class DateRangeHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("SPY").Symbol;
        // Get the daily-resolution TradeBar data of the asset during 2020.
        var history = History<TradeBar>(symbol, new DateTime(2020, 1, 1), new DateTime(2021, 1, 1),
Resolution.Daily);
    }
}
```

If there is no data for the date range you request, the result is empty. For more information about missing data points, see Missing Data Points .

Flat Universe DataFrames

To get a DataFrame of historical data, use Python.

Default Values

The following table describes the assumptions of the History API:

Argument	Assumption
`resolution`	LEAN guesses the resolution you request by looking at the securities you already have in your algorithm. If you have a security subscription in your algorithm with a matching `Symbol` , the history request uses the same resolution as the subscription. If you don't have a security subscription in your algorithm with a matching `Symbol` , `Resolution.Minute` is the default.
`<T>`	If you don't specify a type for the history request, `TradeBar` is the default. If the asset you request data for doesn't have `TradeBar` data, specify the `QuoteBar` type to receive history.

Additional Options

The `History` method accepts the following additional arguments:

Argument	Data Type	Description
`fillForward`	`bool?`	True to fill forward missing data. Otherwise, false.
`extendedMarketHours`	`bool?`	True to include extended market hours data. Otherwise, false.
`dataMappingMode`	`DataMappingMode?`	The contract mapping mode to use for the security history request.
`dataNormalizationMode`	`DataNormalizationMode?`	The price scaling mode to use for US Equities or continuous Futures contracts .
`contractDepthOffset`	`int?`	The desired offset from the current front month for continuous Futures contracts .

If you don't provide a value for some of the preceding options, it uses the option value from the security subscription.

```
C#
var future = AddFuture(Futures.Indices.SP500EMini);
var history = History(
    symbols: new[] {future.Symbol},
    start: Time - TimeSpan.FromDays(15),
    end: Time,
    resolution: Resolution.Minute,
    fillForward: false,
    extendedMarketHours: false,
    dataMappingMode: DataMappingMode.LastTradingDay,
    dataNormalizationMode: DataNormalizationMode.Raw,
    contractDepthOffset: 0);
```

Examples

The following examples demonstrate some common practices for trading using historical requests.

Example 1: Mean-Variance Portfolio

The following algorithm constructs a monthly rebalance mean-variance portfolio using the top 20 liquid equities. The position sizing can be optimized by 1-year historical daily return of the universe members.

C#

```
public class HistoricalRequestAlgorithm : QCAlgorithm
{
    private Universe _universe;

    // Instantiate the optimizer to perform mean-variance optimization.
    // Mean-variance optimization will not consider a risk-free rate, so we use 0.
    private readonly MaximumSharpeRatioPortfolioOptimizer _optimizer = new (0, 1, 0);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Seed the last price to set the initial price.
        Settings.SeedInitialPrices = true;

        // Monthly renewal of the top 20 liquid universe to trade popular stocks.
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.Top(20));

        // Set a scheduled event to rebalance the portfolio at the start of every month.
        Schedule.On(DateRules.MonthStart(), TimeRules.At(9, 31), Rebalance);
    }

    private void Rebalance()
    {
        // Historical data request to get 1-year data for optimization.
        var symbols = _universe.Selected.ToList();
        var history = History<TradeBar>(symbols, 253, Resolution.Daily)
            .Where(x => symbols.All(y => x.ContainsKey(y)) && x.All(y => y.Value.Close > 0m))
            .ToList();
        // Daily return on the universe members to calculate the optimized weights.
        var returns = GetReturns(history, symbols);

        // Calculate the optimized weights.
        var weights = _optimizer.Optimize(returns);

        // Rebalance the portfolio according to the optimized weights (greater than 1%)
        var targets = Enumerable.Range(0, weights.Length)
            .Select(i =>
            {
                var weight = Math.Abs(weights[i]) > 0.01 ? Convert.ToDecimal(weights[i]) : 0m;
                return new PortfolioTarget(symbols[i], weight);
            })
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }

    private static double[,] GetReturns(List<DataDictionary<TradeBar>> history, List<Symbol> symbols)
    {
        // Create a 2d array of historical daily returns from historical price data.
        var returns = new double[history.Count, symbols.Count];
        for (int j = 0; j < symbols.Count; j++)
        {
            var lastPrice = 0.0;
            for (int i = 0; i < history.Count; i++)
            {
                var current = (double) history[i][symbols[j]].Close;
                if (i > 0)
                {
                    returns[i, j] = (current / lastPrice) - 1;
                }
                lastPrice = current;
            }
        }
        return returns;
    }
}
```

Other Examples

HistoryAlgorithm.cs C#

Historical Data

History Responses

Introduction

When you make a history request, consider what data returns. Depending on how you request the data, history requests return a specific data type. The data that returns is in ascending order from oldest to newest. This order is necessary to use the data to warm up indicators.

DataFrames

To get a DataFrame from a history request, use Python.

Slices

To request `Slice` objects of historical data, call the `History` method. If you pass a list of `Symbol` objects, it returns data for all the securities and datasets that the `Symbol` objects reference.

```
C#
// Get the latest 3 data points of some securities/datasets, packaged into Slice objects.
var history = History(symbols, 3);
```

If you don't pass any `Symbol` objects, it returns data for all the data subscriptions in your notebook.

```
C#
// Get the latest 3 data points of all the securities/datasets in the notebook, packaged into Slice objects.
var history = History(3);
```

When your history request returns `Slice` objects, the `Time` properties of these objects are based on the algorithm time zone, but the `EndTime` properties of the individual data objects (for example, `TradeBar` , `QuoteBar` , and `Tick` objects) are based on the data time zone . The `EndTime` is the end of the sampling period and when the data is actually available. For more information about time periods, see Periods .

Lists

If you intend to use the data in the DataFrame to create objects like a `TradeBar` or `QuoteBar` , request that the history request returns the data type you need. Otherwise, LEAN consumes unnecessary computational resources populating the DataFrame. To request a list of objects containing the historical data, call one of the `History< Type >` methods.

```C#
public class ListHistoryResponseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        // Create an indicator that is a function of historical bars.
        var indicator = new AverageTrueRange(21);
        // Get the latest TradeBar objects of the asset.
        var history = History<TradeBar>(symbol, indicator.WarmUpPeriod);
        // Update the indicator with the historical TradeBar objects.
        foreach (var bar in history)
        {
            indicator.Update(bar);
        }
    }
}
```

The methods return different data types, depending on how you call it. The following table shows the return type for each input:

Input Generic `< Type >`	**Input** `Symbol` **Type**	**Output Data Type**
`TradeBar`	`Symbol`	`List<TradeBar>`
`TradeBar`	`List<Symbol>`	`List<TradeBars>`
`QuoteBar`	`Symbol`	`List<QuoteBar>`
`QuoteBar`	`List<Symbol>`	`List<QuoteBars>`
`Tick`	`Symbol`	`List<Tick>`
`Tick`	`List<Symbol>`	`List<Ticks>`
`alternativeDataClass` (ex: `CBOE`)	`Symbol`	`List< alternativeDataClass >` (ex: `List<CBOE>`)
`alternativeDataClass` (ex: `CBOE`)	`List<Symbol>`	`List<Dictionary<Symbol, alternativeDataClass >>` (ex: `List<Dictionary<Symbol, CBOE>>`)

```C#
public class ListHistoryResponseAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of some assets.
        var spy = AddEquity("SPY").Symbol;
        var aapl = AddEquity("AAPL").Symbol;

        // Example: List<QuoteBars>
        foreach (var quoteBars in History<QuoteBar>(new[] { spy, aapl }, 3))
        {
            var t = quoteBars.Time;
            foreach (var kvp in quoteBars)
            {
                var symbol = kvp.Key;
                var quoteBar = kvp.Value;
                var bid = quoteBar.Bid;
            }
        }

        // Example: List<Ticks>
        foreach (var ticks in History(new[] { spy, aapl }, TimeSpan.FromDays(3), Resolution.Tick))
        {
            foreach (var kvp in ticks)
            {
                var symbol = kvp.Key;
                var tick = kvp.Value;
                var t = tick.Time;
                var price = tick.Price;
            }
        }

        // Example: List<Dictionary<Symbol, QuiverInsiderTrading>>
        var spyInsider = AddData<QuiverInsiderTrading>(spy).Symbol;
        var aaplInsider = AddData<QuiverInsiderTrading>(aapl).Symbol;
        foreach (var dataBySymbol in History<QuiverInsiderTrading>(new[] { spyInsider, aaplInsider }, 365,
Resolution.Daily))
        {
            foreach (var kvp in dataBySymbol)
            {
                var datasetSymbol = kvp.Key;
                var insiderTrading = kvp.Value;
                var assetSymbol = datasetSymbol.Underlying;
                var t = insiderTrading.EndTime;
                var sharesTraded = insiderTrading.Shares;
            }
        }
    }
}
```

When your history request returns a list of objects, the `Time` properties of these objects are based on the =$writingAlgorithms ? "algorithm" : "notebook" ?> time zone, but the `EndTime` properties of the individual objects in the list are based on the data time zone . The `EndTime` is the end of the sampling period and when the data is actually available. For more information about time periods, see Periods .

Missing Data Points

There are several cases where you may get fewer data points from a history request than you expect.

Illiquid Securities

The default behavior for history requests is to fill-forward the data. However, if an asset had no trading activity during the time period you request historical data for, you won't get any data for that asset.

Requesting Data Before an Asset's IPO

All assets have a day when they first started trading. If your history request includes time before an asset's initial public offering

(IPO) date, you won't get any data before the IPO date because the data doesn't exist.

Requesting Data Outside Market Hours

History requests for a trailing number of data samples return data based on the market hours of assets, so they can wrap across multiple trading days to gather the amount of data you request. In contrast, history requests for trailing time periods return data based on a rolling calendar time and history requests for specific date ranges return data for whatever range you request. In these two latter types of history requests, if the period of time is outside of the market hours of an asset, you won't get any data.

Data Issues

Data issues are generally a result of human error or from mistakes in the data collection process. Any QuantConnect member can report a data issue , which our Data Team works to quickly resolve. However, while the data is still missing, your history requests won't be able to return the data. To view the list of current data issues, log in to the Algorithm Lab and then, in the left navigation bar, click Datasets > Data Issues .

Historical Data

Asset Classes

Asset Classes

US Equities

Introduction

This page explains how to get historical data for US Equities. Some of the data you can get include prices, fundamentals, corporate actions, and universe selection data.

Trades

To get historical trade data , call the `History<TradeBar>` method with a security's `Symbol` .

```C#
public class USEquityTradeBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddEquity("SPY").Symbol;
        // Get the 5 trailing daily TradeBar objects of the security.
        var history = History<TradeBar>(symbol, 5, Resolution.Daily);
        // Iterate through each TradeBar and calculate its dollar volume.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var dollarVolume = bar.Close * bar.Volume;
        }
    }
}
```

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```C#
public class USEquityQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddEquity("SPY").Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

Request second or minute resolution data. Otherwise, the history request won't return any data.

Ticks

To get historical tick data , call the `History<Tick>` method with a security's `Symbol` and `Resolution.Tick` .

```C#
public class USEquityTickHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddEquity("SPY").Symbol;
        // Get the trailing 2 days of ticks for the security.
        var history = History<Tick>(symbol, TimeSpan.FromDays(2), Resolution.Tick);
        // Select the ticks that represent trades, excluding the quote ticks.
        var trades = history.Where(tick => tick.TickType == TickType.Trade);
    }
}
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        AddEquity("SPY");
        // Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Daily);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Fundamentals

To get historical fundamental data , call the `History<Fundamental>` method with an asset's `Symbol` .

```
C#
public class USEquityFundamentalHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 27);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("AAPL").Symbol;
        // Get the 3 trailing daily Fundamental objects of the asset.
        var history = History<Fundamental>(symbol, 3, Resolution.Daily);
        // Iterate through each Fundamental object.
        foreach (var fundamental in history)
        {
            var t = fundamental.EndTime;
            var currentRatio = fundamental.OperationRatios.CurrentRatio.Value;
        }
    }
}
```

Splits

To get historical split data , call the `History<Split>` method with an asset's `Symbol` . Splits are a sparse dataset, so use a time period history request since most days have no data.

```
C#
public class USEquitySplitHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("AAPL").Symbol;
        // Get the splits that occured for the stock over the last 5 years.
        var history = History<Split>(symbol, TimeSpan.FromDays(5*365));
        // Select the dates when splits occurred.
        var splitDates = history.Where(split => split.Type == SplitType.SplitOccurred).Select(split =>
split.EndTime);
    }
}
```

Dividends

To get historical dividend data , call the `History<Dividend>` method with an asset's `Symbol` . Dividends are a sparse dataset, so use a time period history request since most days have no data.

```
C#
public class USEquityDividendHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("AAPL").Symbol;
        // Get the dividends that the stock paid over the last 2 years.
        var history = History<Dividend>(symbol, TimeSpan.FromDays(2*365));
        // Calculate the mean dividend payment.
        var meanDividend = history.Average(split => split.Distribution);
    }
}
```

Symbol Changes

To get historical symbol change data , call the `History<SymbolChangedEvent>` method with an asset's `Symbol` .

```
C#
public class USEquitySymbolChangedEventHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("META").Symbol;
        // Get the symbol changes of the stock over the last 10 years.
        var history = History<SymbolChangedEvent>(symbol, TimeSpan.FromDays(10*365));
        // Iterate through each SymbolChangedEvent object to access their data point attributes.
        foreach (var symbolChangedEvent in history)
        {
            var t = symbolChangedEvent.EndTime;
            var oldSymbol = symbolChangedEvent.OldSymbol;
            var newSymbol = symbolChangedEvent.NewSymbol;
        }
    }
}
```

Delistings

To get historical delisting data , call the `History<Delisting>` method with an asset's `Symbol` . Delistings are a sparse dataset, so use a time period history request since most days have no data.

```
C#
public class USEquityDelistingHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("BBBY").Symbol;
        // Get the deslistings of the asset over the last 10 years.
        var history = History<Delisting>(symbol, TimeSpan.FromDays(10*365));
        // Get the dates of the delist warnings.
        var delistWarningDates = history
            .Where(delisting => delisting.Type == DelistingType.Warning)
            .Select(delisting => delisting.EndTime);
    }
}
```

Universes

To get historical universe data , call the `History` method with the `Universe` object.

```
C#
public class USEquityUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of US Equities based on the constituents of an ETF.
        var universe = AddUniverse(Universe.ETF("SPY"));
        // Get 5 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var constituents in history)
        {
            // Select the 2 assets with the smallest weights in the ETF on this day.
            var dailyLargest = constituents.Select(c => c as ETFConstituentData).OrderByDescending(c =>
c.Weight).Take(2);
        }
    }
}
```

Alternative Data

To get historical alternative data, call the `History< alternativeDataClass >` method with the dataset `Symbol` .

```
C#
public class USEquityAlternativeDataHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("GME").Symbol;
        // Add the alternative dataset and save a reference to its Symbol.
        var datasetSymbol = AddData<QuiverWallStreetBets>(symbol).Symbol;
        // Get the trailing 5 days of QuiverWallStreetBets data for the asset.
        var history = History<QuiverWallStreetBets>(datasetSymbol, 5, Resolution.Daily);
        // Iterate each data point and access its attributes.
        foreach (var dataPoint in history)
        {
            var t = dataPoint.EndTime;
            var sentiment = dataPoint.Sentiment;
        }
    }
}
```

Some alternative datasets provide multiple entries per asset per time step . For example, the True Beats dataset provides EPS and revenue predictions for several upcoming quarters per asset per day. In this case, use a nested loop to access all the data point attributes.

```
C#
public class USEquityTrueBeatsHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Get the ExtractAlphaTrueBeats data for AAPL on 01/02/2024.
        var symbol = AddEquity("AAPL", Resolution.Daily).Symbol;
        var datasetSymbol = AddData<ExtractAlphaTrueBeats>(symbol).Symbol;
        var history = History<ExtractAlphaTrueBeats>(
            datasetSymbol, new DateTime(2024, 9, 1), new DateTime(2024, 12, 31), Resolution.Daily
        );
        // Iterate through each day of history.
        foreach (var trueBeats in history)
        {
            // Calculate the mean TrueBeat estimate for this day.
            var t = trueBeats.EndTime;
            var meanTrueBeat = trueBeats.Data
                .Select(estimate => estimate as ExtractAlphaTrueBeat)
                .Average(estimate => estimate.TrueBeat);
        }
    }
}
```

For information on historical data for other alternative datasets, see the documentation in the Dataset Market .

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```
C#
public class USEquityIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddEquity("SPY").Symbol;
        // Get the 21-day SMA values of the security for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
C#
public class USEquityMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the target and reference securities.
        var targetSymbol = AddEquity("AAPL").Symbol;
        var referenceSymbol = AddEquity("SPY").Symbol;
        // Create a 21-period Beta indicator.
        var beta = new Beta("", targetSymbol, referenceSymbol, 21);
        // Get the historical values of the indicator over the last 10 trading days.
        var history = IndicatorHistory(beta, new[] {targetSymbol, referenceSymbol}, 10, Resolution.Daily);
        // Get the average Beta value.
        var avgBeta = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```
C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Short Availability

To get historical values for the borrow fee rate, borrow rebate rate, or shortable quantity of a US Equity, call the `FeeRate` , `RebateRate` , or `ShortableQuantity` methods of its shortable provider .

```
C#
public class USEquityShortAvailabilityHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add an asset and save a reference to the Equity object.
        var security = AddEquity("SPY");
        // Overwrite the default shortable provider to one that provides data.
        security.SetShortableProvider(new InteractiveBrokersShortableProvider());
        // Select a time in the past.
        var t = Time.AddDays(-30);
        // Pass the time argument to shortable provider to get historical values.
        var feeRate = security.ShortableProvider.FeeRate(security.Symbol, t);
        var rebateRate = security.ShortableProvider.RebateRate(security.Symbol, t);
        var shortableQuantity = security.ShortableProvider.ShortableQuantity(security.Symbol, t);
    }
}
```

For more information about security initializers, see Set Security Initializer .

Examples

The following examples demonstrate some common practices for trading using historical requests.

Example 1: Mean-Variance Portfolio

The following algorithm constructs a monthly rebalance mean-variance portfolio using the top 20 liquid equities. The position sizing can be optimized by 1-year historical daily return of the universe members.

C#

```
public class HistoricalRequestAlgorithm : QCAlgorithm
{
    private Universe _universe;

    // Instantiate the optimizer to perform mean-variance optimization.
    // Mean-variance optimization will not consider a risk-free rate, so we use 0.
    private readonly MaximumSharpeRatioPortfolioOptimizer _optimizer = new (0, 1, 0);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Seed the last price to set the initial price.
        Settings.SeedInitialPrices = true;

        // Monthly renewal of the top 20 liquid universe to trade popular stocks.
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.Top(20));

        // Set a scheduled event to rebalance the portfolio at the start of every month.
        Schedule.On(DateRules.MonthStart(), TimeRules.At(9, 31), Rebalance);
    }

    private void Rebalance()
    {
        // Historical data request to get 1-year data for optimization.
        var symbols = _universe.Selected.ToList();
        var history = History<TradeBar>(symbols, 253, Resolution.Daily)
            .Where(x => symbols.All(y => x.ContainsKey(y)) && x.All(y => y.Value.Close > 0m))
            .ToList();
        // Daily return on the universe members to calculate the optimized weights.
        var returns = GetReturns(history, symbols);

        // Calculate the optimized weights.
        var weights = _optimizer.Optimize(returns);

        // Rebalance the portfolio according to the optimized weights (greater than 1%)
        var targets = Enumerable.Range(0, weights.Length)
            .Select(i =>
            {
                var weight = Math.Abs(weights[i]) > 0.01 ? Convert.ToDecimal(weights[i]) : 0m;
                return new PortfolioTarget(symbols[i], weight);
            })
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }

    private static double[,] GetReturns(List<DataDictionary<TradeBar>> history, List<Symbol> symbols)
    {
        // Create a 2d array of historical daily returns from historical price data.
        var returns = new double[history.Count, symbols.Count];
        for (int j = 0; j < symbols.Count; j++)
        {
            var lastPrice = 0.0;
            for (int i = 0; i < history.Count; i++)
            {
                var current = (double) history[i][symbols[j]].Close;
                if (i > 0)
                {
                    returns[i, j] = (current / lastPrice) - 1;
                }
                lastPrice = current;
            }
        }
        return returns;
    }
}
```

Asset Classes

Equity Options

Introduction

This page explains how to get historical data for Equity Options. Some of the data you can get include prices, open interest, Greeks, and universe selection data.

Trades

To get historical trade data , call the `History<TradeBar>` method with a security's `Symbol` .

C#

```
public class EquityOptionTradeBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var equity = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw);
        var symbol = OptionChain(equity.Symbol).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 5 trailing daily TradeBar objects of the security.
        var history = History<TradeBar>(symbol, 5, Resolution.Daily);
        // Iterate through each TradeBar and calculate its dollar volume.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var dollarVolume = bar.Close * bar.Volume;
        }
    }
}
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

C#

```
public class EquityOptionsQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var equity = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw);
        var symbol = OptionChain(equity.Symbol).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        var equity = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw);
        var contract = OptionChain(equity.Symbol).OrderBy(c => c.OpenInterest).Last();
        AddOptionContract(contract.Symbol);
        // Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Daily);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Open Interest

To get historical open interest data , call the `History<OpenInterest>` method with a security's `Symbol` .

```
C#
public class EquityOptionOpenInterestHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var equity = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw);
        var symbol = OptionChain(equity.Symbol).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 5 trailing daily OpenInterest objects of the security.
        var history = History<OpenInterest>(symbol, 5, Resolution.Daily);
        // Iterate through each OpenInterest and get it's value.
        foreach (var oi in history)
        {
            var t = oi.EndTime;
            var openInterest = oi.Value;
        }
    }
}
```

Daily Option Chains

To get historical daily Option chain data , call the `History` method with the Option `Symbol` object. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter.

```C#
public class EquityOptionDailyOptionChainHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add an Equity Option universe.
        var option = AddOption("SPY");
        // Get the trailing 5 daily Option chains.
        var history = History<OptionUniverse>(option.Symbol, 5);
        // Iterate through each day of the history.
        foreach (var optionUniverse in history)
        {
            var t = optionUniverse.EndTime;
            // Select the 2 contracts with the most volume.
            var mostTraded = optionUniverse.Select(c => c as OptionUniverse).OrderByDescending(c =>
c.Volume).Take(2);
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```C#
public class EquityOptionIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of the Option contract.
        var underlying = AddEquity("SPY").Symbol;
        var symbol = OptionChain(underlying).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 21-day SMA values of the contract for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of multiple securities to compute their value (for example, the indicators for the Greeks and implied volatility). In this case, pass a list of the `Symbol` objects to the method.

```C#
public class EquityOptionMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of the underlying asset.
        var underlying = AddEquity("SPY").Symbol;
        // Get the Option contract Symbol.
        var option = OptionChain(underlying).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the Symbol of the mirror contract.
        var mirror = QuantConnect.Symbol.CreateOption(
            underlying, option.ID.Market, option.ID.OptionStyle,
            option.ID.OptionRight == OptionRight.Put ? OptionRight.Call : OptionRight.Put,
            option.ID.StrikePrice, option.ID.Date
        );
        // Create the indicator.
        var indicator = new ImpliedVolatility(option, RiskFreeInterestRateModel, new
DividendYieldProvider(underlying), mirror, OptionPricingModelType.ForwardTree);
        // Get the historical values of the indicator over the last 60 trading minutes.
        var history = IndicatorHistory(indicator, new[] {underlying, option, mirror}, 60, Resolution.Minute);
        // Get the average IV value.
        var avgIV = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading using historical requests.

Example 1: Trend Following on 0DTE Option Contract

This algorithm strategically trades 0DTE SPY options by analyzing bid and ask volumes shortly after the market opens. Using scheduled events, it effectively executes trades based on historical quote data, optimizing decision-making. The algorithm aims for timely entries and exits, ensuring efficient capital management and quick adaptability in volatile markets.

C#

```
public class ZeroDTEOptionsTradingAlgorithm : QCAlgorithm
{
    private Symbol _option;

    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 10);
        SetCash(100000);

        // Request SPY option data for trading and signal generation.
        var option = AddOption("SPY");
        // We are interested in ATM 0DTE options since they are the most popular.
        option.SetFilter(u => u.IncludeWeeklys().Expiration(0, 0).Strikes(-3, 3));
        _option = option.Symbol;

        // Schedule event to enter and exit option contract position.
        Schedule.On(DateRules.EveryDay(_option), TimeRules.AfterMarketOpen(_option, 16), TradeOption);
        Schedule.On(DateRules.EveryDay(_option), TimeRules.BeforeMarketClose(_option, 15), () => Liquidate());
    }

    public void TradeOption()
    {
        // Get the option chain for SPY to trade.
        if (CurrentSlice.OptionChains.TryGetValue(_option, out var optionChain))
        {
            foreach (var option in optionChain)
            {
                // Request historical quote data for signal generation.
                var history = History<QuoteBar>(option.Symbol, 15, Resolution.Minute);
                // Calculate the total bid and ask for dollar volume to determine the capital directional force.
                var totalBidVolume = 0m;
                var totalAskVolume = 0m;
                foreach (var bar in history)
                {
                    totalBidVolume += bar.Bid.Close * bar.LastBidSize;
                    totalAskVolume += bar.Ask.Close * bar.LastAskSize;
                }

                // Follow the capital flow to trade.
                if (totalBidVolume > totalAskVolume)
                {
                    MarketOrder(option.Symbol, 1);
                }
                else
                {
                    MarketOrder(option.Symbol, -1);
                }
            }
        }
    }
}
```

Asset Classes

Crypto

Introduction

This page explains how to get historical data for Crypto. Some of the data you can get include prices, indicators, and universe selection data.

Trades

To get historical trade data , call the `History<TradeBar>` method with a security's `Symbol` .

```
C#
public class CryptoTradeBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCrypto("BTCUSD").Symbol;
        // Get the 5 trailing daily TradeBar objects of the security.
        var history = History<TradeBar>(symbol, 5, Resolution.Daily);
        // Iterate through each TradeBar and calculate its dollar volume.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var dollarVolume = bar.Close * bar.Volume;
        }
    }
}
```

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```
C#
public class CryptoQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCrypto("BTCUSD", market: Market.Bitfinex).Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

Ticks

To get historical tick data , call the `History<Tick>` method with a security's `Symbol` and `Resolution.Tick` .

```C#
public class CryptoTickHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCrypto("BTCUSD", market: Market.Bitfinex).Symbol;
        // Get the trailing 2 days of ticks for the security.
        var history = History<Tick>(symbol, TimeSpan.FromDays(2), Resolution.Tick);
        // Select the ticks that represent trades, excluding the quote ticks.
        var trades = history.Where(tick => tick.TickType == TickType.Trade);
    }
}
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        AddCrypto("BTCUSD");
        // Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Daily);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Universes

To get historical universe data , call the `History` method with the `Universe` object. This method doesn't apply your selection function . It returns all of the universe data.

```
C#
public class CryptoUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of Cryptocurrencies on Coinbase.
        var universe = AddUniverse(CryptoUniverse.Coinbase(constituents => constituents.Select(c => c.Symbol)));
        // Get 5 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var constituents in history)
        {
            // Select the 2 assets with the largest dollar volume on this day.
            var dailyLargest = constituents.Select(c => c as CryptoUniverse).OrderByDescending(c =>
c.VolumeInUsd).Take(2);
        }
    }
}
```

Alternative Data

To get historical alternative data, call the `History< alternativeDataClass >` method with the dataset `Symbol` .

```
C#
public class CryptoAlternativeDataHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an asset.
        var symbol = AddEquity("BTCUSD").Symbol;
        // Add the alternative dataset and save a reference to its Symbol.
        var datasetSymbol = AddData<BitcoinMetadata>(symbol).Symbol;
        // Get the trailing 5 days of alternative data for the asset.
        var history = History<BitcoinMetadata>(datasetSymbol, 5, Resolution.Daily);
        // Iterate each data point and access its attributes.
        foreach (var dataPoint in history)
        {
            var t = dataPoint.EndTime;
            var marketCap = dataPoint.MarketCapitalization;
        }
    }
}
```

For information on historical data for other alternative datasets, see the documentation in the Dataset Market .

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```
C#
public class CryptoIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCrypto("BTCUSD").Symbol;
        // Get the 21-day SMA values of the security for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
C#
public class CryptoMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the target and reference securities.
        var targetSymbol = AddCrypto("DOGEUSD").Symbol;
        var referenceSymbol = AddCrypto("BTCUSD").Symbol;
        // Create a 21-period Beta indicator.
        var beta = new Beta("", targetSymbol, referenceSymbol, 21);
        // Get the historical values of the indicator over the last 10 trading days.
        var history = IndicatorHistory(beta, new[] {targetSymbol, referenceSymbol}, 10, Resolution.Daily);
        // Get the average Beta value.
        var avgBeta = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```
C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading Cryptos using historical requests.

Example 1: Risk-Parity Crypto Pairs Portfolio

The following algorithm constructs a monthly rebalance risk-parity portfolio using the top 10 liquid Crypto pairs in the BitFinex market. A risk Parity portfolio can dissipate the risk of each crypto pair to reduce overall drawdown. The position sizing can be optimized by 1-year historical daily return of the universe members.

C#

```
public class CryptoHistoricalDataAlgorithm : QCAlgorithm
{
    private Universe _universe;
    // Instantiate the optimizer to perform risk-parity optimization.
    // Risk Parity portfolio can dissipate the risk of each crypto pair to reduce overall drawdown.
    private readonly RiskParityPortfolioOptimizer _optimizer = new(0, 1);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Seed the last price to set the initial price of the BTCUSDT holdings.
        Settings.SeedInitialPrices = true;

        // Monthly renewal of the top 10 liquid universe to trade popular crypto pairs.
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(new CryptoCoarseFundamentalUniverse(Market.Bitfinex, UniverseSettings, Selection));

        // Set a scheduled event to rebalance the portfolio at the start of every month.
        Schedule.On(DateRules.MonthStart(), TimeRules.At(9, 31), Rebalance);
    }

    private IEnumerable<Symbol> Selection(IEnumerable<CryptoUniverse> data)
    {
        // Filter out the crypto pair with a price below $10 to avoid excessive volatility.
        return (from datum in data
                where datum.VolumeInUsd.HasValue
                orderby datum.VolumeInUsd.Value descending
                select datum.Symbol).Take(10);
    }

    private void Rebalance()
    {
        // Historical data request to get 1-year data for optimization.
        var symbols = _universe.Selected.ToList();
        var history = History<TradeBar>(symbols, 253, Resolution.Daily)
            .Where(x => symbols.All(y => x.ContainsKey(y)) && x.All(y => y.Value.Close > 0m))
            .ToList();
        // Daily return on the universe members to calculate the optimized weights.
        var returns = GetReturns(history, symbols);

        // Calculate the optimized weights.
        var weights = _optimizer.Optimize(returns);

        // Rebalance the portfolio according to the optimized weights.
        var targets = Enumerable.Range(0, weights.Length)
            .Select(i =>
            {
                var weight = Math.Abs(weights[i]) > 0.01 ? Convert.ToDecimal(weights[i]) : 0m;
                return new PortfolioTarget(symbols[i], weight);
            })
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }

    private static double[,] GetReturns(List<DataDictionary<TradeBar>> history, List<Symbol> symbols)
    {
        // Create a 2d array of historical daily returns from historical price data.
        var returns = new double[history.Count, symbols.Count];
        for (int j = 0; j < symbols.Count; j++)
        {
            var lastPrice = 0.0;
            for (int i = 0; i < history.Count; i++)
            {
                var current = (double) history[i][symbols[j]].Close;
                if (i > 0)
                {
                    returns[i, j] = current / lastPrice - 1;
                }
                lastPrice = current;
            }
        }
        return returns;
    }
}
```

Asset Classes

Crypto Futures

Introduction

This page explains how to get historical data for Crypto Futures. Some of the data you can get include prices, margin interest rates, and indicator data.

Trades

To get historical trade data , call the `History<TradeBar>` method with a security's `Symbol` .

```
C#
public class CryptoFutureTradeBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCryptoFuture("BTCUSD").Symbol;
        // Get the 5 trailing daily TradeBar objects of the security.
        var history = History<TradeBar>(symbol, 5, Resolution.Daily);
        // Iterate through each TradeBar and calculate its dollar volume.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var dollarVolume = bar.Close * bar.Volume;
        }
    }
}
```

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```
C#
public class CryptoFutureQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCryptoFuture("BTCUSD").Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

Ticks

To get historical tick data , call the `History<Tick>` method with a security's `Symbol` and `Resolution.Tick` .

```
C#
public class CryptoFutureTickHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCryptoFuture("BTCUSD").Symbol;
        // Get the trailing 2 days of ticks for the security.
        var history = History<Tick>(symbol, TimeSpan.FromDays(2), Resolution.Tick);
        // Select the ticks that represent trades, excluding the quote ticks.
        var trades = history.Where(tick => tick.TickType == TickType.Trade);
    }
}
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        AddCryptoFuture("BTCUSD");
        // Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Daily);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Margin Interest Rates

To get historical margin interest rate data , call the `History<MarginInterestRate>` method with a security's `Symbol` .

```C#
public class CryptoFutureMarginInterestRateHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCryptoFuture("BTCUSD").Symbol;
        // Get the MarginInterestRate objects of the security over the last 2 trading days.
        var history = History<MarginInterestRate>(symbol, 2, Resolution.Daily);
        // Iterate through each MarginInterestRate object and get its value.
        foreach (var dataPoint in history)
        {
            var t = dataPoint.EndTime;
            var interestRate = dataPoint.InterestRate;
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```C#
public class CryptoFutureIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCryptoFuture("BTCUSD").Symbol;
        // Get the 21-day SMA values of the security for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```C#
public class CryptoFutureMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the target and reference securities.
        var targetSymbol = AddCryptoFuture("DOGEUSD").Symbol;
        var referenceSymbol = AddCryptoFuture("BTCUSD").Symbol;
        // Create a 21-period Beta indicator.
        var beta = new Beta("", targetSymbol, referenceSymbol, 21);
        // Get the historical values of the indicator over the last 10 trading days.
        var history = IndicatorHistory(beta, new[] {targetSymbol, referenceSymbol}, 10, Resolution.Daily);
        // Get the average Beta value.
        var avgBeta = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate common practices for trading cryptocurrency futures with historical data.

Example 1: Spot-Future Arbitrage

The example below uses linear regression with historical Spot and Future BTCUSDT data to obtain the cointegrating vector between them. We measure the spread between the two securities and trade mean reversal upon their spread divergence.

```C#
using MathNet.Numerics.LinearRegression;
using Accord.Math;

public class CointegrationVectorRegressionAlgorithm : QCAlgorithm
{
    private Symbol _spot, _future;
    private decimal[] _cointegrationVector = new[] { 0m, 0m };
    private decimal _residualMean = 0m;
    private decimal _residualStd = 1m;
    private decimal _entryThreshold = 2m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetAccountCurrency("USDT", 100000);
        SetCash("BTC", 2);
        Settings.SeedInitialPrices = true;

        // Request BTCUSDT Crypto and Crypto Future data to form the cointegrating vectors and trade.
        _spot = AddCrypto("BTCUSDT", market: Market.Bybit).Symbol;
        _future = AddCryptoFuture("BTCUSDT", market: Market.Bybit).Symbol;

        // Daily recalibration on the cointegrating vectors.
        Schedule.On(
            DateRules.EveryDay(_future),
            TimeRules.At(0, 1),
            Recalibrate
        );
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_future, out var y) && slice.Bars.TryGetValue(_spot, out var x1))
        {
```

```
        {
            // Calculate the spread based on the cointegration vector.
            var spread = CalculateSpread(y.Close, x1.Close, _cointegrationVector);
            var normalizedSpread = (spread - _residualMean) / _residualStd;

            // If the spread is too high, short the dependent and long the independent variables based on the
weightings of the cointegrating vectors.
            // Else, and vice versa.
            var totalWeights = Math.Abs(_cointegrationVector[1]) + 1m;
            if (normalizedSpread > _entryThreshold && !Portfolio[_future].IsShort)
            {
                SetHoldings(_future, -1m / totalWeights);
                SetHoldings(_spot, _cointegrationVector[1] / totalWeights);
            }
            else if (normalizedSpread < -_entryThreshold && !Portfolio[_future].IsLong)
            {
                SetHoldings(_future, 1m / totalWeights);
                SetHoldings(_spot, -_cointegrationVector[1] / totalWeights);
            }

            // Exit if spread is converged.
            if ((Portfolio[_future].IsShort && normalizedSpread < 0m) || (Portfolio[_future].IsLong &&
normalizedSpread > 0m))
            {
                Liquidate();
            }
        }
    }

    private void Recalibrate()
    {
        // Calculate the cointegration vector from historical data.
        var history = History<TradeBar>(new[] { _future, _spot }, 252, Resolution.Daily)
            .Where(x => x.ContainsKey(_future) && x.ContainsKey(_spot))
            .ToList();
        _cointegrationVector = CalculateCointegrationVector(history);
        var residual = history.Select(x => CalculateSpread(x[_future].Close, x[_spot].Close,
_cointegrationVector)).ToArray();
        _residualMean = residual.Average();
        _residualStd = Convert.ToDecimal(Math.Sqrt(residual.Sum(x => Math.Pow((double)(x - _residualMean), 2)) /
residual.Length));
    }

    private decimal[] CalculateCointegrationVector(IEnumerable<DataDictionary<TradeBar>> history)
    {
        // Use log price to eliminate the compounding effect.
        var y = history.Select(x => Math.Log((double)x[_future].Close)).ToArray();
        var x1 = history.Select(x => Math.Log((double)x[_spot].Close)).ToArray();

        // Create a matrix for the regression analysis.
        var n = new[] { y.Length, x1.Length }.Min();
        var designMatrix = new double[n][];
        for (int i = 0; i < n; i++)
        {
            designMatrix[i] = new[] { x1[i] };
        }

        try
        {
            // Perform regression using MathNet.Numerics
            var coefficients = MultipleRegression.QR(designMatrix, y.TakeLast(n).ToArray(), intercept: true);
            // The coefficients array will contain the intercept and the coefficients for each independent variable.
            return new[] { (decimal)coefficients[0], (decimal)coefficients[1] };
        }
        catch
        {
            return _cointegrationVector;
        }
    }

    private decimal CalculateSpread(decimal y, decimal x1, decimal[] cointegrationVector)
    {
        // Using the cointegration vector to calculate the spread.
        return LogPrice(y) - (cointegrationVector[0] + LogPrice(x1) * cointegrationVector[1]);
    }

    private decimal LogPrice(decimal price)
    {
        return Convert.ToDecimal(Math.Log((double)price));
    }
}
```

Asset Classes

Forex

Introduction

This page explains how to get historical data for Forex. Some of the data you can get include quotes, ticks, and indicator data.

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```
C#
public class ForexQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddForex("EURUSD").Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

Ticks

To get historical tick data , call the `History<Tick>` method with a security's `Symbol` and `Resolution.Tick` .

```
C#
public class ForexTickHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddForex("EURUSD").Symbol;
        // Get the trailing 2 days of ticks for the security.
        var history = History<Tick>(symbol, TimeSpan.FromDays(2), Resolution.Tick);
        // Calculate the spread.
        var spread = history.Select(tick => tick.AskPrice - tick.BidPrice);
    }
}
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        AddForex("EURUSD");
        // Get the historical Slice objects over the last 5 minutes for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Minute);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each QuoteBar in this Slice.
            foreach (var kvp in slice.QuoteBars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```C#
public class ForexIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddForex("EURUSD").Symbol;
        // Get the 21-day SMA values of the security for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's ask
price.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.AskClose);
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```
C#
public class ForexMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the target and reference securities.
        var targetSymbol = AddForex("AUDUSD").Symbol;
        var referenceSymbol = AddForex("EURUSD").Symbol;
        // Create a 21-period Beta indicator.
        var beta = new Beta("", targetSymbol, referenceSymbol, 21);
        // Get the historical values of the indicator over the last 10 trading days.
        var history = IndicatorHistory(beta, new[] {targetSymbol, referenceSymbol}, 10, Resolution.Daily);
        // Get the average Beta value.
        var avgBeta = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```
C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading Forex with historical data.

Example 1: Arbitration with Cointegration

The below example uses linear regression with historical data of 3 related Forex pairs to obtain the cointegrating vector between them. We measure the spread between the 3 Forex pairs and trade mean reversal upon their spread divergence.

```
C#
using MathNet.Numerics.LinearRegression;

public class CointegrationVectorRegressionAlgorithm : QCAlgorithm
{
    private List<Symbol> _currencyPairs;
    private double[] _cointegrationVector = [0.0, 0.0, 0.0];
    private double _entryThreshold = 0.0001;
    private static readonly string[] sourceArray = ["USDJPY", "EURUSD", "EURJPY"];

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        Settings.SeedInitialPrices = true;

        // Request Forex data to form the cointegrating vectors and trade.
        _currencyPairs = sourceArray.Select(pair => AddForex(pair).Symbol).ToList();

        // Daily recalibration on the cointegrating vectors.
        Schedule.On(DateRules.EveryDay(_currencyPairs[0]), TimeRules.At(0, 1), Recalibrate);
    }

    public override void OnData(Slice slice)
    {
        if (slice.QuoteBars.TryGetValue(_currencyPairs[0], out var y) &&
slice.QuoteBars.TryGetValue(_currencyPairs[1], out var x1) && slice.QuoteBars.TryGetValue(_currencyPairs[2], out var
x2))
        {
            // Calculate the spread based on the cointegration vector.
            var spread = CalculateSpread(y.Close, x1.Close, x2.Close, _cointegrationVector);

            // Exit if spread is converged.
            if ((Portfolio[_currencyPairs[0]].IsShort && spread < 0) || (Portfolio[_currencyPairs[0]].IsLong &&
spread > 0))
```

```
spread > 0))
            {
                Liquidate();
                return;
            }

            // If spread is too high, short the dependent and long the independent variables based on the weightings
of the cointegrating vectors.
            // Else, vice versa.
            var totalWeights = 1 / (Math.Abs(_cointegrationVector[1]) + Math.Abs(_cointegrationVector[2]) + 1);
            if (spread > _entryThreshold)
            {
                SetHoldings(_currencyPairs[0], -totalWeights);
                SetHoldings(_currencyPairs[1], _cointegrationVector[1] * totalWeights);
                SetHoldings(_currencyPairs[2], _cointegrationVector[2] * totalWeights);
            }
            else if (spread < -_entryThreshold)
            {
                SetHoldings(_currencyPairs[0], totalWeights);
                SetHoldings(_currencyPairs[1], -_cointegrationVector[1] * totalWeights);
                SetHoldings(_currencyPairs[2], -_cointegrationVector[2] * totalWeights);
            }
        }
    }

    private void Recalibrate()
    {
        // Calculate the cointegration vector from historical data.
        var history = History<QuoteBar>(_currencyPairs, 252, Resolution.Daily);
        _cointegrationVector = CalculateCointegrationVector(history);
    }

    private double[] CalculateCointegrationVector(IEnumerable<DataDictionary<QuoteBar>> history)
    {
        // Use log price to eliminate the compounding effect.
        var y = history.Select(x => Math.Log((double)x[_currencyPairs[0]].Close)).ToArray();    // dependent
variable: USDJPY
        var x1 = history.Select(x => Math.Log((double)x[_currencyPairs[1]].Close)).ToArray();   // independent
variable 1: EURUSD
        var x2 = history.Select(x => Math.Log((double)x[_currencyPairs[2]].Close)).ToArray();   // independent
variable 2: EURJPY

        // Create a matrix for the regression analysis.
        var n = new[] { y.Length, x1.Length, x2.Length }.Min();
        var designMatrix = new double[n][];
        for (int i = 0; i < n; i++)
        {
            designMatrix[i] = [ x1[i], x2[i] ];
        }

        try
        {
            // Perform regression using MathNet.Numerics
            // The coefficients array will contain the intercept and the coefficients for each independent variable.
            // Format: [intercept, coeff_EURUSD, coeff_EURJPY]
            return MultipleRegression.QR(designMatrix, [.. y.TakeLast(n)], intercept: true);
        }
        catch
        {
            return _cointegrationVector;
        }
    }

    private static double CalculateSpread(decimal y, decimal x1, decimal x2, double[] cointegrationVector)
    {
        static double logPrice(decimal price) => Math.Log((double)price);
        // Using the cointegration vector to calculate the spread.
        return logPrice(y) - (cointegrationVector[0] + logPrice(x1) * cointegrationVector[1] + logPrice(x2) *
cointegrationVector[2]);
    }
}
```

Asset Classes

Futures

Introduction

This page explains how to get historical data for Futures. Some of the data you can get include prices, open interest, indicators, and contract chain data.

Trades

To get historical trade data , call the `History<TradeBar>` method with a security's `Symbol` .

```
C#
public class FutureTradeBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var future = AddFuture(Futures.Indices.SP500EMini);
        var symbol = FuturesChain(future.Symbol).First().Symbol;
        // Get the 5 trailing daily TradeBar objects of the security.
        var history = History<TradeBar>(symbol, 5, Resolution.Daily);
        // Iterate through each TradeBar and calculate its dollar volume.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var dollarVolume = bar.Close * bar.Volume;
        }
    }
}
```

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```
C#
public class FutureQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var future = AddFuture(Futures.Indices.SP500EMini);
        var symbol = FuturesChain(future.Symbol).First().Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

Ticks

To get historical tick data , call the `History<Tick>` method with a security's `Symbol` and `Resolution.Tick` .

```
C#
public class FutureTickHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var future = AddFuture(Futures.Indices.SP500EMini);
        var symbol = FuturesChain(future.Symbol).First().Symbol;
        // Get the trailing 2 days of ticks for the security.
        var history = History<Tick>(symbol, TimeSpan.FromDays(2), Resolution.Tick);
        // Select the ticks that represent trades, excluding the quote ticks.
        var trades = history.Where(tick => tick.TickType == TickType.Trade);
    }
}
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        AddFuture(Futures.Indices.SP500EMini);
        // Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Daily);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Continuous Contract Prices

To get historical trade, quote, or tick data for the continuous contract , use the `Symbol` property of the `Future` object when you make the history request.

```C#
public class FutureContinuousContractHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the Future and specify the contract rollover settings.
        var future = AddFuture(
            Futures.Indices.SP500EMini,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0
        );
        // Get the 5 trailing daily TradeBar objects of the continuous contract.
        var history = History<TradeBar>(future.Symbol, 5, Resolution.Daily);
        // Iterate through each TradeBar and calculate its dollar volume.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var dollarVolume = bar.Close * bar.Volume;
        }
    }
}
```

Symbol Changes

To get historical symbol change data , call the `History<SymbolChangedEvent>` method with the continuous contract Symbol.

```C#
public class FutureSymbolChangeEventsHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the Future and specify the contract rollover settings.
        var future = AddFuture(
            Futures.Indices.SP500EMini,
            dataMappingMode: DataMappingMode.OpenInterest,
            dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
            contractDepthOffset: 0
        );
        // Get the contract rollovers for the trailing year.
        var history = History<SymbolChangedEvent>(future.Symbol, TimeSpan.FromDays(365));
        // Iterate through each rollover and select the Symbol of each contract.
        foreach (var symbolChangedEvent in history)
        {
            var t = symbolChangedEvent.EndTime;
            var oldSymbol = symbolChangedEvent.OldSymbol;
            var newSymbol = symbolChangedEvent.NewSymbol;
        }
    }
}
```

Open Interest

To get historical open interest data , call the `History<OpenInterest>` method with a security's `Symbol` .

```
C#
public class FutureOpenInterestHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var future = AddFuture(Futures.Indices.SP500EMini);
        var symbol = FuturesChain(future.Symbol).First().Symbol;
        // Get the 5 trailing daily OpenInterest objects of the security.
        var history = History<OpenInterest>(symbol, 5, Resolution.Daily);
        // Iterate through each OpenInterest and get it's value.
        foreach (var oi in history)
        {
            var t = oi.EndTime;
            var openInterest = oi.Value;
        }
    }
}
```

Contracts

To get historical Futures contracts, call the `History<FutureUniverse>` method with the continuous contract `Symbol` . The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter.

```
C#
public class FutureContractsHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add a Future.
        var future = AddFuture(Futures.Indices.SP500EMini);
        // Get the daily contract data over the last two trading days.
        var history = History<FutureUniverse>(future.Symbol, 2);
        // Iterate through each day of the history.
        foreach (var futureUniverse in history)
        {
            var t = futureUniverse.EndTime;
            // Select the contract with the greatest open interest.
            var mostOi = futureUniverse.Select(c => c as FutureUniverse).OrderByDescending(c =>
c.OpenInterest).First();
        }
    }
}
```

Contango

To get historical contango data for VX Futures , call the `History< VIXCentralContango >` method with the dataset `Symbol` .

```C#
public class VIXContangoHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the dataset and save a reference to its Symbol.
        var symbol = AddData<VIXCentralContango>("VIX", Resolution.Daily).Symbol;
        //  Get the trailing 7 days of contango data
        var history = History<VIXCentralContango>(symbol, 7, Resolution.Daily);
        // Iterate each data point and access its attributes.
        foreach (var dataPoint in history)
        {
            var t = dataPoint.EndTime;
            var value = dataPoint.Contango_F2_Minus_F1;
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```C#
public class FuturesIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddFuture(Futures.Indices.SP500EMini).Symbol;
        // Get the 21-day SMA values of the security for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```C#
public class FuturesMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the target and reference securities.
        var targetSymbol = AddFuture(Futures.Metals.Gold).Symbol;
        var referenceSymbol = AddFuture(Futures.Indices.SP500EMini).Symbol;
        // Create a 21-period Beta indicator.
        var beta = new Beta("", targetSymbol, referenceSymbol, 21);
        // Get the historical values of the indicator over the last 10 trading days.
        var history = IndicatorHistory(beta, new[] {targetSymbol, referenceSymbol}, 10, Resolution.Daily);
        // Get the average Beta value.
        var avgBeta = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading Futures with historical data.

Example 1: Stock-Gold All-Weather Portfolio

The following algorithm constructs a monthly-rebalanced, risk-parity portfolio using S&P 500 E-Mini and Micro Gold Futures contracts. A risk-parity approach balances the contribution to risk from each asset class, helping reduce overall portfolio drawdowns and improve diversification. The position sizing is determined using 1-year of historical daily returns for the selected Futures universe.

C#

```
public class FutureHistoricalDataAlgorithm : QCAlgorithm
{
    private List<Future> _futures;
    private IPortfolioOptimizer _optimizer;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1_000_000);
        Settings.SeedInitialPrices = true;

        // Select the future contracts representing various asset classes to diversify the portfolio.
        _futures = [.. new[] { Futures.Indices.SP500EMini, Futures.Metals.MicroGold }
            .Select(x => AddFuture(x,
                fillForward: true,
                extendedMarketHours: true,
                dataNormalizationMode: DataNormalizationMode.BackwardsRatio,
                dataMappingMode: DataMappingMode.OpenInterest,
                contractDepthOffset: 0))];

        // Instantiate the optimizer to perform risk-parity optimization.
        // Risk Parity portfolio can dissipate the risk of each crypto pair to reduce overall drawdown.
        _optimizer = new RiskParityPortfolioOptimizer(0, 1);

        // Set a scheduled event to rebalance the portfolio at the start of every month.
        Schedule.On(
            DateRules.MonthStart(),
            TimeRules.AfterMarketOpen(_futures[0].Symbol, 1),
            Rebalance
        );

        SetWarmUp(1);
    }

    private void Rebalance()
    {
        // Historical data request to get 1-year data for optimization.
        var symbols = _futures.Select(x => x.Symbol).ToList();
        var history = History<TradeBar>(symbols, 253, Resolution.Daily)
            .Where(x => _futures.All(y => x.ContainsKey(y.Symbol)))
            .ToList();
        // Daily return on the universe members to calculate the optimized weights.
        var returns = GetReturns(history, symbols);

        // Calculate the optimized weights.
        var weights = _optimizer.Optimize(returns);

        // Rebalance the portfolio according to the optimized weights.
        var targets = Enumerable.Range(0, weights.Length)
            .Select(i => new PortfolioTarget(_futures[i].Mapped, Convert.ToDecimal(weights[i])/2))
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }

    private double[,] GetReturns(List<DataDictionary<TradeBar>> history, List<Symbol> symbols)
    {
        // Create a 2d array of historical daily returns from historical price data.
        var returns = new double[history.Count, symbols.Count];
        for (int j = 0; j < symbols.Count; j++)
        {
            var lastPrice = 0m;
            for (int i = 0; i < history.Count; i++)
            {
                var current = history[i][symbols[j]].Close;
                if (i > 0)
                {
                    returns[i, j] = (double)((current - lastPrice) / lastPrice);
                }
                lastPrice = current;
            }
        }
        return returns;
    }
}
```

Asset Classes

Future Options

Introduction

This page explains how to get historical data for Future Options. Some of the data you can get include prices and indicator data.

Trades

To get historical trade data , call the `History<TradeBar>` method with a security's `Symbol` .

```C#
public class FutureOptionsTradeBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add a FOP universe.
        var future = AddFuture(Futures.Indices.SP500EMini);
        future.SetFilter(universe => universe.FrontMonth());
        AddFutureOption(future.Symbol, universe => universe.FrontMonth().Strikes(-1, 0).CallsOnly());
    }

    // Get trailing data whenever a new FOP contract enters the universe.
    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            if (security.Type == SecurityType.FutureOption)
            {
                // Get the 3 trailing daily TradeBar objects of the security.
                var history = History<TradeBar>(security.Symbol, 3, Resolution.Daily);
                // Iterate through each TradeBar and calculate its dollar volume.
                foreach (var bar in history)
                {
                    var t = bar.EndTime;
                    var dollarVolume = bar.Close * bar.Volume;
                }
            }
        }
    }
}
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```
C#
public class FutureOptionsQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add a FOP universe.
        var future = AddFuture(Futures.Indices.SP500EMini);
        future.SetFilter(universe => universe.FrontMonth());
        AddFutureOption(future.Symbol, universe => universe.FrontMonth().Strikes(-1, 0).CallsOnly());
    }

    // Get trailing data whenever a new FOP contract enters the universe.
    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            if (security.Type == SecurityType.FutureOption)
            {
                // Get the 3 trailing daily QuoteBar objects of the security.
                var history = History<QuoteBar>(security.Symbol, 3, Resolution.Daily);
                // Iterate through the QuoteBar objects and calculate the spread.
                foreach (var bar in history)
                {
                    var t = bar.EndTime;
                    var spread = bar.Ask.Close - bar.Bid.Close;
                }
            }
        }
    }
}
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        var future = AddFuture(Futures.Indices.SP500EMini);
        future.SetFilter(universe => universe.FrontMonth());
        AddFutureOption(future.Symbol, universe => universe.FrontMonth().Strikes(-1, 0).CallsOnly());
        // Add a Scheduled Event that runs at the start of each month.
        Schedule.On(DateRules.MonthStart(future.Symbol), TimeRules.AfterMarketOpen(future.Symbol, 60), Trade);
    }

    public void Trade()
    {
        // Get the historical Slice objects over the last 30 minutes for all the subcriptions in your algorithm.
        var history = History(30, Resolution.Minute);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```
C#
public class FutureOptionIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add a FOP universe.
        var future = AddFuture(Futures.Indices.SP500EMini);
        future.SetFilter(universe => universe.FrontMonth());
        AddFutureOption(future.Symbol, universe => universe.FrontMonth().Strikes(0, 0).CallsOnly());
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            if (security.Type != SecurityType.FutureOption)
            {
                continue;
            }
            // Get the 21-day SMA values of the contract for the last 5 trading days.
            var history = IndicatorHistory(new SimpleMovingAverage(21), security.Symbol, 5, Resolution.Daily);
            // Get the maximum of the SMA values.
            var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
        }
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the contract's volume.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of multiple securities to compute their value (for example, the indicators for the Greeks and implied volatility). In this case, pass a list of the `Symbol` objects to the method.

```C#
public class FutureOptionMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add a FOP universe.
        var future = AddFuture(Futures.Indices.SP500EMini);
        future.SetFilter(universe => universe.FrontMonth());
        AddFutureOption(future.Symbol, universe => universe.FrontMonth().Strikes(0, 0).CallsOnly());
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        foreach (var security in changes.AddedSecurities)
        {
            if (security.Type != SecurityType.FutureOption)
            {
                continue;
            }
            var option = security.Symbol;
            // Get the Symbol of the mirror contract.
            var mirror = QuantConnect.Symbol.CreateOption(
                option.Underlying, option.ID.Market, option.ID.OptionStyle,
                option.ID.OptionRight == OptionRight.Put ? OptionRight.Call : OptionRight.Put,
                option.ID.StrikePrice, option.ID.Date
            );
            // Create the indicator.
            var indicator = new ImpliedVolatility(option, RiskFreeInterestRateModel, new
ConstantDividendYieldModel(0), mirror, OptionPricingModelType.ForwardTree);
            // Get the historical values of the indicator over the last 10 trading minutes.
            var history = IndicatorHistory(indicator, new[] {option.Underlying, option, mirror}, 10,
Resolution.Minute);
            // Get the average IV value.
            var avgIV = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
        }
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading Future Options with historical data.

Example 1: Trend Following on Front Month ATM Option Contract

This algorithm strategically trades the front month S&P 500 EMini Future Options by analyzing bid and ask volumes shortly after the market opens. Using scheduled events, it effectively executes trades based on historical quote data, optimizing decision-making. The algorithm aims for timely entries and exits, ensuring efficient capital management and quick adaptability in volatile markets.

C#

```
public class FutureOptionsTradingAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(200000);
        Settings.SeedInitialPrices = true;

        // Request ES option data for trading and signal generation.
        var future = AddFuture(Futures.Indices.SP500EMini);
        future.SetFilter(universe => universe.FrontMonth());
        // We are interested in ATM front-month options since they are the most popular.
        AddFutureOption(future.Symbol, universe => universe.Expiration(0, 90).Strikes(-3, 3));

        // Schedule event to enter and exit option contract position.
        Schedule.On(DateRules.EveryDay(future.Symbol), TimeRules.AfterMarketOpen(future.Symbol, 16), TradeOption);
        Schedule.On(DateRules.EveryDay(future.Symbol), TimeRules.BeforeMarketClose(future.Symbol, 15), () =>
Liquidate());
    }

    public void TradeOption()
    {
        // Get the option chain to trade.
        foreach (var chain in CurrentSlice.OptionChains.Values)
        {
            foreach (var option in chain)
            {
                // Request historical quote data for signal generation.
                var history = History<QuoteBar>(option.Symbol, 15, Resolution.Minute);
                if (history.Any()){
                    // Calculate the total bid and ask for dollar volume to determine the capital directional force.
                    var totalBidVolume = 0m;
                    var totalAskVolume = 0m;
                    foreach (var bar in history)
                    {
                        if (bar.Bid != null)
                        {
                            totalBidVolume += bar.Bid.Close * bar.LastBidSize;
                        }
                        if (bar.Ask != null)
                        {
                            totalAskVolume += bar.Ask.Close * bar.LastAskSize;
                        }
                    }

                    // Follow the capital flow to trade.
                    if (totalBidVolume > totalAskVolume)
                    {
                        MarketOrder(option.Symbol, 1);
                    }
                    else
                    {
                        MarketOrder(option.Symbol, -1);
                    }
                }
            }

        }
    }
}
```

Asset Classes

Index

Introduction

This page explains how to get historical price and indicator data for Indices.

Bars

To get historical price data , call the `History` method with an Index `Symbol` .

```C#
public class IndexPriceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of an Index.
        var symbol = AddIndex("SPX").Symbol;
        // Get the 5 trailing daily bars of the Index.
        var history = History(symbol, 5, Resolution.Daily);
        // Iterate through each bar and get its price.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var price = bar.Close;
        }
    }
}
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        AddIndex("SPX");
        // Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Daily);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```
C#
public class IndexIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddIndex("SPX").Symbol;
        // Get the 21-day SMA values of the security for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

	current	**rollingsum**
2024-12-12 15:15:00	6003.055714	126064.17
2024-12-13 15:15:00	6006.096667	126128.03
2024-12-16 15:15:00	6012.036190	126252.76
2024-12-17 15:15:00	6020.634286	126433.32
2024-12-18 15:15:00	6019.442381	126408.29

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```
C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's high
price.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.High);
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```C#
public class IndexMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the target and reference securities.
        var targetSymbol = AddIndex("NDX").Symbol;
        var referenceSymbol = AddIndex("SPX").Symbol;
        // Create a 21-period Beta indicator.
        var beta = new Beta("", targetSymbol, referenceSymbol, 21);
        // Get the historical values of the indicator over the last 10 trading days.
        var history = IndicatorHistory(beta, new[] {targetSymbol, referenceSymbol}, 10, Resolution.Daily);
        // Get the average Beta value.
        var avgBeta = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading with Index historical data.

Example 1: Replicating Portfolio

The example below constructed a replicating SGX portfolio using the top 100 weighted SPY constituents. It provides an alternative way for retail investors to invest in SGX without access to certain financial instruments and a hedging idea on SGX close hours.

```C#
using MathNet.Numerics.LinearRegression;

public class SGXMatchingTradingAlgorithm : QCAlgorithm
{
    private Symbol _sgx;
    private Universe _universe;
    private decimal[] _weights = null;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        SetWarmUp(7, Resolution.Daily);

        // Request SGX Index data for matching.
        _sgx = AddIndex("SGX").Symbol;

        // We will try to use SPY constituents to reproduce the SGX index.
        _universe = AddUniverse(Universe.ETF("SPY", UniverseSettings, constituents =>
        {
            return constituents
                .Where(x => x.Weight.HasValue)
                .OrderByDescending(x => x.Weight.Value)
                .Take(100)
                .Select(x => x.Symbol);
        }));

        // Schedule an event to rebalance the portfolio.
        Schedule.On(
            DateRules.EveryDay("SPY"),
            TimeRules.AfterMarketOpen("SPY", 1),
            Rebalance
```

```
        Rebalance
    );
}

private void Rebalance()
{
    if (IsWarmingUp || _universe.Selected.Count == 0)
    {
        return;
    }

    var symbols = _universe.Selected.ToList();

    // Obtain the historical data.
    var allSymbols = new List<Symbol> { _sgx };
    allSymbols.AddRange(symbols);
    var historyRequest = History<TradeBar>(allSymbols, 252, Resolution.Daily).ToList();

    if (historyRequest.Count == 0)
    {
        return;
    }

    // Organize data by date.
    var dataByDate = new Dictionary<DateTime, Dictionary<Symbol, TradeBar>>();
    foreach (var slice in historyRequest)
    {
        foreach (var kvp in slice)
        {
            var symbol = kvp.Key;
            var bar = kvp.Value;
            var date = bar.Time.Date;

            if (!dataByDate.TryGetValue(date, out Dictionary<Symbol, TradeBar> value))
            {
                value = [];
                dataByDate[date] = value;
            }

            value[symbol] = bar;
        }
    }

    // Filter to dates where we have all symbols.
    var completeDates = dataByDate
        .Where(kvp => kvp.Value.ContainsKey(_sgx) && symbols.All(s => kvp.Value.ContainsKey(s)))
        .OrderBy(kvp => kvp.Key)
        .Select(kvp => kvp.Value)
        .ToList();

    if (completeDates.Count < 50)
    {
        return;
    }

    var benchmark = completeDates.Select(d => (double)d[_sgx].Close).ToArray();

    var designMatrix = new double[completeDates.Count][];
    for (int i = 0; i < completeDates.Count; i++)
    {
        designMatrix[i] = [.. symbols.Select(s => (double)completeDates[i][s].Close)];
    }

    CalculateWeights(designMatrix, benchmark);

    if (_weights != null)
    {
        var targets = _weights
            .Zip(symbols, (weight, symbol) => new PortfolioTarget(symbol, weight))
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}

private void CalculateWeights(double[][] history, double[] benchmark)
{
    try
    {
        // Use log price to eliminate the compounding effect.
        var y = benchmark.Select(x => Math.Log(x)).ToArray();
        var designMatrix = history.Select(row => row.Select(x => Math.Log(x)).ToArray()).ToArray();
```

```
            // Perform regression to obtain the best-replicating portfolio of SGX.
            var coefficients = MultipleRegression.QR(designMatrix, y, intercept: false);

            // The coefficients array will contain the coefficients for each constituents.
            var sum = coefficients.Sum(c => Math.Abs(c));
            if (sum > 0)
            {
                _weights = [.. coefficients.Select(c => Convert.ToDecimal(c / sum))];
            }
        }
        catch
        {
        }
    }
}
```

Asset Classes

Index Options

Introduction

This page explains how to get historical data for Index Options. Some of the data you can get include prices, open interest, Greeks, and universe selection data.

Trades

To get historical trade data , call the `History<TradeBar>` method with a security's `Symbol` .

```C#
public class IndexOptionTradeBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var index = AddIndex("SPX");
        var symbol = OptionChain(index.Symbol).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 5 trailing daily TradeBar objects of the security.
        var history = History<TradeBar>(symbol, 5, Resolution.Daily);
        // Iterate through each TradeBar and calculate its dollar volume.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var dollarVolume = bar.Close * bar.Volume;
        }
    }
}
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```C#
public class IndexOptionQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var index = AddIndex("SPX");
        var symbol = OptionChain(index.Symbol).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

Request minute, hour, or daily resolution data. Otherwise, the history request won't return any data.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        var index = AddIndex("SPX");
        var contract = OptionChain(index.Symbol).OrderBy(c => c.OpenInterest).Last();
        AddOptionContract(contract.Symbol);
        // Get the historical Slice objects over the last 5 days for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Daily);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each TradeBar in this Slice.
            foreach (var kvp in slice.Bars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Open Interest

To get historical open interest data , call the `History<OpenInterest>` method with a security's `Symbol` .

```
C#
public class IndexOptionOpenInterestHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var index = AddIndex("SPX");
        var symbol = OptionChain(index.Symbol).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 5 trailing daily OpenInterest objects of the security.
        var history = History<OpenInterest>(symbol, 5, Resolution.Daily);
        // Iterate through each OpenInterest and get it's value.
        foreach (var oi in history)
        {
            var t = oi.EndTime;
            var openInterest = oi.Value;
        }
    }
}
```

Daily Option Chains

To get historical daily Option chain data , call the `History` method with the Option `Symbol` object. The data this method returns contains information on all the currently tradable contracts, not just the contracts that pass your filter.

```C#
public class IndexOptionDailyOptionChainHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add an Index Option universe.
        var option = AddIndexOption("SPX");
        // Get the trailing 5 daily Option chains.
        var history = History<OptionUniverse>(option.Symbol, 5);
        // Iterate through each day of the history.
        foreach (var optionUniverse in history)
        {
            var t = optionUniverse.EndTime;
            // Select the 2 contracts with the most volume.
            var mostTraded = optionUniverse.Select(c => c as OptionUniverse).OrderByDescending(c =>
c.Volume).Take(2);
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```C#
public class IndexOptionIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of the Option contract.
        var underlying = AddIndex("SPX").Symbol;
        var symbol = OptionChain(underlying).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the 21-day SMA values of the contract for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's volume.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.Volume);
```

Some indicators require the prices of multiple securities to compute their value (for example, the indicators for the Greeks and implied volatility). In this case, pass a list of the `Symbol` objects to the method.

```C#
public class IndexOptionMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of the underlying asset.
        var underlying = AddIndex("SPX").Symbol;
        // Get the Option contract Symbol.
        var option = OptionChain(underlying).OrderBy(c => c.OpenInterest).Last().Symbol;
        // Get the Symbol of the mirror contract.
        var mirror = QuantConnect.Symbol.CreateOption(
            underlying, option.ID.Market, option.ID.OptionStyle,
            option.ID.OptionRight == OptionRight.Put ? OptionRight.Call : OptionRight.Put,
            option.ID.StrikePrice, option.ID.Date
        );
        // Create the indicator.
        var indicator = new ImpliedVolatility(option, RiskFreeInterestRateModel, new
DividendYieldProvider(underlying), mirror, OptionPricingModelType.ForwardTree);
        // Get the historical values of the indicator over the last 60 trading minutes.
        var history = IndicatorHistory(indicator, new[] {underlying, option, mirror}, 60, Resolution.Minute);
        // Get the average IV value.
        var avgIV = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading Index Options with historical data.

Example 1: Standard-Weekly Contracts Cointegration

The following example analyzes the cointegration relationship between the front-month ATM SPX and SPXW calls. By measuring their spread divergence, we trade mean reversal on their spread convergence.

```C#
using MathNet.Numerics.LinearRegression;

public class IndexOptionHistoricalDataAlgorithm : QCAlgorithm
{
    private Symbol _spxContract, _spxwContract;
    private decimal[] _cointegrationVector = new[] { 0m, 0m };
    private decimal _threshold = 2m;
    private decimal _spreadMean = 0m;
    private decimal _spreadSd = 1m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10000000);

        // Select the Index Options to analyze and trade by week.
        Schedule.On(
            DateRules.WeekStart(),
            TimeRules.At(9, 15),
            SelectContract
        );
    }

    public override void OnData(Slice slice)
    {
        if (_spxwContract != null && slice.QuoteBars.TryGetValue(_spxwContract, out var x) &&
```

```
        if (_spxwContract != null && slice.QuoteBars.TryGetValue(_spxwContract, out var y) &&
slice.QuoteBars.TryGetValue(_spxContract, out var x1))
        {
            // Obtain the current spread to see if there is any price divergence to trade.
            var spread = CalculateSpread(y.Close, x1.Close, _cointegrationVector);
            var z = (spread - _spreadMean) / _spreadSd;

            // If the spread diverges above or below the threshold, trade to bet on mean reversal.
            if (z > _threshold && !Portfolio[_spxContract].IsLong)
            {
                MarketOrder(_spxContract, 10 * _cointegrationVector[1]);
                MarketOrder(_spxwContract, -10);
            }
            else if (z < -_threshold && !Portfolio[_spxwContract].IsLong)
            {
                MarketOrder(_spxContract, -10 * _cointegrationVector[1]);
                MarketOrder(_spxwContract, 10);
            }

            // If prices converge, exit positions.
            if ((Portfolio[_spxContract].IsLong && z < 0m) || (Portfolio[_spxwContract].IsLong && z > 0m))
            {
                Liquidate();
            }
        }
    }

    private void SelectContract()
    {
        var index = QuantConnect.Symbol.Create("SPX", SecurityType.Index, Market.USA);
        // Obtain the SPX ATM call contract since it is the most liquid with which to trade.
        var spx = QuantConnect.Symbol.CreateCanonicalOption(index);
        var spxContracts = OptionChain(spx).Where(x => x.Expiry <= Time.AddDays(30)).ToList();
        if (spxContracts.Count == 0)
        {
            _spxContract = null;
            _spxwContract = null;
            return;
        }
        var expiry = spxContracts.Max(x => x.Expiry);
        _spxContract = spxContracts.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call)
            .OrderBy(x => Math.Abs(x.Strike - x.UnderlyingLastPrice))
            .First().Symbol;
        // Obtain the SPXW contract with the same strike, right, and expiry.
        var spxw = QuantConnect.Symbol.CreateCanonicalOption(index, "SPXW", Market.USA, "?SPXW");
        _spxwContract = OptionChain(spxw).Where(x => x.Expiry == expiry && x.Right == OptionRight.Call && x.Strike ==
_spxContract.ID.StrikePrice).FirstOrDefault()?.Symbol;

        if (_spxwContract != null)
        {
            // Subscribe to the contracts we will trade
            AddIndexOptionContract(_spxContract);
            AddIndexOptionContract(_spxwContract);
            // Obtain the historical data and find their cointegration relationship.
            var history = History<QuoteBar>(new[] { _spxContract, _spxwContract }, 1000, Resolution.Minute).Where(x
=> x.ContainsKey(_spxContract) && x.ContainsKey(_spxwContract)).ToList();
            _cointegrationVector = CalculateCointegrationVector(history);
            // Obtain the mean and SD of the spread between the options.
            var residual = history.Select(x => CalculateSpread(x[_spxwContract].Close, x[_spxContract].Close,
_cointegrationVector)).ToList();
            _spreadMean = residual.Average();
            _spreadSd = Convert.ToDecimal(Math.Sqrt(residual.Sum(x => Math.Pow((double)(x - _spreadMean), 2) /
residual.Count)));
        }
    }

    private decimal[] CalculateCointegrationVector(IEnumerable<DataDictionary<QuoteBar>> history)
    {
        // Use log price to eliminate the compounding effect.
        var y = history.Select(x => Math.Log((double)x[_spxwContract].Close)).ToArray();
        var x1 = history.Select(x => Math.Log((double)x[_spxContract].Close)).ToArray();

        // Create a matrix for the regression analysis.
        var n = new[] { y.Length, x1.Length }.Min();
        var designMatrix = new double[n][];
        for (int i = 0; i < n; i++)
        {
            designMatrix[i] = new[] { x1[i] };
        }

        try
        {
```

```
        {
            // Perform regression using MathNet.Numerics
            var coefficients = MultipleRegression.QR(designMatrix, y.TakeLast(n).ToArray(), intercept: true);

            // The coefficients array will contain the intercept and the coefficients for each independent variable.
            // Format: [intercept, x1]
            return new[] { (decimal)coefficients[0], (decimal)coefficients[1] };
        }
        catch
        {
            return _cointegrationVector;
        }
    }

    private decimal CalculateSpread(decimal y, decimal x1, decimal[] cointegrationVector)
    {
        // Using the cointegration vector to calculate the spread.
        return LogPrice(y) - (cointegrationVector[0] + LogPrice(x1) * cointegrationVector[1]);
    }

    private decimal LogPrice(decimal price)
    {
        return Convert.ToDecimal(Math.Log((double)price));
    }
}
```

Asset Classes

CFD

Introduction

This page explains how to get historical quotes and indicator data for CFDs.

Quotes

To get historical quote data , call the `History<QuoteBar>` method with a security's `Symbol` .

```C#
public class CFDQuoteBarHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCfd("XAUUSD").Symbol;
        // Get the 5 trailing minute QuoteBar objects of the security.
        var history = History<QuoteBar>(symbol, 5, Resolution.Minute);
        // Iterate through the QuoteBar objects and calculate the spread.
        foreach (var bar in history)
        {
            var t = bar.EndTime;
            var spread = bar.Ask.Close - bar.Bid.Close;
        }
    }
}
```

		askclose	askhigh	asklow	askopen	bidclose	bidhigh	bidlow	bidopen	close	high	low	open
symbol	**time**												
XAUUSD	**2024-12-18 23:56:00**	2607.96	2608.53	2607.91	2608.53	2607.49	2607.99	2607.43	2607.99	2607.725	2608.26	2607.67	2608.26
	2024-12-18 23:57:00	2608.31	2608.36	2607.92	2607.96	2607.74	2607.80	2607.45	2607.49	2608.025	2608.08	2607.685	2607.72
	2024-12-18 23:58:00	2608.47	2608.55	2608.28	2608.31	2607.89	2608.01	2607.71	2607.74	2608.180	2608.28	2607.995	2608.02
	2024-12-18 23:59:00	2609.48	2609.70	2608.43	2608.47	2609.05	2609.12	2607.89	2607.89	2609.265	2609.41	2608.160	2608.18
	2024-12-19 00:00:00	2609.48	2610.17	2609.48	2609.48	2609.10	2609.65	2609.03	2609.05	2609.290	2609.91	2609.255	2609.26

Ticks

To get historical tick data , call the `History<Tick>` method with a security's `Symbol` and `Resolution.Tick` .

```
C#
public class CFDTickHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCfd("XAUUSD").Symbol;
        // Get the trailing 2 days of ticks for the security.
        var history = History<Tick>(symbol, TimeSpan.FromDays(2), Resolution.Tick);
        // Calculate the spread.
        var spread = history.Select(tick => tick.AskPrice - tick.BidPrice);
    }
}
```

Ticks are a sparse dataset, so request ticks over a trailing period of time or between start and end times.

Slices

To get historical Slice data, call the `History` method without passing any `Symbol` objects. This method returns `Slice` objects, which contain data points from all the datasets in your algorithm. If you omit the `resolution` argument, it uses the resolution that you set for each security and dataset when you created the subscriptions.

```
C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);
        // Add some securities and datasets.
        AddCfd("XAUUSD");
        // Get the historical Slice objects over the last 5 minutes for all the subcriptions in your algorithm.
        var history = History(5, Resolution.Minute);
        // Iterate through each historical Slice.
        foreach (var slice in history)
        {
            // Iterate through each QuoteBar in this Slice.
            foreach (var kvp in slice.QuoteBars)
            {
                var symbol = kvp.Key;
                var bar = kvp.Value;
            }
        }
    }
}
```

Indicators

To get historical indicator values, call the `IndicatorHistory` method with an indicator and the security's `Symbol` .

```C#
public class CFDIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a security.
        var symbol = AddCfd("SPX500USD").Symbol;
        // Get the 21-day SMA values of the security for the last 5 trading days.
        var history = IndicatorHistory(new SimpleMovingAverage(21), symbol, 5, Resolution.Daily);
        // Get the maximum of the SMA values.
        var maxSMA = history.Max(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

The `IndicatorHistory` method resets your indicator, makes a history request, and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

To make the `IndicatorHistory` method update the indicator with an alternative price field instead of the close (or mid-price) of each bar, pass a `selector` argument.

```C#
// Get the historical values of an indicator over the last 30 days, applying the indicator to the security's ask
price.
var history = IndicatorHistory(indicator, symbol, TimeSpan.FromDays(30), selector: Field.AskClose);
```

Some indicators require the prices of two securities to compute their value (for example, Beta). In this case, pass a list of the `Symbol` objects to the method.

```C#
public class CFDMultiAssetIndicatorHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 19);
        SetEndDate(2024, 12, 31);
        // Add the target and reference securities.
        var targetSymbol = AddCfd("XAUUSD").Symbol;
        var referenceSymbol = AddCfd("SPX500USD").Symbol;
        // Create a 21-period Beta indicator.
        var beta = new Beta("", targetSymbol, referenceSymbol, 21);
        // Get the historical values of the indicator over the last 10 trading days.
        var history = IndicatorHistory(beta, new[] {targetSymbol, referenceSymbol}, 10, Resolution.Daily);
        // Get the average Beta value.
        var avgBeta = history.Average(indicatorDataPoint => indicatorDataPoint.Current.Value);
    }
}
```

If you already have a list of Slice objects, you can pass them to the `IndicatorHistory` method to avoid the internal history request.

```C#
var slices = History(new[] {symbol}, 30, Resolution.Daily);
var history = IndicatorHistory(indicator, slices);
```

Examples

The following examples demonstrate some common practices for trading CFD with historical data.

Example 1: Demand Force Following

The following algorithm measures the historical bid-ask spread of XAUUSD CFD contract. If the current spread is higher than the historical spread, meaning the demand force is lower than usual, we sell the contract; else, we buy. To realize the directional speculation, we apply a 2% take profit risk management model and a 1% trailing stop loss risk management model.

C#

```
public class CFDHistoricalDataAlgorithm : QCAlgorithm
{
    private const decimal Threshold = 2m;
    private decimal _spreadMean = 0m;
    private decimal _spreadSd = 1m;
    private Symbol _xauusd;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Request the XAUUSD CFD contract for trade.
        _xauusd = AddCfd("XAUUSD").Symbol;

        // Update the spread mean and SD to calculate the Z-score accurately every day.
        Schedule.On(
            DateRules.EveryDay(_xauusd),
            TimeRules.At(0, 0),
            UpdateSpread
        );

        // Take profit at 2%.
        AddRiskManagement(new MaximumUnrealizedProfitPercentPerSecurity(0.02m));
        // Trailing stop loss at 1%.
        AddRiskManagement(new TrailingStopRiskManagementModel(0.01m));
    }

    private void UpdateSpread()
    {
        // Obtain historical quote data to obtain the mean and SD of the bid-ask spread.
        var history = History<QuoteBar>(_xauusd, 390, Resolution.Minute)      // minute bar of 1 day
            .Where(x => x.Ask != null && x.Bid != null)
            .ToList();
        if (history.Count > 0)
        {
            var spread = history.Select(x => x.Ask.Close - x.Bid.Close).ToList();
            _spreadMean = spread.Average();
            _spreadSd = Convert.ToDecimal(Math.Sqrt(spread.Sum(x => Math.Pow((double)(x - _spreadMean), 2)) /
spread.Count));
        }
    }

    public override void OnData(Slice slice)
    {
        // Obtain the current bid-ask spread as a trade signal.
        if (slice.QuoteBars.TryGetValue(_xauusd, out var quote))
        {
            if (quote.Ask != null && quote.Bid != null)
            {
                var spread = quote.Ask.Close - quote.Bid.Close;
                var z = (spread - _spreadMean) / _spreadSd;

                // If the spread is lower than expected, expect demand to be higher than usual, and buy XAUUSD.
                if (z <= -Threshold)
                {
                    SetHoldings(_xauusd, 1m);
                }
                // If the spread is higher than expected, expect demand to be lower than usual and sell XAUUSD.
                else if (z >= Threshold)
                {
                    SetHoldings(_xauusd, -1m);
                }
            }
        }
    }
}
```

Historical Data

Alternative Data

Introduction

Alternative datasets provide signals to inform trading decisions. To view all the alternative datasets available on QuantConnect, see the Dataset Market . This page explains how to get historical data for alternative datasets.

Data Points

To get a list of historical alternative data, call the `History< alternativeDataClass >` method with the dataset `Symbol` .

```
C#
public class AlternativeDataHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 20);
        SetEndDate(2024, 12, 31);
        // Get the Symbol of a dataset.
        var datasetSymbol = AddData<Fred>("RVXCLS").Symbol;
        // Get the trailing 5 days of Fred data.
        var history = History<Fred>(datasetSymbol, 5, Resolution.Daily);
        // Iterate through the historical data points.
        foreach (var dataPoint in history)
        {
            var t = dataPoint.EndTime;
            var value = dataPoint.Value;
        }
    }
}
```

Some alternative datasets provide multiple entries per asset per time step . For example, the US Regulatory Alerts dataset can provide multiple alerts per day. In this case, use a nested loop to access all the data point attributes.

```
C#
public class RegalyticsHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 20);
        SetEndDate(2024, 12, 31);
        // Get the all the Regalytics articles that were published over the last day.
        var datasetSymbol = AddData<RegalyticsRegulatoryArticles>("REG").Symbol;
        var history = History<RegalyticsRegulatoryArticles>(datasetSymbol, 1, Resolution.Daily);
        // Iterate through each day of articles.
        foreach (var articles in history)
        {
            var t = articles.EndTime;
            // Get the unique alert types for this day.
            var altertTypes = articles.Select(article => (article as
RegalyticsRegulatoryArticle).AlertType).Distinct().ToList();
        }
    }
}
```

Universes

To get historical data for an alternative data universe , call the `History` method with the `Universe` object.

```C#
public class AltDataUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of US Equities based on an alternative dataset.
        var universe = AddUniverse<BrainStockRankingUniverse>();
        // Get 5 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var altCoarse in history)
        {
            // Iterate through each asset in the universe on this day and access its data point attributes.
            foreach (BrainStockRankingUniverse stockRanking in altCoarse)
            {
                var symbol = stockRanking.Symbol;
                var t = stockRanking.EndTime;
                var rank2Days = stockRanking.Rank2Days;
            }
        }
    }
}
```

Slices

To request `Slice` objects of historical data, call the `History` method. If you pass a list of `Symbol` objects, it returns data for all the alternative datasets that the `Symbol` objects reference.

```C#
public class SliceHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add an alternative dataset.
        var symbol = AddCrypto("BTCUSD", Resolution.Daily, Market.Bitfinex).Symbol;
        var datasetSymbol = AddData<BitcoinMetadata>(symbol).Symbol;
        // Get the latest 3 data points of some alternative dataset(s), packaged into Slice objects.
        var history = History(new[] { datasetSymbol }, 3);
        // Iterate through each Slice and get the alternative data points.
        foreach (var slice in history)
        {
            var t = slice.Time;
            var hashRate = slice[datasetSymbol].HashRate;
        }
    }
}
```

If you don't pass any `Symbol` objects, it returns data for all the data subscriptions in your algorithm, so the result may include more than just alternative data.

```
// Get the latest 3 data points of all the securities/datasets in the algorithm, packaged into Slice objects.
var history = History(3);
// Iterate through each Slice and get the synchronized data points at each moment in time.
foreach (var slice in history)
{
    var t = slice.Time;
    if (slice.ContainsKey(symbol))
    {
        var price = slice[symbol].Price;
    }
    if (slice.ContainsKey(datasetSymbol))
    {
        var hashRate = ((BitcoinMetadata)slice[datasetSymbol]).HashRate;
    }
}
```

C#

When your history request returns `Slice` objects, the `Time` properties of these objects are based on the algorithm time zone, but the `EndTime` properties of the individual data objects are based on the data time zone . The `EndTime` is the end of the sampling period and when the data is actually available.

Sparse Datasets

A sparse dataset is a dataset that doesn't have data for every time step of its resolution. For example, the US Energy Information Administration (EIA) datasets have a daily resolution but the data for the "U.S. Ending Stocks of Finished Motor Gasoline in Thousand Barrels (Mbbl)" series only updates once a week. So when you request the trailing 30 days of historical data for it, you only get a few data points.

```
public class SparseDatasetHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a sparse dataset. In this case, the default resolution is daily.
        var symbol = AddData<USEnergy>("PET.WGFSTUS1.W").Symbol;
        // Get 30 days of history for the dataset.
        var history = History(symbol, 30);
        // Iterate through each data point.
        foreach (var dataPoint in history)
        {
            var t = dataPoint.EndTime;
            var weeklyImports = dataPoint.Value;
        }
    }
}
```

C#

Most alternative datasets have only one resolution, which is usually daily. To check if a dataset is sparse and to view its resolution(s), see the documentation in the Dataset Market .

Examples

The following examples demonstrate some common practices for trade with historical Alternative Data.

Example 1: Inverted Yield Curve

The following algorithm trades the smoothened yield curve difference, calculated from the difference between 10-year yield and 2-year yield historical data and smoothened by the exponential moving average. If the yield curve is inverted, short SPY from this market downturn indicator.

C#

```
public class AlternativeHistoricalDataAlgorithm : QCAlgorithm
{
    private const decimal SmoothingFactor = 2m / (1m + 250m);
    private Symbol _spy, _yieldCurveSymbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Requesting yield curve data for trade signal generation (inversion)
        _yieldCurveSymbol = AddData<USTreasuryYieldCurveRate>("USTYCR").Symbol;
        // Request the XAUUSD CFD contract for trade.
        _spy = AddEquity("SPY").Symbol;

        // Ignore orders with very small sizes.
        Settings.MinimumOrderMarginPortfolioPercentage = 0.01m;

        // Trade every day after the market opens with an updated smoothened yield curve difference.
        Schedule.On(
            DateRules.EveryDay(_spy),
            TimeRules.AfterMarketOpen(_spy, 1),
            Trade
        );
    }

    private void Trade()
    {
        // Obtain historical quote data to obtain the mean and SD of the bid-ask spread.
        var history = History<USTreasuryYieldCurveRate>(_yieldCurveSymbol, 250, Resolution.Daily)
            .Where(x => x.TenYear.HasValue && x.TwoYear.HasValue)
            .ToList();
        if (history.Count > 0)
        {
            var diffs = history.Select(x => x.TenYear.Value - x.TwoYear.Value).ToList();
            var smoothedDiff = diffs.Aggregate((ema, nextQuote) => SmoothingFactor * nextQuote + (1m -
SmoothingFactor) * ema);

            // If the smoothened yield curve difference is inverted, short SPY with the downside signal.
            SetHoldings(_spy, smoothedDiff < 0 ? -1m : 1m);
        }
    }
}
```

Historical Data

Custom Data

Introduction

You can import external datasets into your algorithm to use alongside other datasets from the Dataset Market. This page explains how to get historical data for custom datasets. Before you can get historical data for the dataset, define the `GetSource` and `Reader` methods of the custom data class. For examples of custom dataset implementations, see Key Concepts .

Slices

To request `Slice` objects of historical data, call the `History` method. If you pass a list of `Symbol` objects, it returns data for all the custom datasets that the `Symbol` objects reference.

```
C#
// Get the latest 3 data points of some custom datasets, packaged into Slice objects.
var history = History(datasetSymbols, 3);
```

If you don't pass any `Symbol` objects, it returns data for all the data subscriptions in your notebook, so the result may include more than just custom data.

```
C#
// Get the latest 3 data points of all the securities/datasets in the notebook, packaged into Slice objects.
var history = History(3);
```

When your history request returns `Slice` objects, the `Time` properties of these objects are based on the algorithm time zone, but the `EndTime` properties of the individual data objects are based on the data time zone . The `EndTime` is the end of the sampling period and when the data is actually available.

Data Points

To get a list of historical data points for a custom dataset, call the `History< customDatasetClass >` method with the dataset `Symbol` . For an example definition of a custom data class, see the CSV Format Example .

```
C#
public class CustomSecurityHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2014, 7, 10);
        // Add a custom dataset and save a reference to it's Symbol.
        var datasetSymbol = AddData<MyCustomDataType>("MyCustomDataType", Resolution.Daily).Symbol;
        // Get the trailing 5 days of MyCustomDataType data.
        var history = History<MyCustomDataType>(datasetSymbol, 5, Resolution.Daily);
    }
}
```

Universes

To get historical data for a custom data universe , call the `History` method with the `Universe` object. For an example definition of a custom data universe class, see the CSV Format Example .

```C#
public class CustomDataUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2017, 7, 9);
        // Add a universe from a custom data source and save a reference to it.
        var universe = AddUniverse<StockDataSource>(
            "myStockDataSource", Resolution.Daily, data => data.Select(x => x.Symbol)
        );
        // Get the historical universe data over the last 5 days.
        var history = History(universe, TimeSpan.FromDays(5)).Cast<StockDataSource>().ToList();
        // Iterate through each day in the universe history and count the number of constituents.
        foreach (var stockData in history)
        {
            var t = stockData.Time;
            var size = stockData.Symbols.Count;
        }
    }
}
```

Missing Data Points

History requests for a trailing number of data samples return data based on the market hours of assets. The default market hours for custom securities is to be always open. Therefore, history requests for a trailing number of data samples may return fewer samples than you expect. To set the market hours of the dataset, see Market Hours .

Examples

The following examples demonstrate some common practices for trading with historical custom data.

Example 1: Custom Universe Data

The following algorithm trades based on a custom universe dataset. It obtains historical data on the universe's weights and uses the exponential moving average as the investment weight.

C#

```
public class CustomUniverseExampleAlgorithm : QCAlgorithm
{
    private const decimal SmoothingFactor = 2m / (1m + 5m);
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2016, 1, 1);
        SetEndDate(2025, 1, 1);
        // Add a universe that reads from the Object Store.
        _universe = AddUniverse<CustomUniverseData>("CustomUniverse", Resolution.Daily, (altCoarse) => {
            return altCoarse.Select(d => d.Symbol);
        });
        // Add a Scheduled Event to rebalance the portfolio.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        Schedule.On(
            DateRules.EveryDay(spy),
            TimeRules.AfterMarketOpen(spy, 1),
            Rebalance
        );
    }

    private void Rebalance()
    {
        // We invest by the EMA of the given weight.
        var history = History(_universe, 5, Resolution.Daily);
        var symbols = history.Select(x => x.Symbol).ToHashSet();
        var weights = symbols.Select(symbol => {
                var ema = history.Where(x => x.Symbol == symbol)
                    .Select(x => (x as CustomUniverseData).Weight)
                    .Aggregate((ema, nextQuote) => SmoothingFactor * nextQuote + (1m - SmoothingFactor) * ema);
                return (symbol, ema);
            }).ToList();
        // Normalized weights.
        var weightSum = weights.Sum(x => x.Item2);
        var targets = weights.Select(x => new PortfolioTarget(x.Item1, x.Item2 / weightSum)).ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}

public class CustomUniverseData : BaseDataCollection
{
    public decimal Weight;
    public override DateTime EndTime
    {
        // Set the data period to 1 day.
        get { return Time + QuantConnect.Time.OneDay; }
        set { Time = value - QuantConnect.Time.OneDay; }
    }

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        // Define the location and format of the data file.
        return new SubscriptionDataSource(
            "portfolioTargets.csv", SubscriptionTransportMedium.ObjectStore, FileFormat.Csv
        );
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        // Skip the header row.
        if (!Char.IsDigit(line[0]))
        {
            return null;
        }
        // Split the line by each comma.
        var items = line.Split(",");

        // Parse the data from the CSV file.
        return new CustomUniverseData
        {
            EndTime = Parse.DateTimeExact(items[0], "yyyy-MM-dd"),
            Symbol = Symbol.Create(items[1], SecurityType.Equity, Market.USA),
            Weight = decimal.Parse(items[2], NumberStyles.Any, CultureInfo.InvariantCulture)
        };
    }
}
```

Other Examples

For more examples, see the following algorithms:

Demonstration Algorithm
HistoryAlgorithm.cs C#

Historical Data

Universe Data

Introduction

Universe selection is the process of selecting a basket of assets you may trade. Dynamic universe selection increase diversification and decrease selection bias in your algorithm. To get the history of a universe, call the `History` method with the universe object. Note that the `History` method doesn't filter the universe with your filter function. It simply returns all of the assets and data points in the universe dataset.

US Equity Fundamentals

The following example gets the history of a US Equity fundamental universe :

C#

```
public class USEquityFundamentalUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of US Equities based on the Fundamentals dataset.
        var universe = AddUniverse(fundamentals => fundamentals.Select(f => f.Symbol));
        // Get 5 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var fundamentals in history)
        {
            // Iterate through each asset in the universe on this day and access its data point attributes.
            foreach (Fundamental f in fundamentals)
            {
                var symbol = f.Symbol;
                var t = f.EndTime;
                var peRatio = f.ValuationRatios.PERatio;
            }
        }
    }
}
```

US Equity ETF Constituents

The following example gets the history of a US Equity ETF constituents universe :

C#

```
public class ETFConstituentUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of US Equities based on the constituents of an ETF.
        var universe = AddUniverse(Universe.ETF("SPY"));
        // Get 5 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var constituents in history)
        {
            // Select the 2 assets with the smallest weights in the ETF on this day.
            var dailyLargest = constituents.Select(c => c as ETFConstituentData).OrderBy(c => c.Weight).Take(2);
        }
    }
}
```

US Equity Alternative Data

The following example gets the history of a US Equity alternative data universe :

```
C#
public class USEquityAltDataUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of US Equities based on an alternative dataset.
        var universe = AddUniverse<BrainStockRankingUniverse>();
        // Get 5 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var altCoarse in history)
        {
            // Select the asset with the greatest value each day.
            var dailyWinner = altCoarse
                .Select(c => c as BrainStockRankingUniverse)
                .OrderByDescending(c => c.Value)
                .First();
        }
    }
}
```

Equity Options

The following example gets the history of an Equity Options universe :

```
C#
public class EquityOptionUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of Equity Option contracts.
        var option = AddOption("SPY");
        // Get 5 days of history for the universe.
        var history = History<OptionUniverse>(option.Symbol, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var chain in history)
        {
            var t = chain.EndTime;
            // Select contracts that have open interest > 0 on this day.
            var openContracts = chain.Data
                .Select(contract => contract as OptionUniverse)
                .Where(contract => contract.OpenInterest > 0m);
        }
    }
}
```

Index Options

The following example gets the history of an Index Options universe :

```
C#
public class IndexOptionsUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of Index Option contracts.
        var option = AddIndexOption("VIX");
        // Get 5 days of history for the universe.
        var history = History<OptionUniverse>(option.Symbol, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var chain in history)
        {
            var t = chain.EndTime;
            // Calculate the trading volume across all the contracts on this day.
            var dailyVolume = chain.Data
                .Select(contract => contract as OptionUniverse)
                .Sum(contract => contract.Volume);
        }
    }
}
```

Crypto

The following example gets the history of a Crypto universe :

```
C#
public class CryptoUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 23);
        SetEndDate(2024, 12, 31);
        // Add a universe of Cryptocurrencies.
        var universe = AddUniverse(CryptoUniverse.Coinbase(data => data.Select(x => x.Symbol)));
        // Get 5 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(5));
        // Iterate through each day of the universe history.
        foreach (var universeDay in history)
        {
            var t = universeDay.EndTime;
            // Select the Crypto with the largest daily return on this day.
            var topGainer = universeDay
                .Select(c => c as CryptoUniverse)
                .OrderByDescending(c => (c.Close - c.Open) / c.Open)
                .First();
        }
    }
}
```

Crypto Market Cap

The following example gets the history of a Crypto market cap universe :

```C#
public class CryptoMarketCapUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 24);
        SetEndDate(2024, 12, 31);
        // Add a universe of Cryptocurrencies.
        var universe = AddUniverse<CoinGecko>();
        // Get 365 days of history for the universe.
        var history = History(universe, TimeSpan.FromDays(365));
        // Iterate through each day of the universe history.
        foreach (var universeDay in history)
        {
            var t = universeDay.EndTime;
            // Select the Crypto with the largest market cap on this day.
            var largestCoin = universeDay.Select(c => c as CoinGecko).OrderByDescending(c => c.MarketCap).First();
        }
    }
}
```

Custom Data

The following example gets the history of a custom data universe :

C#

```
// Define the custom data class outside of the algorithm class.
public class StockDataSource : BaseData
{
    public List<string> Symbols { get; set; } = new();
    public override DateTime EndTime => Time.AddDays(1);

    public override SubscriptionDataSource GetSource(SubscriptionDataConfig config, DateTime date, bool isLiveMode)
    {
        return new SubscriptionDataSource(
            "https://raw.githubusercontent.com/QuantConnect/Documentation/master/Resources/datasets/custom-data/csv-
universe-example.csv",
            SubscriptionTransportMedium.RemoteFile,
            FileFormat.Csv
        );
    }

    public override BaseData Reader(SubscriptionDataConfig config, string line, DateTime date, bool isLiveMode)
    {
        var stocks = new StockDataSource();
        stocks.Symbol = config.Symbol;
        try
        {
            var csv = line.Split(',');
            stocks.Time = DateTime.ParseExact(csv[0], "yyyyMMdd", null);
            stocks.Symbols.AddRange(csv.Skip(1));
        }
        catch { return null; }
        return stocks;
    }
}

public class CustomDataUniverseHistoryAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add a custom data universe.
        var universe = AddUniverse<StockDataSource>("StockDataSource", Resolution.Daily);
        // Get the universe history.
        var history = History(universe, new DateTime(2018, 1, 1), new DateTime(2018, 1, 10)).Cast<StockDataSource>();
        // Iterate through each day in the universe history and count the number of constituents.
        foreach (var stockData in history)
        {
            var t = stockData.Time;
            var size = stockData.Symbols.Count;
        }
    }
}
```

Examples

The following examples demonstrate some common practices for trading with historical universe data.

Example 1: Historical Ranking Prediction

The following example forms an equal-weighted portfolio at the start of each month with the 5 assets that have the greatest 21-day ranking in the Brain ML Stock Ranking dataset.

C#

```
public class UniverseHistoricalDataAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);
        Settings.SeedInitialPrices = true;

        // Add a monthly update to the universe of BrainStockRanking data.
        UniverseSettings.Schedule.On(DateRules.MonthStart("SPY"));
        _universe = AddUniverse<BrainStockRankingUniverse>();

        // Trade every day after the market opens with an updated smoothened yield curve difference.
        Schedule.On(
            DateRules.MonthStart("SPY"),
            TimeRules.At(9, 31),
            Trade
        );

        SetWarmUp(1);
    }

    private void Trade()
    {
        // Get the last 5 bars of history for the universe.
        var symbolRanks = new Dictionary<Symbol, decimal>();
        var history = History(_universe, 5, Resolution.Daily, fillForward: false);
        foreach (var bar in history)
        {
            foreach (var data in bar.Select(c => c as BrainStockRankingUniverse)
                .Where(x => x.Rank21Days.HasValue))
            {
                if (!symbolRanks.TryGetValue(data.Symbol, out var rank))
                {
                    symbolRanks[data.Symbol] = 0m;
                }
                symbolRanks[data.Symbol] += data.Rank21Days.Value;
            }
        }
        // Obtain the 5 highest rank stocks to invest on equally.
        var targets = symbolRanks.OrderByDescending(x => x.Value)
            .Take(5)
            .Select(x => new PortfolioTarget(x.Key, 0.2m))
            .ToList();
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}
```

Historical Data

Warm Up Periods

Introduction

LEAN supports an automated fast-forward system called "Warm Up". It simulates winding back the date you deployed your algorithm by a specific time period. In backtests, it changes the start date of your algorithm to an earlier time. In live trading, it fetches data from before your deployment and fast forwards through your strategy up to the present day. Warm Up is a great way to prepare your algorithm and its indicators for trading. You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state.

Set Warm Up Periods

You can set a warm-up period based on a number of bars or a period of time.

Trailing Data Samples

To set a warm-up based on a trailing number of data samples, in your algorithm's `Initialize` method, call the `SetWarmUp` method with an integer argument.

```C#
// Feed in 100 bars before start date
SetWarmUp(100);
```

LEAN calculates the start of the warm-up period for each of your security subscriptions by using the number of bars you specify, the resolution of each security, and the trading calendar of each security. After it calculates the start time of the warm-up period for each security, it sets the earliest start time as the start of the algorithm warm-up period. For instance, in the following example, the warm-up period consists of 100 minute resolution bars for SPY and as many second resolution bars for BTCUSD that occur from the start of the SPY warm-up period to the algorithm `StartDate` .

```C#
public class WarmUpWithTrailingDataSamplesAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        AddEquity("SPY", Resolution.Minute, fillForward: false);
        AddCrypto("BTCUSD", Resolution.Second, fillForward: false);
        SetWarmUp(100);
    }
}
```

To use a specific resolution of data for the warm-up period, pass a `resolution` argument to the `SetWarmUp` method.

```C#
// Feed in data for 100 trading days of daily data before the start date
SetWarmUp(100, Resolution.Daily);
```

If you pass an integer and a resolution, the warm-up period consists of the number of bars and resolution you set, regardless of the resolution of your data subscriptions. In this case, LEAN calculates the start of the warm-up period for each of your security

subscriptions just like it does when you only pass an integer argument. After it calculates the start time of the warm-up period for each security, it sets the earliest start time as the start of the algorithm warm-up period.

If you pass a resolution argument and you registered indicators or consolidators for automatic updates, the warm-up period resolution must be less than or equal to the lowest resolution of your automatic indicators and consolidators. For instance, in the following example, the indicators use minute resolution data, so you can set the warm-up period to use tick, second, or minute resolution data.

```C#
public class WarmUpWithTrailingDataSamplesAndResolutionAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var spy = AddEquity("SPY", Resolution.Minute, fillForward: false).Symbol;
        var btc = AddCrypto("BTCUSD", Resolution.Second, fillForward: false).Symbol;

        var spySma = SMA(spy, 10);
        var btcSMA = SMA(btc, 10, Resolution.Minute);

        SetWarmUp(100, Resolution.Minute);
    }
}
```

Trailing Time Periods

To set a warm-up based on a trailing time period, in your algorithm's `Initialize` method, call the `SetWarmUp` method with a `TimeSpan` . The warm-up period consists of that `TimeSpan` before the start date and pipes in data that matches the resolution of your data subscriptions.

```C#
// Wind time back 7 days from start
SetWarmUp(TimeSpan.FromDays(7));
```

To use a specific resolution of data for the warm-up period, pass a `resolution` argument to the `SetWarmUp` method.

```C#
// Feed in 100 days of daily data before the start date
SetWarmUp(TimeSpan.FromDays(100), Resolution.Daily);
```

If you pass a `TimeSpan` and a resolution, the warm-up period consists of the time period and resolution you set, regardless of the resolution of your data subscriptions.

Warm Up Status

You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state. To check if the algorithm is currently in a warm up period, use the `IsWarmingUp` property.

```C#
public class WarmUpStatusAlgorithm : QCAlgorithm
{
    private ExponentialMovingAverage _ema;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var symbol = AddEquity("IBM", Resolution.Daily).Symbol;
        _ema = EMA(symbol, 100);
        SetWarmup(100);
    }

    public override void OnData(Slice data)
    {
        if (IsWarmingUp)
        {
            return;
        }
        Plot("EMA", "Is ready", _ema.IsReady ? 1 : 0);
    }
}
```

Event Handler

The `OnWarmupFinished` event handler executes when the warm up period ends, even if you don't set a warm up period.

```C#
public override void OnWarmupFinished()
{
    // Done warming up
}
```

Missing Data Points

There are several cases where you may get fewer data points from during warm-up than you expect.

Illiquid Securities

The default behavior for LEAN is to fill-forward the data. However, if an asset had no trading activity during the time period you request historical data for, you won't get any data for that asset.

Requesting Data Before an Asset's IPO

All assets have a day when they first started trading. If your warm-up period includes time before an asset's initial public offering (IPO) date, you won't get any data before the IPO date because the data doesn't exist.

Requesting Data Outside Market Hours

Warming up with a trailing number of data samples means the data is based on the market hours of assets, so they can wrap across multiple trading days to gather the amount of data you request. In contrast, warming up with a trailing time period provides means the data is based on a rolling calendar time. In this latter types of warm-up, if the period of time is outside of the market hours of an asset, you won't get any data.

Data Issues

Data issues are generally a result of human error or from mistakes in the data collection process. Any QuantConnect member can report a data issue , which our Data Team works to quickly resolve. However, while the data is still missing, your warm-up won't be able to provide the data. To view the list of current data issues, log in to the Algorithm Lab and then, in the left navigation bar, click Datasets > Data Issues .

Data Provider Limitations

When you run warm-up, consider the functionality of the data provider you use. For example, the QuantConnect data provider has quotas on the amount of data you can request and the Interactive Brokers data provider can be slow, so it can timeout if you run warm-up with too many assets. For more information about all the data providers, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Warm Up vs History Requests

Warm-up and history requests both provide historical data. The approach you take depends on your specific use case. A benefit to using warm-up is that it only takes one line of code to pump historical data into your algorithm, which processes universe selection and updates all the indicators. A consequence to using warm-up is that it may provide more historica data than you actually need since it provides data on all the subscriptions in your algorithm. If you have derivative assets in your algorithm, warm-up can be very slow to process.

Examples

The following examples demonstrate some common practices for warm up.

Example 1: Warm Up Indicator

The following algorithm trades mean-reversion according to signals from a Bollinger Bands indicator. It uses warm up so the indicator is ready by the start date of the algorithm.

C#

```
public class WarmUpPeriodsAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private BollingerBands _bbands = new(20, 2);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // The candlestick patterns are based on a daily consolidated trade bar.
        var consolidator = new TradeBarConsolidator(TimeSpan.FromDays(1));
        // Subscribe to update the indicators with the 1-day consolidator automatically.
        RegisterIndicator(_spy, _bbands, consolidator);
        // Add an event handler on candlestick indicators that are updated to trade the indicator.
        _bbands.Updated += OnUpdated;

        // Warm up the indicator and the SPY price data.
        SetWarmUp(20, Resolution.Daily);
    }

    private void OnUpdated(object sender, IndicatorDataPoint point)
    {
        var indicator = sender as BollingerBands;
        if (!indicator.IsReady) return;

        var holdings = Portfolio[_spy];

        // Trade mean-reversal of the Bollinger Band.
        if (holdings.Price > indicator.UpperBand && !holdings.IsShort)
        {
            SetHoldings(_spy, -0.5m);
        }
        else if (holdings.Price < indicator.LowerBand && !holdings.IsLong)
        {
            SetHoldings(_spy, 0.5m);
        }
    }
}
```

Example 2: Warm Up Universe Selection

The following algorithm forms an equal-weighted portfolio with the 100 most liquid US Equities that are above their 60-day Exponential Moving Average (EMA). It uses the warm-up feature to prime the indicators in advance so it can start trading by the start date of the algorithm.

C#

```
public class WarmUpPeriodsAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private Dictionary<Symbol, ExponentialMovingAverage> _emaBySymbol = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.SeedInitialPrices = true;

        // Universe filtered by only the ones with prices above EMA, suggesting an uptrend.
        _universe = AddUniverse(SelectionByEma);

        // Rebalance weekly.
        Schedule.On(
            DateRules.WeekStart(),
            TimeRules.At(9, 31),
            Rebalance
        );

        SetWarmUp(60, Resolution.Daily);
    }

    private IEnumerable<Symbol> SelectionByEma(IEnumerable<Fundamental> fundamentals)
    {
        foreach (var f in fundamentals)
        {
            // Create an EMA indicator for the symbol if it is unavailable.
            if (!_emaBySymbol.TryGetValue(f.Symbol, out var ema))
            {
                _emaBySymbol[f.Symbol] = ema = new ExponentialMovingAverage(60);
            }
            // Update the indicator by the updated price data to select on the updated data.
            ema.Update(f.EndTime, f.AdjustedPrice);
        }

        // We don't add new securities during the warm-up process
        if (IsWarmingUp) return Universe.Unchanged;

        return fundamentals
            // Only trades the top 100 liquid stocks since their trend capitalizes quicker.
            .OrderByDescending(f => f.DollarVolume)
            // Select the ones with the current price above EMA to filter for the uptrend stocks.
            .Where(f => _emaBySymbol[f.Symbol].IsReady && _emaBySymbol[f.Symbol] > f.AdjustedPrice)
            .Take(100)
            .Select(f => f.Symbol);
    }

    private void Rebalance()
    {
        // Equally invest in uptrend stocks to dissipate capital risk evenly.
        var weight = 1m / _universe.Selected?.Count ?? 0m;
        if (weight == 0) return;
        var targets = _universe.Selected.Select(symbol => new PortfolioTarget(symbol, weight)).ToList();
        SetHoldings(targets);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Exit position if the equity is below EMA since it becomes a downgoing trend.
        changes.RemovedSecurities.DoForEach(r => Liquidate(r.Symbol));
    }
}
```

Demonstration Algorithms
WarmupAlgorithm.cs C#

Historical Data

Rolling Window

Introduction

A `RollingWindow` is an array of a fixed-size that holds trailing data. It's more efficient to use `RollingWindow` objects to hold periods of data than to make multiple historical data requests . With a `RollingWindow` , you just update the latest data point while a `History` call fetches all of the data over the period you request. `RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

Create Rolling Windows

To create rolling windows, instantiate the `RollingWindow` object of a given type with a maximum size.

```
C#

closePriceWindow = new RollingWindow<decimal>(4);
tradeBarWindow = new RollingWindow<TradeBar>(2);
quoteBarWindow = new RollingWindow<QuoteBar>(2);
```

Add Data

To add data to a `RollingWindow` , call the `Add` method.

```
C#

closePriceWindow.Add(data["SPY"].Close);
tradeBarWindow.Add(data["SPY"]);
quoteBarWindow.Add(data["EURUSD"]);
```

To update the data at a specific index, set the value for that index. If the index doesn't currently exist, it increases the size and fills the empty indices with a default value (zero or `null`).

```
C#

closePriceWindow[0] = data["SPY"].Close;
tradeBarWindow[0] = data["SPY"];
quoteBarWindow[0] = data["EURUSD"];
```

Warm Up

To warm up a `RollingWindow` , make a history request and then iterate through the result to add the data to the `RollingWindow` .

```C#
public class WarmUpRollingWindowAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var spy = AddEquity("SPY", Resolution.Daily).Symbol;
        var historyTradeBar = History<TradeBar>(spy, 10, Resolution.Daily);
        var historyQuoteBar = History<QuoteBar>(spy, 10, Resolution.Minute);

        // Warm up the close price and trade bar rolling windows with the previous 10-day trade bar data
        var closePriceWindow = new RollingWindow<decimal>(10);
        var tradeBarWindow = new RollingWindow<TradeBar>(10);
        foreach (var tradeBar in historyTradeBar)
        {
            closePriceWindow.Add(tradeBar.Close);
            tradeBarWindow.Add(tradeBar);
        }

        // Warm up the quote bar rolling window with the previous 10-minute quote bar data
        var quoteBarWindow = new RollingWindow<QuoteBar>(10);
        foreach (var quoteBar in historyQuoteBar)
        {
            quoteBarWindow.Add(quoteBar);
        }
    }
}
```

Check Readiness

To check if a `RollingWindow` is full, use its `IsReady` flag.

```C#
if (!closePriceWindow.IsReady)
{
    return;
}
```

Adjust Size

To adjust the `RollingWindow` size, set the `Size` property.

```C#
closePriceWindow.Size = 3;
tradeBarWindow.Size = 3;
quoteBarWindow.Size = 3;
```

When you decrease the size, it removes the oldest values that no longer fit in the `RollingWindow` . When you explicitly increase the `Size` member, it doesn't automatically add any new elements to the `RollingWindow` . However, if you set the value of an index in the `RollingWindow` and the index doesn't currently exist, it fills the empty indices with a default value (zero or `null`). For example, the following code increases the `Size` to 10, sets the 10th element to 3, and sets the 4th-9th elements to the default value:

```C#
closePriceWindow[9] = 3;
```

Access Data

`RollingWindow` objects operate on a first-in, first-out process to allow for reverse list access semantics with positive and negative indexing. Index 0 refers to the most recent item in the window and the largest index refers to the last item in the window. Index -1 refers to the latest item as well.

```
var currentClose = closePriceWindow[0];
var previousClose = closePriceWindow[1];
var oldestClose = closePriceWindow[closePriceWindow.Count-1];
oldestClose = closePriceWindow[-1];   // Negative indexing
```

To get the item that was most recently removed from the `RollingWindow` , use the `MostRecentlyRemoved` property.

```
var removedClose = closePriceWindow.MostRecentlyRemoved;
```

Combine with Indicators

The `Window` property of the indicators is a built-in `RollingWindow` that stores historical values. It holds a collection of `IndicatorDataPoint` objects, enabling quick access to the most recent historical indicator values for analysis, calculations, or comparisons in trading and financial strategies. Its default size 2, but you can adjust its size. To warm up the indicator and its `RollingWindow` , call the `IndicatorHistory` method with the window size as an argument.

```
public class IndicatorRollingWindowAlgorithm : QCAlgorithm
{
    // Manual SMA indicator example.
    private SimpleMovingAverage _sma = new(20);
    private Beta _beta;

    public override void Initialize()
    {
        var spy = AddEquity("SPY").Symbol;
        var qqq = AddEquity("QQQ").Symbol;

        // Automatic Beta indicator example.
        _beta = B(spy, qqq, 20);

        // Adjust the window size to 5 to access the previous 5 indicator data points.
        _sma.Window.Size = 5;
        _beta.Window.Size = 5;

        // Warm up the indicator and window for immediate usage.
        IndicatorHistory(_sma, spy, _sma.Window.Size, Resolution.Daily);
        // For indicators using 2+ symbols, use an iterable symbol list.
        IndicatorHistory(_beta, new[] { spy, qqq },  _beta.Window.Size, Resolution.Daily);
    }
}
```

Combine with Consolidators

To store a history of consolidated bars , in the consolidation handler, add the consolidated bar to the `RollingWindow` .

```
_consolidator.DataConsolidated += (sender, consolidatedBar) => tradeBarWindow.Add(consolidatedBar);
```

Market Session

The `session` property of a `Security` object contains the open, high, low, close, volume, and open interest of trading sessions. The `Session` object is a `RollingWindow` object with size of zero by default. To enable market session tracking, set the size of the `Session` object to 2, so the previous session data is at index 1.

```
var session = Securities[_symbol].Session;
session.Size = 2;
var todayOpen = session.Open;
var todayHigh = session.High;
var todayLow = session.Low;
var todayCumulativeVolume = session.Volume;
if (session.IsReady)
{
    var yesterdayClose = session[1].Close;
}
```

Increase the size of the `Session` object to store more session data. You can use cached data in the `session` property instead of requesting historical daily data .

```
var equity = AddEquity("SPY");
// Increase the session lookback to 252 from default (0)
equity.Session.Size = 252;
// Get all closing prices in the session history
var closes = session.OrderBy(x => x.EndTime).Select(x => x.Close);
```

Cast to Other Types

You can cast a `RollingWindow` to a list. If you cast it to a list, reverse the list so the most recent element is at the last index of the list. This is the order the elements would be in if you added the elements to the list with the `Add` method.

```
var closes = closePriceWindow.Reverse().ToList();
```

Delete Data

To remove all of the elements from a `RollingWindow` , call the `Reset` method.

```
closePriceWindow.Reset();
```

Examples

The following examples demonstrate some common practices for rolling windows.

Example 1: Price Actions

The following algorithm saves the trailing 3 `TradeBar` objects into a `RollingWindow` . When it identifies a volume contraction breakout price action pattern on the SPY, it buys to ride on the capital inflow. To exit positions, it places a 2% take profit and 1% stop loss order in the `OnOrderEvent` method.

```
public class RollingWindowAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Set up a rolling window to hold the last 3 trade bars for price action detection as the trade signal.
    private RollingWindow<TradeBar> _windows = new(3);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;
```

```
        // Warm up the rolling window.
        var history = History<TradeBar>(_spy, 3, Resolution.Minute);
        foreach (var bar in history)
        {
            _windows.Add(bar);
        }
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trade the price action if the previous bars fulfill a contraction breakout.
            if (ContractionAction() && BreakoutAction(bar.Close))
            {
                SetHoldings(_spy, 0.5m);
            }

            // Add the current bar to the window.
            _windows.Add(bar);
        }
    }

    private bool ContractionAction()
    {
        // We trade contraction type price action, where the buying preesure is increasing.
        // 1. The last 3 bars are green.
        // 2. The price is increasing in trend.
        // 3. The trading Volume is increasing as well.
        // 4. The range of the bars are decreasing.
        return _windows[2].Close > _windows[2].Open &&
            _windows[1].Close > _windows[1].Open &&
            _windows[0].Close > _windows[0].Open &&
            _windows[0].Close > _windows[1].Close && _windows[1].Close > _windows[2].Close &&
            _windows[0].Volume > _windows[1].Volume && _windows[1].Volume > _windows[2].Volume &&
            _windows[2].Close - _windows[2].Open > _windows[1].Close - _windows[1].Open &&
            _windows[1].Close - _windows[1].Open > _windows[0].Close - _windows[0].Open;
    }

    private bool BreakoutAction(decimal currentPrice)
    {
        // Trade breakout from contraction: the breakout should be much greater than the contracted range of the last
bar.
        return currentPrice - _windows[0].Close > (_windows[0].Close - _windows[0].Open) * 2m;
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            if (orderEvent.Ticket.OrderType == OrderType.Market)
            {
                // Stop loss order at 1%.
                var stopPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 0.99m : orderEvent.FillPrice *
1.01m;
                StopMarketOrder(_spy, -Portfolio[_spy].Quantity, stopPrice);
                // Take profit order at 2%.
                var takeProfitPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 1.02m :
orderEvent.FillPrice * 0.98m;
                LimitOrder(_spy, -Portfolio[_spy].Quantity, takeProfitPrice);
            }
            else if (orderEvent.Ticket.OrderType == OrderType.StopMarket || orderEvent.Ticket.OrderType ==
OrderType.Limit)
            {
                // Cancel open orders if the stop loss or take profit order fills.
                Transactions.CancelOpenOrders();
            }
        }
    }
}
```

Example 2: Bid-Ask Spread

The following algorithm trades the microeconomy of SPY's supply-demand relationship. It buys when the current bid-ask spread is less than average spread over the last 20 QuoteBar objects, indicating demand is approaching supply. When the

spread is greater than the average, it shorts SPY. To save the last spread values, it uses a `RollingWindow` .

```C#
public class RollingWindowAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Set up a rolling window to hold the last 20 bar's bid-ask spread for trade signal generation.
    private RollingWindow<decimal> _windows = new(20);

    public override void Initialize()
    {
        SetStartDate(2024, 12, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // Warm up for the rolling window with quote data.
        var history = History<QuoteBar>(_spy, 20, Resolution.Minute);
        foreach (var bar in history)
        {
            _windows.Add(bar.Ask.Close - bar.Bid.Close);
        }
    }

    public override void OnData(Slice slice)
    {
        if (slice.QuoteBars.TryGetValue(_spy, out var bar))
        {
            // Update the window with the current bid-ask spread.
            var spread = bar.Ask.Close - bar.Bid.Close;
            _windows.Add(spread);

            // Buy if the current spread is smaller than average, indicating demand is approaching supply. Buy force
will drive up price.
            if (spread < _windows.Average())
            {
                SetHoldings(_spy, -0.5m);
            }
            // Short if the current spread is larger than average, indicating supply is gradually overwhelming
demand.
            else if (spread > _windows.Average())
            {
                SetHoldings(_spy, 0.5m);
            }
        }
    }
}
```

Example 3: EMA Acceleration

The following algorithm trades SPY based on the direction and acceleration of its exponential moving average (EMA). It buys when the EMA is increasing and accelerating upward, indicating a strong uptrend. It short sells when the EMA is decreasing and accelerating downward, indicating a strong downtrend. To compare the current EMA value to its previous values, the algorithm utilizes the EMA's internal `RollingWindow` .

```C#
public class RollingWindowAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data for trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // Set up an automatic EMA indicator for trade signal generation.
        _ema = EMA(_spy, 20, Resolution.Daily);
        // Extend the size of the EMA's internal rolling window so we can access its historical values.
        _ema.Window.Size = 3;
        // Warm-up the indicator and its internal rolling window
        IndicatorHistory(_ema, _spy, _ema.Window.Size);

        // Schedule an event to rebalance SPY position at daily market open.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.AfterMarketOpen(_spy, 0), Rebalance);
    }

    private void Rebalance()
    {
        // Buy if the current EMA is increasing with acceleration, indicating a strong uptrend.
        if (_ema.Window[1] < _ema && _ema.Window[0] - _ema.Window[1] > _ema.Window[1] - _ema.Window[2])
        {
            SetHoldings(_spy, 0.5m);
        }
        // Short if the current EMA is decreasing with acceleration, indicating a strong downtrend.
        else if (_ema.Window[1] > _ema && _ema.Window[0] - _ema.Window[1] < _ema.Window[1] - _ema.Window[2])
        {
            SetHoldings(_spy, -0.5m);
        }
        // Liquidate if no strong trend indicated.
        else if (Portfolio.Invested)
        {
            Liquidate(_spy);
        }
    }
}
```

Example 4: Market Session as History

Using `Session` instead of history requests or rolling window to cache the last 252 OHLCV bars, the following algorithm buys SPY accordingly when the market opens above the 252-day max of closing prices.

C#

```
public class MarketSessionAsDailyHistory : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        var equity = AddEquity("SPY");

        // Increase the session lookback to 252 from default (0)
        // since our strategy break out the 252-day max of closing prices
        equity.Session.Size = 252;
        // Warm up with daily data for speed
        SetWarmUp(equity.Session.Size, Resolution.Daily);

        Schedule.On(DateRules.EveryDay("SPY"), TimeRules.AfterMarketOpen("SPY", 1), () =>
        {
            // Break-out strategy. If the market opens above the 252-day max of closing prices,
            // allocate all in SPY. Liquidate if it opens below the mean.

            var session = Securities["SPY"].Session;
            // The session is ready when the number of samples is greater than the size (252)
            if (IsWarmingUp || !session.IsReady)
                return;

            var closes = session.OrderBy(x => x.EndTime).Select(x => x.Close);
            var open = session.Open;
            var max = closes.Max();
            var mean = closes.Average();

            // Invest all in SPY if the open break out the 252-day max and liquidate below the mean
            if (open > max)
                SetHoldings("SPY", 1, tag: $"_open={open:F2}, _max={max:F2}");
            if (open < mean)
                Liquidate(symbol: "SPY", tag:$"_open={open:F2}, _mean={mean:F2}");
        });
    }
}
```

Historical Data

Common Errors

Introduction

Errors can occur when you request historical data. This page explains some of the most common ones you may encounter.

Indicator Readiness

Indicators can't produce a valid value until they have enough historical data to be ready . If your indicators require more data than what is currently available (for example, data before an asset's IPO), the `IndicatorHistory` method will return fewer data points than you request and the warm-up techniques for manual and automatic indicators won't be able to make your indicators ready.

Trading During Warm Up

You can't place trades during the warm-up period because the data feed is replaying historical data for setting algorithm state. If you try to place a trade during warm-up, LEAN throws the following error:

Backtest Handled Error: This operation is not allowed in Initialize initialize or during warm up: OrderRequest.Submit. Please move this code to the OnWarmupFinished() on_warmup_finished() method.

Numerical Precision

Some factor files have INF split values, which indicate that the stock has so many splits that prices can't be calculated with correct numerical precision. To allow history requests with these symbols, we need to move the starting date forward when reading the data or use raw data normalization . If there are numerical precision errors in the factor files for a security in your history request, LEAN throws the following error:

"Warning: when performing history requests, the start date will be adjusted if there are numerical precision errors in the factor files."

Live Intraday Data Source

In live trading, if you make a history request for minute data at noon and the history period covers the start of the previous day to the present moment, the data from the previous day will be backtest data. The data of the current day will be live data that we collected throughout the morning. If you make this history request in a backtest, you might get slightly different data for the current day because of post-processing from the data vendor.

In cloud deployments, QuantConnect is the default data provider. If you remove it and use a different data provider, you won't get any price data from QuantConnect. However, we provide the following datasets:

- US Equity Security Master
- US Futures Security Master
- US Equity Option Universe
- US Index Option Universe
- Universe selection datasets
- Non-streaming alternative datasets

QC Data Provider Limitations

When you request historical data or run warm-up , the amount of historical data you can access depends on the resolution of

your data subscriptions. The following table shows the amount of trailing historical data you can access for each data resolution:

Resolution	Available History
Daily	All historical data
Hour	All historical data
Minute	1 year
Second	2 months
Tick	1 month

In live trading, history requests for Index or Options with the QuantConnect data provider only returns data up to the end of the previous day. For example, if you make a history request for these asset classes at 1 PM Eastern Time (ET), you won't get any data for the current day.

For more information about the QuantConnect data provider, see QuantConnect .

Other Data Provider Limitations

LEAN supports other data providers, including IQFeed and Polygon. For more information about the limitations of these other data providers, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Brokerage Limitations

LEAN supports several brokerages that can provide historical data. However, some of them have limitations on historical data. For example, Interactive Brokers can be slow, so it can timeout if you request historical data for too many assets at once. For more information about these brokerages and the data they provide, see Datasets .

Historical Data

Live Trading

Introduction

When you make history requests in live trading, be aware of the associated data delays and the data provider's functionality.

Data Delays

Backtests have access to data up to $t - 1$ to $t - 4$ days, where t is the current day. The availability depends on the data type.

In live trading, history requests take 5-10 seconds to return the data. While LEAN processes the request, the algorithm doesn't receive any new data points.

Multiple Data Providers

When you deploy a live algorithm, you can add multiple data provider. If you use multiple data providers, the order you select them in defines their order of precedence in Lean. For example, if you set QuantConnect as the first provider and Interactive Brokers (IB) as the second provider, Lean only uses the IB data provider for securities that aren't available from the QuantConnect data provider. This configuration makes it possible to use the QuantConnect data provider for Equity universe selection and then place Options trades on the securities in the universe.

Data Provider Limitations

History requests from third-party data providers are much slower than from the QuantConnect data provider. If you need data from a third-party data provider, request small amounts or your algorithm may take longer than 10 minutes to process and cause a timeout. For more information about the data providers, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Trading and Orders

Trading and Orders

Key Concepts

Introduction

LEAN has dozens of methods to create, update, and cancel orders. You can place orders automatically with helper methods or manually through methods on the algorithm API. You can fetch, update, and cancel manual orders with order tickets . As the state of your orders change, LEAN creates events that notify your algorithm.

In backtesting, LEAN simulates order fills with historical data, but you can create your own fill, fee, slippage, and margin models via plugin points. You control how optimistic or pessimistic order fills are with transaction model classes. For more information about these types of models, see Reality Modeling .

Orders and Tickets

When you call one of the order methods to place an order, LEAN performs pre-order checks to ensure that the order meets some requirements and uses the last known price to check you have enough capital . To see the requirements of each order, see the Requirements section of the documentation for the order types and the Orders section of your brokerage model . If you can place the order, LEAN creates `Order` and OrderTicket objects. The order ticket is sent to your brokerage. As the brokerage processes your order, it returns another order ticket and it's compared against the order to see if the order is satisfied. Orders fill asynchronously in live trading, so if you want to change an order, you must request it with the order ticket. Order changes are not guaranteed since your order may fill by the time brokerage receives the request.

Order Types

LEAN supports the following order types:

- Market
- Limit
- Limit if touched
- Stop market
- Stop limit
- Trailing stop
- Market on open
- Market on close
- Combo market
- Combo limit
- Combo leg limit
- Option exercise

Symbol Properties

The SymbolProperties are a property of the Security object. LEAN uses some of the SymbolProperties to prevent invalid orders, and to calculate order quantities for a given target.

SymbolProperties objects have the following properties:

To get the SymbolProperties , use the property on the Security object.

```
C#

var symbolProperties = Securities["BTCUSD"].SymbolProperties;
var lotSize = symbolProperties.LotSize;
var minimumOrderSize = symbolProperties.MinimumOrderSize;
var minimumPriceVariation = symbolProperties.MinimumPriceVariation;
```

LEAN uses the MinimumPriceVariation to round the LimitPrice , StopPrice , and the TriggerPrice .

Quote Currency

The quote currency is the currency you must give the seller to buy an asset. For currency trades, the quote currency is the currency ticker on the right side of the currency pair. For other types of assets, the quote currency is usually USD, but the quote currency for India Equities is INR. To get the quote currency of a Security , use the QuoteCurrency property.

```
C#

var aaplQuoteCurrency = Securities["AAPL"].QuoteCurrency; // USD
var btcusdtQuoteCurrency = Securities["BTCUSDT"].QuoteCurrency; // USDT
```

The QuoteCurrency is a Cash object, which have the following properties:

You can use the ConversionRate property to calculate the value of the minimum price movement in the account currency

```
C#

var cfd = Securities["SG30SGD"];
var quoteCurrency = cfd.QuoteCurrency; // SGD
var contractMutiplier = cfd.SymbolProperties.ContractMultiplier;
var minimumPriceVariation = cfd.SymbolProperties.MinimumPriceVariation;

// Value of a pip in account currency
var pip = minimumPriceVariation * contractMutiplier * quoteCurrency.ConversionRate;
```

Trade Models

Reality models make backtests as realistic as possible to how the strategy would perform in live trading.

Split Adjustment

If a split event occurs before your order is filled, the unfilled portion of the order is adjusted automatically, where its quantity is multiplied by the split factor and the limit/stop/trigger price (if any) is divided by the split factor.

Open Order Margin Requirements

When an order fills, LEAN uses the portfolio information to check if you have enough capital to maintain the remaining open orders. If you don't, they are canceled.

The following table shows the order events of three orders of SPY 240109C00470000:

Time	Id	Type	Price	Quantity	Status
2024-01-08 09:31	1	Buy Market	0.91	20	`Filled`
	2	Sell Stop Market	0.81	-20	`Submitted`
2024-01-08 10:31	3	Sell Market	1.50	-10	`Filled`
	2	Sell Stop Market	0.81	-20	`Invalid`

When the sell market order fills at 10:31, LEAN checks the sell stop order and sets its status to `OrderStatus.Invalid` due to insufficient buying power to complete it.

Asynchronous Execution

In live trading, we send your orders to the API of your brokerage and wait for their response to update the status of the order ticket from `New` to `Submitted` , `Canceled` , or `Invalid` . When you place multiple orders, waiting for responses from the brokerage delays the last orders of the batch. To avoid this delay, you can place orders asynchronously. When you place an order asynchronously, LEAN sends the order to your brokerage and immediately continues executing your algorithm without waiting for a response. When the response from the brokerage arrives, LEAN updates the status of the order ticket accordingly, and your algorithm receives an order event .

Live Trading Considerations

In live trading, orders fill asynchronously. We send your order to the API of your brokerage and wait for their response to update the state of your algorithm and portfolio. The timing of live order fills doesn't depend on the resolution of your security subscriptions. When your order fills, the fill price and fee is set by your brokerage. You can add event handlers to your algorithm to monitor the brokerage connection and brokerage messages .

In backtesting, the trade fill timing depends on the resolution of your security subscription. For example, if you subscribe to a security with minute resolution data, the algorithm only receives data in one-minute time slices . As a result, the fill model can only evaluate if the order should fill on a minute-by-minute frequency.

Trading and Orders

Order Management

Order Management

Order Tickets

Introduction

When you create an order, you get an `OrderTicket` object to manage your order.

Properties

`OrderTicket` objects have the following attributes:

Track Orders

As the state of your order updates over time, your order ticket automatically updates. To track an order, you can check any of the preceding order ticket properties.

To get an order field, call the `Get` method with an `OrderField` .

```C#
private Symbol _symbol;
private OrderTicket _ticket;

public override void Initialize()
{
    _symbol = AddEquity("SPY").Symbol;
}

public override void OnData(Slice slice)
{
    // Place order if not invested and save the order ticket for later retrival.
    if (!Portfolio.Invested && slice.Bars.TryGetValue(_symbol, out var bar))
    {
        _ticket = LimitOrder(_symbol, 10, bar.Close);
    }
    // Get the limit price if the order is filled.
    else if (Portfolio.Invested)
    {
        var limitPrice = _ticket.Get(OrderField.LimitPrice);
    }
}
```

The `OrderField` enumeration has the following members:

In addition to using order tickets to track orders, you can receive order events through the `OnOrderEvent` event handler.

Update Orders

To update an order, use its `OrderTicket` . You can update other orders until they are filled or the brokerage prevents modifications. You just can't update orders during warm up and initialization .

Updatable Properties

The specific properties you can update depends on the order type. The following table shows the properties you can update for each order type.

Order Type	Updatable Properties				
	Tag	Quantity	LimitPrice	TriggerPrice	StopPrice
Market Order					
Limit Order	✓	✓	✓		
Limit If Touched Order	✓	✓	✓	✓	
Stop Market Order	✓	✓			✓
Stop Limit Order	✓	✓	✓		✓
Market On Open Order	✓	✓			
Market On Close Order	✓	✓			

Update Methods

To update an order, pass an `UpdateOrderFields` object to the `Update` method. The method returns an `OrderResponse` to signal the success or failure of the update request.

C#

```
private Symbol _symbol;
private OrderTicket _ticket;

public override void Initialize()
{
    _symbol = AddEquity("SPY").Symbol;
}

public override void OnData(Slice slice)
{
    // Place order if not order yet and save the order ticket for later retrival.
    if (_ticket == null && slice.Bars.TryGetValue(_symbol, out var bar))
    {
        _ticket = LimitOrder(_symbol, 10, bar.Close * 0.98m);
    }
    // If order is placed, update the limit price to be 90% of the orginal.
    else if (_ticket != null && _ticket.Status == OrderStatus.Submitted)
    {
        // Update the order tag and limit price
        var response = _ticket.Update(new UpdateOrderFields()
        {
            Tag = "Our New Tag for SPY Trade",
            LimitPrice = _ticket.Get(OrderField.LimitPrice * 0.9m)
        });

        // Check if the update request is successfully submitted to the broker.
        // Note that it may not represent the order is updated successfully: during the order updating process, it
may be filled or canceled.
        if (response.IsSuccess)
        {
            Debug("Order update request is submitted successfully");
        }
    }
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`

- `UpdateQuantity`
- `UpdateStopPrice`
- `UpdateTag`

```C#
var limitResponse = ticket.UpdateLimitPrice(limitPrice, tag);
var quantityResponse = ticket.UpdateQuantity(quantity, tag);
var stopResponse = ticket.UpdateStopPrice(stopPrice, tag);
var tagResponse = ticket.UpdateTag(tag);
```

Update Order Requests

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```C#
var updateRequests = ticket.UpdateRequests();
```

Workaround for Brokerages That Don't Support Updates

Not all brokerages fully support order updates. To check what functionality your brokerage supports for order updates, see the Orders section of the documentation for your brokerage model . If your brokerage doesn't support order updates and you want to update an order, cancel the order . When you get an order event that confirms the order is no longer active, place a new order.

```C#
private Symbol _symbol;
private OrderTicket _ticket;

public override void Initialize()
{
    _symbol = AddEquity("SPY").Symbol;
}

public override void OnData(Slice slice)
{
    // Place order if not order yet and save the order ticket for later retrival.
    if (_ticket == null && slice.Bars.TryGetValue(_symbol, out var bar))
    {
        _ticket = LimitOrder(_symbol, 10, bar.Close);
    }
    // If order is placed, cancel the order and place a new one as substituent.
    else if (_ticket != null && _ticket.Status == OrderStatus.Submitted)
    {
        // Cancel the order
        _ticket.Cancel();
    }
}

public override void OnOrderEvent(OrderEvent orderEvent)
{
    if (_ticket != null
        && orderEvent.OrderId == _ticket.OrderId
        && orderEvent.Status == OrderStatus.Canceled)
    {
        // Place a new order
        var quantity = _ticket.Quantity - _ticket.QuantityFilled;
        var limitPrice = Securities[_ticket.Symbol].Price + 1;
        _ticket = LimitOrder(_ticket.Symbol, quantity, limitPrice);
    }
}
```

Cancel Orders

To cancel an order, call the `Cancel` method on the `OrderTicket` . The method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```C#
private Symbol _symbol;
private OrderTicket _ticket;

public override void Initialize()
{
    _symbol = AddEquity("SPY").Symbol;
}

public override void OnData(Slice slice)
{
    // Place order if not order yet and save the order ticket for later retrival.
    if (_ticket == null && slice.Bars.TryGetValue(_symbol, out var bar))
    {
        _ticket = LimitOrder(_symbol, 10, bar.Close);
    }
    // If order is placed, cancel the order if it is not filled within 2 minutes.
    else if (_ticket != null && _ticket.Time <= slice.Time.AddMinutes(-2) && _ticket.Status == OrderStatus.Submitted)
    {
        // Cancel the order
        var response = ticket.Cancel("Canceled SPY trade");

        // Check if the cancel request is successfully submitted to the broker.
        // Note that it may not represent the order is canceled successfully: during the order updating process, it
may be filled.
        if (response.IsSuccess)
        {
            Debug("Order cancel request successfully submitted");
        }
    }
}
```

You can't cancel market orders because they are immediately transmitted to the brokerage. You also can't cancel any orders during warm up and initialization .

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method. The method returns `null` if the order hasn't been cancelled.

```
C#
var request = ticket.cancel_order_request();
```

Order Response

When you update or cancel an order, LEAN returns an `OrderReponse` object, which have the following attributes:

If your order changes fail, check the `ErrorCode` or `ErrorMessage` . For more information about specific order errors, see the Order Response Error Reference .

To get most recent order response, call the `GetMostRecentOrderResponse` method.

```
C#
var response = ticket.get_most_recent_order_response();
```

Examples

The following examples demonstrate some common practices for order ticket management.

Example 1: Timed Exit

The following algorithm is an EMA-crossover strategy. Using the filled time of the order ticket, we can control to exit the position after 45 minutes.

C#

```
public class OrderTicketExampleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ExponentialMovingAverage _ema;
    private OrderTicket _ticket;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _symbol = AddEquity("SPY").Symbol;
        // Set up EMA indicator for trade signal generation.
        _ema = EMA(_symbol, 20, Resolution.Daily);
        // Warm up the indicator for its readiness to use immediately.
        WarmUpIndicator(_symbol, _ema);
    }

    public override void OnData(Slice slice)
    {
        // Place order if not order yet and save the order ticket for later retrival.
        if (_ticket == null && slice.Bars.TryGetValue(_symbol, out var bar))
        {
            // EMA crossover: buy if price is above EMA, which indicate uptrend.
            if (_ema < bar.Close)
            {
                _ticket = LimitOrder(_symbol, 100, bar.Close * 0.995m);
            }
            // EMA crossover: sell if price is below EMA, which indicate down trend.
            else
            {
                _ticket = LimitOrder(_symbol, -100, bar.Close * 1.005m);
            }
        }
        // Exit position if it is in the portfolio for more than 45 minutes.
        else if (_ticket != null && _ticket.Time <= UtcTime.AddMinutes(-45))
        {
            Liquidate();
            _ticket = null;
        }
    }
}
```

Example 2: Intraday Stop Loss

The following algorithm demonstrates an intraday long position with a 10% stop loss order. Before the market closes, cancel the stop loss order if it is not filled and exit the position at market close with a market on close order.

```C#
public class OrderTicketExampleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    // A variable to save the stop loss order and track if it is filled.
    private OrderTicket _ticket;
    private int _day = -1;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        _symbol = AddEquity("QQQ").Symbol;

        // Schedule an event to handle exiting position before market close if stop loss is not hit.
        // Market on close order requires ordering 15 minutes before market close.
        Schedule.On(
            DateRules.EveryDay(_symbol),
            TimeRules.BeforeMarketClose(_symbol, 16),
            ExitPosition
        );
    }

    public override void OnData(Slice slice)
    {
        // Place order if not invested. Make sure only trade once a day to avoid chasing the loss.
        if (!Portfolio.Invested && _day != slice.Time.Day && slice.Bars.TryGetValue(_symbol, out var bar))
        {
            MarketOrder(_symbol, 10);
            // Update the day variable to avoid repeat ordering.
            _day = slice.Time.Day;
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // Make sure to order the stop loss order on the filled market order only.
        if (orderEvent.Status == OrderStatus.Filled && orderEvent.FillQuantity > 0)
        {
            // Place a 10% stop loss order to avoid large loss. Save the order ticket for tracking its status later.
            _ticket = StopMarketOrder(orderEvent.Symbol, -orderEvent.FillQuantity, orderEvent.FillPrice*0.9m);
        }
    }

    private void ExitPosition()
    {
        // Only need to cancel the order and handle exit position if the stop loss order is not fully filled.
        if (_ticket != null && _ticket.Status != OrderStatus.Filled)
        {
            _ticket.Cancel();
            // Market on close order to exit position at market close with the remaining quantity.
            MarketOnCloseOrder(_symbol, -10 - _ticket.QuantityFilled);
        }
    }
}
```

Example 3: Crypto Trailing Stop Order

This example trades BTCUSD with a similar logic of Example 2, but apply a trailing stop loss of 10% instead. Crypto exchanges does not support trailing stop loss order. Yet, we can cancel and reorder a stop loss order with the updated stop loss price. If the market price of the crypto pair is above the previous level, update the stop loss order by the above.

```C#
public class OrderTicketExampleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    // A variable to hold the stop loss order to track if it should be updated.
    private OrderTicket _ticket;
    // A day variable to avoid over-ordering (trade once per day)
    private int _day = -1;
    // A variable to hold the price of the high price in the lifetime of the open position for updating the stop loss
price.
    private decimal _highPrice = 0m;
    // Update the stop loss when new high is 1% higher
    private decimal _updateStep = 1.01m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Set the market argument to trade in specific exchange.
        _symbol = AddCrypto("BTCUSD", market: Market.Coinbase).Symbol;
    }

    public override void OnData(Slice slice)
    {
        if (!slice.Bars.TryGetValue(_symbol, out var bar)) return;

        // Place order if not invested. Make sure only trade once a day to avoid chasing the loss.
        if (!Portfolio.Invested && _day != Time.Day)
        {
            MarketOrder(_symbol, 1);
            // Place a 10% stop loss order to avoid large loss. Save the order ticket for tracking its status later.
            _ticket = StopMarketOrder(_symbol, -1, bar.Close*0.9m);
            // Update the day variable to avoid repeat ordering.
            _day = Time.Day;
        }

        // Update the trailing stop order. Since order updating is not supported in crypto exchanges, we cancel and
reorder.
        // Trailing stop price will only need to be updated when the market price is higher than the current price.
        if (_ticket != null &&_ticket.Status.IsOpen() && bar.High > _highPrice)
        {
            _ticket.Cancel();
            _ticket = StopMarketOrder(_symbol, -Portfolio[_symbol].Quantity, bar.High*0.9m);
            _highPrice = bar.High * _updateStep;
        }
    }
}
```

Order Management

Transaction Manager

Introduction

The algorithm transactions manager (`SecurityTransactionManager`) contains a collection of helper methods to quickly access all your orders. To access the transaction manager, use the `Transactions` property of your algorithm. If you save a reference to your order tickets , you shouldn't need to use the transaction manager. LEAN updates the order tickets as the brokerage processes your orders.

Get a Single Order Ticket

If you didn't save a reference to the order ticket when you created an order, you can call the `GetOrderTicket` method to get it. You need to pass the order ID to the method. If you don't have the order ID, you can use the `LastOrderId` property to get the order ID of the most recent order.

```
C#
var orderId = Transactions.LastOrderId;
var ticket = Transactions.GetOrderTicket(orderId);
```

Get Order Tickets

To get order tickets, call the `GetOrderTickets` or `GetOpenOrderTickets` method. You can pass in a filter function to filter all of the order tickets or pass a `Symbol` to get the order tickets for a specific asset.

```
C#
// Get all order tickets
var orderTickets = Transactions.GetOrderTickets();

// Get order tickets that pass a filter
var filteredOrderTickets = Transactions.GetOrderTickets(orderTicket => orderTicket.Symbol == symbol);

// Get all open order tickets
var openOrderTickets = Transactions.GetOpenOrderTickets();

// Get all open order tickets for a symbol
var symbolOpenOrderTickets = Transactions.GetOpenOrderTickets(symbol);

// Get open order tickets that pass a filter
var filteredOpenOrderTickets = Transactions.GetOpenOrderTickets(orderTicket => orderTicket.Quantity > 10);
```

Get a Single Order

To get a clone of a specific order, call the `GetOrderById` method with the order Id. To get the order Id, use the `OrderId` property of the order ticket or use the `LastOrderID` property if you want the most recent order.

```
C#
var orderId = Transactions.LastOrderID;
var order = Transactions.GetOrderById(orderId);
```

Order objects are immutable and changes to the order object will not impact the trade. To make an update to an order you must use Order Tickets . `Order` objects have the following attributes:

Get Orders

To get a list of orders, call the `GetOrders` , `GetOpenOrders` , or `GetOrdersByBrokerageId` method. These method returns a list of `Order` objects.

```
C#

// Get all completed orders
var completedOrders = Transactions.GetOrders();

// Get all completed orders that pass a filter
var filteredCompletedOrders = Transactions.GetOrders(x => x.Quantity > 10);

// Get a list of all completed orders for a symbol
var symbolCompletedOrders = Transactions.GetOrders(x => x.Symbol == symbol);

// Get all open orders
var openOrders = Transactions.GetOpenOrders();

// Get all open orders that pass a filter
var filteredOpenOrders = Transactions.GetOpenOrders(x => x.Quantity > 10);

// Get a list of all open orders for a symbol
var symbolOpenOrders = Transactions.GetOpenOrders(symbol);

// Get all open and completed orders that correspond to an Id that the brokerage assigned in live trading
var ordersByBrokerageId = Transactions.GetOrdersByBrokerageId(brokerageId);
```

`Order` objects have the following attributes:

The `OrdersCount` property gets the current number of orders that have been processed.

Get Remaining Order Quantity

To get the unfilled quantity of open orders, call the `GetOpenOrdersRemainingQuantity` method.

```
C#

// Get the quantity of all open orders
var allOpenQuantity = Transactions.GetOpenOrdersRemainingQuantity();

// Get the quantity of open orders that pass a filter
var filteredOpenQuantity = Transactions.GetOpenOrdersRemainingQuantity(
    orderTicket => orderTicket.Quantity > 10
);

// Get the quantity of open orders for a symbol
var symbolOpenQuantity = Transactions.GetOpenOrdersRemainingQuantity(symbol);
```

Cancel Orders

To cancel open orders, call the `CancelOpenOrders` method. This method returns a list of `OrderTicket` objects that correspond to the canceled orders.

```
C#

// Cancel all open orders
var allCancelledOrders = Transactions.CancelOpenOrders();

// Cancel orders related to IBM and apply a tag
var ibmCancelledOrders = Transactions.CancelOpenOrders("IBM", "Hit stop price");
```

Live Trading Considerations

LEAN doesn't save orders and order tickets across live deployments.

When you deploy your algorithm, LEAN fetches the open orders from your brokerage and populate the algorithm transactions

manager (`SecurityTransactionManager`).

Examples

The following examples demonstrate some common practices for using the transaction manager.

Example 1: 2-Level Take Profit And Stop Loss

The following algorithm trades volatility using the CBOE VIX dataset . It makes use of the transaction manager to handle a 2-layer take profit and stop loss risk management.

```
C#
public class TransactionManagerAlgorithm : QCAlgorithm
{
    private Symbol _spy, _vix;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request SPY data for trading and trade on daily signals so we use daily resolution.
        _spy = AddEquity("SPY", Resolution.Daily).Symbol;
        // Subscribe to VIX data to generate trade signals.
        _vix = AddData<CBOE>("VIX", Resolution.Daily).Symbol;

        // Use the EMA indicator to generate trade signals from VIX.
        _ema = EMA(_vix, 20, Resolution.Daily);
        // Warm up the EMA indicator to enable immediate use.
        WarmUpIndicator(_vix, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var spyBar))
        {
            var vix = Securities[_vix].Price;

            // Trade based on volatility. Sell SPY if VIX is in an uptrend, indicating low market volatility.
            // Buy SPY if VIX is in a downtrend, indicating a volatile market.
            if (vix > _ema && !Portfolio[_spy].IsLong)
            {
                // Cancel all open orders to remove redundant take profit and stop loss orders.
                Transactions.CancelOpenOrders();

                var quantity = 10 - Portfolio[_spy].Quantity;
                MarketOrder(_spy, quantity);
                // Stop Loss at 2%.
                StopMarketOrder(_spy, -10, spyBar.Close * 0.98m, tag: "stop loss");
                // Take profit at 4%.
                LimitOrder(_spy, -5, spyBar.Close * 1.04m, tag: "take profit");
            }
            else if (vix < _ema && !Portfolio[_spy].IsShort)
            {
                // Cancel all open orders to remove redundant take profit and stop loss orders.
                Transactions.CancelOpenOrders();

                var quantity = -10 - Portfolio[_spy].Quantity;
                MarketOrder(_spy, quantity);
                // Stop Loss at 2%.
                StopMarketOrder(_spy, 10, spyBar.Close * 1.02m, tag: "stop loss");
                // Take profit at 4%.
                LimitOrder(_spy, 5, spyBar.Close * 0.96m, tag: "take profit");
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // If the take profit order was filled out, we place the 2nd layer of take profit.
        var takeProfitOrders = Transactions.GetOrderTickets(x => x.OrderType == OrderType.Limit).ToList();
        if (takeProfitOrders.Count == 0)
        {
            return;
        }
        var lastTakeProfitOrderId = takeProfitOrders.MaxBy(x => x.Time).OrderId;
```

```
        var lastTakeProfitOrderId = takeProfitOrders.MaxBy(x => x.Time).OrderId;

        if (orderEvent.Status == OrderStatus.Filled && orderEvent.Id == lastTakeProfitOrderId)
        {
            // Cancel all open orders to remove redundant stop loss orders.
            Transactions.CancelOpenOrders();
            // 2nd layer Take profit at extra 4%.
            var takeProfitPrice = orderEvent.FillQuantity > 0 ? orderEvent.FillPrice * 0.96m : orderEvent.FillPrice
* 1.04m;
            LimitOrder(_spy, 5, takeProfitPrice, tag: "second-layer take profit");
        }
        else if (orderEvent.Status == OrderStatus.Filled && orderEvent.Ticket.OrderType == OrderType.StopMarket)
        {
            // Cancel all open orders to remove redundant take profit orders if stop loss.
            Transactions.CancelOpenOrders();
        }
    }
}
```

Market Orders

Introduction

Market orders are instructions to trade a specific number of units, regardless of the fill price. If your highest priority is to fill an order as fast as possible, use market orders. If the order book of the security you're trading has sufficient liquidity when the brokerage receives your order, it immediately fills. However, if there is not enough liquidity by the brokerage, you may need to wait a few minutes to fill the order, you may get partial fills, and you may incur additional costs from market impact.

Place Orders

To send a market order, call the `MarketOrder` , `Buy` , `Sell` , or `Order` method and provide a `Symbol` and quantity. If you don't have sufficient capital for the order, it's rejected. By default, market orders are synchronous and fill immediately.

```
C#
// Buy orders
MarketOrder("IBM", 100);
Buy("AAPL", 10);
Order("SPY", 20);

// Sell orders
MarketOrder("AMZN", -15);
Sell("TSLA", 25);
Order("SPY", -20);
```

You can also provide a tag and order properties to the `Order` and `MarketOrder` methods.

```
C#
MarketOrder(symbol, quantity, tag: tag, orderProperties: orderProperties);
```

If you place a market order during pre-market or post-market hours, LEAN converts your order to market on open order. To override this behavior, create a custom fill model . To be notified when the default fill model allows you to submit market orders outside of regular trading hours, subscribe to GitHub Issue #3947 .

Monitor Order Fills

If the brokerage has sufficient liquidity in their order book, market orders fill immediately. Otherwise, you get partial fills. To monitor the fills of your order, save a reference to the order ticket .

```
C#
var ticket = MarketOrder("XLK", 10);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Cancel Orders

To cancel a market order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
MarketOrder("IBM", 100, asynchronous: true);
```

Synchronous Timeouts

Market orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `Transactions.MarketOrderFillTimeout` property.

```
// Adjust the market fill-timeout to 30 seconds.
Transactions.MarketOrderFillTimeout = TimeSpan.FromSeconds(30);
```

Market orders may take a few minutes to fill for illiquid assets such as out-of-the-money Options or penny stocks.

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with market orders, set the brokerage model to a brokerage that supports them.

```
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for market orders, see the Orders section of the brokerage model documentation .

Requirements

You can submit market orders during regular trading hours for all asset classes. For Futures and Future Options, you can place market orders during regular and extended market hours. For all other asset classes, if you place market orders at/after the last minute of regular market hours, LEAN converts the market orders into market-on-open orders as long as the asset class supports them . To view the trading hours of each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Market Hours .

Examples

The following backtest verifies the `MarketOrder` behavior. The algorithm buys SPY on the first day and liquidates the position on the second day. The following table shows the first two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	SPY	429.11	10	Market	Filled	4291.10	
2021-07-02T09:31:00Z	SPY	431.54	-10	Market	Filled	-4315.40	

On July 1, 2021, the algorithm buys SPY at $429.11. The fill model fills this order at the ask close price.

On July 2, 2021, the algorithm sells the SPY holdings at $431.54. The fill model fills this order at the bid close price.

To reproduce these results, backtest the following algorithm:

C#

```
public class MarketOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 4);
        SetCash(100000);
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        _symbol = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested && Time.Day == 1)
        {
            MarketOrder(_symbol, 10);
        }
        else if (Portfolio.Invested && Time.Day == 2)
        {
            MarketOrder(_symbol, -10);
        }
    }
}
```

Order Types

Limit Orders

Introduction

Limit orders are instructions to trade a quantity of an asset at a specific price or a better price. A marketable limit order has a limit price that crosses the spread. An unmarketable limit order has a limit price that doesn't cross the spread. For example, if an asset has an ask price of 100*andyouplacealimitordertobuyat*100 or higher, that's a marketable limit order that should immediately fill. If you place a limit order to buy at $99.99 or lower, that's an unmarketable limit order that should go on the order book. Unmarketable limit orders save you from paying spread costs. Some brokerages even charge you a lower transaction fee if you use unmarketable limit orders rather than marketable limit orders.

Limit orders are helpful in illiquid markets. You can use them to get a good entry price or to set a take-profit level on an existing holding. However, if the market trades away from your limit price, you may have to adjust your limit price or wait for the market to trade back to your limit price to fill the order.

Place Orders

To send a limit order, call the `LimitOrder` method with a `Symbol` , quantity, and limit price. You can also provide a tag and order properties to the `LimitOrder` method. If you do not have sufficient capital for the order, it's rejected.

```
C#
LimitOrder(symbol, quantity, limitPrice, tag, orderProperties);
```

To buy an asset with a marketable limit order, set the limit price to the current ask price or higher.

To sell an asset with a marketable limit order, set the limit price to the current bid price or lower.

To buy an asset with an unmarketable limit order, set the limit price below the current ask price.

```
C#
// Buy 1 Bitcoin when the price drops to $34,000
LimitOrder("BTCUSD", 1, 34000);
```

To sell an asset with an unmarketable limit order, set the limit price above the current bid price.

```C#
// Sell 1 Bitcoin when the price moves up to $60,000
LimitOrder("BTCUSD", -1, 60000);
```

Monitor Order Fills

Limit orders fill when the security price passes the limit price. To monitor the fills of your order, save a reference to the order ticket .

```C#
// Buy 10 shares of XLK at $140
var ticket = LimitOrder("XLK", 10, 140);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of limit orders until the order fills or the brokerage prevents modifications. To

update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```C#
// Create a new order and save the order ticket
var ticket = LimitOrder("SPY", 100, 221.05m, tag: "original tag");

// Update the order
var response = ticket.Update(new UpdateOrderFields()
{
    Quantity = 80,
    LimitPrice = 222.00m,
    Tag = "new tag"
});

// Check if the update was successful
if (response.IsSuccess)
{
    Debug("Order updated successfully");
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateTag`

```C#
var limitResponse = ticket.UpdateLimitPrice(limitPrice, tag);

var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```C#
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a limit order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```C#
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
LimitOrder("SPY", 10, 429.0m, asynchronous: true);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with limit orders, set the brokerage model to a brokerage that supports them.

```
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for limit orders, see the Orders section of the brokerage model documentation .

Requirements

Limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `LimitOrder` method behavior. On the first day, the algorithm buys SPY with an unmarketable limit order. On the second day, the algorithm sells SPY with an unmarketable limit order and places another unmarketable limit order to buy SPY, which doesn't fill. The following table shows the first three trades in the backtest:

Submitted Time	Filled Time	Symbol	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:32:00Z	SPY	429.00	429.00	10	Limit	Filled	4290.00	Limit Price: ¤429.00
2021-07-02T09:31:00Z	2021-07-02T09:35:00Z	SPY	431.70	431.70	-10	Limit	Filled	-4317.00	Limit Price: ¤431.70
2021-07-02T09:31:00Z	/	SPY	400.00	/	10	Limit	Submitted	/	Limit Price: ¤400.00

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a buy limit order with a limit price of 429*whentheasklowpriceis* 428.81 and the ask high price is 429.15.*Theorderfillsat*9:32*AMETatapriceof*429. The fill model fills buy limit orders when the ask low price is less than the limit price. It sets the fill price of the order to the minimum of ask high price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a sell limit order at 431.70*andabuylimitorderat*400. At the time of the order, the bid high price is 431.65, *thebidlowpriceis*431.49, and the ask low price is 431.50.*TheselllimitorderfillsatA*9:35*AMETatapriceof*431.70

and the buy limit order doesn't fill. The fill model fills sell limit order when the bid high price is greater than the limit price. It sets the fill price of the order to the maximum of the bid low price and the limit price. The buy limit order doesn't fill because the ask low price is above the limit price for the remainder of the backtest period.

To reproduce these results, backtest the following algorithm:

```C#
public class LimitOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 4);
        SetCash(100000);
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        _symbol = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (Time.Day == 1 && Time.Hour == 9 && Time.Minute == 31)
        {
            LimitOrder(_symbol, 10, 429.0m);
        }
        else if (Time.Day == 2 && Time.Hour == 9 && Time.Minute == 31)
        {
            LimitOrder(_symbol, -10, 431.7m);
            LimitOrder(_symbol, 10, 400.0m);
        }
    }
}
```

Order Types

Limit if Touched Orders

Introduction

Limit if touched (LIT) orders are instructions to place a limit order once an asset touches a specific price level. A buy LIT order has a trigger price below the current market price and a sell LIT order has a trigger price above the current market price. In effect, LIT orders are the opposite of stop limit orders .

Place Orders

To send a LIT order, call the `LimitIfTouchedOrder` method and provide a `Symbol` , quantity, trigger price, and limit price. You can also provide a tag and order properties to the `LimitIfTouchedOrder` method. If you do not have sufficient capital for the order, it's rejected.

```
C#
LimitIfTouchedOrder(symbol, quantity, triggerPrice, limitPrice, tag, orderProperties);
```

To buy an asset with a LIT order that has a marketable limit price, set the trigger price below the current market price and set the limit price above the trigger price.

```
C#
// Once Bitcoin trades down to $36,000, place a limit order to buy 1 Bitcoin at $38,000
LimitIfTouchedOrder("BTCUSD", 1, 33000, 36000);
```

To sell an asset with a LIT order that has a marketable limit price, set the trigger price above the current market price and set the limit price below the trigger price.

```
C#
// Once Bitcoin trades up to $62,000, place a limit order to sell 1 Bitcoin at $59,000
LimitIfTouchedOrder("BTCUSD", -1, 62000, 59000);
```

To buy an asset with a LIT order that has an unmarketable limit price, set the trigger price below the current market price and set the limit price below the trigger price.

```C#
// Once Bitcoin trades down to $46,000, place a limit order to buy 1 Bitcoin at $36,000
LimitIfTouchedOrder("BTCUSD", 1, 46000, 36000);
```

To sell an asset with a LIT order that has an unmarketable limit price, set the trigger price above the current market price and set the limit price above the trigger price.

```C#
// Once Bitcoin trades up to $54,000, place a limit order to sell 1 Bitcoin at $62,000
LimitIfTouchedOrder("BTCUSD", -1, 54000, 62000);
```

Monitor Order Fills

LIT orders fill when the security price touches the trigger price and is at least as favorable as the limit price. To monitor the fills of your order, save a reference to the order ticket .

```
// Once SPY trades down to $425, place a limit order to buy 10 shares at $415
var ticket = LimitIfTouchedOrder("SPY", 10, 425, 415);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, trigger price, limit price, and tag of LIT orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
// Create a new order and save the order ticket
var ticket = LimitIfTouchedOrder("SPY", 100, 350, 340, tag: "Original tag");

// Update the order
var updateOrderFields = new UpdateOrderFields()
{
    Quantity = 80,
    TriggerPrice = 380,
    LimitPrice = 370,
    Tag = "New tag"
}
var response = ticket.Update(updateOrderFields);

// Check the OrderResponse
if (response.IsSuccess)
{
    Debug("Order updated successfully");
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`

- `UpdateQuantity`
- `UpdateTriggerPrice`
- `UpdateTag`

```
C#
var limitResponse = ticket.UpdateLimitPrice(limitPrice, tag);

var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var triggerResponse = ticket.UpdateTriggerPrice(triggerPrice, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
C#
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a LIT order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
C#
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
C#
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
C#
LimitIfTouchedOrder("SPY", 10, 429.0m, 428.95m, asynchronous: true);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with LIT orders, set the brokerage model to a brokerage that supports them.

```
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for LIT orders, see the Orders section of the brokerage model documentation .

Requirements

LIT orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `LimitIfTouchedOrder` behavior. The following table shows the trades in the backtest:

Submitted Time	Filled Time	Symbol	Trigger Price	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:38:00Z	SPY	429.00	428.95	428.95	10	Limit if touched	Filled	4285.00	Trigger Price: ¤429.00 Limit Price: ¤428.95
2021-07-02T09:31:00Z	2021-07-02T09:49:00Z	SPY	431.70	431.75	431.84	-10	Limit if touched	Filled	-4318.40	Trigger Price: ¤431.70 Limit Price: ¤431.75
2021-07-02T09:31:00Z	/	SPY	431.70	400.00	/	10	Limit if touched	Submitted	/	Trigger Price: ¤431.70 Limit Price: ¤400.00
/	/	SPY	400.00	400.00	/	10	Limit if touched	Submitted	/	Trigger Price: ¤400.00 Limit Price: ¤400.00

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a LIT order to buy SPY with a trigger price of 429*and a limit price of* 428.95. At the time of the order submission, the low price was 428.80 *and the bid close price was* 429.10. The order fills at 9:38 AM ET at a price of $428.95. The fill model sets the limit price for buy orders when the low price is less than or equal to the trigger price, fills the order when the bid close price is less than or equal to the limit price, and sets the fill price to the minimum of the ask price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a LIT order to sell SPY with a trigger price of 431.70 *and a limit price of* 431.75. At the time of the order submission, the high price was 431.78 *and the ask close price was* 431.55. The order fills at 9:49 AM ET at a price of $431.84. The fill model sets the limit price for sell orders when the high price is greater than or equal to the trigger price, fills the order when the ask close price is greater than or equal to the limit price, and sets the fill price to the maximum of the bid price and the limit price.

On July 2, 2021, the algorithm places a third LIT order to buy SPY with a trigger price of $431.70 and a limit price of $400. The fill model sets the fill price, but it doesn't fill the order because the limit price is too low. On the same day, the algorithm places a fourth LIT order to buy SPY with a trigger price of $400 and a limit price of $400. The fill model doesn't set the limit price for this order because SPY doesn't touch the trigger price before the backtest ends.

To reproduce these results, backtest the following algorithm:

```C#
public class LimitOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 4);
        SetCash(100000);
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        _symbol = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (Time.Day == 1 && Time.Hour == 9 && Time.Minute == 31)
        {
            LimitIfTouchedOrder(_symbol, 10, 429.0m, 428.95m);
        }
        else if (Time.Day == 2 && Time.Hour == 9 && Time.Minute == 31)
        {
            LimitIfTouchedOrder(_symbol, -10, 431.7m, 431.75m);
            LimitIfTouchedOrder(_symbol, 10, 431.7m, 400.0m);
            LimitIfTouchedOrder(_symbol, 10, 400.0m, 400.0m);
        }
    }
}
```

Order Types

Stop Market Orders

Introduction

Stop market orders fill as a market order when the asset reaches a specific price. A buy stop market order triggers when the asset price is greater than or equal to the stop price. A sell stop market order triggers when the asset price is less than or equal to the stop price. You can use stop market orders to buy breakouts or to mitigate the risk of large losses. However, if the market gaps past your stop price, the order may fill at a worse price than the stop price you set. There is no guarantee that a stop market order fills at the stop price.

Place Orders

To send a stop market order, call the `StopMarketOrder` method and provide a `Symbol` , quantity, and stop price. You can also provide a tag and order properties to the `StopMarketOrder` method. If you do not have sufficient capital for the order, it is rejected.

```
StopMarketOrder(symbol, quantity, stopPrice, tag, orderProperties);
```

To buy an asset with a stop market order, set the stop price above the current ask price.

```
// When Bitcoin trades up to $60,000, buy 1 Bitcoin
StopMarketOrder("BTCUSD", 1, 60000);
```

To sell an asset with a stop market order, set the stop price below the current bid price.

```
// When Bitcoin trades down to $43,000, sell 1 Bitcoin
StopMarketOrder("BTCUSD", -1, 43000);
```

Monitor Order Fills

Stop market orders fill as a market order when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket .

```
C#
// When XLK trades down to $130, sell 10 shares
var ticket = StopMarketOrder("XLK", -10, 130);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, stop price, and tag of stop market orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
C#
// Create a new order and save the order ticket
var ticket = StopMarketOrder("SPY", -100, 415, tag: "original tag");

// Update the order
var response = ticket.Update(new UpdateOrderFields() {
  Quantity = -80,
  StopPrice = 400,
  Tag = "new tag"
});

// Check if the update was successful
if (response.IsSuccess) {
     Debug("Order updated successfully");
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateQuantity`
- `UpdateStopPrice`
- `UpdateTag`

```
var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var stopResponse = ticket.UpdateStopPrice(stopPrice, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a stop market order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
StopMarketOrder("SPY", 10, 429.0m, asynchronous: true);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with stop market orders, set the brokerage model to a brokerage that supports them.

```
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for stop market orders, see the Orders section of the brokerage model documentation .

Requirements

Stop market orders can be submitted at any time for all security types.

Examples

The following backtest verifies the `StopMarketOrder` behavior. On even days, the algorithm buys SPY at the current market price and sells when the price drops 1%. On odd days, the algorithm shorts SPY and buys when the price rises 1%. The following table shows the first four trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T13:31:00Z	SPY	429.10	-1	Market	Filled	-429.10	
2021-07-01T13:31:00Z	SPY	433.44	1	Stop Market	Filled	433.44	Stop Price: 433.43
2021-07-02T17:04:00Z	SPY	433.44	1	Market	Filled	433.44	
2021-07-02T17:04:00Z	SPY	429.00	-1	Stop Market	Filled	-429.00	Stop Price: 429.10

On July 1, 2021, the algorithm shorts SPY at 429.10*andthenbuysitbackat*433.44 when the stop price is 433.43.*Thestoppriceis*1 429.10 is not the market price when the algorithm places the first two orders. 429.10*isthefillpriceatthebid*, *butit*'*snotfarfromthemarketpricebecause*429.1 ∗ 1.01 = 433.39.*Thefillpriceofthestopmarketorderis*433.44, which, as expected, is higher than $433.43. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the maximum of the market price and stop price.

On July 2, 2021, the algorithm buys SPY at 433.44*andsellsitat*429 when the stop price is 429.10.*Thestoppriceis*1433.44 is not the market price when the algorithm places the second two orders. 433.44*isthefillpriceattheask*, *butit*'*snotfarofffromthemarketpricebecause*433.44 ∗ 0.99 = 429.11.*Thefillpriceofthestopmarketorderis*429, which, as expected, is lower than $429.10. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the minimum of the market price and stop price.

To reproduce these results, backtest the following algorithm:

C#

```
public class StopMarketOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 7);
        SetCash(100000);
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        _symbol = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            var quantity = 1;
            var factor = 0.99;
            if (Time.Day % 2 != 0)
            {
                quantity = -1;
                factor = 1.01;
            }

            MarketOrder(_symbol, quantity);
            StopMarketOrder(_symbol, -quantity, data[_symbol].Close * (decimal)factor);
        }
    }
}
```

Order Types

Stop Limit Orders

Introduction

Stop limit orders are instructions to place a limit order once an asset passes a specific price level. They are similar to stop market orders , but use limit orders instead of market orders to give you more control over the fill price. A buy stop limit order has a stop price above the current market price and a sell stop limit order has a stop price below the current market price. In effect, they are the opposite of limit if touched orders .

Place Orders

To send a stop limit order, call the `StopLimitOrder` method and provide a `Symbol` , quantity, stop price, and limit price. You can also provide a tag and order properties to the `StopLimitOrder` method. If you do not have sufficient capital for the order, it is rejected.

```
C#
StopLimitOrder(symbol, quantity, stopPrice, limitPrice, tag, orderProperties);
```

To buy an asset with a stop limit order that has a marketable limit price, set the stop price above the current market price and set the limit price above the stop price.

```
C#
// When Bitcoin trades up to $59,000, buy 1 Bitcoin with a limit order at $62,000
StopLimitOrder("BTCUSD", 1, 59000, 62000);
```

To buy an asset with a stop limit order that has an unmarketable limit price, set the stop price above the current market price and set the limit price below the stop price.

```
C#
// When Bitcoin trades up to $52,000, buy 1 Bitcoin with a limit order at $41,000
StopLimitOrder("BTCUSD", 1, 52000, 41000);
```

To sell an asset with a stop limit order that has an unmarketable limit price, set the stop price below the current market price and set the limit price above the stop price.

```C#
// When Bitcoin trades down to $49,000, sell 1 Bitcoin with a limit order at $58,000
StopLimitOrder("BTCUSD", -1, 49000, 58000);
```

To sell an asset with a stop limit order that has a marketable limit price, set the stop price below the current market price and set the limit price below the stop price.

```C#
// When Bitcoin trades down to $37,000, sell 1 Bitcoin with a limit order at $34,000
StopLimitOrder("BTCUSD", -1, 37000, 34000);
```

Monitor Order Fills

Stop limit orders fill as limit orders when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket .

```
C#
// When GLD trades up to $200, buy 10 shares with a limit order at $205
var ticket = StopLimitOrder("GLD", 10, 200, 205);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, stop price, limit price, and tag of stop limit orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
C#
// Create a new order and save the order ticket
var ticket = StopLimitOrder("SPY", -10, 400, 390, tag: "original tag");

// Update the order
var response = ticket.Update(new UpdateOrderFields() {
  Quantity = -15,
  StopPrice = 415,
  LimitPrice = 395,
  Tag = "new tag"
});

// Check if the update was successful
if (response.IsSuccess) {
     Debug("Order updated successfully");
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`

- `UpdateStopPrice`
- `UpdateTag`

```
C#
var limitResponse = ticket.UpdateLimitPrice(limitPrice, tag);
var quantityResponse = ticket.UpdateQuantity(quantity, tag);
var stopResponse = ticket.UpdateStopPrice(stopPrice, tag);
var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
C#
var updateRequests = ticket.UpdateRequests();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
C#
StopLimitOrder("SPY", -10, 428.95m, 429.00m, asynchronous: true);;
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with stop limit orders, set the brokerage model to a brokerage that supports them.

```
C#
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for stop limit orders, see the Orders section of the brokerage model documentation .

Requirements

Stop limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `StopLimitOrder` behavior. The following table shows the trades in the backtest:

Submitted Time	Filled Time	Symbol	Stop Price	Limit Price	Filled Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	2021-07-01T09:37:00Z	SPY	428.95	429.00	429.00	-10	Stop Limit	Filled	-4290.00	Stop Price: ¤428.95 Limit Price: ¤429.00
2021-07-02T09:31:00Z	2021-07-02T10:12:00Z	SPY	431.80	431.75	431.75	10	Stop Limit	Filled	4317.50	Stop Price: ¤431.80 Limit Price: ¤431.75

On July 1, 2021 at 9:31 AM Eastern Time (ET), the algorithm places a stop limit order to sell SPY with a stop price of 428.95*andalimitpriceof*429. At the time of the order submission, the ask high price is429.16*andtheaskclosepriceis*429.11. The order fills at 9:37 AM ET at a price of $429. The fill model triggers the stop for buy orders when the ask high price is greater than the stop price, fills the order when the ask close price is less than the limit price, and sets the fill price to the maximum of the ask high price and the limit price.

On July 2, 2021 at 9:31 AM ET, the algorithm places a stop limit order to buy SPY with a stop price of 431.80*andalimitpriceof* 431.75. At the time of the order submissions, the bid low price is431.49*andthebidclosepriceis*431.54. The order fills at 10:12 AM ET at a price of $431.75. The fill model triggers the stop for sell orders when bid low price is less than the stop price, fills the order when the ask close price is less than the limit price, and sets the fill price to the minimum of the ask high price and the limit price.

C#

```
public class StopLimitOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 4);
        SetCash(100000);
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        _symbol = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (Time.Day == 1 && Time.Hour == 9 && Time.Minute == 31)
        {
            StopLimitOrder(_symbol, -10, 428.95m, 429.00m);
        }
        else if (Time.Day == 2 && Time.Hour == 9 && Time.Minute == 31)
        {
            StopLimitOrder(_symbol, 10, 431.80m, 431.75m);
        }
    }
}
```

Order Types

Trailing Stop Orders

Introduction

Trailing stop orders are stop market orders with a dynamic stop price. A sell trailing stop starts with the stop price at a fixed amount below the market price. As the market price rises, the stop price rises by the trail amount, but if the stock price falls, the stop loss price doesn't change. A buy trailing stop order starts with the stop price at a fixed amount above the market price. As the market price falls, the stop price falls by the trail amount, but if the stock price rises, the stop loss price doesn't change.

Trailing stop orders fill as a market order when the asset reaches the stop price. You can use trailing stop orders to buy breakouts or to mitigate the risk of large losses while protecting your gains. However, if the market gaps past your stop price, the order may fill at a worse price than the stop price you set. There's no guarantee that a trailing stop order fills at the stop price.

Place Orders

To send a trailing stop order, call the `TrailingStopOrder` method and provide a `Symbol` , quantity, trailing amount, and the trailing type. You can also provide a tag and order properties to the `TrailingStopOrder` method. If you do not have sufficient capital for the order, it is rejected.

```C#
TrailingStopOrder(symbol, quantity, trailingAmount, trailingAsPercentage, tag, orderProperties);
```

If you set the `trailingAsPercentage` parameter to `false` , the `trailingAmount` is denominated in the asset's quote currency .

Buy With a Currency-Based Trailing Stop

To buy an asset with a currency-based trailing stop order, pass the trailing amount and disable the `trailingAsPercentage` parameter.

```C#
// Buy 1 share of SPY through a trailing stop order that starts $30 above the current price
TrailingStopOrder("SPY", 1, 30m, false);
```

Buy With a Percent-Based Trailing Stop

To buy an asset with a percent-based trailing stop order, pass the trailing percent and enable the `trailingAsPercentage` parameter.

```C#
// Buy 1 share of SPY through a trailing stop order that starts 7% above the current price
TrailingStopOrder("SPY", 1, 0.07m, true);
```

Sell With a Currency-Based Trailing Stop

To sell an asset with a currency-based trailing stop order, pass the trailing amount and disable the `trailingAsPercentage` parameter.

```C#
// Sell 1 share of SPY through a trailing stop order that starts $20 below the current price
TrailingStopOrder("SPY", -1, 20m, false)
```

Sell With a Percent-Based Trailing Stop

To sell an asset with a percent-based trailing stop order, pass the trailing percent and enable the `trailingAsPercentage` parameter.

```C#
// Sell 1 share of SPY through a trailing stop order that starts 5% above the current price
TrailingStopOrder("SPY", -1, 0.05m, true);
```

Custom Starting Prices

In the preceding examples, LEAN calculates the stop price based on the current security price. If you want the order to start with a stop price closer to the security price than the `trailingAmount`, pass a `stopPrice` parameter to the `TrailingStopOrder` method.

```
C#

TrailingStopOrder(symbol, quantity, stopPrice, trailingAmount, trailingAsPercentage, tag, orderProperties);
```

Monitor Order Fills

Trailing stop orders fill as a market order when the security price passes the stop price. To monitor the fills of your order, save a reference to the order ticket.

```
C#

// When XLK trades down to less than 5% of the current price, sell 10 shares, and update
var ticket = TrailingStopOrder("XLK", -10, 0.05, trailingAsPercentage: true);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

For more information about how LEAN models order fills in backtests, see Trade Fills.

Update Orders

The security's fill model automatically updates the stop price of trailing stop orders as the security's price moves away from the stop price. You can update the quantity, stop price, and tag of trailing stop orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket`. If you don't have the order ticket, get it from the transaction manager. The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
C#

// Create a new order and save the order ticket
var ticket = TrailingStopOrder("SPY", -100, 415, 10, trailingAsPercentage: false, tag: "original tag");

// Update the order
var response = ticket.Update(new UpdateOrderFields() {
  Quantity = -80,
  StopPrice = 400,
  Tag = "new tag"
});

// Check if the update was successful
if (response.IsSuccess) {
     Debug("Order updated successfully");
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateQuantity`
- `UpdateStopPrice`
- `UpdateTag`

```
C#

var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var stopResponse = ticket.UpdateStopPrice(stopPrice, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
C#
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a trailing stop order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
C#
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
C#
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
C#
TrailingStopOrder("SPY", -100, 0.01m, trailingAsPercentage: true, asynchronous: true);;
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with trailing stop orders, set the brokerage model to a brokerage that supports them.

```
C#
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for trailing stop orders, see the Orders section of the brokerage model documentation .

If your brokerage doesn't support them, you can implement a workaround with stop market orders . For an example, see the Buy and Hold with a Trailing Stop Bootcamp lesson.

Requirements

Trailing stop orders can be submitted at any time for all security types.

Examples

The following backtest verifies the `TrailingStopOrder` behavior. On even days, the algorithm buys SPY at the current market price and sells when the price drops 1%. On odd days, the algorithm shorts SPY and buys when the price rises 1%. The following table shows the first four trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T13:31:00Z	SPY	429.10	-1	Market	Filled	-429.10	
2021-07-01T13:31:00Z	SPY	433.16	1	Trailing Stop	Filled	433.16	Stop Price: 433.431400 Trailing Amount: 1.00%
2021-07-02T16:53:00Z	SPY	433.16	1	Market	Filled	433.16	
2021-07-02T16:53:00Z	SPY	429.00	-1	Trailing Stop	Filled	-429.00	Stop Price: 428.823450 Trailing Amount: 1.00%

On July 1, 2021, the algorithm shorts SPY at 429.10*andthenbuysitbackat*433.16 when the stop price is 433.16.*Thestoppriceis*0.95 429.10 is not the market price when the algorithm places the first two orders. The market price is 429.14,*andtheinitialstoppriceis*429.14 ∗ 1.01 = 433.4314.*Themarketpricedropsto*428.86 at 9:40, and the stop price is set to 428.86 * 1.01 = 433.1486. The fill price of the stop market order is 433.16,*which*,*asexpected*,*ishigherthan*433.15. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the maximum of the market price and stop price.

On July 2, 2021, the algorithm buys SPY at 433.16*andthensellsitat*429 when the stop price is 429.00.*Thestoppriceis*0.96433.16 is not the market price when the algorithm places the second two orders. The market price is 433.155,*andtheinitialstoppriceis*433.155 ∗ 0.99 = 428.82345.*Themarketpricesincreasedto*434.76 on July 7 at 3:35 PM, and the stop price is set to 434.76 * 0.99 = 430.4124. The fill price of the stop market order is 429,*which*,*asexpected*,*islowerthan*430.41. The fill model assumes the worst-case scenario between the market price and the stop price. In this case, the worst-case scenario is the minimum of the market price and stop price in a gap down opening.

To reproduce these results, backtest the following algorithm:

C#

```
public class TrailingStopOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    const decimal _trailingAmount = 0.01m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 9);
        SetCash(100000);
        _symbol = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            var quantity = Time.Day % 2 == 0 ? 1 : -1;
            MarketOrder(_symbol, quantity);
            TrailingStopOrder(_symbol, -quantity, _trailingAmount, true);
        }
    }
}
```

Order Types

Market On Open Orders

Introduction

Market on open (MOO) orders fill at the official opening auction price for a security. Market that operate 24/7 don't support MOO orders.

Place Orders

To send a MOO order, call the `MarketOnOpenOrder` method and provide a `Symbol` and quantity. Submit the order at least two minutes before the market opens to be included in the opening auction. If you do not have sufficient capital for the order, it's rejected.

```
C#
// Buy 100 shares of IBM at the market open
MarketOnOpenOrder("IBM", 100);

// Sell 100 shares of IBM at the market open
MarketOnOpenOrder("IBM", -100);
```

You can provide a tag and order properties to the `MarketOnOpenOrder` method.

```
C#
MarketOnOpenOrder(symbol, quantity, tag: tag, orderProperties: orderProperties);
```

Monitor Order Fills

MOO orders fill at the opening auction. If the auction is heavily skewed to one side of the market, your MOO order may not fill. To monitor the fills of your order, save a reference to the order ticket .

```
C#
// Buy 10 shares of SPY at the market open
var ticket = MarketOnOpenOrder("SPY", 10);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

You won't know the fill price of the order until after the market opens. If the asset price moves before the market open to where you can't afford the quantity of the order, the brokerage rejects your order. To increase the probability of a successful trade, leave a sufficient buying power buffer to handle daily price gaps.

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity and tag of MOO orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
// Create a new order and save the order ticket
var ticket = MarketOnOpenOrder("AAPL", 100, tag:"original tag");

// Update the order
var response = ticket.Update(new UpdateOrderFields()
{
    Quantity = 75,
    Tag = "new tag"
});

// Check if the update was successful
if (response.IsSuccess)
{
    Debug("Order updated successfully");
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateQuantity`
- `UpdateTag`

```
var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a MOO order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one.

To send asynchronous orders , set the `asynchronous` argument to `true` .

```
C#
MarketOnOpenOrder("SPY", 10, asynchronous: true);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with MOO orders, set the brokerage model to a brokerage that supports them.

```
C#
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for MOO orders, see the Orders section of the brokerage model documentation .

Requirements

You can submit MOO orders at any time for Equity, Equity Options, and Index Options.

Markets that operate 24/7 don't support MOO orders. The Forex market doesn't operate during the weekend. However, MOO orders are invalid if you place them after this market closes for the weekend.

MOO orders don't support the `GoodTilDate` time in force . If you submit a MOO order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

Examples

The following backtest verifies the `MarketOnOpenOrder` behavior. The following table shows the first trade in the backtest:

Submitted Time	Filled Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T10:31:00Z	2021-07-02T09:31:00Z	SPY	431.67	10	Market On Open	Filled	4316.70	

On July 1, 2021 at 10:31 AM Eastern Time (ET), the algorithm places a market on open order to buy SPY. The fill model fills the order on July 2, 2021 at 9:31 AM at a price of $431.67, which is the official opening auction price for July 2, 2021.

To reproduce these results, backtest the following algorithm:

C#

```
public class MarketOnOpenOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 4);
        SetCash(100000);
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        _symbol = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (Time.Day == 1 && Time.Hour == 10 && Time.Minute == 31)
        {
            MarketOnOpenOrder(_symbol, 10);
        }
    }
}
```

Order Types

Market On Close Orders

Introduction

Market on close (MOC) orders fill at the official closing auction price for a security. Markets that operate 24/7 don't support MOC orders.

Place Orders

To send a MOC order, call the `MarketOnCloseOrder` method with a `Symbol` and quantity. If you don't have sufficient capital for the order, it is rejected.

```
C#
// Buy 100 shares of AAPL at the market open
MarketOnCloseOrder("AAPL", 100);

// Sell 100 shares of AAPL at the market open
MarketOnCloseOrder("AAPL", -100);
```

You can provide a tag and order properties to the `MarketOnCloseOrder` method.

```
C#
MarketOnCloseOrder(symbol, quantity, tag: tag, orderProperties: orderProperties);
```

By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.SubmissionTimeBuffer` property.

```
C#
Orders.MarketOnCloseOrder.SubmissionTimeBuffer = TimeSpan.FromMinutes(10);
```

You can also place MOC orders after the market close.

Monitor Order Fills

MOC orders fill at the closing auction. If the auction is heavily skewed to one side of the market, your MOC order may not fill. To monitor the fills of your order, save a reference to the order ticket .

```
C#
// Buy 10 shares of SPY at the market close
var ticket = MarketOnCloseOrder("SPY", 10);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

You won't know the fill price of the order until after the market closes. If the asset price moves before the market close to where you can't afford the quantity of the order, the brokerage rejects your order. To increase the probability of a successful trade, leave a sufficient buying power buffer to handle the price movements before the close.

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity and tag of MOC orders until the order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```C#
// Create a new order and save the order ticket
var ticket = MarketOnCloseOrder("SLV", 25, tag: "original tag");

// Update the order
var response = ticket.Update(new UpdateOrderFields()
{
    Quantity = 50,
    Tag = "new tag"
});

// Check if the update was successful
if (response.IsSuccess)
{
    Debug("Order updated successfully");
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateQuantity`
- `UpdateTag`

```C#
var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```C#
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a MOC order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```C#
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
MarketOnCloseOrder("SPY", 10, asynchronous: true);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with MOC orders, set the brokerage model to a brokerage that supports them.

```
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for MOC orders, see the Orders section of the brokerage model documentation .

Requirements

By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.SubmissionTimeBuffer` property.

```
Orders.MarketOnCloseOrder.SubmissionTimeBuffer = TimeSpan.FromMinutes(10);
```

Markets that operate 24/7 don't support MOC orders. The Forex market doesn't operate during the weekend.

MOC orders don't support the `GoodTilDate` time in force . If you submit a MOC order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

Examples

The following backtest verifies the `MarketOnCloseOrder` behavior. The following table shows the first trade in the backtest:

Submitted Time	Filled Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T10:31:00Z	2021-07-01T16:00:00Z	SPY	430.43	10	Market On Close	Filled	4304.30	

On July 1, 2021 at 10:31 AM Eastern Time (ET), the algorithm places a market on open order to buy SPY. The fill model fills the order on July 1, 2021 at 4:00 PM ET at a price of $430.43, which is the official closing auction price for July 1, 2021.

To reproduce these results, backtest the following algorithm:

C#

```
public class MarketOnCloseOrderAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 4);
        SetCash(100000);
        UniverseSettings.DataNormalizationMode = DataNormalizationMode.Raw;
        _symbol = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice data)
    {
        if (Time.Day == 1 && Time.Hour == 10 && Time.Minute == 31)
        {
            MarketOnCloseOrder(_symbol, 10);
        }
    }
}
```

Order Types

Combo Market Orders

Introduction

Combo market orders are individual orders that contain market orders for muliple securities. Combo market orders currently only work for trading Option contracts.

Place Orders

To send a combo market order, create multiple `Leg` objects to represent the legs of the combo order, then call the `ComboMarketOrder` method. At least one leg must have a positive quantity and at least one leg must have a negative quantity. The legs must each target a unique contract. If you don't have sufficient capital for the order, it's rejected. By default, combo market orders are synchronous and fill immediately.

```C#
foreach (var kvp in slice.OptionChains)
{
    // Select contracts
    var contracts = kvp.Value.Contracts.Values.ToList();
    if (contracts.Count < 2)
    {
        return;
    }

    // Create order legs
    var legs = new List<Leg>()
    {
        Leg.Create(contracts[0].Symbol, 1),
        Leg.Create(contracts[1].Symbol, -1)
    };

    // Place order
    ComboMarketOrder(legs, 1);
}
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `ComboMarketOrder` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity argument of the `ComboMarketOrder` method also sets the order direction of the combo order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `ComboMarketOrder` method.

```C#
ComboMarketOrder(legs, quantity, tag: tag, orderProperties: orderProperties);
```

Monitor Order Fills

If the brokerage has sufficient liquidity in their order book, combo market orders fill immediately. Otherwise, you get partial fills. To monitor the fills of your order, save a reference to the order tickets .

```
var tickets = ComboMarketOrder(legs, 1);
foreach (var ticket in tickets)
{
    Debug($"Symbol: {ticket.Symbol}; Quantity filled: {ticket.QuantityFilled}; Fill price:
{ticket.AverageFillPrice}");
}
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Cancel Orders

To cancel a combo market order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
ComboMarketOrder(legs, quantity, asynchronous: true);;
```

Synchronous Timeouts

Combo market orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `Transactions.MarketOrderFillTimeout` property.

```
// Adjust the market fill-timeout to 30 seconds.
Transactions.MarketOrderFillTimeout = TimeSpan.FromSeconds(30);
```

Combo market orders may take a few minutes to fill for illiquid assets such as out-of-the-money Options.

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo market orders, set the brokerage model to a brokerage that supports them.

```
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for combo market orders, see the Orders section of the brokerage model documentation .

Requirements

You can submit combo market orders during regular trading hours for all asset classes. For Futures and Future Options, you can place combo market orders during regular and extended market hours. For all other asset classes, if you place combo market orders at/after the last minute of regular market hours, LEAN converts the combo market orders into market-on-open orders as long as the asset class supports them . To view the trading hours of each asset class, follow these steps:

1. Open the Asset Classes documentation.
2. Click an asset class.
3. Click Market Hours .

Examples

The following backtest verifies the `ComboMarketOrder` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.90	1	Buy	Filled	16.90	
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.20	-1	Sell	Filled	-14.20	

On December 24, 2015, the algorithm buys GOOG 16011SC00745000 at $16.90 and sells GOOG 160115C00747500 at $14.20. The fill model fills the buy order at the ask close price and fills the sell order at the bid close price.

To reproduce these results, backtest the following algorithm:

C#

```
public class ComboMarketOrderAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 12, 24);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        var option = AddOption("GOOG");
        option.SetFilter(minStrike: -2, maxStrike: 2, minExpiry: TimeSpan.FromDays(0), maxExpiry:
TimeSpan.FromDays(180));

    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested)
        {
            return;
        }
        foreach (var kvp in slice.OptionChains)
        {
            var contracts = kvp.Value.Contracts.Values.ToList();
            if (contracts.Count < 2)
            {
                return;
            }

            var legs = new List<Leg>()
            {
                Leg.Create(contracts[0].Symbol, 1),
                Leg.Create(contracts[1].Symbol, -1)
            };

            var tickets = ComboMarketOrder(legs, 1);
        }
    }
}
```

Order Types

Combo Limit Orders

Introduction

Combo limit orders are individual orders that contain limit orders for muliple securities. Combo limit orders are different from combo leg limit orders because you must set the limit price of all the leg orders to be the same with combo limit orders. With combo leg limit orders, you can create the order without forcing each leg to have the same limit price. Combo limit orders currently only work for trading Option contracts and their underlying Equities.

Place Orders

To send a combo limit order, create multiple `Leg` objects to represent the legs of the combo order, then call the `ComboLimitOrder` method. At least one leg must have a positive quantity and a tleast one leg must have a negative quantity. The legs must each target a unique contract, but don't set the `OrderPrice` property for any of the legs. If you don't have sufficient capital for the order, it's rejected.

```C#
foreach (var kvp in slice.OptionChains)
{
    // Select contracts
    var contracts = kvp.Value.Contracts.Values.ToList();
    if (contracts.Count < 2)
    {
        return;
    }

    // Create order legs
    var legs = new List&lgt;Leg>()
    {
        Leg.Create(contracts[0].Symbol, 1),
        Leg.Create(contracts[1].Symbol, -1)
    };

    // Calculate limit price
    var limitPrice = Math.Round(legs.Select(leg => Securities[leg.Symbol].Close).Sum() * 0.95m, 2);

    // Place order
    ComboLimitOrder(legs, quantity: 1, limitPrice: limitPrice);
}
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `ComboLimitOrder` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity also sets the order direction of the combo limit order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `ComboLimitOrder` method.

```C#
ComboLimitOrder(legs, quantity, limitPrice, tag: tag, orderProperties: orderProperties);
```

Monitor Order Fills

Combo limit orders fill all the legs at the same time. Each leg can fill when the sum of the security prices of the legs pass the limit price of the combo order. To monitor the fills of your order, save a reference to the order tickets .

```
var tickets = ComboLimitOrder(legs, 1, limitPrice);
foreach (var ticket in tickets)
{
    Debug($"Symbol: {ticket.Symbol}; Quantity filled: {ticket.QuantityFilled}; Fill price:
{ticket.AverageFillPrice}");
}
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of the limit orders in each leg until the combo order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . To update the limit price of the combo order, you only need to update the limit price of one of the leg orders. The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
// Create a new order and save the order ticket
var tickets = ComboLimitOrder(legs, quantity: 1, limitPrice: limitPrice);

// Update the leg orders
foreach (var ticket in tickets)
{
    var response = ticket.Update(new UpdateOrderFields()
    {
        Quantity = 2 * Math.Sign(ticket.Quantity),
        LimitPrice = ticket.Get(OrderField.LimitPrice) + 0.01m,
        Tag = $"Update #{ticket.UpdateRequests.Count + 1}"
    });

    // Check if the update was successful
    if (response.IsSuccess)
    {
        Debug($"Order updated successfully for {ticket.Symbol}");
    }
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateTag`

```
var limitResponse = ticket.UpdateLimitPrice(limitPrice, tag);

var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a combo limit order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
C#
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
C#
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
C#
ComboLimitOrder(legs, 1, limitPrice, asynchronous: true);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo limit orders, set the brokerage model to a brokerage that supports them.

```
C#
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for combo limit orders, see the Orders section of the brokerage model documentation .

Requirements

Combo limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `ComboLimitOrder` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.50	1	Buy	Filled	16.50	
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.60	-1	Sell	Filled	-14.60	

On December 24, 2015 at 9:31 AM Eastern Time (ET), the algorithm places a combo limit order to buy one GOOG 16011SC00745000 contract and sell one GOOG 160115C00747500 contracts. The limit price is 75% of the contract spread, which equals 2.02.*Thecomboorderdoesn*′*tfillimmediatelybecausethecontractspread*2.40 > 2.02.*By*9:36*AM*,*thespreaddropsto*1.90, which is below the limit price, so the fill model fills the combo limit order.

To reproduce these results, backtest the following algorithm:

C#

```
public class ComboMarketOrderAlgorithm : QCAlgorithm
{
    private List<OrderTicket> _tickets = new();
    private decimal _limitPrice;
    public override void Initialize()
    {
        SetStartDate(2024, 12, 24);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG");
        option.SetFilter(minStrike: -2, maxStrike: 2, minExpiry: TimeSpan.FromDays(0), maxExpiry:
TimeSpan.FromDays(180));
    }

    public override void OnData(Slice slice)
    {
        if (_tickets.IsNullOrEmpty())
        {
            foreach (var kvp in slice.OptionChains)
            {
                // Select contracts
                var contracts = kvp.Value.Where(contract => contract.Right == OptionRight.Call)
                    .GroupBy(x => x.Expiry)
                    .OrderBy(grouping => grouping.Key)
                    .First()
                    .OrderBy(x => x.Strike)
                    .ToList();

                if (contracts.Count < 2)
                {
                    return;
                }

                // Create order legs
                var legs = new List<Leg>()
                {
                    Leg.Create(contracts[0].Symbol, 1),
                    Leg.Create(contracts[1].Symbol, -1)
                };

                // Calculate limit price
                _limitPrice = Math.Round((slice.QuoteBars[contracts[0].Symbol].Ask.Low -
slice.QuoteBars[contracts[1].Symbol].Bid.Low) * 0.75m, 2);

                // Place order
                _tickets = ComboLimitOrder(legs, 1, _limitPrice);
            }
        }
        else
        {
            if (Time.Hour == 9 && Time.Minute == 37)
            {
                Quit();
                return;
            }

            // Log the limit price and aggregate contract price
            var price = 0.0m;
            foreach (var ticket in _tickets)
            {
                var quoteBar = slice.QuoteBars[ticket.Symbol];
                price += (ticket.Quantity > 0 ? quoteBar.Ask : quoteBar.Bid).Low * Math.Sign(ticket.Quantity);
            }
            Log($"{Time}. Limit price: {_limitPrice}; Aggregate price: {Math.Round(price, 2)}; Ready to fill: {price
< _limitPrice}");
        }
    }
    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            Log($"{Time} -- Order {orderEvent.OrderId} filled at {orderEvent.FillPrice}");
        }
    }
}
```

Order Types

Combo Leg Limit Orders

Introduction

Combo leg limit orders are individual orders that contain limit orders for muliple securities. Combo leg limit orders are different from combo limit orders because you can create combo leg limit orders without forcing each leg to have the same limit price. Combo leg limit orders currently only work for trading Option contracts.

Place Orders

To send a combo leg limit order, create multiple `Leg` objects to represent the legs of the combo order, then call the `ComboLegLimitOrder` method. The legs must each target a unique contract. At least one leg must have a positive quantity and at least one leg must have a negative quantity. If you don't have sufficient capital for the order, it's rejected.

```C#
foreach (var kvp in slice.OptionChains)
{
    // Select contracts
    var contracts = kvp.Value.Contracts.Values.ToList();
    if (contracts.Count < 2)
    {
        return;
    }

    // Create order legs
    var legs = new List<Leg>()
    {
        Leg.Create(contracts[0].Symbol, 1, contracts[0].LastPrice * 0.98m),
        Leg.Create(contracts[1].Symbol, -1, contracts[1].LastPrice * 1.02m)
    };

    // Place order
    ComboLegLimitOrder(legs, 1);
}
```

The quantity of the legs sets the ratio of the leg orders while the quantity argument of the `ComboLegLimitOrder` method sets the combo order size and acts as a global multiplier. In the preceding example, if we set the global multiplier to two, then the algorithm buys two units of the first contract and sells two units of the second contract. The quantity also sets the order direction of the combo limit order, which affects how the fill model fills the order.

You can also provide a tag and order properties to the `ComboLegLimitOrder` method.

```C#
ComboLegLimitOrder(legs, quantity, tag: tag, orderProperties: orderProperties);
```

Monitor Order Fills

Combo leg limit orders fill all the legs at the same time. Each leg can fill when the security price passes the limit price of the leg. To monitor the fills of your order, save a reference to the order tickets .

```
var tickets = ComboLegLimitOrder(legs, 1);
foreach (var ticket in tickets)
{
    Debug($"Symbol: {ticket.Symbol}; Quantity filled: {ticket.QuantityFilled}; Fill price:
{ticket.AverageFillPrice}");
}
```

For more information about how LEAN models order fills in backtests, see Trade Fills .

Update Orders

You can update the quantity, limit price, and tag of the leg limit orders until the combo order fills or the brokerage prevents modifications. To update an order, pass an `UpdateOrderFields` object to the `Update` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Update` method returns an OrderResponse to signal the success or failure of the update request.

```
// Create a new order and save the order ticket
var tickets = ComboLegLimitOrder(legs, 1);

// Update the leg orders
foreach (var ticket in tickets)
{
    var direction = Math.Sign(ticket.Quantity);
    var response = ticket.Update(new UpdateOrderFields()
    {
        Quantity = 2 * direction,
        LimitPrice = ticket.Get(OrderField.LimitPrice) + 0.01m * direction,
        Tag = $"Update #{ticket.UpdateRequests.Count + 1}"
    });

    // Check if the update was successful
    if (response.IsSuccess)
    {
        Debug($"Order updated successfully for {ticket.Symbol}");
    }
}
```

To update individual fields of an order, call any of the following methods:

- `UpdateLimitPrice`
- `UpdateQuantity`
- `UpdateTag`

```
var limitResponse = ticket.UpdateLimitPrice(limitPrice, tag);

var quantityResponse = ticket.UpdateQuantity(quantity, tag);

var tagResponse = ticket.UpdateTag(tag);
```

When you update an order, LEAN creates an `UpdateOrderRequest` object, which have the following attributes:

To get a list of `UpdateOrderRequest` objects for an order, call the `UpdateRequests` method.

```
var updateRequests = ticket.UpdateRequests();
```

Cancel Orders

To cancel a combo leg limit order, call the `Cancel` method on the `OrderTicket` . If you don't have the order ticket, get it from the transaction manager . The `Cancel` method returns an `OrderResponse` object to signal the success or failure of the cancel request.

```
C#
var response = ticket.Cancel("Cancelled trade");
if (response.IsSuccess)
{
    Debug("Order successfully cancelled");
}
```

When you cancel an order, LEAN creates a `CancelOrderRequest` , which have the following attributes:

To get the `CancelOrderRequest` for an order, call the `CancelRequest` method on the order ticket. The method returns `null` if the order hasn't been cancelled.

```
C#
var request = ticket.cancel_order_request();
```

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
C#
ComboLegLimitOrder(legs, 1, asynchronous: true);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with combo leg limit orders, set the brokerage model to a brokerage that supports them.

```
C#
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for combo leg limit orders, see the Orders section of the brokerage model documentation .

Requirements

Combo leg limit orders can be submitted at any time for all security types.

If your algorithm subscribes to extended market hours, they can be filled outside regular trading hours.

Examples

The following backtest verifies the `ComboLegLimitOrder` behavior. The algorithm buys one contract and sells one contract at the same time. The following table shows the two trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2015-12-24T09:31:00Z	GOOG 16011SC00745000	16.10	2	Buy	Filled	32.20	Update #72
2015-12-24T09:31:00Z	GOOG 160115C00747500	14.11515	-2	Sell	Filled	-28.2303	Update #72

On December 24, 2015 at 9:31 AM Eastern Time (ET), the algorithm places a combo leg limit order to buy one GOOG 16011SC00745000 contract and sell two GOOG 160115C00747500 contracts. The limit price of both orders is 99.9% of the respective contract price, which is 16.2837*forGOOG*16011*SC*00745000*and*14.83515 for GOOG 160115C00747500. The combo order doesn't fill immediately, so the algorithm updates the leg orders at each time step. During the first update, the algorithm sets the quantity of the GOOG 160115C00747500 leg to -2. During each update, the limit price moves 0.01*closertothemarket*. *Thatis*, *thelimitpriceofGOOG*16011*SC*00745000*increasesby*0.01 and the limit price of GOOG 160115C00747500 decreases by $0.01. After the 72nd update, the ask low price is below the limit price of the leg to buy GOOG 16011SC00745000 and the bid high price is above the limit price of the leg to sell GOOG 160115C00747500, so the fill model fills the combo leg limit order at 10:44 AM ET.

To reproduce these results, backtest the following algorithm:

C#

```
public class ComboLegLimitOrderAlgorithm : QCAlgorithm
{
    private List<OrderTicket> _tickets = new();

    public override void Initialize()
    {
        SetStartDate(2024, 12, 24);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG");
        option.SetFilter(minStrike: -2, maxStrike: 2, minExpiry: TimeSpan.FromDays(0), maxExpiry:
TimeSpan.FromDays(180));
    }

    public override void OnData(Slice slice)
    {
        if (_tickets.IsNullOrEmpty())
        {
            foreach (var kvp in slice.OptionChains)
            {
                // Select contracts
                var contracts = kvp.Value.Where(contract => contract.Right == OptionRight.Call)
                    .GroupBy(x => x.Expiry)
                    .OrderBy(grouping => grouping.Key)
                    .First()
                    .OrderBy(x => x.Strike)
                    .ToList();

                if (contracts.Count < 2)
                {
                    return;
                }

                // Create order legs
                var legs = new List<Leg>()
                {
                    Leg.Create(contracts[0].Symbol, 1, slice[contracts[0].Symbol].Close * 0.999m),
                    Leg.Create(contracts[1].Symbol, -2, slice[contracts[1].Symbol].Close * 0.999m)
                };

                // Place order
                _tickets = ComboLegLimitOrder(legs, 1);
            }
        }
        else
        {
            if (Time.Hour == 10 && Time.Minute == 45)
```

```
            {
                Quit();
                return;
            }

            foreach (var ticket in _tickets)
            {
                var orderDirection = Math.Sign(ticket.Quantity);
                var limitPrice = ticket.Get(OrderField.LimitPrice);

                // Log the limit prices and contract prices
                var quoteBar = slice.QuoteBars[ticket.Symbol];
                var currentPrice = orderDirection == 1 ? quoteBar.Ask.Low : quoteBar.Bid.High;
                var readyToFill = orderDirection == 1 ? currentPrice < limitPrice : currentPrice > limitPrice;
                Log($"{Time} - {ticket.Symbol}. Current price: {currentPrice}; Limit price: {Math.Round(limitPrice,
2)}; Order direction: {orderDirection}; Ready to fill: {readyToFill}");

                // Update the leg orders
                var response = ticket.Update(new UpdateOrderFields()
                {
                    Quantity = 2 * orderDirection,
                    LimitPrice = limitPrice + 0.01m * orderDirection,
                    Tag = $"Update #{ticket.UpdateRequests.Count + 1}"
                });
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            Log($"{Time} -- Order {orderEvent.OrderId} filled at {orderEvent.FillPrice}");
        }
    }
}
```

Order Types

Option Exercise Orders

Introduction

If you buy an Option contract, you can exercise your right to buy or sell the underlying asset at the strike price. However, you don't need to exercise it. You can sell the Option or let it expire worthless if it's out of the money. If you hold a long position in an Option that expires in the money, LEAN automatically exercises it at the expiration date. If you sell an Option contract and the buyer exercises their right to buy or sell the underlying asset, you are assigned the Option and must trade with the buyer at the strike price.

Place Orders

You can exercise American-style Option contracts anytime before they expire. Depending on your brokerage and the delivery method, you may be able to exercise European-style Option contracts on their expiration date. To exercise an Option, call the `ExerciseOption` method with the Option contract `Symbol` and a quantity. If you do not have sufficient capital for the order, it's rejected. By default, Option exercise orders are synchronous and fill immediately.

```
C#
var ticket = ExerciseOption(contractSymbol, quantity);
```

You can provide a tag and order properties to the `ExerciseOption` method.

```
C#
ExerciseOption(symbol, quantity, tag: tag, orderProperties: orderProperties);
```

Monitor Order Fills

To monitor the fills of your order, save a reference to the order ticket .

```
C#
var ticket = ExerciseOption(contractSymbol, quantity);
Debug($"Quantity filled: {ticket.QuantityFilled}; Fill price: {ticket.AverageFillPrice}");
```

For more information about how LEAN models Option exercise orders in backtests, see the Exercise Option model .

Option Assignments

If you sell an Option in a backtest, LEAN can simulate an Option exercise order on behalf of the buyer. By default, LEAN scans your portfolio every hour. It considers exercising American-style Options if they are within 4 days of their expiration and it considers exercising European-style Options on their day of expiration. If you have sold an Option that's 5% in-the-money and the Option exercise order is profitable after the cost of fees, LEAN exercises the Option. For more information about how we simulate Option assignments, see the Assignment reality model.

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
var ticket = ExerciseOption(contractSymbol, quantity, asynchronous: true);
```

Synchronous Timeouts

Option exercise orders are synchronous by default, so your algorithm waits for the order to fill before moving to the next line of code. If your order takes longer than five seconds to fill, your algorithm continues executing even if the trade isn't filled. To adjust the timeout period, set the `Transactions.MarketOrderFillTimeout` property.

```
// Adjust the market fill-timeout to 30 seconds.
Transactions.MarketOrderFillTimeout = TimeSpan.FromSeconds(30);
```

Brokerage Support

Each brokerage has a set of assets and order types they support. To avoid issues with Option exercise orders, set the brokerage model to a brokerage that supports them.

```
SetBrokerageModel(BrokerageName.QuantConnectBrokerage);
```

To check if your brokerage has any special requirements for Option exercise orders, see the Orders section of the brokerage model documentation .

Requirements

Option exercise orders can only be submitted for option contracts with a long position. European-style options cannot be exercised before their expiration date.

Examples

The following backtest verifies the `ExerciseOption` behavior. The following table shows the first three trades in the backtest:

Time	Symbol	Price	Quantity	Type	Status	Value	Tag
2021-07-01T09:31:00Z	SPY 221216C00085000	345.30	1	Buy Market	Filled	34530.00	
2021-07-01T09:31:00Z	SPY 221216C00085000	0.00	-1	Sell Option Exercise	Filled	0.00	Automatic Exercise
2021-07-01T09:31:00Z	SPY	85.00	100	Sell Option Exercise	Filled	8500.00	Option Exercise

The algorithm first brought a deep ITM option based on the set option selection conditions by 345.30, *thenexerciseitactively*, *so*100*sharesofSPY*(*inwhich*1*contractrepresents*)*wasboughtatitsstrikepriceat*85.00, with the option discarded from the portfolio.

To reproduce these results, backtest the following algorithm:

C#

```
public class OptionExerciseOrderAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private decimal _strike;
    private Symbol _contract;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 4);
        SetCash(100000);
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(CustomSecurityInitializer);

        var spy = AddEquity("SPY", Resolution.Minute);
        _spy = spy.Symbol;
    }

    private void CustomSecurityInitializer(Security security)
    {
        security.SetDataNormalizationMode(DataNormalizationMode.Raw);
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            var contracts = OptionChainProvider.GetOptionContractList(_spy, Time);
            contracts = from contract in contracts
                        where contract.ID.OptionRight == OptionRight.Call
                        orderby contract.ID.StrikePrice ascending
                        select contract;
            if (contracts.Count() == 0) return;

            _strike = contracts.First().ID.StrikePrice;

            contracts = from contract in contracts
                        where contract.ID.StrikePrice == _strike
                        orderby contract.ID.Date ascending
                        select contract;

            _contract = contracts.First();
            AddOptionContract(_contract, Resolution.Minute);

            Buy(_contract, 1);
        }

        if (Portfolio[_contract].Invested && _strike < Securities[_spy].Price)
        {
            ExerciseOption(_contract, 1);
            Quit();
        }
    }
}
```

Order Types

Other Order Types

Introduction

We are often asked to support other order types like one cancels the other, trailing stop, and multi-leg orders. Currently, LEAN doesn't support these order types, but we will add them over time. Part of the difficulty of implementing them is the incomplete brokerage support.

One Cancels the Other Orders

One cancels the other (OCO) orders are a set of orders that when one fills, it cancels the rest of the orders in the set. An example is to set a take-profit and a stop-loss order right after you enter a position. In this example, when either the take-profit or stop-loss order fills, you cancel the other order. OCO orders usually create an upper and lower bound on the exit price of a trade.

When you place OCO orders, their price levels are usually relative to the fill price of an entry trade. If your entry trade is a synchronous market order, you can immediately get the fill price from the order ticket. If your entry trade doesn't execute immediately, you can get the fill price in the OnOrderEvents event handler. Once you have the entry fill price, you can calculate the price levels for the OCO orders.

```C#
// Get the fill price from the order ticket of a sync market order
_market = MarketOrder("SPY", 1);
var fillPrice = _market.AverageFillPrice;

// Get the fill price from the OnOrderEvent event handler
public override void OnOrderEvent(OrderEvent orderEvent)
{
    if (orderEvent.Status == OrderStatus.Filled && orderEvent.Ticket.OrderType == OrderType.Market)
    {
        var fillPrice = orderEvent.FillPrice;
    }
}
```

After you have the target price levels, to implement the OCO orders, you can place active orders or track the security price to simulate the orders.

Place Active Orders

To place active orders for the OCO orders, use a combination of limit orders and stop limit orders . Place these orders so that their price levels that are far enough apart from each other. If their price levels are too close, several of the orders can fill in a single time step. When one of the orders fills, in the `OnOrderEvent` event handler, cancel the other orders in the OCO order set.

```C#
private OrderTicket _stopLoss;
private OrderTicket _takeProfit;

public override void OnOrderEvent(OrderEvent orderEvent)
{
    if (orderEvent.Status != OrderStatus.Filled) return;

    switch (orderEvent.Ticket.OrderType)
    {
        case OrderType.Market:
            _stopLoss = StopMarketOrder(orderEvent.Symbol, -orderEvent.FillQuantity, orderEvent.FillPrice*0.95m);
            _takeProfit = LimitOrder(orderEvent.Symbol, -orderEvent.FillQuantity, orderEvent.FillPrice*1.10m);
            return;
        case OrderType.StopMarket:
            _takeProfit?.Cancel();
            return;
        case OrderType.Limit:
            _stopLoss?.Cancel();
            return;
    }
}
```

Simulate Orders

To simulate OCO orders, track the asset price in the `OnData` method and place market or limit orders when asset price reaches the take-profit or stop-loss level. The benefit of manually simulating the OCO orders is that both of the orders can't fill in the same time step.

```C#
decimal _entryPrice;

public override void OnData(Slice slice)
{
    if (!Portfolio.Invested)
    {
        var ticket = MarketOrder("SPY", 1);
        _entryPrice = ticket.AverageFillPrice;
    }

    if (!slice.Bars.ContainsKey("SPY")) return;

    if (slice.Bars["SPY"].Price >= _entryPrice * 1.10m)
    {
        Liquidate(symbol: "SPY", -1, tag: "take profit");
    }
    else if (slice.Bars["SPY"].Price <= _entryPrice * 0.95m)
    {
        Liquidate(symbol: "SPY", -1, tag: "stop loss");
    }
}
```

Multi-Leg Orders

Multi-leg orders are orders that contain multiple sub-orders. Examples of multi-leg orders include Option strategies like spreads , straddles , and strangles . You can manually implement other types of multi-leg orders with the built-in order types.

Trading and Orders

Position Sizing

Introduction

LEAN provides several methods to help you set specific portfolio weights for assets. These methods account for lot size and pre-calculated order fees.

Single Asset Targets

The `SetHoldings` method calculates the number of asset units to purchase based on the portfolio weight you provide and then submits market orders . This method provides a quick way to set up a portfolio with a set of weights for assets. If you already have holdings, you may want to liquidate the existing holdings first to free up buying power.

```C#
// Allocate 50% of portfolio value to IBM
SetHoldings("IBM", 0.5);

// Allocate 50% of portfolio value to IBM, but liquidate other holdings first
SetHoldings("IBM", 0.5, liquidateExistingHoldings: true);

// Provide a tag and order properties to the SetHoldings method
SetHoldings(symbol, weight, liquidateExistingHoldings, tag, orderProperties);
```

If the percentage you provide translates to an order quantity of 0 or to a small quantity that doesn't exceed the `MinimumOrderMarginPortfolioPercentage` algorithm setting , then the `SetHoldings` method doesn't place an order and doesn't log anything.

Multiple Asset Targets

When you trade a weighted basket of assets, sometimes you must intelligently scale down existing positions before increasing allocations to other assets. If you call the `SetHoldings` method with a list of `PortfolioTarget` objects, LEAN sorts the orders based on your position delta and then places the orders that reduce your position size in an asset before it places orders that increase your position size in an asset. When you call the `SetHoldings` method with a list of `PortfolioTarget` objects, the decimal you pass to the `PortfolioTarget` constructor represents the portfolio weight. In this situation, don't use the `PortfolioTarget.Percent` method.

```C#
// Purchase a portfolio of targets, processing orders intelligently.
var targets = new List<PortfolioTarget>() { new ("SPY", 0.8m), new ("IBM", 0.2m) };
SetHoldings(targets);
```

If you want the targets you pass to define the target portfolio state, enable the `liquidateExistingHoldings` argument.

```C#
SetHoldings(targets, liquidateExistingHoldings: true);
```

The method also accepts tag and order properties arguments.

```
SetHoldings(targets, liquidateExistingHoldings, tag, orderProperties);
```

If the percentage you provide translates to an order quantity of 0 or to a small quantity that doesn't exceed the `MinimumOrderMarginPortfolioPercentage` algorithm setting , then the `SetHoldings` method doesn't place an order and doesn't log anything.

Asynchronous Orders

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```
SetHoldings("IBM", 0.5, asynchronous: true);
```

When you set multiple asset targets, you likely want to send asynchronous orders.

```
var targets = new List<PortfolioTarget>() { new("SPY", 0.8m), new("IBM", 0.2m) };
SetHoldings(targets, asynchronous: true);
```

Calculate Order Quantities

The `SetHoldings` method uses market order to reach the target portfolio weight you provide. If you want to use a different order type, you need to specify the quantity to trade. To calculate the number of units to trade based on a portfolio weight, call the `CalculateOrderQuantity` method. The method calculates the quantity based on the current price of the asset and adjusts it for the fee model of the security. The target weight you provide is an unleveraged value. For instance, if you have 2x leverage and request a 100% weight, the method calculates the quantity that uses half of your available margin.

```
// Calculate the fee-adjusted quantity of shares with given buying power
var quantity = CalculateOrderQuantity("IBM", 0.4);
```

Buying Power Buffer

If you place a market on open order near the market close, the market can gap overnight to a worse open price. If the gap is large enough against your trade direction, you may not have sufficient buying power at the open to fill your trade. To ensure a high probability of order fills through market gaps and discontinuities, the `SetHoldings` method assumes a 0.25% cash buffer. If LEAN rejects your orders due to buying power, widen the cash buffer through the algorithm `Settings` property.

```
// Set the cash buffer to 5%
Settings.FreePortfolioValuePercentage = 0.05m;

// Set the cash buffer to $10,000
Settings.FreePortfolioValue = 10000m;
```

If you use `FreePortfolioValuePercentage` , you must set it in the `Initialize` or `PostInitialize` event handler. If you use `FreePortfolioValue` , you must set it after the `PostInitialize` event handler.

Examples

The following examples demonstrate some common practices for position sizing.

Example 1: Covered Call

```C#
public class PositionSizingAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(10_000_000);

        // Seed the price to ensure securities have information for margin calculations.
        Settings.SeedInitialPrices = true;

        // Request SPY data for trading. We use raw price data to compare the strike price fairly for ATM contract
selection.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set a scheduled event to rebalance the covered call positions.
        Schedule.On(
            DateRules.WeekStart(_spy),
            TimeRules.AfterMarketOpen(_spy, 1),
            Rebalance
        );
    }

    private void Rebalance()
    {
        var optionChain = OptionChain(_spy);
        // Filter for the calls within 1-week expiry.
        var expiry = optionChain.Where(x => x.Expiry <= Time.AddDays(6))
            .Max(x => x.Expiry);
        // Select the ATM call.
        var atmCall = optionChain.Where(x => x.Right == OptionRight.Call && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - Securities[_spy].Price))
            .First();
        var atmCallSymbol = AddOptionContract(atmCall).Symbol;

        // Calculate the order size for the covered call.
        var quantity = (int)Math.Floor(CalculateOrderQuantity(_spy, 0.5) / 100m);

        // Covered call involves 100 SPY shares and a -1 ATM call contract.
        if (quantity > 0)
        {
            ComboMarketOrder(
            [
                Leg.Create(_spy, 100),
                Leg.Create(atmCallSymbol, -1)
            ], quantity,
            asynchronous: true);
        }
    }
}
```

Trading and Orders

Liquidating Positions

Introduction

The `Liquidate` method lets you liquidate individual assets or your entire portfolio. The method creates market orders to close positions and returns the tickets of the liquidation orders. If you have pending open orders for the security when you call `Liquidate` , LEAN tries to cancel them. The `Liquidate` method works for all asset classes, except Crypto. To liquidate Crypto positions, see Crypto Trades .

Liquidate Individual Positions

To liquidate your holdings in an individual security, call the `Liquidate` method and provide a ticker or `Symbol` .

```C#
// Liquidate all IBM in your portfolio
var orderTickets = Liquidate("IBM");
```

You can pass an order tag and properties to the `Liquidate` method.

```C#
var orderProperties = new OrderProperties() { TimeInForce = TimeInForce.Day };
var orderTickets = Liquidate("AAPL", tag: "Liquidated", orderProperties: orderProperties);
```

Liquidate All Positions

To liquidate all of the positions in your portfolio, call the `Liquidate` method without any ticker of `Symbol` arguments.

```C#
// Liquidate your entire portfolio
var orderTickets = Liquidate();
```

You can pass an order tag and properties to the `Liquidate` method.

```C#
var orderProperties = new OrderProperties() { TimeInForce = TimeInForce.Day };
var orderTickets = Liquidate(tag: "Liquidated", orderProperties: orderProperties);
```

Asynchronous Liquidations

When you trade a large portfolio of assets, you may want to send orders in batches and not wait for the response of each one. To send asynchronous orders , set the `asynchronous` argument to `true` .

```C#
var orderTickets = Liquidate(asynchronous: true, orderProperties: orderProperties);
```

Enable and Disable Liquidations

By default, the `Liquidate` method is functional. To enable and disable it, set the `LiquidateEnabled` algorithm setting .

```
// Disable liquidations
Settings.LiquidateEnabled = false;

// Enable liquidations
Settings.LiquidateEnabled = true;
```

Market Closed Considerations

If you liquidate your positions when the market is closed, LEAN converts the orders into market on open orders. If your brokerage doesn't support market on open orders , the order is invalid.

Examples

The following examples demonstrate some common practices for liquidating positions.

Example 1: Liquidate Universe Removal

The following algorithm holds equal positions for the top 10 liquid universe to follow their hype while updating weekly. When a stock is removed from the universe, we liquidate the position in the `OnSecuritiesChanged` method.

```
public class LiquidatingPositionsAlgorithm : QCAlgorithm
{
    private Universe _universe;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        Settings.SeedInitialPrices = true;
        SetWarmUp(TimeSpan.FromDays(7), Resolution.Minute);

        // Update the universe weekly to allow time to capitalize on the hype.
        UniverseSettings.Schedule.On(DateRules.WeekStart("SPY"));
        UniverseSettings.Resolution = Resolution.Minute;
        // Filter for the 10 most popular stocks to invest the hype.
        _universe = AddUniverse(Universe.Top(10));

        // Set a schedule event to rebalance weekly.
        Schedule.On(
            DateRules.WeekStart("SPY"),
            TimeRules.AfterMarketOpen("SPY", 1),
            Rebalance
        );
    }

    private void Rebalance()
    {
        // Evenly invest in the universe members to dissipate the capital risk equally.
        var count = _universe.Members.Count;
        var targets = _universe.Members.Select(x => new PortfolioTarget(x.Key, 1m / count)).ToList();
        SetHoldings(targets);
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        // Liquidate the ones leaving the universe since they are not the most popular.
        // Note that the liquidation will be market-on-open orders due to the time of securities removal.
        foreach (var removed in changes.RemovedSecurities)
        {
            if (Securities.TryGetValue(removed.Symbol, out var security) && security.Invested)
            {
                Liquidate(removed.Symbol);
            }
        }
    }
}
```

Example 2: Liquidate Existing Positions

The example below trades the same strategy as the previous one. Still, instead of liquidating the positions when the stocks leave the universe, we liquidate the position using the `liquidateExistingHoldings` argument in the `SetHoldings` . Note that the time of the liquidation will be slightly delayed due to the time of the scheduled event.

```C#
public class LiquidatingPositionsAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private Symbol spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        // Update the universe weekly to allow time to capitalize on the hype.
        UniverseSettings.Schedule.On(DateRules.WeekStart(spy));
        // Filter for the 10 most popular stocks to invest the hype.
        _universe = AddUniverse(Universe.Top(10));

        // Set a schedule event to rebalance weekly.
        Schedule.On(
            DateRules.WeekStart(spy),
            TimeRules.AfterMarketOpen(spy, 1),
            Rebalance
        );
    }

    private void Rebalance()
    {
        // Evenly invest in the universe members to dissipate the capital risk equally.
        var activeMembers = _universe.Members
            .Where(kvp => kvp.Value.HasData && kvp.Value.Price > 0)
            .ToList();
        var count = activeMembers.Count;
        var targets = activeMembers.Select(x => new PortfolioTarget(x.Key, 1m / count)).ToList();
        // We can use `liquidateExistingHoldings` arguments to liquidate the ones not in the universe anymore.
        SetHoldings(targets, liquidateExistingHoldings: true);
    }
}
```

Example 3: Liquidate Upon Assignment

The following algorithm sells SPY ATM puts weekly to earn the premium when SPY price is rising. In the case where the price of SPY drops and the put is being assigned, we liquidate the SPY position in the `OnAssignmentOrderEvent` .

C#

```
public class LiquidatingPositionsAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Seed the price with the last known price to ensure the underlying price data is available on initial
option contract filtering.
        Settings.SeedInitialPrices = true;

        // Request SPY data for option selection using its price.
        // Use raw data normalization mode since we need to compare the SPY price with the strike price.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set a schedule event to rebalance weekly.
        Schedule.On(
            DateRules.WeekStart(),
            TimeRules.At(9, 31),
            Rebalance
        );
    }

    private void Rebalance()
    {
        // Select the 1-week ATM put SPY option to short.
        var optionChain = OptionChain(_spy);
        var expiry = optionChain.Where(x => x.Expiry < Time.AddDays(6))
            .Max(x => x.Expiry);
        var atmPut = optionChain.Where(x => x.Right == OptionRight.Put && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - Securities[_spy].Price))
            .First();
        var atmPutSymbol = AddOptionContract(atmPut).Symbol;

        // Sell the ATM put option to earn the premium.
        Sell(atmPutSymbol, 2);
    }

    public override void OnAssignmentOrderEvent(OrderEvent assignmentEvent)
    {
        // Liquidate any assigned positions of SPY since we only earn the premium.
        Liquidate(_spy);
    }
}
```

Trading and Orders

Crypto Trades

Introduction

All fiat and Crypto currencies are individual assets. When you buy a pair like BTCUSDT, you trade USDT for BTC. In this case, LEAN removes some USDT from your portfolio cash book and adds some BTC. The virtual pair BTCUSDT represents your position in the trade, but the virtual pair doesn't actually exist. It simply represents an open trade.

Place Trades

When you place Crypto trades, don't use the `CalculateOrderQuantity` or `SetHoldings` methods. Instead, calculate the order quantity based on the currency amounts in your cash book and place manual orders.

The following code snippet demonstrates how to allocate 90% of your portfolio to BTC.

```C#
public override void OnData(Slice data)
{
    SetCryptoHoldings(_symbol, 0.9m);
}

private void SetCryptoHoldings(Symbol symbol, decimal percentage)
{
    var crypto = Securities[symbol] as Crypto;
    var baseCurrency = crypto.BaseCurrency;

    // Calculate the target quantity in the base currency
    var targetQuantity = percentage * (Portfolio.TotalPortfolioValue - Settings.FreePortfolioValue) /
baseCurrency.ConversionRate;
    var quantity = targetQuantity - baseCurrency.Amount;

    // Round down to observe the lot size
    var lotSize = crypto.SymbolProperties.LotSize;
    quantity = Math.Round(quantity / lotSize) * lotSize;

    if (IsValidOrderSize(crypto, quantity))
    {
        MarketOrder(symbol, quantity);
    }
}

// Brokerages have different order size rules
// Binance considered the minimum volume (price x quantity):
private bool IsValidOrderSize(Crypto crypto, decimal quantity)
{
    return Math.Abs(crypto.Price * quantity) > crypto.SymbolProperties.MinimumOrderSize;
}
```

The preceding example doesn't take into account order fees. You can add a 0.1% buffer to accommodate it.

The following example demonstrates how to form an equal-weighted Crypto portfolio and stay within the cash buffer .

```C#
public override void OnData(Slice data)
{
    var percentage = (1m - Settings.FreePortfolioValuePercentage) / _symbols.Count;
    foreach (var symbol in _symbols)
    {
        SetCryptoHoldings(_symbol, percentage);
    }
}
```

You can replace the `Settings.FreePortfolioValuePercentage` for a class variable (e.g. `_cashBuffer`).

When you place Crypto trades, ensure you have a sufficient balance of the base or quote currency before each trade. If you hold multiple assets and you want to put all of your capital into BTCUSDT, you need to first convert all your non-BTC assets into USDT and then purchase BTCUSDT.

By default, the account currency is USD and your starting cash is $100,000. Some Crypto exchanges don't support fiat currencies, which means you can't convert the 100,000 USD to the pair's quote currency . In this case, set your account currency to the quote currency with a positive quantity.

```C#
SetAccountCurrency("USDT", 1000);   // Set the account currency to Tether and its quantity to 1,000 USDT
```

For a full example of placing crypto trades, see the BasicTemplateCryptoAlgorithm .

Liquidate Positions

If you use the `Liquidate` method to liquidate a Crypto position, it only liquidates the quantity of the virtual pair. Since the virtual pair BTCUSDT may not represent all of your BTC holdings, don't use the `Liquidate` method to liquidate Crypto positions. Instead, calculate the order quantity based on the currency amounts in your cash book and place manual orders. The following code snippet demonstrates how to liquidate a BTCUSDT position.

```C#
public override void OnData(Slice data)
{
    LiquidateCrypto(_symbol);
}

private void LiquidateCrypto(Symbol symbol)
{
    var crypto = Securities[symbol] as Crypto;
    var baseCurrency = crypto.BaseCurrency;

    // Avoid negative amount after liquidate
    var quantity = Math.Min(crypto.Holdings.Quantity, baseCurrency.Amount);

    // Round down to observe the lot size
    var lotSize = crypto.SymbolProperties.LotSize;
    quantity = (Math.Round(quantity / lotSize) - 1) * lotSize;

    if (IsValidOrderSize(crypto, quantity))
    {
        MarketOrder(symbol, -quantity);
    }
}
```

The order fees don't respect the lot size. When you try to liquidate a position, the absolute value of the base currency quantity can be less than the lot size and greater than zero. In this case, your algorithm holds a position that you can't liquidate, yet `Portfolio[symbol].Invested` is `false` . For more information about `Portfolio[symbol].Invested` , see Holdings Status . The following code snippet demonstrates how to determine if you can liquidate a position:

```C#
public override void OnData(Slice data)
{
    var crypto = Securities[_symbol];
    if (Math.Abs(crypto.Holdings.Quantity) > crypto.SymbolProperties.LotSize)
    {
        LiquidateCrypto(_symbol);
    }
}
```

Examples

The following examples demonstrate some common practices for crypto holdings.

Example 1: ETH-BTC Proxy Trading

The following algorithm trades trend-following of the ETHBTC crypto pair using a 20-day EMA indicator. To reduce friction (e.g. slippage), we trade the more liquid and popular BTCUSDT and ETHUSDT pair instead. For example, if ETHBTC is above EMA (uptrend), we sell all BTCUSDT holdings and buy ETHUSDT with the same USDT value, going flat on BTC while holding ETH.

C#

```
public class CryptoHoldingsAlgorithm : QCAlgorithm
{
    private Symbol _btcusdt, _ethusdt, _ethbtc;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetAccountCurrency("USDT", 1000000m);

        // We would like to trade the EMA cross between 2 popular cryptos: BTC & ETH,
        // so request ETHBTC data to find trading opportunities.
        _ethbtc = AddCrypto("ETHBTC", Resolution.Daily, market: Market.Coinbase).Symbol;
        // Trade through BTCUSDT & ETHUSDT, though, since stable coin trades have lower friction costs and higher
liquidity.
        var btcusdt = AddCrypto("BTCUSDT", Resolution.Daily, market: Market.Coinbase);
        var ethusdt = AddCrypto("ETHUSDT", Resolution.Daily, market: Market.Coinbase);
        _btcusdt = btcusdt.Symbol;
        _ethusdt = ethusdt.Symbol;

        // Simulate an account with various crypto cash through holdings.
        btcusdt.Holdings.SetHoldings(btcusdt.Price, 5m);
        btcusdt.BaseCurrency.AddAmount(5m);
        ethusdt.Holdings.SetHoldings(ethusdt.Price, 22.5m);
        ethusdt.BaseCurrency.AddAmount(22.5m);

        // Add automatic updating of the EMA indicator for trend trade signal emission.
        _ema = EMA(_ethbtc, 20, Resolution.Daily);
        // Warm up the indicator for its readiness usage immediately.
        WarmUpIndicator(_ethbtc, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_ethbtc, out var bar) && _ema.IsReady &&
            slice.Bars.TryGetValue(_btcusdt, out var btc) && slice.Bars.TryGetValue(_ethusdt, out var eth))
        {
            var ema = _ema.Current.Value;
            var btcHoldings = Portfolio.CashBook["BTC"].Amount;
            var ethHoldings = Portfolio.CashBook["ETH"].Amount;

            // ETHBTC's current price is higher than EMA, suggesting an uptrend.
            if (bar.Close > ema && !Portfolio[_btcusdt].IsShort)
            {
                // To follow the up trend of ETHBTC, sell ALL BTCUSDT and buy ETHUSDT with the same value.
                if (btcHoldings > 0)
                {
                    var btcValue = btcHoldings * btc.Close;
                    MarketOrder(_btcusdt, -btcHoldings);
                    var ethSize = btcValue / eth.Close;
                    MarketOrder(_ethusdt, ethSize);
                }
            }
            // ETHBTC's current price is below the EMA, suggesting a downtrend.
            else if (bar.Close < ema && !Portfolio[_btcusdt].IsLong)
            {
                // To follow the downtrend of ETHBTC, sell ALL ETHUSDT and buy BTCUSDT with the same value.
                if (ethHoldings > 0)
                {
                    var ethValue = ethHoldings * eth.Close;
                    MarketOrder(_ethusdt, -ethHoldings);
                    var btcSize = ethValue / btc.Close;
                    MarketOrder(_btcusdt, btcSize);
                }
            }
        }
    }
}
```

Option Strategies

Bear Call Spread

Introduction

Bear call spread , also known as short call spread , consists of selling an ITM call and buying an OTM call. Both calls have the same underlying Equity and the same expiration date. The ITM call serves as a hedge for the OTM call. The bear call spread profits from a drop in underlying asset price.

Implementation

Follow these steps to implement the bear call spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(30, 5));
}
```

   The `CallSpread` filter narrows the universe down to just the two contracts you need to form a bear call spread.

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the ITM and OTM contract strike prices from the remaining contracts
    var strikes = calls.Select(x => x.Strike).ToList();
    var otmStrike = strikes.Max();
    var itmStrike = strikes.Min();
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.BearCallSpread` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var optionStrategy = OptionStrategies.BearCallSpread(_symbol, itmStrike, otmStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
var itmCall = calls.Single(x => x.Strike == itmStrike);
var otmCall = calls.Single(x => x.Strike == otmStrike);

var legs = new List<Leg>()
    {
        Leg.Create(itmCall.Symbol, -1),
        Leg.Create(otmCall.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

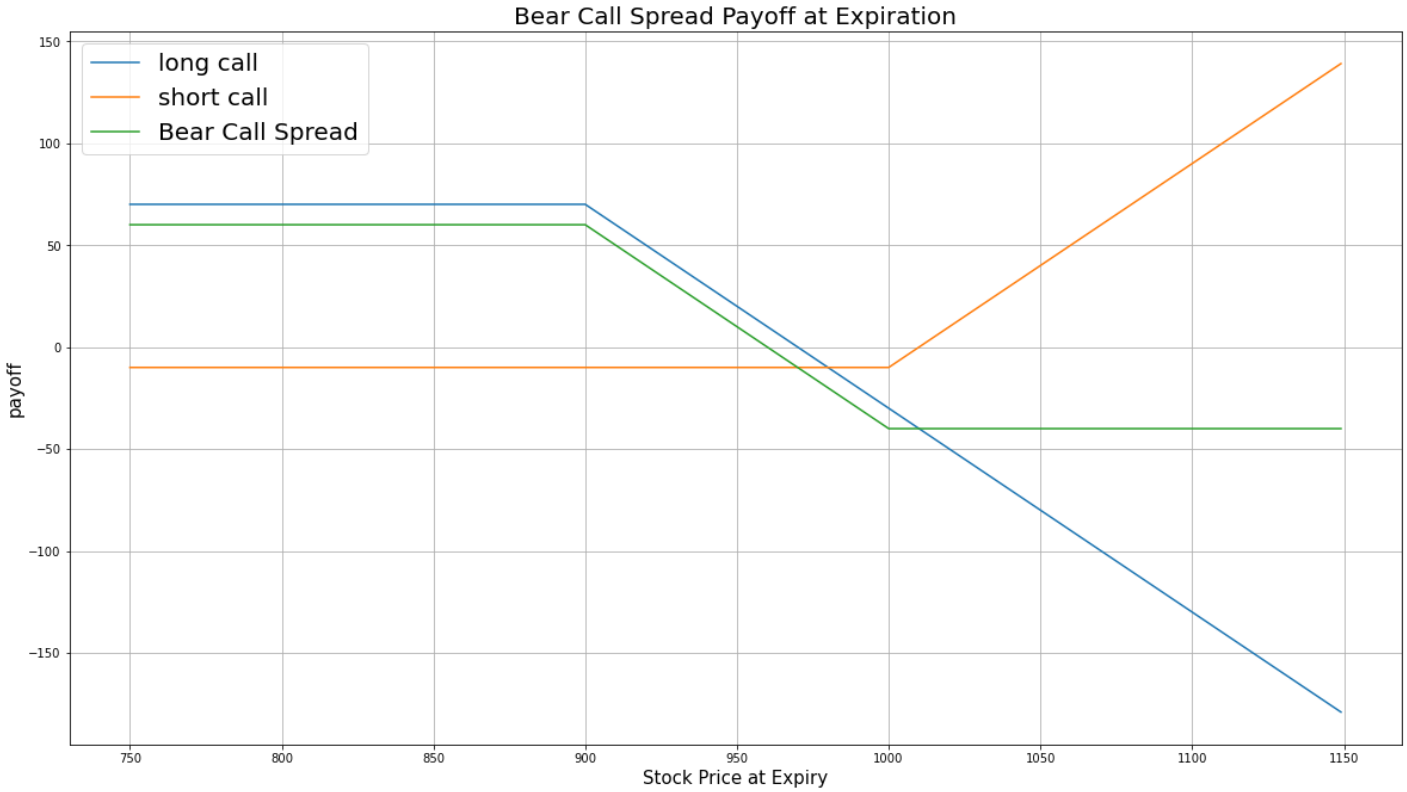
The bear call spread is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
P_T &= (C_T^{OTM} - C_T^{ITM} + C_0^{ITM} - C_0^{OTM}) \times m - fee
\end{aligned}
$$

where

C_T^{OTM}	=	OTM call value at time T
C_T^{ITM}	=	ITM call value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM call strike price
K^{ITM}	=	ITM call strike price
P_T	=	Payout total at time T
C_0^{ITM}	=	ITM call value at position opening (debit paid)
C_0^{OTM}	=	OTM call value at position opening (credit received)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is the net credit you receive from opening the trade, $C_0^{ITM} - C_0^{OTM}$. If the price declines, both calls expire worthless.

The maximum loss is $K^{OTM} - K^{ITM} + C_0^{ITM} - C_0^{OTM}$, which occurs when the underlying price is above the strike prices of both call Option contracts.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
OTM call	26.90	1197.50
ITM call	57.80	1125.00
Underlying Equity at expiration	1078.92	-

Therefore, the payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
&= (1078.92 - 1197.50)^+ \\
&= 0 \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
&= (1078.92 - 1125.00)^+ \\
&= 0 \\
P_T &= (C_T^{OTM} - C_T^{ITM} + C_0^{ITM} - C_0^{OTM}) \times m - fee \\
&= (0 - 0 + 57.80 - 26.90) \times 100 - 1.00 \times 2 \\
&= 3088
\end{aligned}
$$

So, the strategy profits $3,088.

The following algorithm implements a bear call spread Option strategy:

```C#
public class BearCallSpreadExampleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain
        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // Select the ITM and OTM contract
        var orderedCalls = calls.OrderBy(x => x.Strike);
        var itmCall = orderedCalls.First();
        var otmCall = orderedCalls.Last();

        // Place the order
        var optionStrategy = OptionStrategies.BearCallSpread(_symbol, itmCall.Strike, otmCall.Strike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Bear Put Spread

Introduction

Bear put spread , also known as short put spread , consists of buying an ITM put and selling an OTM put. Both puts have the same underlying Equity and the same expiration date. The OTM put serves as a hedge for the ITM put. The bear put spread profits from a decline in underlying asset price.

Implementation

Follow these steps to implement the bear put spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(30, 5));
}
```

   The `PutSpread` filter narrows the universe down to just the two contracts you need to form a bear put spread.

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the put Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the ITM and OTM contract strike prices from the remaining contracts
    var strikes = puts.Select(x => x.Strike).ToList();
    var otmStrike = strikes.Min();
    var itmStrike = strikes.Max();
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.BearPutSpread` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var optionStrategy = OptionStrategies.BearPutSpread(_symbol, itmStrike, otmStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
var itmPut = puts.Single(x => x.Strike == itmStrike);
var otmPut = puts.Single(x => x.Strike == otmStrike);

var legs = new List<Leg>()
    {
        Leg.Create(itmPut.Symbol, 1),
        Leg.Create(otmPut.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

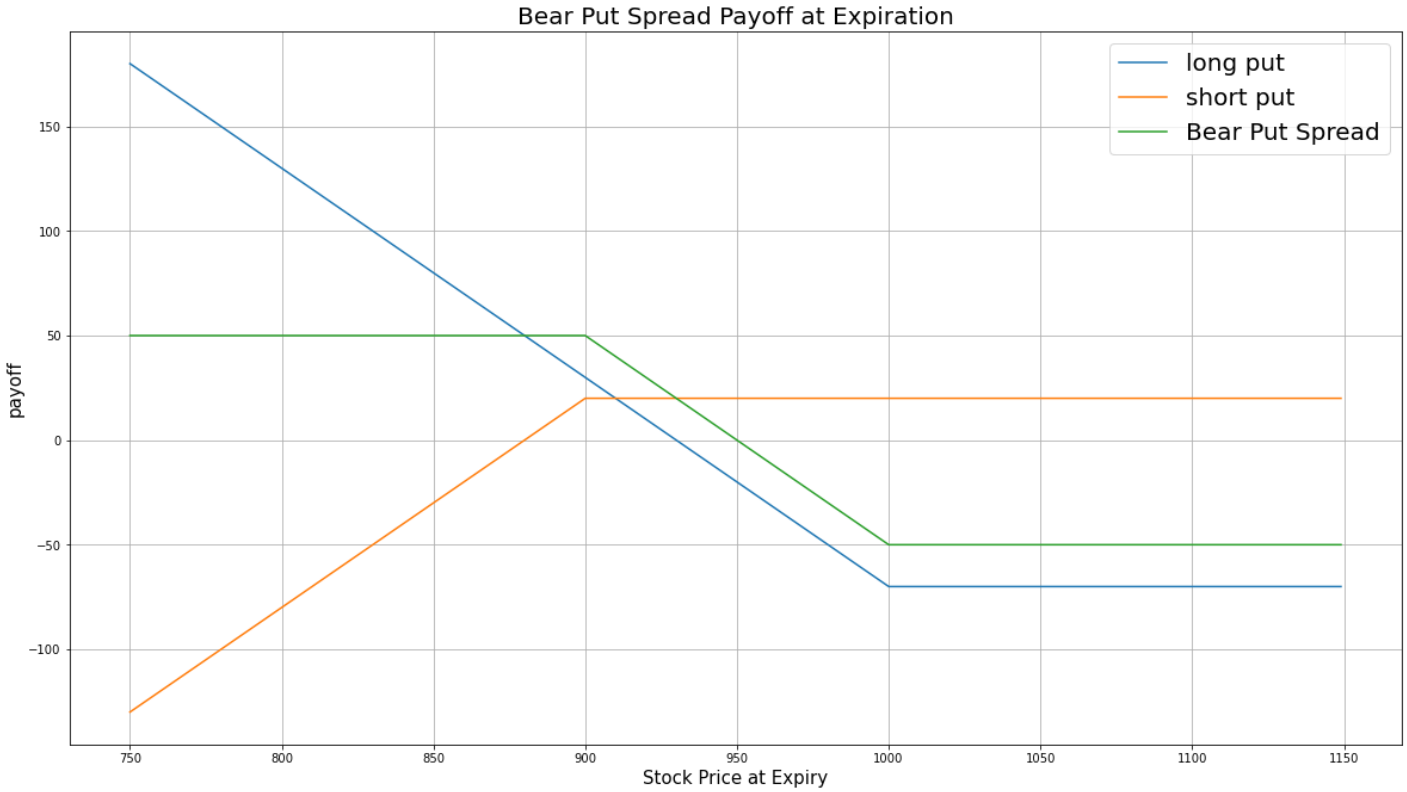
The bear put spread is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
P_T &= (P_T^{ITM} - P_T^{OTM} + P_0^{OTM} - P_0^{ITM}) \times m - fee
\end{aligned}
$$

where

P_T^{OTM}	=	OTM put value at time T
P_T^{ITM}	=	ITM put value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM put strike price
K^{ITM}	=	ITM put strike price
P_T	=	Payout total at time T
P_0^{ITM}	=	ITM put value at position opening (debit paid)
P_0^{OTM}	=	OTM put value at position opening (credit received)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is $K^{ITM} - K^{OTM} + P_0^{OTM} - P_0^{ITM}$. If the underlying price is below than the strike prices of both put Option contracts, they are worth $(K - S_T)$ at expiration.

The maximum loss is the net debit you paid to open the position, $P_0^{OTM} - P_0^{ITM}$.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM put	4.60	767.50
ITM put	40.00	835.00
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
&= (767.50 - 829.08)^+ \\
&= 0 \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
&= (835.00 - 829.08)^+ \\
&= 5.92 \\
P_T &= (P_T^{ITM} - P_T^{OTM} + P_0^{OTM} - P_0^{ITM}) \times m - fee \\
&= (5.92 - 0 + 4.60 - 40.00) \times 100 - 1.00 \times 2 \\
&= -2950
\end{aligned}
$$

So, the strategy loses $2,950.

The following algorithm implements a bear put spread strategy:

```C#
public class BearPutSpreadExampleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain.Count() == 0) return;

        // Get the furthest expiry date of the contracts
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;

        // Select the put Option contracts with the furthest expiry
        var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // Select the ITM and OTM contract strike prices from the remaining contracts
        var putStrikes = puts.Select(x => x.Strike).OrderBy(x => x);
        var itmStrike = putStrikes.Last();
        var otmStrike = putStrikes.First();

        var optionStrategy = OptionStrategies.BearPutSpread(_symbol, itmStrike, otmStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Bull Call Spread

Introduction

Bull call spread , also known as long call spread , consists of buying an ITM call and selling an OTM call. Both calls have the same underlying Equity and the same expiration date. The OTM call serves as a hedge for the ITM call. The bull call spread profits from a rise in underlying asset price.

Implementation

Follow these steps to implement the bull call spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(30, 5));
}
```

   The `CallSpread` filter narrows the universe down to just the two contracts you need to form a bull call spread.

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the ITM and OTM contract strike prices from the remaining contracts
    var strikes = calls.Select(x => x.Strike).ToList();
    var otmStrike = strikes.Max();
    var itmStrike = strikes.Min();
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.BullCallSpread` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var optionStrategy = OptionStrategies.BullCallSpread(_symbol, itmStrike, otmStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var itmCall = calls.Single(x => x.Strike == itmStrike);
var otmCall = calls.Single(x => x.Strike == otmStrike);

var legs = new List<Leg>()
    {
        Leg.Create(itmCall.Symbol, 1),
        Leg.Create(otmCall.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The bull call spread is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
P_T &= (C_T^{ITM} - C_T^{OTM} + C_0^{OTM} - C_0^{ITM}) \times m - fee
\end{aligned}
$$

where C_T^{OTM} = OTM call value at time T

C_T^{ITM} = ITM call value at time T

S_T = Underlying asset price at time T

K^{OTM} = OTM call strike price

K^{ITM} = ITM call strike price

P_T = Payout total at time T

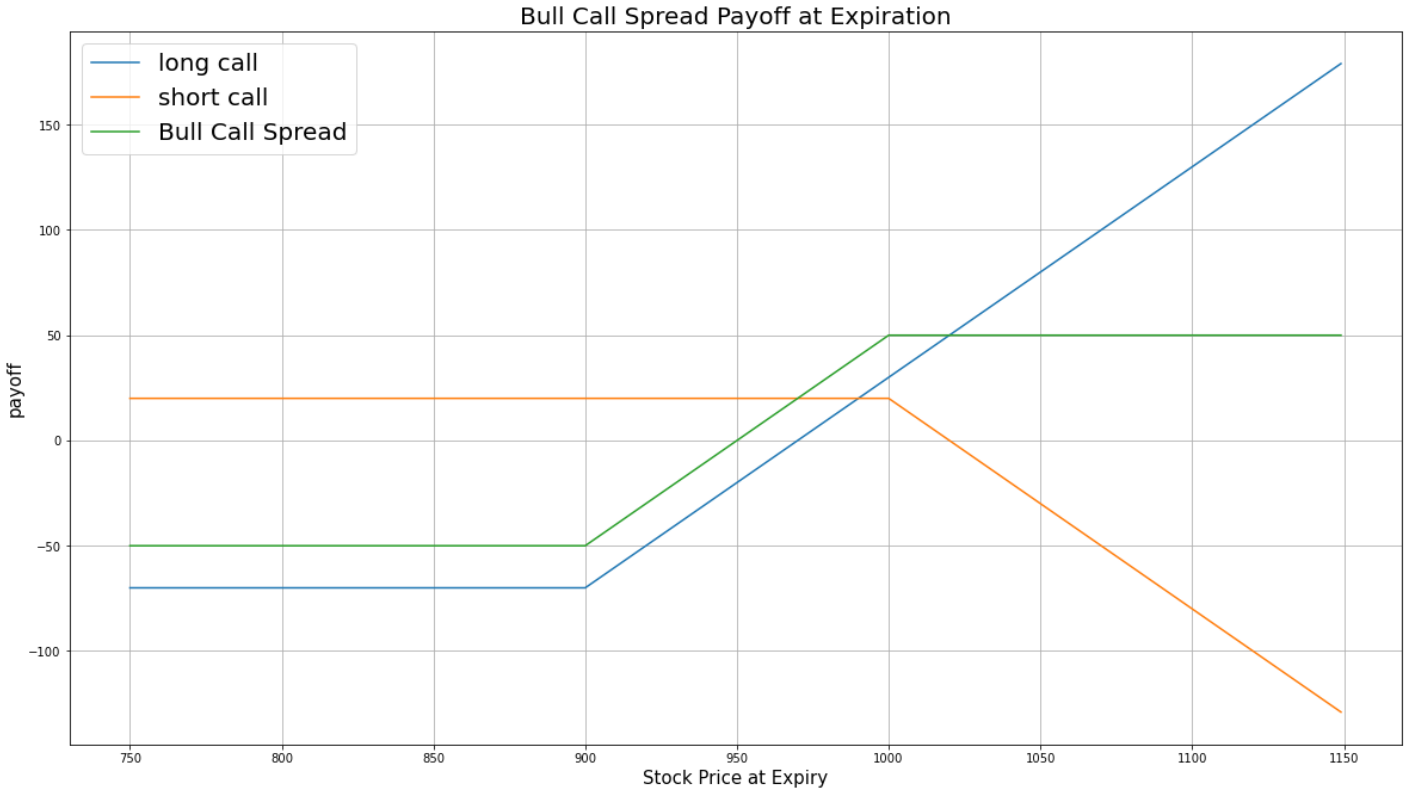
C_0^{ITM} = ITM call value at position opening (debit paid)

C_0^{OTM} = OTM call value at position opening (credit received)

m = Contract multiplier

T = Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is $K^{OTM} - K^{ITM} + C_0^{OTM} - C_0^{ITM}$. If the underlying price increases to exceed both strikes at expiration, both calls are worth $(S_T - K)$ at expiration.

The maximum loss is the net debit you paid to open the position, $C_0^{OTM} - C_0^{ITM}$.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM call	3.00	835.00
ITM call	41.00	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
&= (829.08 - 835.00)^+ \\
&= 0 \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
&= (829.08 - 767.50)^+ \\
&= 61.58 \\
P_T &= (C_T^{ITM} - C_T^{OTM} + C_0^{OTM} - C_0^{ITM}) \times m - fee \\
&= (61.58 - 0 + 3.00 - 41.00) \times 100 - 1.00 \times 2 \\
&= 2356
\end{aligned}
$$

So, the strategy profits $2,356.

The following algorithm implements a bull call spread strategy:

```C#
public class BullCallSpreadExmapleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain.Count() == 0) return;

        // Get the furthest expiration date of the contracts
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;

        // Select the call Option contracts with the furthest expiry
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // Select the ITM and OTM contract strikes from the remaining contracts
        var putStrikes = calls.Select(x => x.Strike).OrderBy(x => x);
        var itmStrike = putStrikes.First();
        var otmStrike = putStrikes.Last();

        var optionStrategy = OptionStrategies.BullCallSpread(_symbol, itmStrike, otmStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Bull Put Spread

Introduction

Bull put spread , also known as long put spread , consists of buying an OTM put and selling an ITM put. Both puts have the same underlying Equity and the same expiration date. The OTM put serves as a hedge for the ITM put. The bull put spread profits from a rise in underlying asset price.

Implementation

Follow these steps to implement the bull put spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(30, 5));
}
```

   The `PutSpread` filter narrows the universe down to just the two contracts you need to form a bull put spread.

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the put Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the ITM and OTM contract strike prices from the remaining contracts
    var strikes = puts.Select(x => x.Strike).ToList();
    var otmStrike = strikes.Min();
    var itmStrike = strikes.Max();
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.BullPutSpread` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var optionStrategy = OptionStrategies.BullPutSpread(_symbol, itmStrike, otmStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
var itmPut = puts.Single(x => x.Strike == itmStrike);
var otmPut = puts.Single(x => x.Strike == otmStrike);

var legs = new List<Leg>()
    {
        Leg.Create(itmPut.Symbol, -1),
        Leg.Create(otmPut.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

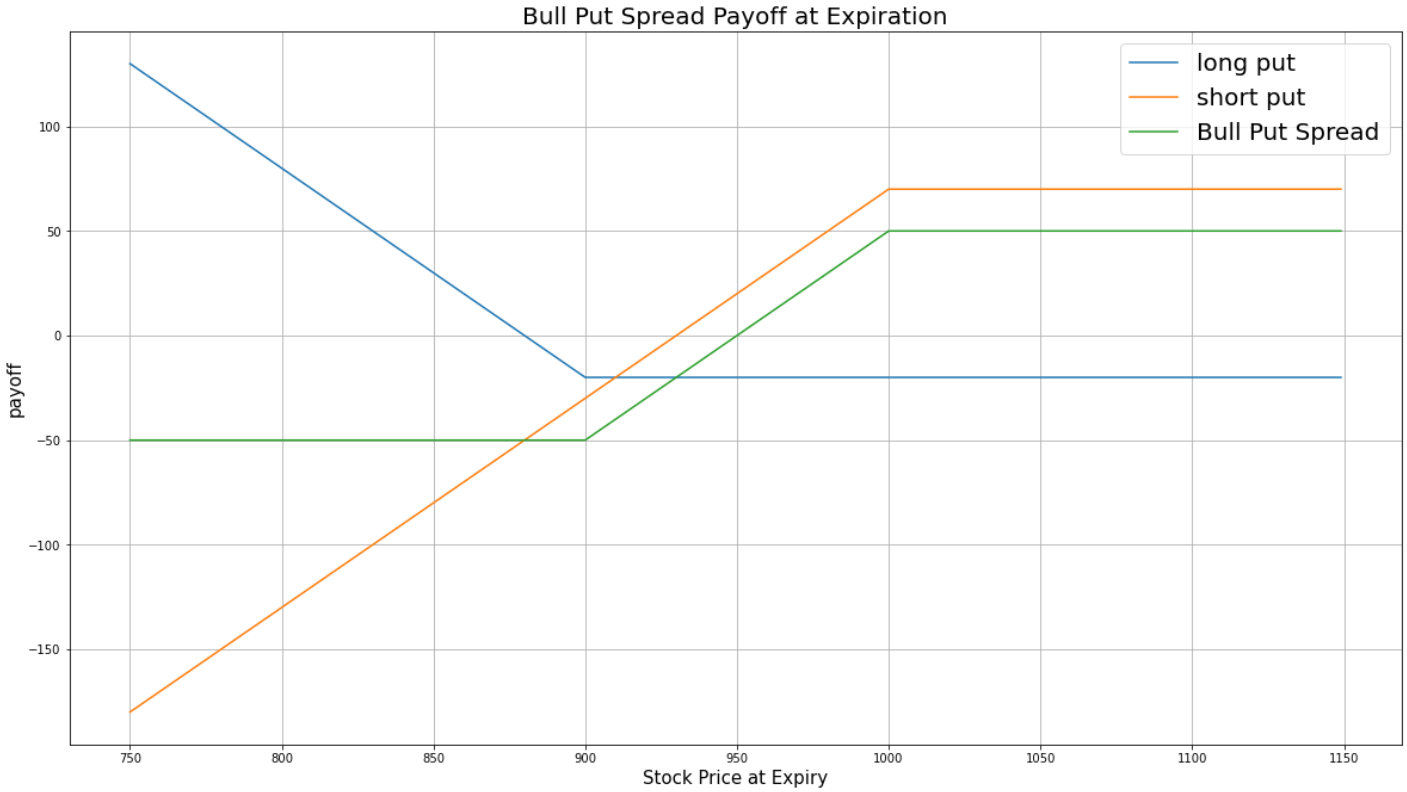
This is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
P_T &= (P_T^{OTM} - P_T^{ITM} + P_0^{ITM} - P_0^{OTM}) \times m - fee
\end{aligned}
$$

where

P_T^{OTM}	=	OTM put value at time T
P_T^{ITM}	=	ITM put value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM put strike price
K^{ITM}	=	ITM put strike price
P_T	=	Payout total at time T
P_0^{ITM}	=	ITM put value at position opening (credit received)
P_0^{OTM}	=	OTM put value at position opening (debit paid)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is the net credit you received when opening the position, $P_0^{ITM} - P_0^{OTM}$. If the underlying price is higher than the strike prices of both put contracts at expiration, both puts expire worthless.

The maximum loss is $K^{OTM} - K^{ITM} + P_0^{ITM} - P_0^{OTM}$.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
OTM put	5.70	767.50
ITM put	35.50	835.00
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
&= (767.50 - 829.08)^+ \\
&= 0 \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
&= (835.00 - 829.08)^+ \\
&= 5.92 \\
P_T &= (P_T^{OTM} - P_T^{ITM} + P_0^{ITM} - P_0^{OTM}) \times m - fee \\
&= (0 - 5.92 + 35.50 - 5.70) \times 100 - 1.00 \times 2 \\
&= 2386
\end{aligned}
$$

So, the strategy profits $2,386.

The following algorithm implements a bull put spread strategy:

```C#
public class BullPutSpreadExmapleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain.Count() == 0) return;

        // Get the furthest expiration date of the contracts
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;

        // Select the put Option contracts with the furthest expiry
        var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // Select the ITM and OTM contract strikes from the remaining contracts
        var putStrikes = puts.Select(x => x.Strike).OrderBy(x => x);
        var itmStrike = putStrikes.Last();
        var otmStrike = putStrikes.First();

        var optionStrategy = OptionStrategies.BullPutSpread(_symbol, itmStrike, otmStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Long Call Butterfly

Introduction

The long call butterfly strategy is the combination of a bull call spread and a bear call spread . In the call butterfly, all of the calls should have the same underlying Equity, the same expiration date, and the same strike price distance between the ITM-ATM and OTM-ATM call pairs. The long call butterfly consists of a long ITM call, a long OTM call, and 2 short ATM calls. This strategy profits from low volatility in the underlying Equity price.

Implementation

Follow these steps to implement the long call butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallButterfly(30, 5));
}
```

   The `CallSpread` filter narrows the universe down to just the three contracts you need to form a long call butterfly.

2. In the `OnData` method, select the contracts of the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x =x> x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the ATM, ITM and OTM contracts from the remaining contracts
    var atmCall = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First();
    var itmCall = calls.OrderBy(x => x.Strike).SkipLast(1).Last();
    var otmCall = calls.Single(x => x.Strike == atmCall.Strike * 2 - itmCall.Strike);
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ButterflyCall` method with the details of each leg and then pass the result to the `Buy` method.

```
var optionStrategy = OptionStrategies.ButterflyCall(_symbol, itmCall.Strike, atmCall.Strike, otmCall.Strike,
expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
var legs = new List<Leg>()
    {
        Leg.Create(atmCall.Symbol, -2),
        Leg.Create(itmCall.Symbol, 1),
        Leg.Create(otmCall.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

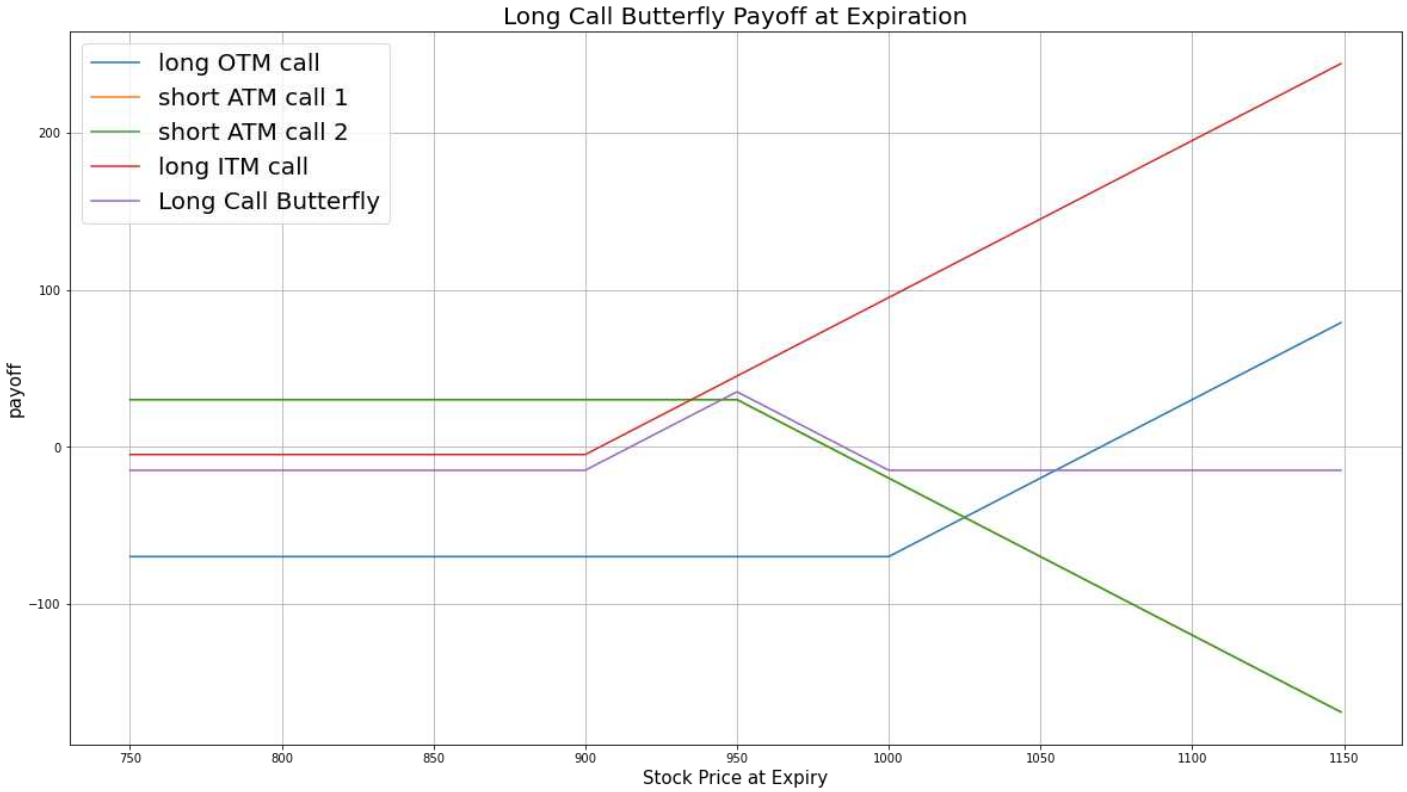
The long call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
C_T^{ATM} &= (S_T - K^{ATM})^+ \\
P_T &= (C_T^{OTM} + C_T^{ITM} - 2 \times C_T^{ATM} + 2 \times C_0^{ATM} - C_0^{ITM} - C_0^{OTM}) \times m - fee
\end{aligned}
$$

where

C_T^{OTM}	=	OTM call value at time T
C_T^{ITM}	=	ITM call value at time T
C_T^{ATM}	=	ATM call value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM call strike price
K^{ITM}	=	ITM call strike price
K^{ATM}	=	ATM call strike price
P_T	=	Payout total at time T
C_0^{ITM}	=	ITM call value at position opening (debit paid)
C_0^{OTM}	=	OTM call value at position opening (debit paid)
C_0^{ATM}	=	OTM call value at position opening (credit received)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is $K^{ATM} - K^{ITM} + 2 \times C_0^{ATM} - C_0^{ITM} - C_0^{OTM}$. It occurs when the underlying price is the same price at expiration as it was when opening the position and the payouts of the bull and bear call spreads are at their maximum.

The maximum loss is the net debit paid: $2 \times C_0^{ATM} - C_0^{ITM} - C_0^{OTM}$. It occurs when the underlying price is less than ITM strike or greater than OTM strike at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the long call butterfly:

Asset	**Price ($)**	**Strike ($)**
OTM call	4.90	767.50
ATM call	15.00	800.00
ITM call	41.00	832.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
&= (767.50 - 829.08)^+ \\
&= 0 \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
&= (832.50 - 829.08)^+ \\
&= 3.42 \\
C_T^{ATM} &= (S_T - K^{ATM})^+ \\
&= (800.00 - 829.08)^+ \\
&= 0 \\
P_T &= (C_T^{OTM} + C_T^{ITM} - 2 \times C_T^{ATM} + 2 \times C_0^{ATM} - C_0^{ITM} - C_0^{OTM}) \times m - fee \\
&= (0 + 3.42 - 0 \times 2 - 4.90 - 41.00 + 15.00 \times 2) \times 100 - 1.00 \times 4 \\
&= -1252
\end{aligned}
$$

So, the strategy loses $1,252.

The following algorithm implements a long call butterfly Option strategy:

```C#
public class BearPutSpreadStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallButterfly(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // sorted the optionchain by expiration date and choose the furthest date
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;

        // filter the call options from the contracts which expire on the furthest expiration date in the option
chain.
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // sort the call options with the same expiration date according to their strike price.
        var callStrikes = calls.Select(x => x.Strike).OrderBy(x => x);

        // get at-the-money strike
        var atmStrike = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        // Get the lower value as the spread distance as equidistance is needed for both side.
        var spread = Math.Min(Math.Abs(callStrikes.First() - atmStrike), Math.Abs(callStrikes.Last() - atmStrike));

        // select the strike prices for forming the option legs
        var itmStrike = atmStrike - spread;
        var otmStrike = atmStrike + spread;

        var optionStrategy = OptionStrategies.CallButterfly(_symbol, otmStrike, atmStrike, itmStrike, expiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);    // if long call butterfly
        //Sell(optionStrategy, 1);   // if short call butterfly
    }
}
```

Option Strategies

Short Call Butterfly

Introduction

The short call butterfly strategy is the combination of a bull call spread and a bear call spread . In the call butterfly, all of the calls should have the same underlying Equity, the same expiration date, and the same strike price distance between the ITM-ATM and OTM-ATM call pairs. The short call butterfly consists of a short ITM call, a short OTM call, and 2 long ATM calls. This strategy profits from high volatility in the underlying Equity price.

Implementation

Follow these steps to implement the short call butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallButterfly(30, 5));
}
```

   The `CallButterfly` filter narrows the universe down to just the three contracts you need to form a short call butterfly.

2. In the `OnData` method, select the contracts of the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x =x> x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the ATM, ITM and OTM contracts from the remaining contracts
    var atmCall = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First();
    var itmCall = calls.OrderBy(x => x.Strike).Skip(1).First();
    var otmCall = calls.Single(x => x.Strike == atmCall.Strike * 2 - itmCall.Strike);
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ShortButterflyCall` method with the details of each leg and then pass the result to the `Buy` method.

```
var optionStrategy = OptionStrategies.ShortButterflyCall(_symbol, otmCall.Strike, atmCall.Strike,
itmCall.Strike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
var legs = new List<Leg>()
    {
        Leg.Create(atmCall.Symbol, 2),
        Leg.Create(itmCall.Symbol, -1),
        Leg.Create(otmCall.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Strategy Payoff

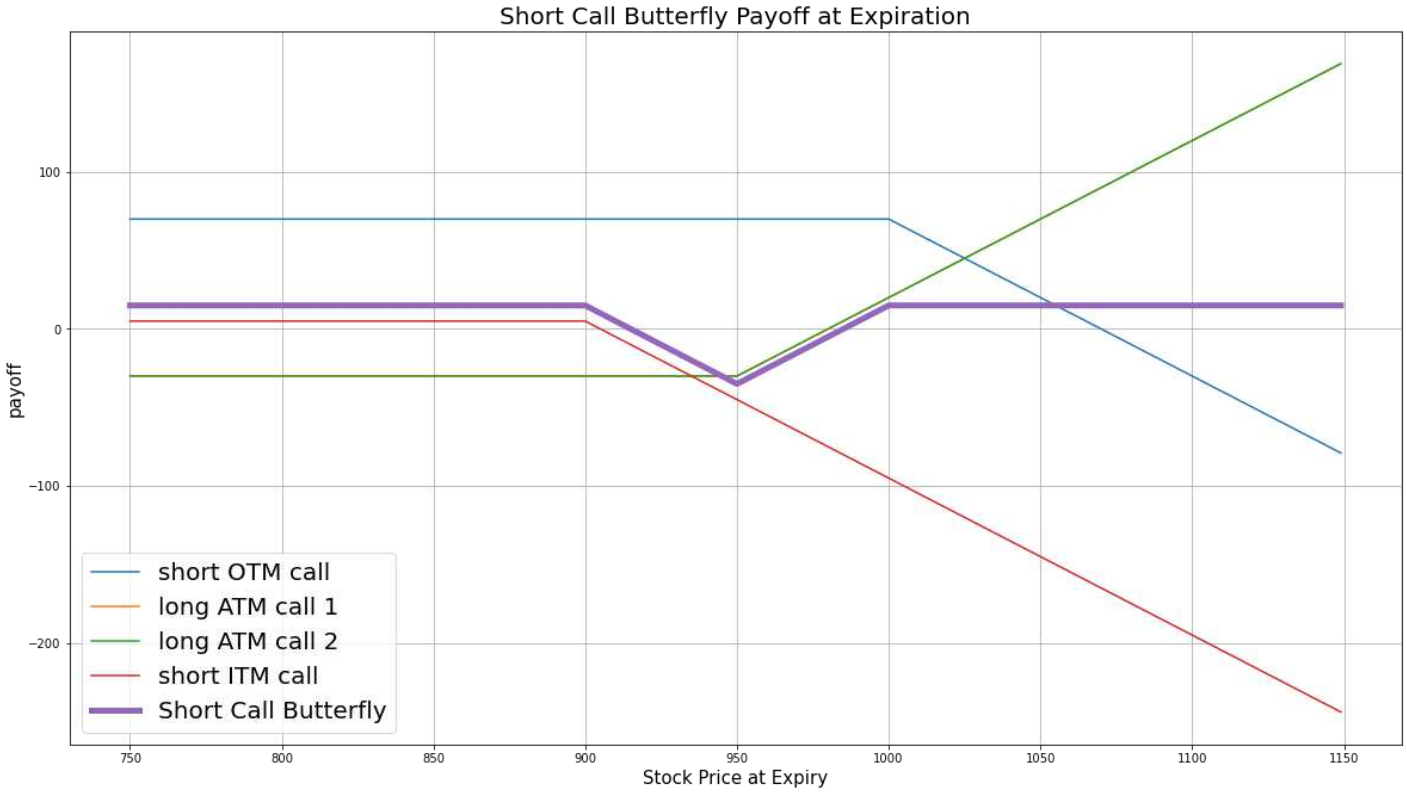
The short call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
C_T^{ATM} &= (S_T - K^{ATM})^+ \\
P_T &= (2 \times C_T^{ATM} - C_T^{OTM} - C_T^{ITM} - 2 \times C_0^{ATM} + C_0^{ITM} + C_0^{OTM}) \times m - fee
\end{aligned}
$$

where

C_T^{OTM}	=	OTM call value at time T
C_T^{ITM}	=	ITM call value at time T
C_T^{ATM}	=	ATM call value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM call strike price
K^{ITM}	=	ITM call strike price
K^{ATM}	=	ATM call strike price
P_T	=	Payout total at time T
C_0^{ITM}	=	ITM call value at position opening (credit received)
C_0^{OTM}	=	OTM call value at position opening (credit received)
C_0^{ATM}	=	ATM call value at position opening (debit paid)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is the net credit received: $C_0^{ITM} + C_0^{OTM} - 2 \times C_0^{ATM}$. It occurs when the underlying price is less than ITM strike or greater than OTM strike at expiration.

The maximum loss is $K^{ATM} - K^{ITM} + C_0^{ITM} + C_0^{OTM} - 2 \times C_0^{ATM}$. It occurs when the underlying price is at the same level as when you opened the trade.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the short call butterfly:

Asset	**Price ($)**	**Strike ($)**
OTM call	4.90	767.50
ATM call	15.00	800.00
ITM call	41.00	832.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
C_T^{OTM} &= (S_T - K^{OTM})^+ \\
&= (767.50 - 829.08)^+ \\
&= 0 \\
C_T^{ITM} &= (S_T - K^{ITM})^+ \\
&= (832.50 - 829.08)^+ \\
&= 3.42 \\
C_T^{ATM} &= (S_T - K^{ATM})^+ \\
&= (800.00 - 829.08)^+ \\
&= 0 \\
P_T &= (-C_T^{OTM} - C_T^{ITM} + 2 \times C_T^{ATM} - 2 \times C_0^{ATM} + C_0^{ITM} + C_0^{OTM}) \times m - fee \\
&= (-0 - 3.42 + 0 \times 2 + 4.90 + 41.00 - 15.00 \times 2) \times 100 - 1.00 \times 4 \\
&= -1252
\end{aligned}
$$

So, the strategy gains $1,244.

The following algorithm implements a short call butterfly Option strategy:

```C#
public class BearPutSpreadStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallButterfly(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // sorted the optionchain by expiration date and choose the furthest date
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;

        // filter the call options from the contracts which expire on the furthest expiration date in the option
chain.
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // sort the call options with the same expiration date according to their strike price.
        var callStrikes = calls.Select(x => x.Strike).OrderBy(x => x);

        // get at-the-money strike
        var atmStrike = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        // Get the lower value as the spread distance as equidistance is needed for both side.
        var spread = Math.Min(Math.Abs(callStrikes.First() - atmStrike), Math.Abs(callStrikes.Last() - atmStrike));

        // select the strike prices for forming the option legs
        var itmStrike = atmStrike - spread;
        var otmStrike = atmStrike + spread;

        var optionStrategy = OptionStrategies.ShortButterflyCall(_symbol, otmStrike, atmStrike, itmStrike, expiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);
    }
}
```

LongAndShortButterflyCallStrategiesAlgorithm.cs C#

Option Strategies

Long Put Butterfly

Introduction

Long Put butterfly is the combination of a bull put spread and a bear put spread . In this strategy, all the puts have the same underlying stock, the same expiration date, and the strike price distance of ITM-ATM and OTM-ATM put pairs are the same. The long put butterfly strategy consists of buying an ITM put, buying an OTM put, and selling 2 ATM puts. This strategy profits from low volatility.

Implementation

Follow these steps to implement the long put butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutButterfly(30, 5));
}
```

   The `PutButterfly` filter narrows the universe down to just the three contracts you need to form a long put butterfly.

2. In the `OnData` method, select the contracts of the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x =x> x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the ATM, ITM and OTM contracts from the remaining contracts
    var atmPut = puts.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First();
    var itmPut = puts.OrderBy(x => x.Strike).SkipLast(1).Last();
    var otmPut = puts.Single(x => x.Strike == atmPut.Strike * 2 - itmPut.Strike);
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ButterflyPut` method with the details of each leg and then pass the result to the `Buy` method.

```
var optionStrategy = OptionStrategies.ButterflyPut(_symbol, itmPut.Strike, atmPut.Strike, otmPut.Strike,
expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
var legs = new List<Leg>()
    {
        Leg.Create(atmPut.Symbol, -2),
        Leg.Create(itmPut.Symbol, 1),
        Leg.Create(otmPut.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

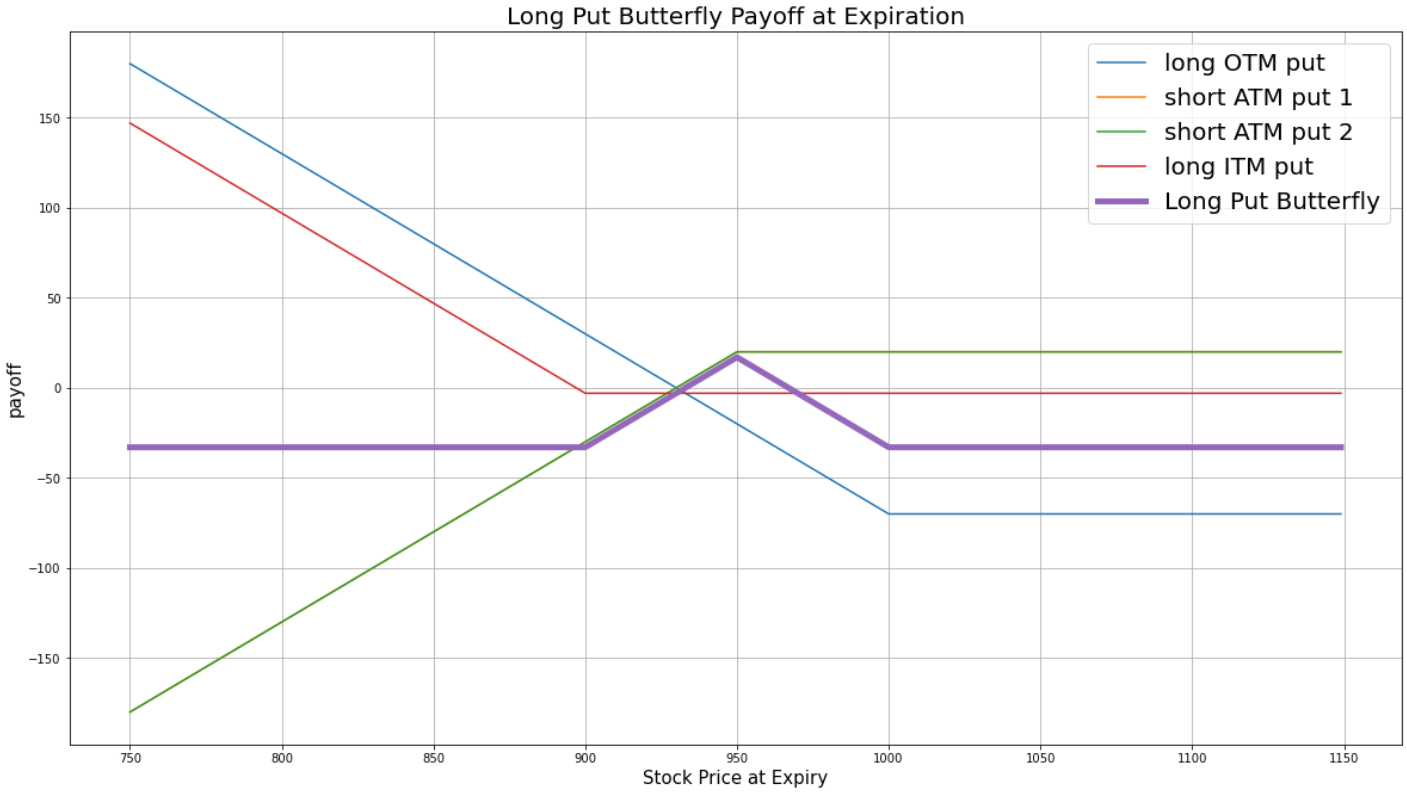
The long put butterfly is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
P_T^{ATM} &= (K^{ATM} - S_T)^+ \\
P_T &= (P_T^{OTM} + P_T^{ITM} - 2 \times P_T^{ATM} + 2 \times P_0^{ATM} - P_0^{ITM} - P_0^{OTM}) \times m - fee
\end{aligned}
$$

where

P_T^{OTM}	=	OTM put value at time T
P_T^{ITM}	=	ITM put value at time T
P_T^{ATM}	=	ATM put value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM put strike price
K^{ITM}	=	ITM put strike price
K^{ATM}	=	ATM put strike price
P_T	=	Payout total at time T
P_0^{ITM}	=	ITM put value at position opening (debit paid)
P_0^{OTM}	=	OTM put value at position opening (debit paid)
P_0^{ATM}	=	ATM put value at position opening (credit received)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is $K^{ATM} - K^{OTM} + 2 \times P_0^{ATM} - P_0^{ITM} - P_0^{OTM}$. It occurs when the underlying price is the same at expiration as it was when you open the trade. In this case, the payout of the combined bull put and bear put spreads are at their maximum.

The maximum loss is the net debit paid, $2 \times P_0^{ATM} - P_0^{ITM} - P_0^{OTM}$. It occurs when the underlying price is below the ITM strike price or above the OTM strike price at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the long put butterfly algorithm:

Asset	**Price ($)**	**Strike ($)**
ITM put	37.80	832.50
ATM put	14.70	800.00
OTM put	5.70	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
&= (829.08 - 832.50)^+ \\
&= 0 \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
&= (829.08 - 767.50)^+ \\
&= 61.58 \\
P_T^{ATM} &= (K^{ATM} - S_T)^+ \\
&= (829.08 - 800.00)^+ \\
&= 29.08 \\
P_T &= (P_T^{OTM} + P_T^{ITM} - 2 \times P_T^{ATM} + 2 \times P_0^{ATM} - P_0^{ITM} - P_0^{OTM}) \times m - fee \\
&= (61.58 + 0 - 29.08 \times 2 - 5.70 - 37.80 + 14.70 \times 2) \times 100 - 1.00 \times 4 \\
&= -1072
\end{aligned}
$$

So, the strategy loses $1,072.

The following algorithm implements a long put butterfly Option strategy:

C#

```
public class BearPutSpreadStrategy : QCAlgorithm
{
    private Symbol _equity;
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _equity = AddEquity("GOOG", Resolution.Minute).Symbol;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutButterfly(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // sorted the optionchain by expiration date and choose the furthest date
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;

        // filter the put options from the contracts which expire on the furthest expiration date in the option
chain.
        var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // sort the put options with the same expiration date according to their strike price.
        var putStrikes = puts.Select(x => x.Strike).OrderBy(x => x);

        // get at-the-money strike
        var atmStrike = puts.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        // Get the lower value as the spread distance as equidistance is needed for both side.
        var spread = Math.Min(Math.Abs(putStrikes.First() - atmStrike), Math.Abs(putStrikes.Last() - atmStrike));

        // select the strike prices for forming the option legs
        var itmStrike = atmStrike + spread;
        var otmStrike = atmStrike - spread;

        var optionStrategy = OptionStrategies.PutButterfly(_symbol, itmStrike, atmStrike, otmStrike, expiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);    // if long put butterfly
        //Sell(optionStrategy, 1);   // if short put butterfly
    }
}
```

Option Strategies

Short Put Butterfly

Introduction

Short Put butterfly is the combination of a bull put spread and a bear put spread . In this strategy, all the puts have the same underlying stock, the same expiration date, and the strike price distance of ITM-ATM and OTM-ATM put pairs are the same. The short put butterfly strategy consists of selling an ITM put, selling an OTM put, and buying 2 ATM puts. This strategy profits from a drastic change in underlying price.

Implementation

Follow these steps to implement the short put butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutButterfly(30, 5));
}
```

   The `PutButterfly` filter narrows the universe down to just the three contracts you need to form a short put butterfly.

2. In the `OnData` method, select the contracts of the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x =x> x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the ATM, ITM and OTM contracts from the remaining contracts
    var atmPut = puts.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First();
    var itmPut = puts.OrderBy(x => x.Strike).SkipLast(1).Last();
    var otmPut = puts.Single(x => x.Strike == atmPut.Strike * 2 - itmPut.Strike);
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ShortButterflyPut` method with the details of each leg and then pass the result to the `Buy` method.

```
var optionStrategy = OptionStrategies.ShortButterflyPut(_symbol, itmPut.Strike, atmPut.Strike, otmPut.Strike,
expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
var legs = new List<Leg>()
    {
        Leg.Create(atmPut.Symbol, 2),
        Leg.Create(itmPut.Symbol, -1),
        Leg.Create(otmPut.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

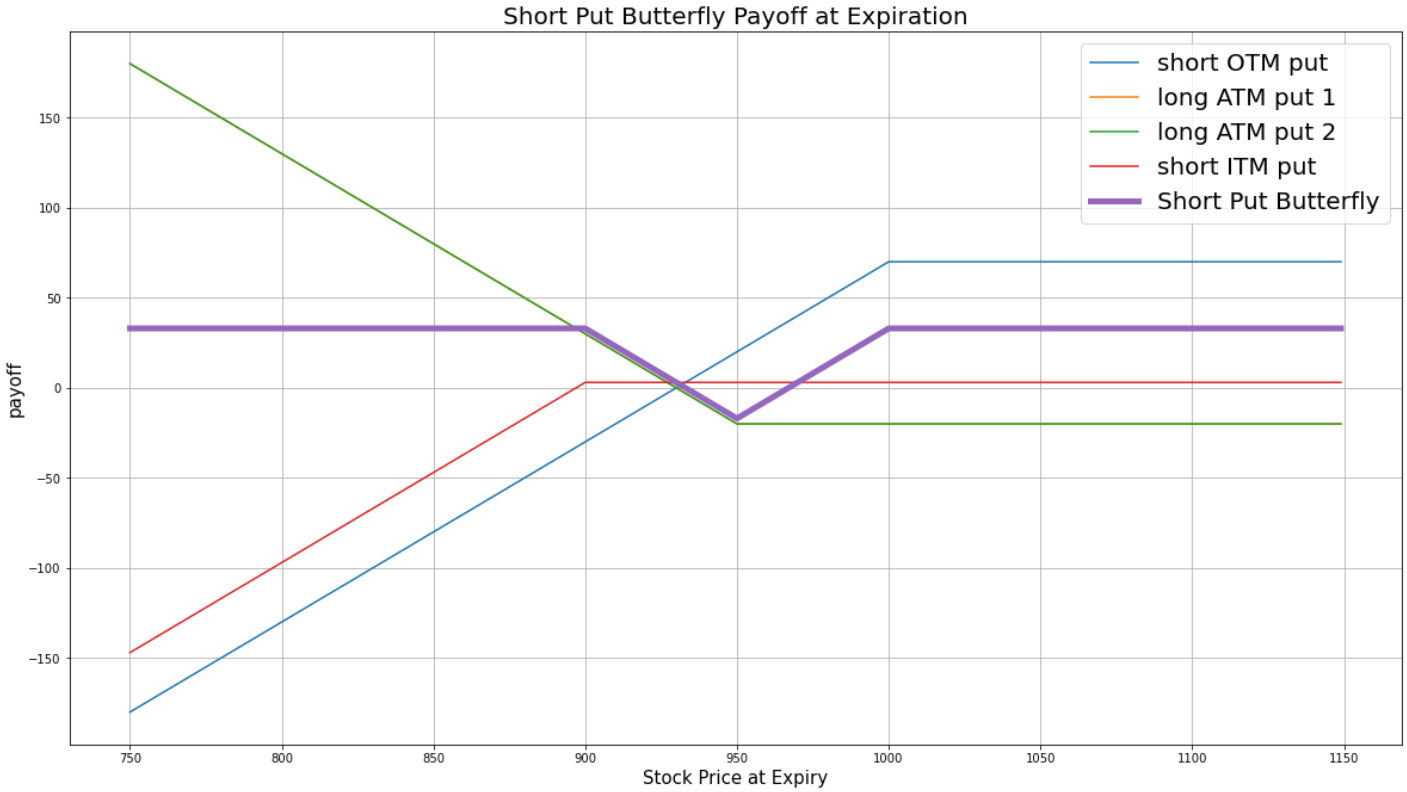
The short put butterfly is a limited-reward-limited-risk strategy. The payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
P_T^{ATM} &= (K^{ATM} - S_T)^+ \\
P_T &= (2 \times P_T^{ATM} - P_T^{OTM} - P_T^{ITM} - 2 \times P_0^{ATM} + P_0^{ITM} + P_0^{OTM}) \times m - fee
\end{aligned}
$$

where

P_T^{OTM}	=	OTM put value at time T
P_T^{ITM}	=	ITM put value at time T
P_T^{ATM}	=	ATM put value at time T
S_T	=	Underlying asset price at time T
K^{OTM}	=	OTM put strike price
K^{ITM}	=	ITM put strike price
K^{ATM}	=	ATM put strike price
P_T	=	Payout total at time T
P_0^{ITM}	=	ITM put value at position opening (credit received)
P_0^{OTM}	=	OTM put value at position opening (credit received)
P_0^{ATM}	=	ATM put value at position opening (debit paid)
m	=	Contract multiplier
T	=	Time of expiration

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $P_0^{ITM} + P_0^{OTM} - 2 \times P_0^{ATM}$. It occurs when the underlying price is below the ITM strike or above the OTM strike at expiration.

The maximum loss is $K^{ATM} - K^{OTM} - 2 \times P_0^{ATM} + P_0^{ITM} + P_0^{OTM}$. It occurs when the underlying price at expiration is at the same price as when you opened the trade.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the short put butterfly algorithm:

Asset	**Price ($)**	**Strike ($)**
ITM put	37.80	832.50
ATM put	14.70	800.00
OTM put	5.70	767.50
Underlying Equity at expiration	829.08	-

Therefore, the payoff is

$$
\begin{aligned}
P_T^{OTM} &= (K^{OTM} - S_T)^+ \\
&= (829.08 - 832.50)^+ \\
&= 0 \\
P_T^{ITM} &= (K^{ITM} - S_T)^+ \\
&= (829.08 - 767.50)^+ \\
&= 61.58 \\
P_T^{ATM} &= (K^{ATM} - S_T)^+ \\
&= (829.08 - 800.00)^+ \\
&= 29.08 \\
P_T &= (-P_T^{OTM} - P_T^{ITM} + 2 \times P_T^{ATM} - 2 \times P_0^{ATM} + P_0^{ITM} + P_0^{OTM}) \times m - fee \\
&= (-61.58 - 0 + 29.08 \times 2 + 5.70 + 37.80 - 14.70 \times 2) \times 100 - 1.00 \times 4 \\
&= 1064
\end{aligned}
$$

So, the strategy gains $1,064.

The following algorithm implements a short put butterfly Option strategy:

```C#
public class BearPutSpreadStrategy : QCAlgorithm
{
    private Symbol _equity;
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _equity = AddEquity("GOOG", Resolution.Minute).Symbol;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutButterfly(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // sorted the optionchain by expiration date and choose the furthest date
        var expiry = chain.OrderByDescending(x => x.Expiry).First().Expiry;

        // filter the put options from the contracts which expire on the furthest expiration date in the option
chain.
        var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // sort the put options with the same expiration date according to their strike price.
        var putStrikes = puts.Select(x => x.Strike).OrderBy(x => x);

        // get at-the-money strike
        var atmStrike = puts.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // Get the distance between lowest strike price and ATM strike, and highest strike price and ATM strike.
        // Get the lower value as the spread distance as equidistance is needed for both side.
        var spread = Math.Min(Math.Abs(putStrikes.First() - atmStrike), Math.Abs(putStrikes.Last() - atmStrike));

        // select the strike prices for forming the option legs
        var itmStrike = atmStrike + spread;
        var otmStrike = atmStrike - spread;

        var optionStrategy = OptionStrategies.ShortButterflyPut(_symbol, itmStrike, atmStrike, otmStrike, expiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);
    }
}
```

Demonstration Algorithm
LongAndShortButterflyPutStrategiesAlgorithm.cs C#

Option Strategies

Long Call Calendar Spread

Introduction

Long call calendar spread , also known as call horizontal spread , is a combination of a longer-term (far-leg/front-month) call and a shorter-term (near-leg/back-month) call, where all calls have the same underlying stock and the same strike price. The long call calendar spread consists of buying a longer-term call and selling a shorter-term call. This strategy profits from a decrease in the underlying price. It also profits from the time decay value because the theta θ (the Option price decay by 1 day closer to maturity) of the shorter-term call is larger than longer-term call.

Implementation

Follow these steps to implement the long call calendar spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallCalendarSpread(0, 30, 60));
}
```

   The `CallCalendarSpread` filter narrows the universe down to just the two contracts you need to form a long call calendar spread.

2. In the `OnData` method, select the strike price and expiration dates of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Get the ATM strike
    var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

    // Select the ATM call Option contracts
    var calls = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the near and far expiry contracts
    var expiries = calls.Select(x => x.Expiry).ToList();
    var nearExpiry = expiries.Min();
    var farExpiry = expiries.Max();
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.CallCalendarSpread` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var optionStrategy = OptionStrategies.CallCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
var nearExpiryCall = calls.Single(x => x.Expiry == nearExpiry);
var farExpiryCall = calls.Single(x => x.Expiry == farExpiry);

var legs = new List<Leg>()
    {
        Leg.Create(nearExpiryCall.Symbol, -1),
        Leg.Create(farExpiryCall.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

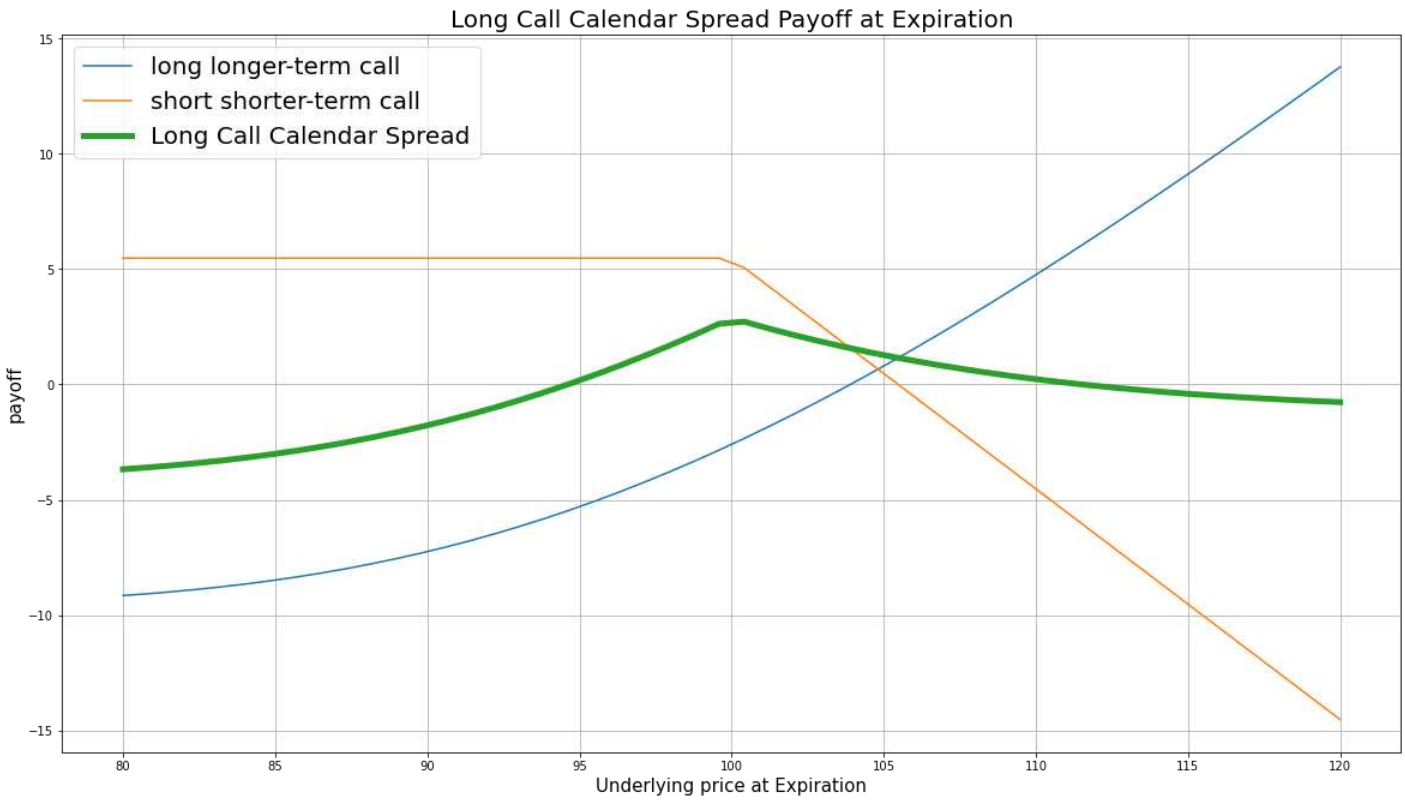
Strategy Payoff

The long call calendar spread is a limited-reward-limited-risk strategy. The payoff at the shorter-term expiration is

$$
\begin{aligned}
C_T^{\text{short-term}} &= (S_T - K)^+ \\
P_T &= (C_T^{\text{long-term}} - C_T^{\text{short-term}} + C_0^{\text{short-term}} - C_0^{\text{long-term}}) \times m - fee
\end{aligned}
$$

\begin{array}{rcll} \textrm{where} & C^{\textrm{short-term}}_T & = & \textrm{Shorter term call value at time T}\\ & C^{\textrm{long-term}}_T & = & \textrm{Longer term call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{\textrm{short-term}}_0 & = & \textrm{Shorter term call value at position opening (credit received)}\\ & C^{\textrm{long-term}}_0 & = & \textrm{Longer term call value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term call expiration} \end{array}

The following chart shows the payoff at expiration:



The maximum profit is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the calls are at their maximum.

The maximum loss is the net debit paid, $C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both calls are close to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell. If the buyer exercises the call you sell, you could lose all the debit you received if you don't close the long call and the underlying price drops below the long call strike price.

Example

The following table shows the price details of the assets in the long call calendar spread:

Asset	**Price ($)**	**Strike ($)**
Longer-term call at the start of the trade	4.40	835.00
Shorter-term call at the start of the trade	36.80	767.50
Longer-term call at time T	31.35	835.00
Underlying Equity at time T	829.08	-

Therefore, the payoff at time T (the expiration of the short-term call) is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ & = & (828.07-800.00)^{+}\\ & = & 28.07\\ P_T & = & (C^{\textrm{long-term}}_T - C^{\textrm{short-term}}_T + C^{\textrm{short-term}}_0 - C^{\textrm{long-term}}_0)\times m - fee\\ & = & (31.35-28.07+11.30-20.00)\times100-1.00\times2\\ & = & -544 \end{array}$$

So, the strategy loses $544.

The following algorithm implements a long call calendar spread Option strategy:

```C#
public class BearPutSpreadStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallCalendarSpread(0, 30, 60));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // get at-the-money strike
        var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // filter the call options from the contracts which is ATM in the option chain.
        var calls = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // sorted the optionchain by expiration date
        var expiries = calls.Select(x => x.Expiry).OrderBy(x => x);

        // select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        var nearExpiry = expiries.First();
        var farExpiry = expiries.Last();

        var optionStrategy = OptionStrategies.CallCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);        // if long call calendar spread
        //Sell(optionStrategy, 1);     // if short call calendar spread
    }
}
```

Option Strategies

Short Call Calendar Spread

Introduction

Call calendar spread , also known as call horizontal spread , is a combination of a longer-term (far-leg/front-month) call and a shorter-term (near-leg/back-month) call, where all calls have the same underlying stock and the same strike price. The short call calendar spread consists of selling a longer-term call and buying a shorter-term call. The strategy profits from from an increase in the underlying price.

Implementation

Follow these steps to implement the short call calendar spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallCalendarSpread(0, 30, 60));
}
```

   The `CallCalendarSpread` filter narrows the universe down to just the two contracts you need to form a short call calendar spread.

2. In the `OnData` method, select the strike price and expiration dates of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Get the ATM strike
    var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

    // Select the ATM call Option contracts
    var calls = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the near and far expiry contracts
    var expiries = calls.Select(x => x.Expiry).ToList();
    var nearExpiry = expiries.Min();
    var farExpiry = expiries.Max();
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.ShortCallCalendarSpread` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var optionStrategy = OptionStrategies.ShortCallCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var nearExpiryCall = calls.Single(x => x.Expiry == nearExpiry);
var farExpiryCall = calls.Single(x => x.Expiry == farExpiry);

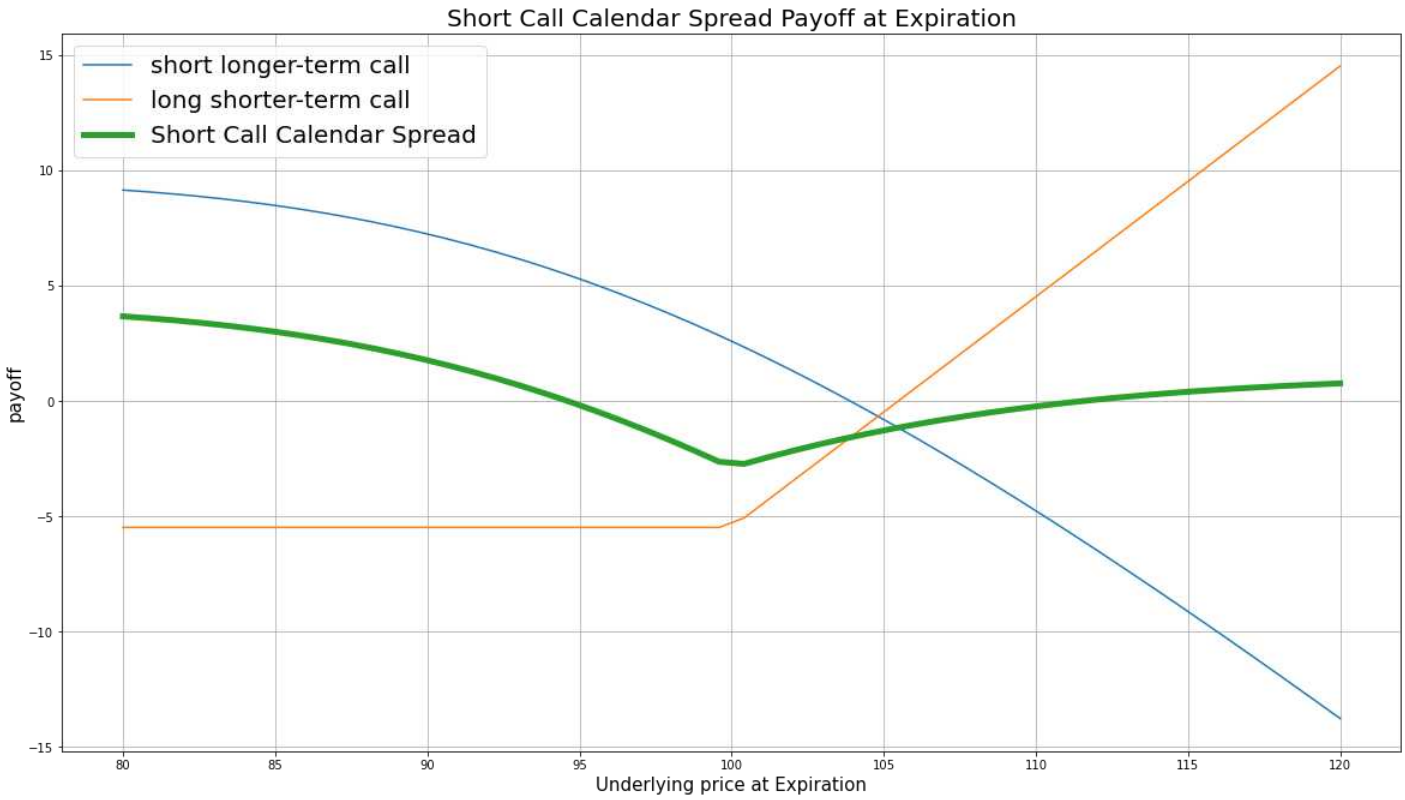
var legs = new List<Leg>()
    {
        Leg.Create(nearExpiryCall.Symbol, 1),
        Leg.Create(farExpiryCall.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The short call calendar spread is a limited-reward-limited-risk strategy. The payoff at the shorter-term expiration is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ P_T & = & (C^{\textrm{short-term}}_T - C^{\textrm{long-term}}_T + C^{\textrm{long-term}}_0 - C^{\textrm{short-term}}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{\textrm{short-term}}_T & = & \textrm{Shorter term call value at time T}\\ C^{\textrm{long-term}}_T & = & \textrm{Longer term call value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K & = & \textrm{Strike price}\\ P_T & = & \textrm{Payout total at time T}\\ C^{\textrm{short-term}}_0 & = & \textrm{Shorter term call value at position opening (debit paid)}\\ C^{\textrm{long-term}}_0 & = & \textrm{Longer term call value at position opening (credit received)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of shorter term call expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $C^{\textrm{long-term}}_0 - C^{\textrm{short-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both calls are close to zero.

The maximum loss is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the 2 calls are at their maximum.

If the Option is American Option, there is a risk of early assignment on the contract you sell. If you don't close the call positions together, the naked short call will have unlimited drawdown risk after the long call expires.

Example

The following table shows the price details of the assets in the short call calendar spread:

Asset	**Price ($)**	**Strike ($)**
Longer-term call at the start of the trade	4.40	835.00
Shorter-term call at the start of the trade	36.80	767.50
Longer-term call at time T	31.35	835.00
Underlying Equity at time T	829.08	-

Therefore, the payoff at time T (the expiration of the short-term call) is

$$\begin{array}{rcll} C^{\textrm{short-term}}_T & = & (S_T - K)^{+}\\ & = & (828.07-800.00)^{+}\\ & = & 28.07\\ P_T & = & (-C^{\textrm{long-term}}_T + C^{\textrm{short-term}}_T - C^{\textrm{short-term}}_0 + C^{\textrm{long-term}}_0)\times m - fee\\ & = & (-31.35+28.07-11.30+20.00)\times100-1.00\times2\\ & = & 540 \end{array}$$

So, the strategy gains $540.

The following algorithm implements a short call calendar spread Option strategy:

```C#
public class BearPutSpreadStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallCalendarSpread(0, 30, 60));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // get at-the-money strike
        var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // filter the call options from the contracts which is ATM in the option chain.
        var calls = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // sorted the optionchain by expiration date
        var expiries = calls.Select(x => x.Expiry).OrderBy(x => x);

        // select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        var nearExpiry = expiries.First();
        var farExpiry = expiries.Last();

        var optionStrategy = OptionStrategies.ShortCallCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Long Put Calendar Spread

Introduction

Put calendar spread , also known as put horizontal spread , is a combination of a longer-term (far-leg/front-month) put and a shorter-term (near-leg/back-month) put, where both puts have the same underlying stock and the same strike price. The long put calendar spread consists of buying a longer-term put and selling a shorter-term put. This strategy profits from a decrease in price movement. The strategy also profits from the time decay value because the theta \theta (the Option price decay by 1 day closer to maturity) of the shorter-term put is larger than the longer-term put.

Implementation

Follow these steps to implement the long put calendar spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutCalendarSpread(0, 30, 60));
}
```

   The `PutCalendarSpread` filter narrows the universe down to just the two contracts you need to form a long put calendar spread.

2. In the `OnData` method, select the strike price and expiration dates of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Get the ATM strike
    var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

    // Select the ATM put Option contracts
    var puts = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the near and far expiry contracts
    var expiries = puts.Select(x => x.Expiry).ToList();
    var nearExpiry = expiries.Min();
    var farExpiry = expiries.Max();
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.PutCalendarSpread` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var optionStrategy = OptionStrategies.PutCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var nearExpiryPut = puts.Single(x => x.Expiry == nearExpiry);
var farExpiryPut = puts.Single(x => x.Expiry == farExpiry);

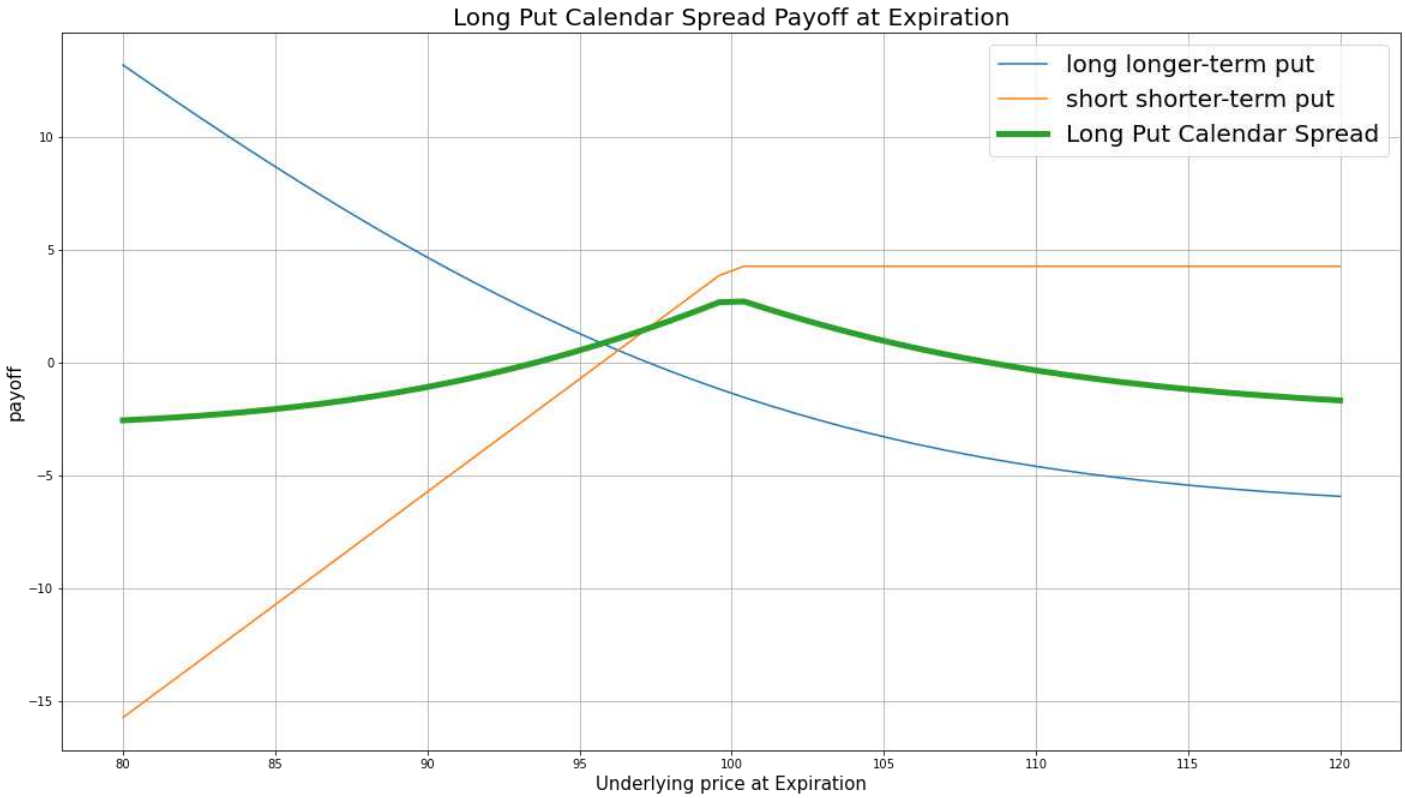
var legs = new List<Leg>()
    {
        Leg.Create(nearExpiryPut.Symbol, -1),
        Leg.Create(farExpiryPut.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The long put calendar spread is a limited-reward-limited-risk strategy. The payoff is taken at the shorter-term expiration. The payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{\textrm{long-term}}_T - P^{\textrm{short-term}}_T + P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & P^{\textrm{short-term}}_T & = & \textrm{Shorter term put value at time T}\\ & P^{\textrm{long-term}}_T & = & \textrm{Longer term put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{\textrm{short-term}}_0 & = & \textrm{Shorter term put value at position opening (credit received)}\\ & P^{\textrm{long-term}}_0 & = & \textrm{Longer term put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of shorter term put expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread

of the puts are at their maximum.

The maximum loss is the net debit paid, $P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0$. It occurs when the underlying price moves very deep ITM or OTM so the values of both puts are close to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell. Naked long puts pose risk of losing all the debit paid if you don't close the position with short put together and the price drops below its strike.

Example

The following table shows the price details of the assets in the long put calendar spread algorithm:

Asset	Price ($)	Strike ($)
Shorter-term put at position opening	11.30	800.00
Longer-term put at position opening	19.30	800.00
Longer-term put at shorter-term expiration	3.50	800.00
Underlying Equity at shorter-term expiration	828.07	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ & = & (800.00-828.07)^{+}\\ & = & 0\\ P_T & = & (P^{\textrm{long-term}}_T - P^{\textrm{short-term}}_T + P^{\textrm{short-term}}_0 - P^{\textrm{long-term}}_0)\times m - fee\\ & = & (3.50-0+11.30-19.30)\times100-1.00\times2\\ & = & -452\\ \end{array}$$

So, the strategy loses $452.

The following algorithm implements a long put calendar spread Option strategy:

```C#
public class OptionStrategy : QCAlgorithm
{
    private Symbol _equity;
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutCalendarSpread(0, 30, 60));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // get at-the-money strike
        var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // filter the put options from the contracts which is ATM in the option chain.
        var puts = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // sorted the optionchain by expiration date
        var expiries = puts.Select(x => x.Expiry).OrderBy(x => x);

        // select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        var nearExpiry = expiries.First();
        var farExpiry = expiries.Last();

        var optionStrategy = OptionStrategies.PutCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);    // if long put calendar spread
        //Sell(optionStrategy, 1);   // if short put calendar spread
    }
}
```

Option Strategies

Short Put Calendar Spread

Introduction

Put calendar spread , also known as put horizontal spread , is a combination of a longer-term (far-leg/front-month) put and a shorter-term (near-leg/back-month) put, where both puts have the same underlying stock and the same strike price. The short put calendar spread consists of selling a longer-term put and buying a shorter-term put. This strategy profits from an increase in price movement.

Implementation

Follow these steps to implement the short put calendar spread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutCalendarSpread(0, 30, 60));
}
```

   The `PutCalendarSpread` filter narrows the universe down to just the two contracts you need to form a short put calendar spread.

2. In the `OnData` method, select the strike price and expiration dates of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Get the ATM strike
    var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

    // Select the ATM put Option contracts
    var puts = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the near and far expiry contracts
    var expiries = puts.Select(x => x.Expiry).ToList();
    var nearExpiry = expiries.Min();
    var farExpiry = expiries.Max();
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.ShortPutCalendarSpread` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var optionStrategy = OptionStrategies.ShortPutCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var nearExpiryPut = puts.Single(x => x.Expiry == nearExpiry);
var farExpiryPut = puts.Single(x => x.Expiry == farExpiry);

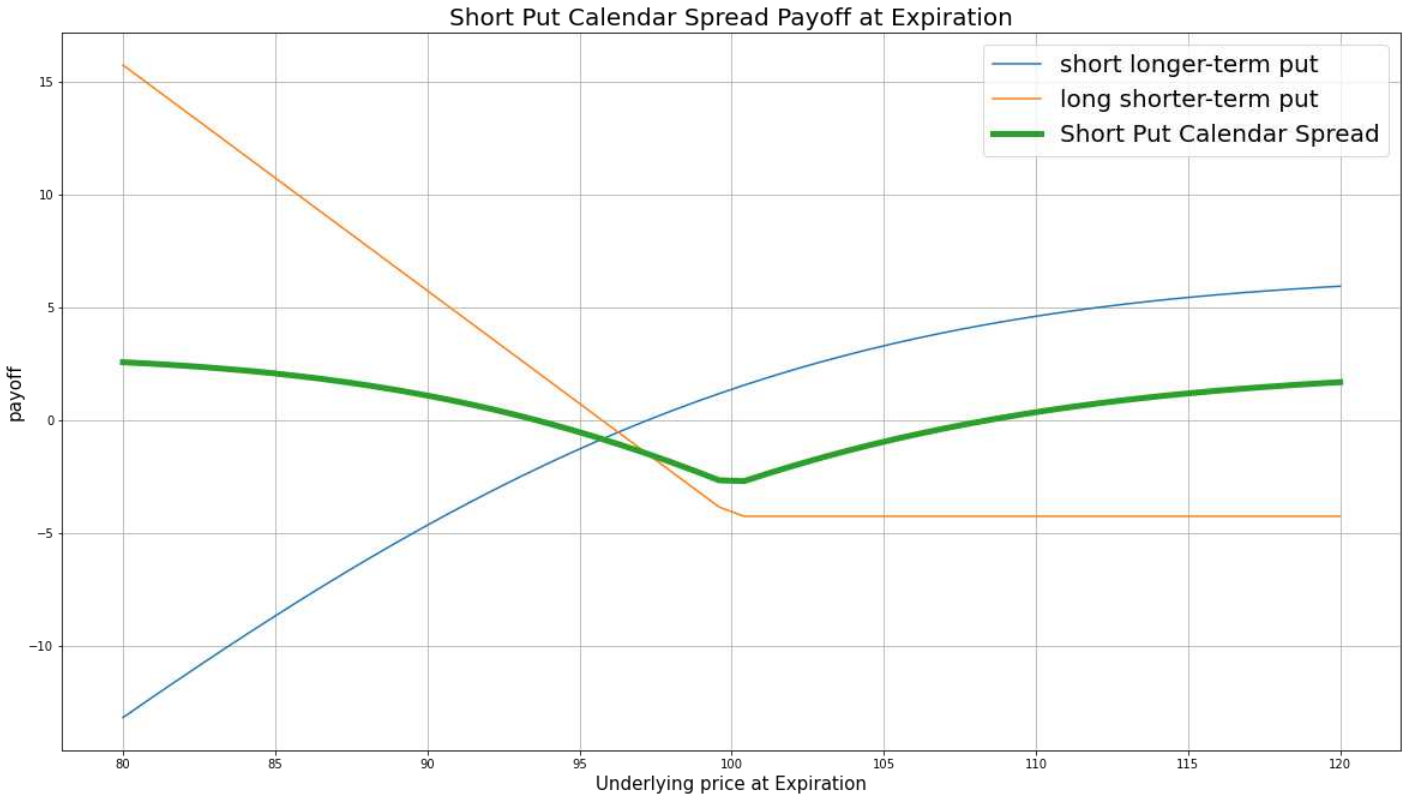
var legs = new List<Leg>()
    {
        Leg.Create(nearExpiryPut.Symbol, 1),
        Leg.Create(farExpiryPut.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The short put calendar spread is a limited-reward-limited-risk strategy. The payoff is taken at the shorter-term expiration. The payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{\textrm{short-term}}_T - P^{\textrm{long-term}}_T + P^{\textrm{long-term}}_0 - P^{\textrm{short-term}}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & & \\ P^{\textrm{short-term}}_T & = & \textrm{Shorter term put value at time T}\\ P^{\textrm{long-term}}_T & = & \textrm{Longer term put value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K & = & \textrm{Strike price}\\ P_T & = & \textrm{Payout total at time T}\\ P^{\textrm{short-term}}_0 & = & \textrm{Shorter term put value at position opening (debit paid)}\\ P^{\textrm{long-term}}_0 & = & \textrm{Longer term put value at position opening (credit received)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of shorter term put expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, $P^{\textrm{long-term}}_0 - P^{\textrm{short-term}}_0$. It occurs when the

underlying price moves very deep ITM or OTM so the values of both puts are close to zero.

The maximum loss is undetermined because it depends on the underlying volatility. It occurs when $S_T = S_0$ and the spread of the 2 puts are at their maximum.

If the Option is American Option, there is a risk of early assignment on the contract you sell. Additionally, if you don't close the put positions together, the naked short put will have unlimited drawdown risk after the long put expires.

Example

The following table shows the price details of the assets in the short put calendar spread algorithm:

Asset	Price ($)	Strike ($)
Shorter-term put at position opening	11.30	800.00
Longer-term put at position opening	19.30	800.00
Longer-term put at shorter-term expiration	3.50	800.00
Underlying Equity at shorter-term expiration	828.07	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{\textrm{short-term}}_T & = & (K - S_T)^{+}\\ & = & (800.00-828.07)^{+}\\ & = & 0\\ P_T & = & (-P^{\textrm{long-term}}_T + P^{\textrm{short-term}}_T - P^{\textrm{short-term}}_0 + P^{\textrm{long-term}}_0)\times m - fee\\ & = & (-3.50+0-11.30+19.30)\times100-1.00\times2\\ & = & 448\\ \end{array}$$

So, the strategy gains $448.

The following algorithm implements a short put calendar spread Option strategy:

C#

```
public class OptionStrategy : QCAlgorithm
{
    private Symbol _equity;
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(500000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutCalendarSpread(0, 30, 60));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // get at-the-money strike
        var atmStrike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // filter the put options from the contracts which is ATM in the option chain.
        var puts = chain.Where(x => x.Strike == atmStrike && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // sorted the optionchain by expiration date
        var expiries = puts.Select(x => x.Expiry).OrderBy(x => x);

        // select the farest expiry as far-leg expiry, and the nearest expiry as near-leg expiry
        var nearExpiry = expiries.First();
        var farExpiry = expiries.Last();

        var optionStrategy = OptionStrategies.ShortPutCalendarSpread(_symbol, atmStrike, nearExpiry, farExpiry);
        // We open a position with 1 unit of the option strategy
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Covered Call

Introduction

A Covered Call consists of a long position in a stock and a short position in call Options for the same amount of stock. Covered calls aim to profit from the Option premium by selling calls written on the stock you already own. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium and still maintain the underlying Equity position. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which means you sell your stock at the strike price and keep the premium. Another risk of a covered call comes from the long stock position, which can drop in value.

Implementation

Follow these steps to implement the covered call strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("IBM");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().NakedCall(30, 0));
}
```

   The `NakedCall` filter narrows the universe down to just the one contract you need to form a covered call.

2. In the `OnData` method, select the Option contract.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find ATM call with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var atmCall = chain
        .Where(x => x.Right == OptionRight.Call && x.Expiry == expiry)
        .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
        .FirstOrDefault();
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.CoveredCall` method with the details of each leg and then pass the result to the `Buy` method.

   ```C#
   var coveredCall = OptionStrategies.CoveredCall(_symbol, atmCall.Strike, expiry);
   Buy(coveredCall, 1);
   ```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

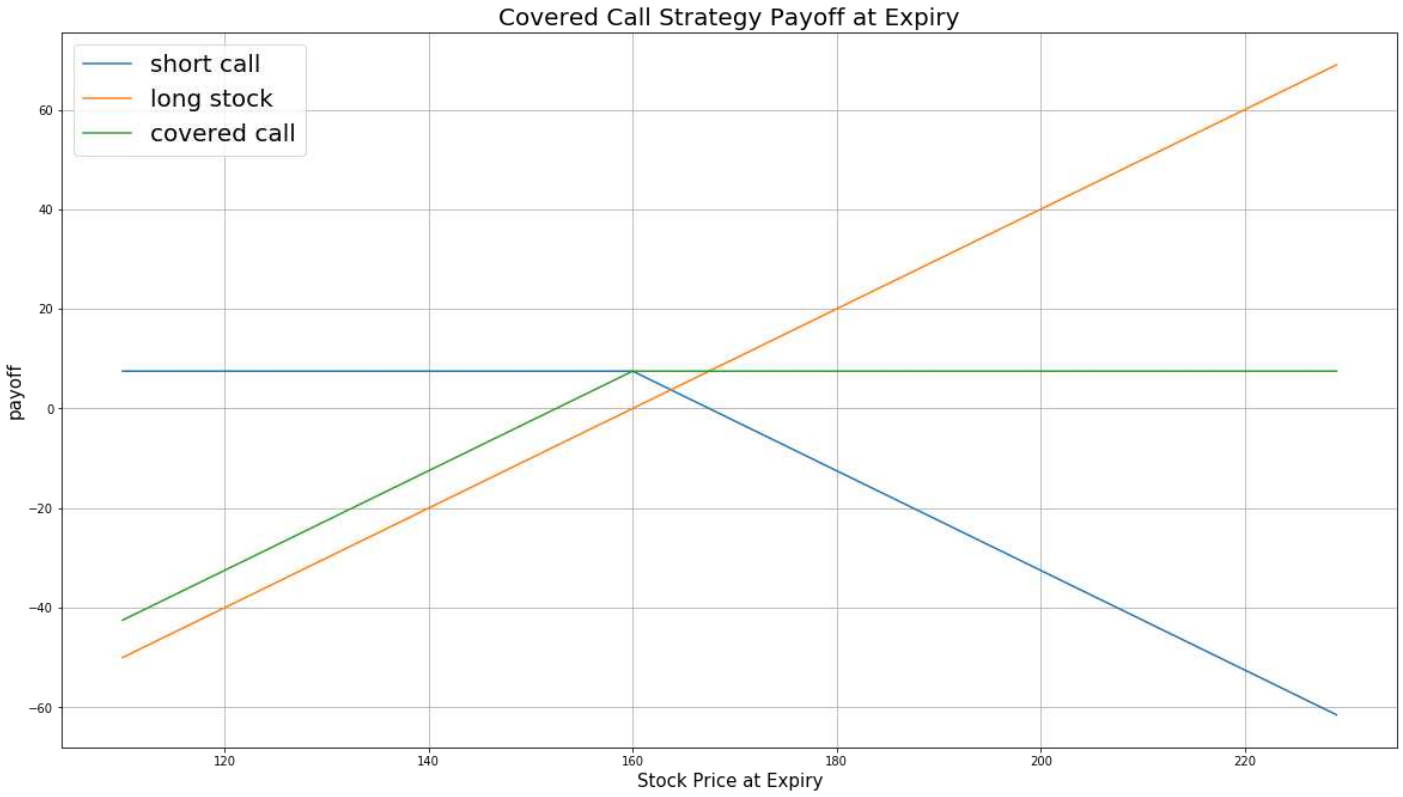
   ```C#
   var legs = new List<Leg>()
       {
           Leg.Create(atmCall.Symbol, -1),
           Leg.Create(chain.Underlying.Symbol, chain.Underlying.SymbolProperties.ContractMultiplier)
       };
   ComboMarketOrder(legs, 1);
   ```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (S_T - S_0 + C^{K}_0 - C^{K}_T)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & C^{K}_T & = & \textrm{Call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C^{K}_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K - S_T + C^{K}_0$, which occurs when the underlying price is at or above the strike price of the call at expiration.

The maximum loss is $S_0 - C^{K}_0$, which ocurrs when the underlying price drops.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	3.35	185.00
Underlying Equity at start of the trade	187.07	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (S_T - S_0 + C^{K}_0 - C^{K}_T)\times m - fee\\ & = & (190.01 - 187.07 + 3.35 - 5.01)\times m - fee\\ & = & 1.28 \times 100 - 2\\ & = & 126 \end{array}$$

So, the strategy gains $126.

The following algorithm implements a covered call strategy:

```C#
public class CoveredCallAlgorithm : QCAlgorithm
{
    private Symbol _call, _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("IBM");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().NakedCall(30, 0));

        // use the underlying equity as the benchmark
        SetBenchmark(_symbol.Underlying);
    }

    public override void OnData(Slice slice)
    {
        if (_call != null && Portfolio[_call].Invested) return;

        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // Find ATM call with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var atmCall = chain
            .Where(x=> x.Right == OptionRight.Call && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
            .FirstOrDefault();

        if (atmCall == null) return;

        var coveredCall = OptionStrategies.CoveredCall(_symbol, atmCall.Strike, expiry);
        Buy(coveredCall, 1);

        _call = atmCall.Symbol;
    }
}
```

Option Strategies

Covered Put

Introduction

A Covered Put consists of a short position in a stock and a short position in put Options for the same amount of stock. Covered puts aim to profit from the Option premium by selling puts written on the stock you already shorted. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium and still maintain the underlying Equity position. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which mean you buy the stock at the strike price but you will still keep the premium. Another risk of a covered put comes from the short stock position, which can drop in value.

Implementation

Follow these steps to implement the covered put strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("IBM");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().NakedPut(30, 0));
}
```

   The `NakedPut` filter narrows the universe down to just the one contract you need to form a covered put.

2. In the `OnData` method, select the Option contract.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find ATM put with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var atmput = chain
        .Where(x => x.Right == OptionRight.Put && x.Expiry == expiry)
        .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
        .FirstOrDefault();
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.CoveredPut` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var coveredPut = OptionStrategies.CoveredPut(_symbol, atmput.Strike, expiry);
Buy(coveredPut, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

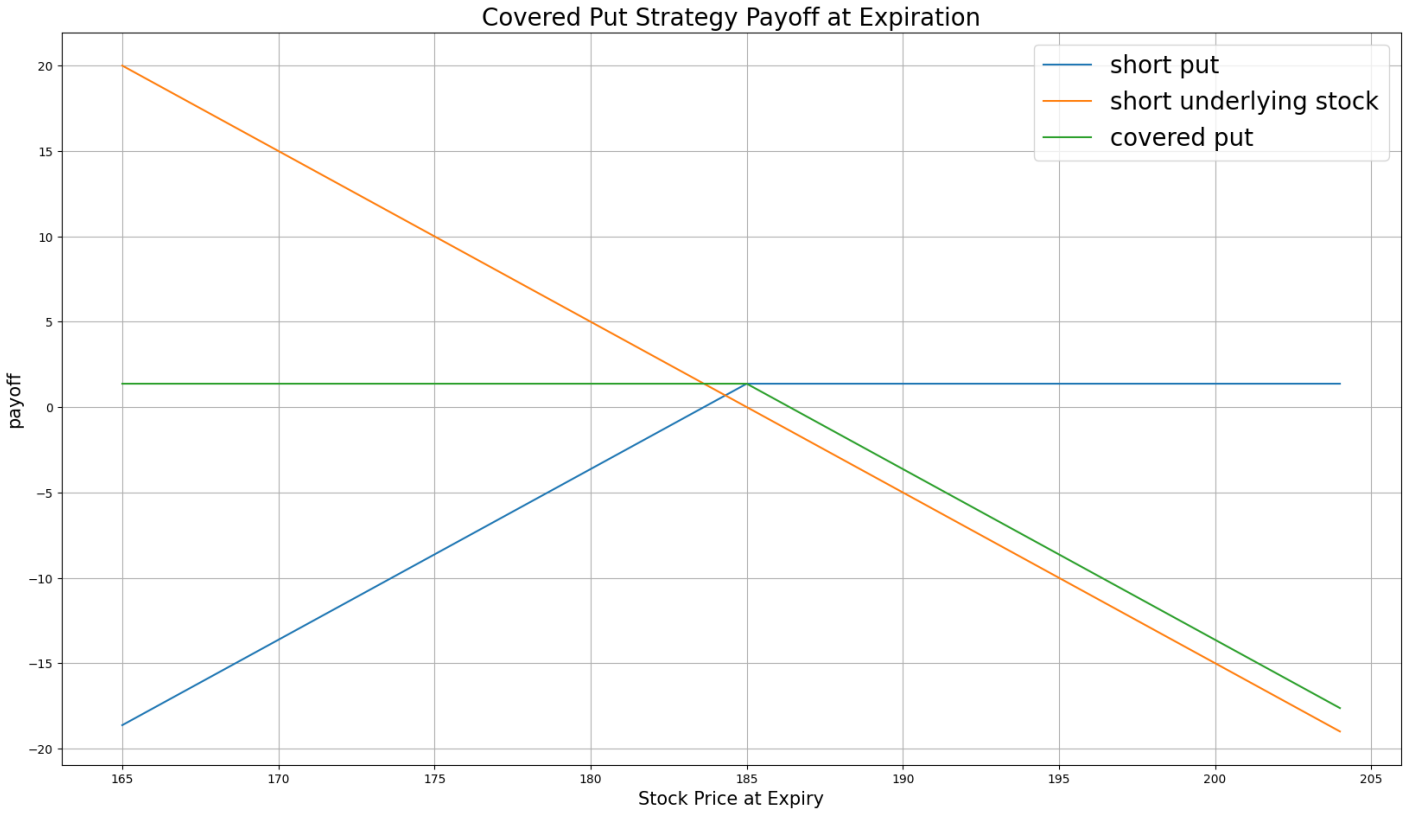
```C#
var legs = new List<Leg>()
    {
        Leg.Create(atmPut.Symbol, -1),
        Leg.Create(chain.Underlying.Symbol, -chain.Underlying.SymbolProperties.ContractMultiplier)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcl} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (S_0 - S_T + P^{K}_0 - P^{K}_T)\times m - fee \end{array}$$
$$\begin{array}{rcl} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $S_T - K + P^{K}_0$. It occurs when the underlying price is at or below the strike price of the put at expiration.

If the underlying price increase, the maximum loss is unlimited.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.37	185.00
Underlying Equity at start of the trade	186.94	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.01)^{+}\\ & = & 0\\ P_T & = & (S_0 - S_T + P^{K}_0 - P^{K}_T)\times m - fee\\ & = & (186.94 - 190.01 + 1.37 - 0)\times m - fee\\ & = & -1.70 \times 100 - 2\\ & = & -172 \end{array}$$

So, the strategy loses $172.

The following algorithm implements a covered put strategy:

```C#
public class CoveredPutAlgorithm : QCAlgorithm
{
    private Symbol _put, _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("IBM");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().NakedPut(30, 0));

        // use the underlying equity as the benchmark
        SetBenchmark(_symbol.Underlying);
    }

    public override void OnData(Slice slice)
    {
        if (_put != null && Portfolio[_put].Invested) return;

        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // Find ATM put with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var atmPut = chain
            .Where(x=> x.Right == OptionRight.Put && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
            .FirstOrDefault();

        if (atmPut == null) return;

        var coveredPut = OptionStrategies.CoveredPut(_symbol, atmPut.Strike, expiry);
        Buy(coveredPut, 1);

        _put = atmPut.Symbol;
    }
}
```

Option Strategies

Long Iron Butterfly

Introduction

The Long Iron Butterfly is an option strategy which involves four Option contracts. All the contracts have the same underlying stock and expiration, but the order of strike prices for the four contracts is A>B>C. The following table describes the strike price of each contract:

Position	Strike
1 OTM call	A
-1 ATM call	B
-1 ATM put	B
1 OTM put	C=B-(A-B)

The long iron butterfly consists of selling an OTM call, selling an OTM put, buying an ATM call, and buying an ATM put. This strategy profits from a decrease in price movement (implied volatility).

Implementation

Follow these steps to implement the long iron butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
```

```
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().IronButterfly(30, 5));
}
```

   The `IronButterfly` filter narrows the universe down to just the four contracts you need to form a long iron butterfly.

2. In the `OnData` method, select the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select expiry
    var expiry = chain.Max(x => x.Expiry);

    // Separate the call and put contracts
    var calls = chain.Where(x => x.Right == OptionRight.Call  && x.Expiry == expiry);
    var puts = chain.Where(x => x.Right == OptionRight.Put && x.Expiry == expiry);
    if (calls.Count() == 0 || puts.Count() == 0) return;

    // Get the ATM and OTM strike prices
    var atmStrike = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;
    var otmPutStrike = puts.Min(x => x.Strike);
    var otmCallStrike = 2 * atmStrike - otmPutStrike;
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.IronButterfly` method with the details of each leg and then pass the result to the `Buy` method.

   ```C#
   var ironButterfly = OptionStrategies.IronButterfly(_symbol, otmPutStrike, atmStrike, otmCallStrike, expiry);
   Buy(ironButterfly, 2);
   ```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

   ```C#
   // Select the contracts
   var atmCall = calls.Single(x => x.Strike == atmStrike);
   var atmPut = puts.Single(x => x.Strike == atmStrike);
   var otmCall = calls.Single(x => x.Strike == otmCallStrike);
   var otmPut = puts.Single(x => x.Strike == otmPutStrike);

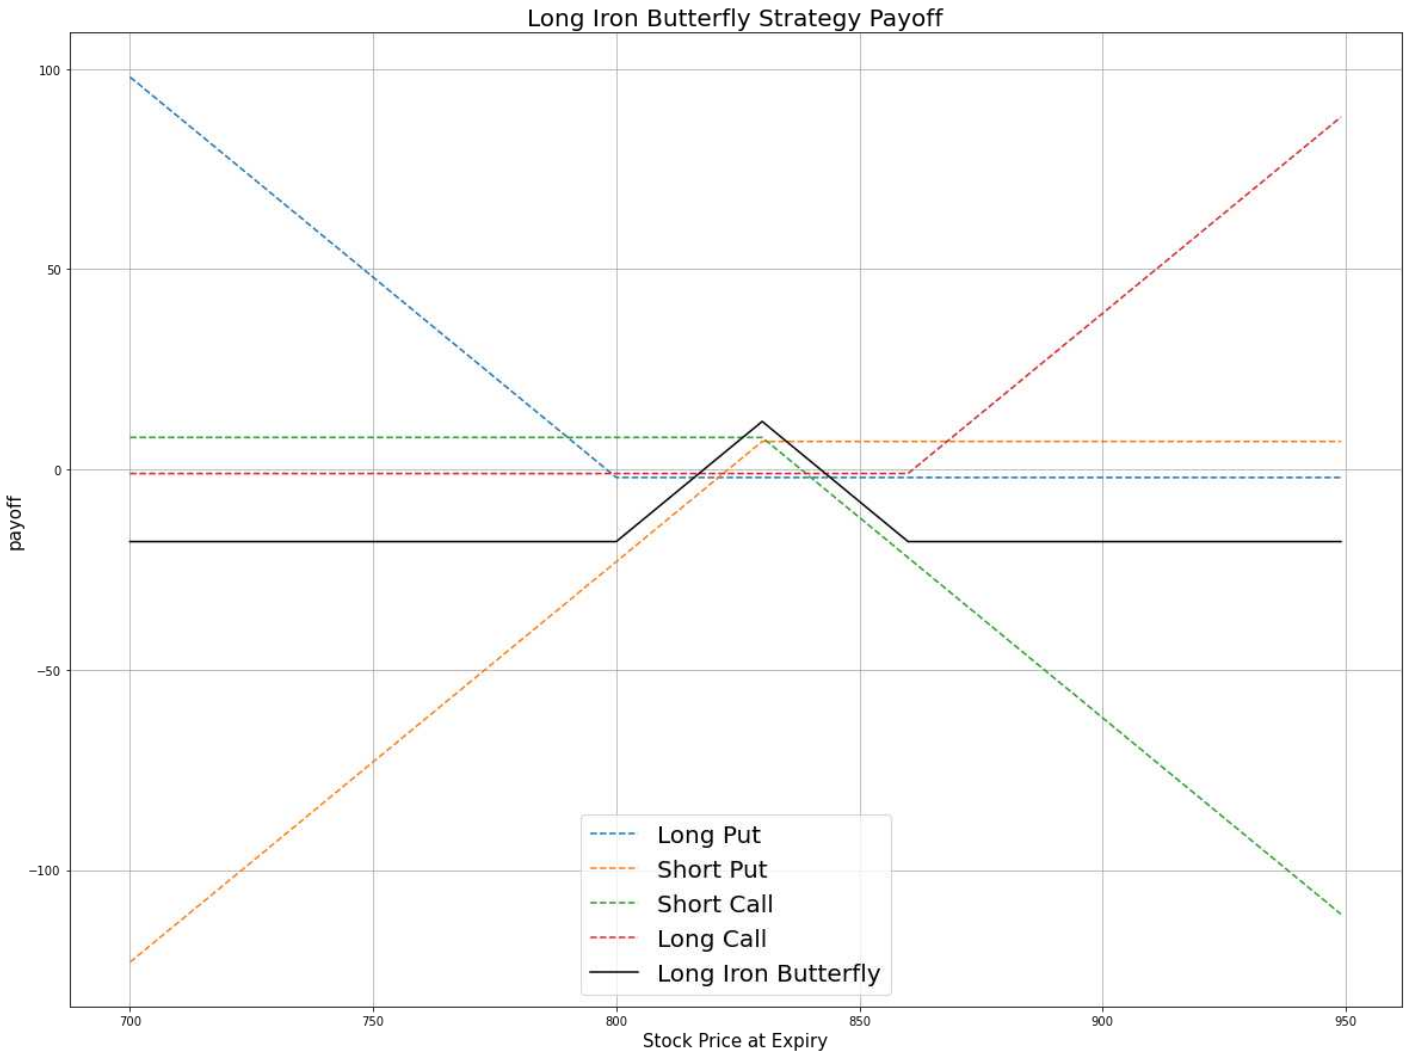
   var legs = new List<Leg>()
       {
           Leg.Create(atmCall.Symbol, -1),
           Leg.Create(atmPut.Symbol, -1),
           Leg.Create(otmCall.Symbol, 1),
           Leg.Create(otmPut.Symbol, 1)
       };
   ComboMarketOrder(legs, 1);
   ```

Strategy Payoff

The long call butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{ATM}_T - P^{ATM}_T - C^{OTM}_0 - P^{OTM}_0 + C^{ATM}_0 + P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{OTM} & = & \textrm{OTM call strike price}\\ & K^C_{ATM} & = & \textrm{ATM call strike price}\\ & K^P_{OTM} & = & \textrm{OTM put strike price}\\ & K^P_{ATM} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (credit received)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is the net credit received, C^{ATM}_0 + P^{ATM}_0 - C^{OTM}_0 - P^{OTM}_0. It occurs when the underlying price stays the same as when you opened the trade.

The maximum loss is K^C_{OTM} - K^C_{ATM} - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price is below the OTM put strike price or above the OTM call strike price at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
OTM call	1.35	855.00
OTM put	1.50	810.00
ATM call	10.30	832.50
ATM put	9.50	832.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ & = & (843.25-855.00)^{+}\\ & = & 0\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ & = & (843.25-832.50)^{+}\\ & = & 10.75\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ & = & (810.00-843.25)^{+}\\ & = & 0\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ & = & (832.50.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{OTM}_T - P^{OTM}_T - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0)\times m - fee\\ & = & (10.75+0-0-0-10.30-9.50+1.35+1.50)\times100-1\times4\\ & = & -624 \end{array}

So, the strategy losses $624.

The following algorithm implements a long iron butterfly Option strategy:

```C#
public class LongButterflyStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().IronButterfly(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select expiry
        var expiry = chain.Max(x => x.Expiry);

        // Separate the call and put contracts
        var calls = chain.Where(x => x.Right == OptionRight.Call  && x.Expiry == expiry);
        var puts = chain.Where(x => x.Right == OptionRight.Put && x.Expiry == expiry);
        if (calls.Count() == 0 || puts.Count() == 0) return;

        // Get the ATM and OTM strike prices
        var atmStrike = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;
        var otmPutStrike = puts.Min(x => x.Strike);
        var otmCallStrike = 2 * atmStrike - otmPutStrike;

        // Order Strategy
        var ironButterfly = OptionStrategies.IronButterfly(_symbol, otmPutStrike, atmStrike, otmCallStrike, expiry);
        Buy(ironButterfly, 1);
    }
}
```

Option Strategies

Short Iron Butterfly

Introduction

The Short Iron Butterfly is an option strategy which involves four Option contracts. All the contracts have the same underlying stock and expiration, but the order of strike prices for the four contracts is A>B>C. The following table describes the strike price of each contract:

Position	Strike
1 OTM call	A
-1 ATM call	B
-1 ATM put	B
1 OTM put	C=B-(A-B)

The short call butterfly consists of buying an OTM call, buying an OTM put, selling an ATM call, and selling an ATM put. This strategy profits from an increase in price movement (implied volatility) and from time decay value since ATM options decay sharper.

Implementation

Follow these steps to implement the short iron butterfly strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().IronButterfly(30, 5));
}
```

   The `IronButterfly` filter narrows the universe down to just the four contracts you need to form a short iron butterly.

2. In the `OnData` method, select the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select expiry
    var expiry = chain.Max(x => x.Expiry);

    // Separate the call and put contracts
    var calls = chain.Where(x => x.Right == OptionRight.Call  && x.Expiry == expiry);
    var puts = chain.Where(x => x.Right == OptionRight.Put && x.Expiry == expiry);
    if (calls.Count() == 0 || puts.Count() == 0) return;

    // Get the ATM and OTM strike prices
    var atmStrike = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;
    var otmPutStrike = puts.Min(x => x.Strike);
    var otmCallStrike = 2 * atmStrike - otmPutStrike;
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.ShortIronButterfly` method with the details of each leg and then pass the result to the `Buy` method.

   ```C#
   var shortIronButterfly = OptionStrategies.ShortIronButterfly(_symbol, otmPutStrike, atmStrike, otmCallStrike,
   expiry);
   Buy(shortIronButterfly, 2);
   ```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

   ```C#
   // Select the contracts
   var atmCall = calls.Single(x => x.Strike == atmStrike);
   var atmPut = puts.Single(x => x.Strike == atmStrike);
   var otmCall = calls.Single(x => x.Strike == otmCallStrike);
   var otmPut = puts.Single(x => x.Strike == otmPutStrike);

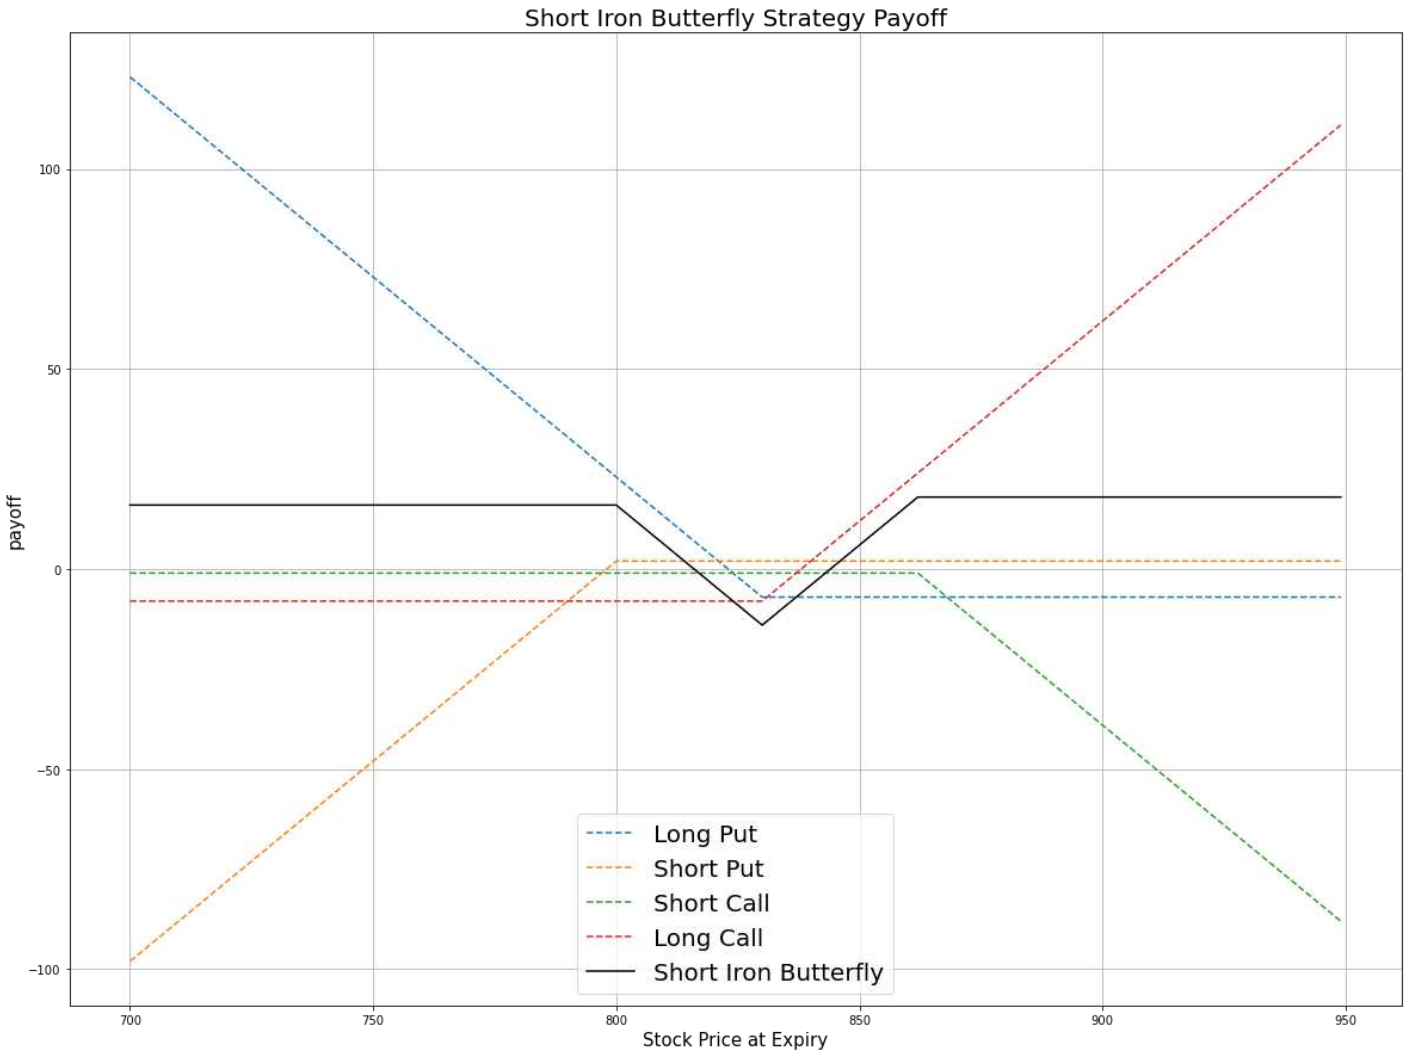
   var legs = new List<Leg>()
       {
           Leg.Create(atmCall.Symbol, 1),
           Leg.Create(atmPut.Symbol, 1),
           Leg.Create(otmCall.Symbol, -1),
           Leg.Create(otmPut.Symbol, -1)
       };
   ComboMarketOrder(legs, 1);
   ```

Strategy Payoff

The short iron butterfly is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{OTM}_T - P^{OTM}_T - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{OTM} & = & \textrm{OTM call strike price}\\ & K^C_{ATM} & = & \textrm{ATM call strike price}\\ & K^P_{OTM} & = & \textrm{OTM put strike price}\\ & K^P_{ATM} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (credit received)}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (credit received)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is K^C_{OTM} - K^C_{ATM} - C^{ATM}_0 - P^{ATM}_0 + C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price is below the OTM put strike price or above the OTM call strike price at expiration.

The maximum loss is the net debit paid, C^{OTM}_0 + P^{OTM}_0 - C^{ATM}_0 - P^{ATM}_0. It occurs when the underlying price stays the same as when you opened the trade.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
OTM call	2.35	855.00
OTM put	2.75	810.00
ATM call	8.10	832.50
ATM put	7.40	832.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^C_{OTM})^{+}\\ & = & (843.25-855.00)^{+}\\ & = & 0\\ C^{ATM}_T & = & (S_T - K^C_{ATM})^{+}\\ & = & (843.25-832.50)^{+}\\ & = & 10.75\\ P^{OTM}_T & = & (K^P_{OTM} - S_T)^{+}\\ & = & (810.00-843.25)^{+}\\ & = & 0\\ P^{ATM}_T & = & (K^P_{ATM} - S_T)^{+}\\ & = & (832.50.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{ATM}_T - P^{ATM}_T - C^{OTM}_0 - P^{OTM}_0 + C^{ATM}_0 + P^{ATM}_0)\times m - fee\\ & = & (0+0-10.75-0-2.35-2.75+8.10+7.40)\times100-1\times4\\ & = & -39 \end{array}

So, the strategy losses $39.

The following algorithm implements a short iron butterfly Option strategy:

C#

```
public class ShortButterflyStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().IronButterfly(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select expiry
        var expiry = chain.Max(x => x.Expiry);

        // Separate the call and put contracts
        var calls = chain.Where(x => x.Right == OptionRight.Call  && x.Expiry == expiry);
        var puts = chain.Where(x => x.Right == OptionRight.Put && x.Expiry == expiry);
        if (calls.Count() == 0 || puts.Count() == 0) return;

        // Get the ATM and OTM strike prices
        var atmStrike = calls.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;
        var otmPutStrike = puts.Min(x => x.Strike);
        var otmCallStrike = 2 * atmStrike - otmPutStrike;

        // Order Strategy
        var shortIronButterfly = OptionStrategies.ShortIronButterfly(_symbol, otmPutStrike, atmStrike, otmCallStrike,
expiry);
        Buy(shortIronButterfly, 1);
    }
}
```

Option Strategies

Long Iron Condor

Introduction

The Long Iron Condor is an Option strategy that consists of four contracts. All the contracts have the same underlying Equity and expiration, but the order of strike prices is A>B>C>D. The following table describes the strike prices of each contract:

Position	Strike
1 far-OTM call	A
-1 near-OTM call	B, where B > underlying\ price
-1 near-OTM put	C, where C < underlying\ price
1 far-OTM put	D, where C-D = A-B

The long iron condor consists of buying a far OTM call, buying a far OTM put, selling a near ATM call, and selling a near ATM put. This strategy profits from an decrease in price movement (implied volatility) and time decay since ATM options decay sharper.

Implementation

Follow these steps to implement the long iron condor strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().IronCondor(30, 5, 10));
}
```

   The `IronCondor` filter narrows the universe down to just the four contracts you need to form a long iron condor.

2. In the `OnData` method, select the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio[_symbol.Underlying].Invested)
    {
        Liquidate();
    }

    if (Portfolio.Invested || !IsMarketOpen(_symbol) ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find put and call contracts with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var contracts = chain.Where(x => x.Expiry == expiry).OrderBy(x => x.Strike);

    var putContracts = contracts.Where(x => x.Right == OptionRight.Put).ToArray();
    var callContracts = contracts.Where(x => x.Right == OptionRight.Call).ToArray();

    if (putContracts.Length < 2 || callContracts.Length < 2) return;

    // Select the strategy legs
    var nearCall = callContracts[0];
    var farCall = callContracts[1];
    var nearPut = putContracts[1];
    var farPut = putContracts.Single(x => x.Strike == nearPut.Strike - farCall.Strike + nearCall.Strike);
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.IronCondor` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var ironCondor = OptionStrategies.IronCondor(
    _symbol,
    farPut.Strike,
    nearPut.Strike,
    nearCall.Strike,
    farCall.Strike,
    expiry);

Buy(ironCondor, 2);
```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var legs = new List<Leg>()
    {
        Leg.Create(farPut.Symbol, 1),
        Leg.Create(nearPut.Symbol, -1),
        Leg.Create(farCall.Symbol, 1),
        Leg.Create(nearCall.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

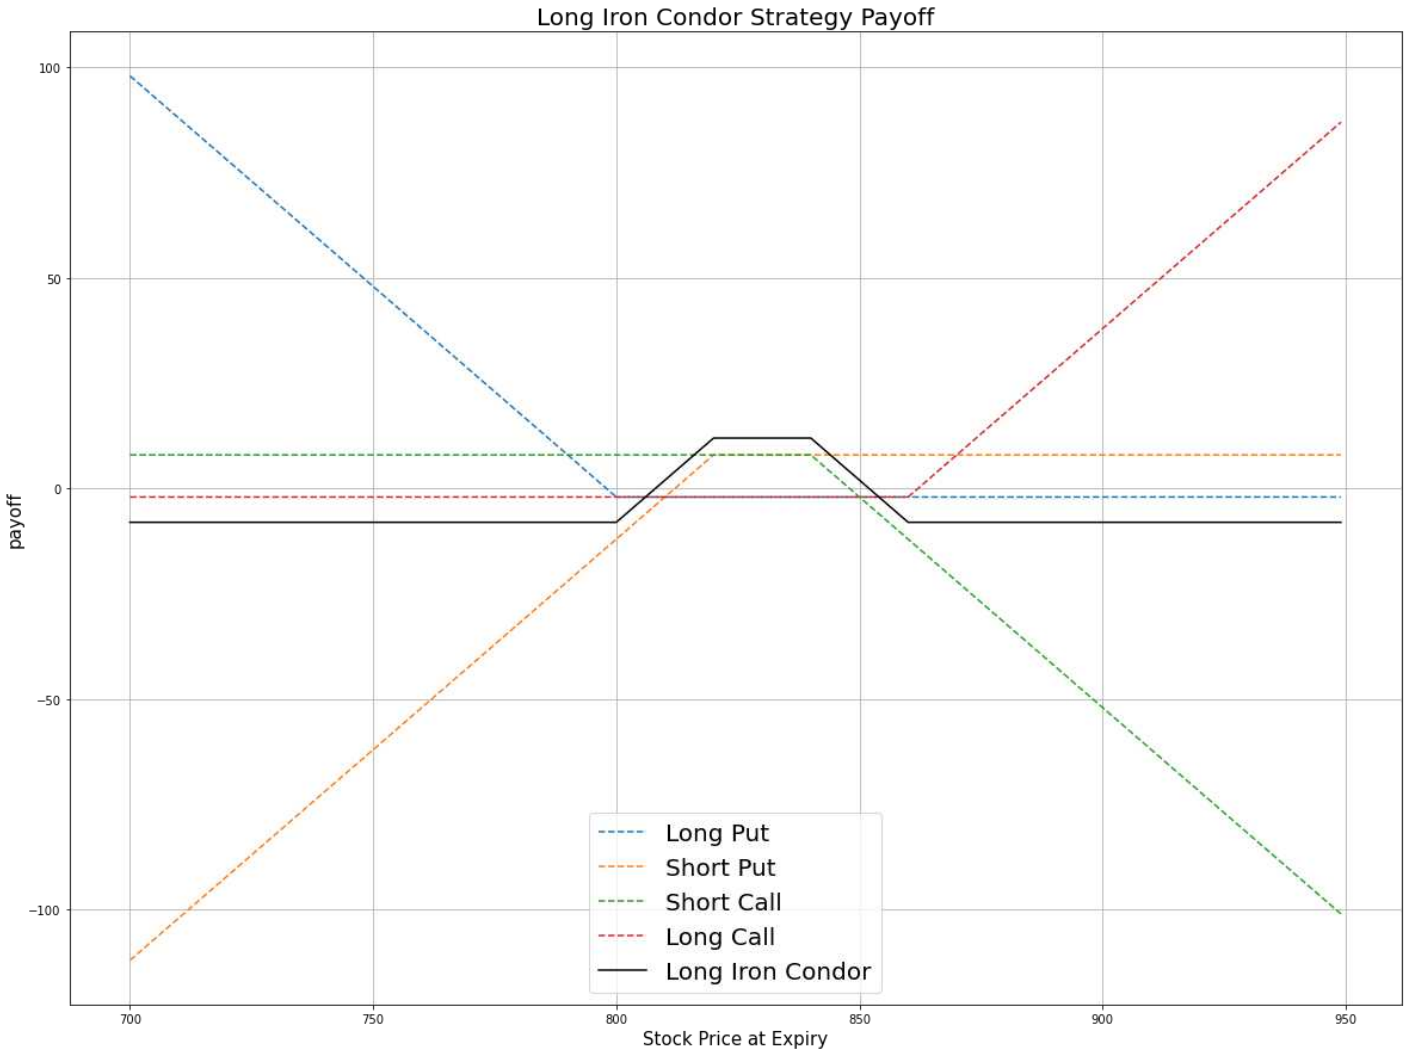
Strategy Payoff

This is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ P_T & = & (C^{far}_T + P^{far}_T - C^{near}_T - P^{near}_T - C^{far}_0 - P^{far}_0 + C^{near}_0 + P^{near}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{far}_T & = & \textrm{Far OTM call value at time T}\\ & C^{near}_T & = & \textrm{Near OTM call value at time T}\\ & P^{far}_T & = & \textrm{Far OTM put value at time T}\\ & P^{near}_T & = & \textrm{Near ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{far} & = & \textrm{Far OTM call strike price}\\ & K^C_{near} & = & \textrm{Near OTM call strike price}\\ & K^P_{far} &$$

= & \textrm{Far OTM put strike price}\\ & K^P_{near} & = & \textrm{Near OTM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{far}_0 & = & \textrm{Far OTM call value at position opening (credit received)}\\ & C^{near}_0 & = & \textrm{Near OTM call value at position opening (debit paid)}\\ & P^{far}_0 & = & \textrm{Far OTM put value at position opening (credit received)}\\ & P^{near}_0 & = & \textrm{Near OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}

The following chart shows the payoff at expiration:



The maximum profit is the net credit received after commission when opening the trade, where K^P_{OTM} < S_T < K^C_{OTM}.

The maximum loss is K^C_{far} - K^C_{near} + C^{near}_0 + P^{near}_0 - C^{far}_0 - P^{far}_0, where K^P_{OTM} > S_T or S_T > K^C_{OTM}.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Far-OTM call	1.85	857.50
Far-OTM put	3.80	815.00
Near-OTM call	1.65	852.50
Near-OTM put	3.50	820.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ & = & (843.25-857.50)^{+}\\ & = & 0\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ & = & (843.25-852.50)^{+}\\ & = & 0\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ & = & (815.00-843.25)^{+}\\ & = & 0\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ & = & (820.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee\\ & = & (0+0-0-0+1.65+3.50-1.85-3.80)\times100-1\times4\\ & = & -54 \end{array}

So, the strategy loses $54.

The following algorithm implements a long iron condor Option strategy:

C#

```
public class LongIronCondorStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().IronCondor(30, 5, 10));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested || !IsMarketOpen(_symbol) ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Find put and call contracts with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var contracts = chain.Where(x => x.Expiry == expiry).OrderBy(x => x.Strike);

        var putContracts = contracts.Where(x => x.Right == OptionRight.Put).ToArray();
        var callContracts = contracts.Where(x => x.Right == OptionRight.Call).ToArray();

        if (putContracts.Length < 2 || callContracts.Length < 2) return;

        // Select the strategy legs
        var nearCall = callContracts[0];
        var farCall = callContracts[1];
        var nearPut = putContracts[1];
        var farPut = putContracts.Single(x => x.Strike == nearPut.Strike - farCall.Strike + nearCall.Strike);

        // Order Strategy
        var ironCondor = OptionStrategies.IronCondor(
            _symbol,
            farPut.Strike,
            nearPut.Strike,
            nearCall.Strike,
            farCall.Strike,
            expiry);

        Buy(ironCondor, 2);
    }
}
```

Option Strategies

Short Iron Condor

Introduction

The Short Iron Condor is an Option strategy that consists of four contracts. All the contracts have the same underlying Equity and expiration, but the order of strike prices is A>B>C>D. The following table describes the strike prices of each contract:

Position	Strike
-1 far-OTM call	A
1 near-OTM call	B, where B > underlying\ price
1 near-OTM put	C, where C < underlying\ price
-1 far-OTM put	D, where C-D = A-B

The short iron condor consists of selling a far OTM call, selling a far OTM put, buying a near OTM call, and buying a near OTM put. This strategy profits from a increase in price movement (implied volatility).

Implementation

Follow these steps to implement the short iron condor strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(500000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().IronCondor(30, 5, 10));
}
```

   The `IronCondor` filter narrows the universe down to just the four contracts you need to form a short iron condor.

2. In the `OnData` method, select the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio[_symbol.Underlying].Invested)
    {
        Liquidate();
    }

    if (Portfolio.Invested || !IsMarketOpen(_symbol) ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find put and call contracts with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var contracts = chain.Where(x => x.Expiry == expiry).OrderBy(x => x.Strike);

    var putContracts = contracts.Where(x => x.Right == OptionRight.Put).ToArray();
    var callContracts = contracts.Where(x => x.Right == OptionRight.Call).ToArray();

    if (putContracts.Length < 2 || callContracts.Length < 2) return;

    // Select the strategy legs
    var farPut = putContracts[0];
    var nearPut = putContracts[1];
    var nearCall = callContracts[0];
    var farCall = callContracts[1];
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ShortIronCondor` method with the details of each leg and then pass the result to the `Buy` method.

   ```C#
   var shortIronCondor = OptionStrategies.ShortIronCondor(
       _symbol,
       farPut.Strike,
       nearPut.Strike,
       nearCall.Strike,
       farCall.Strike,
       expiry);

   Buy(shortIronCondor, 2);
   ```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

   ```C#
   var legs = new List<Leg>()
       {
           Leg.Create(farPut.Symbol, -1),
           Leg.Create(nearPut.Symbol, 1),
           Leg.Create(farCall.Symbol, -1),
           Leg.Create(nearCall.Symbol, 1)
       };
   ComboMarketOrder(legs, 1);
   ```

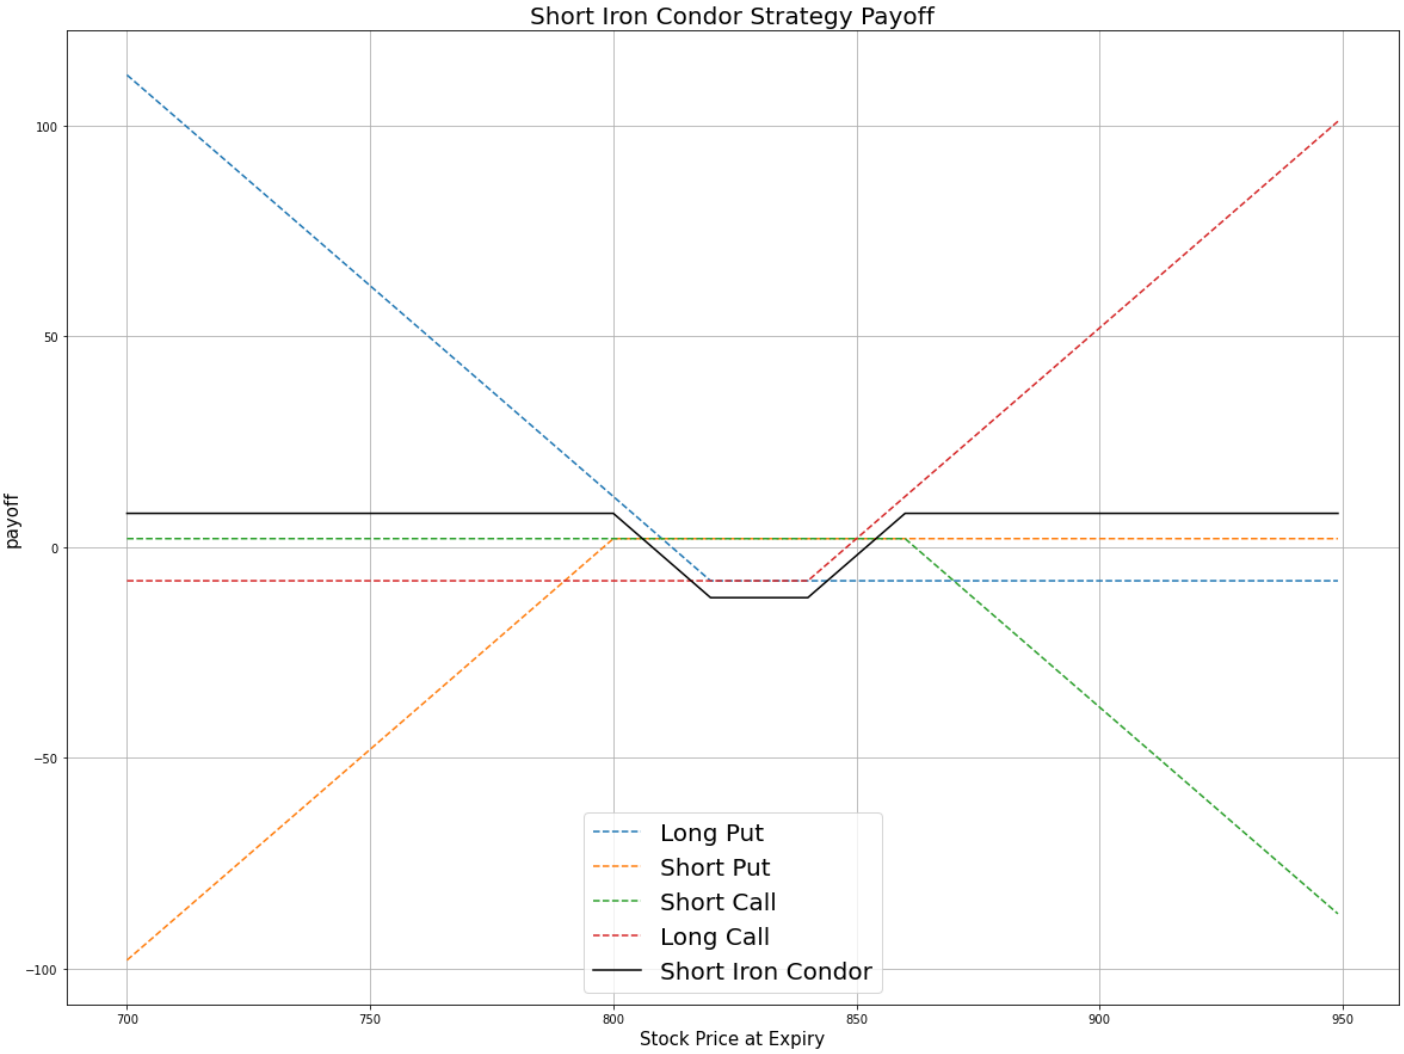
Strategy Payoff

This is a limited-reward-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{far}_T & = & \textrm{Far OTM call value at time T}\\ & C^{near}_T & = & \textrm{Near OTM call value at time T}\\ & P^{far}_T & = & \textrm{Far OTM put value at time T}\\ & P^{near}_T & = & \textrm{Near ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^C_{far} & = & \textrm{Far OTM call strike price}\\ & K^C_{near} & = & \textrm{Near OTM call strike price}\\ & K^P_{far} &$$

= & \textrm{Far OTM put strike price}\\ & K^P_{near} & = & \textrm{Near OTM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{far}_0 & = & \textrm{Far OTM call value at position opening (credit received)}\\ & C^{near}_0 & = & \textrm{Near OTM call value at position opening (debit paid)}\\ & P^{far}_0 & = & \textrm{Far OTM put value at position opening (credit received)}\\ & P^{near}_0 & = & \textrm{Near OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}

The following chart shows the payoff at expiration:



The maximum profit is K^C_{far} - K^C_{near} - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0, where K^P_{OTM} > S_T or S_T > K^C_{OTM}.

The maximum loss is the net debit paid: C^{far}_0 + P^{far}_0 - C^{near}_0 - P^{near}_0, where K^P_{OTM} < S_T < K^C_{OTM}.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Far-OTM call	1.05	857.50
Far-OTM put	2.15	815.00
Near-OTM call	2.75	852.50
Near-OTM put	4.80	820.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{far}_T & = & (S_T - K^C_{far})^{+}\\ & = & (843.25-857.50)^{+}\\ & = & 0\\ C^{near}_T & = & (S_T - K^C_{near})^{+}\\ & = & (843.25-852.50)^{+}\\ & = & 0\\ P^{far}_T & = & (K^P_{far} - S_T)^{+}\\ & = & (815.00-843.25)^{+}\\ & = & 0\\ P^{near}_T & = & (K^P_{near} - S_T)^{+}\\ & = & (820.00-843.25)^{+}\\ & = & 0\\ P_T & = & (C^{near}_T + P^{near}_T - C^{far}_T - P^{far}_T - C^{near}_0 - P^{near}_0 + C^{far}_0 + P^{far}_0)\times m - fee\\ & = & (0+0-0-0-2.75-4.80+1.05+2.15)\times100-1\times4\\ & = & -439 \end{array}

So, the strategy loses $439.

The following algorithm implements a short iron condor Option strategy:

C#

```
public class ShortIronCondorStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().IronCondor(30, 5, 10));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested || !IsMarketOpen(_symbol) ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Find put and call contracts with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var contracts = chain.Where(x => x.Expiry == expiry).OrderBy(x => x.Strike);

        var putContracts = contracts.Where(x => x.Right == OptionRight.Put).ToArray();
        var callContracts = contracts.Where(x => x.Right == OptionRight.Call).ToArray();

        if (putContracts.Length < 2 || callContracts.Length < 2) return;

        // Select the strategy legs
        var nearCall = callContracts[0];
        var farCall = callContracts[1];
        var nearPut = putContracts[1];
        var farPut = putContracts.Single(x => x.Strike == nearPut.Strike - farCall.Strike + nearCall.Strike);

        // Order Strategy
        var shortIronCondor = OptionStrategies.ShortIronCondor(
            _symbol,
            farPut.Strike,
            nearPut.Strike,
            nearCall.Strike,
            farCall.Strike,
            expiry);

        Buy(shortIronCondor, 2);
    }
}
```

Option Strategies

Naked Call

Introduction

A Naked Call , also known as an uncovered call , consists of selling call Options without owning the underlying asset. It's called "naked" because you don't have any cover or protection in the form of owning the underlying asset, which exposes you to potentially unlimited risk. Naked calls aim to profit from the Option premium by selling calls. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, you keep the premium. If the underlying price moves above the strike, the Option buyer can exercise the Options contract , which means you need buy the underlying at market price to fulfill your obligation to sell it at the strike price and keep the premium.

Implementation

Follow these steps to implement the naked call strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
C#
private Symbol _call, _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("IBM");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().NakedCall(30, 0));
}
```

   The `NakedCall` filter narrows the universe down to just the one contract you need to form a naked call.

2. In the `OnData` method, select the Option contract.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

    // Find ATM call with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var atmCall = chain
        .Where(x => x.Right == OptionRight.Call && x.Expiry == expiry)
        .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
        .FirstOrDefault();
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.NakedCall` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var nakedCall = OptionStrategies.NakedCall(_symbol, atmCall.Strike, expiry);
Buy(nakedCall, 1);
```

Approach B: Call the Market Order or Limit Order method.

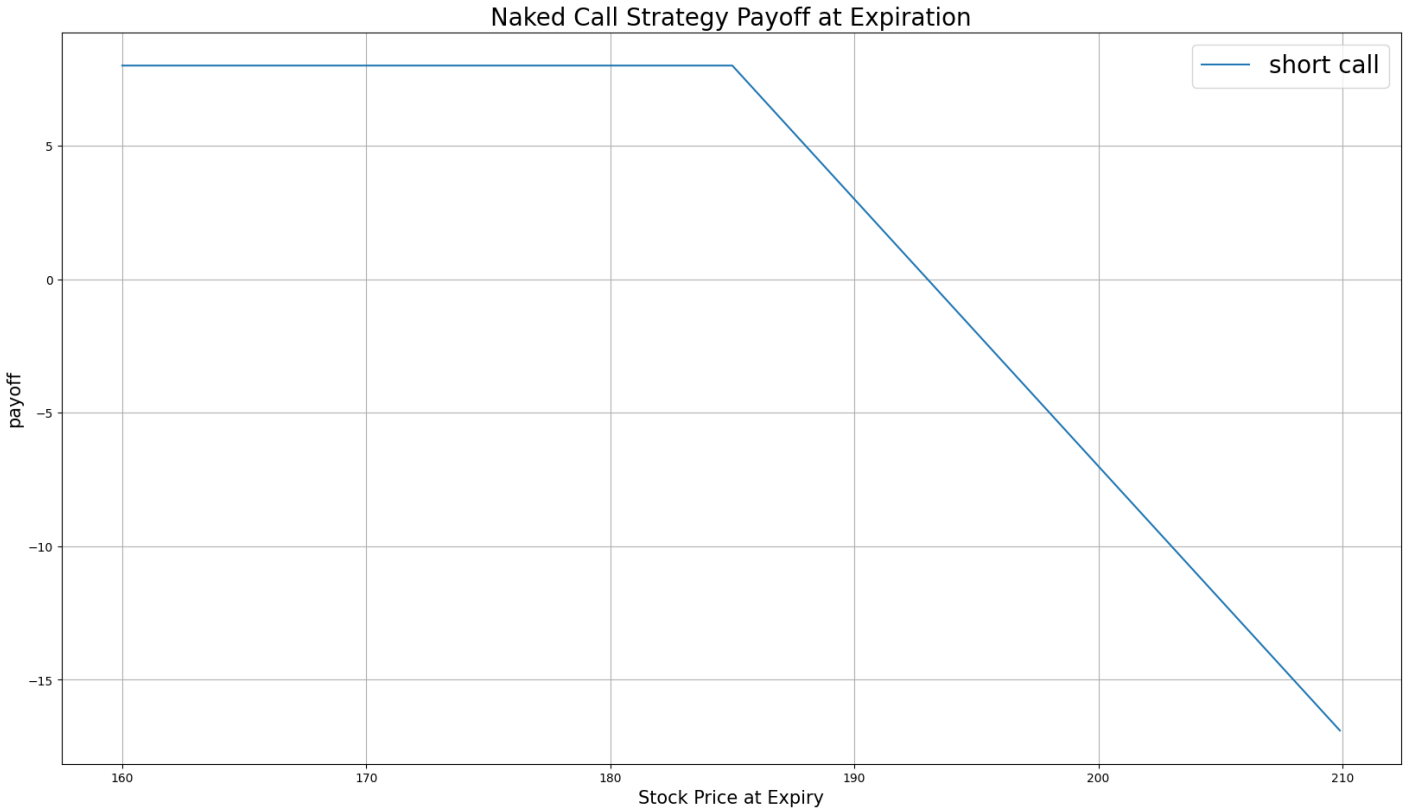
```C#
MarketOrder(atmCall.Symbol, -1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcl} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (C^{K}_0 - C^{K}_T)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{K}_T & = & \textrm{Call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{K}_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is C^{K}_0, which occurs when the underlying price is at or below the strike price of the call at expiration.

The maximum loss is unlimited because there is no limit to how high the underlying asset's price can rise.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	3.35	185.00
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (C^{K}_0 - C^{K}_T)\times m - fee\\ & = & (3.35 - 5.01)\times m - fee\\ & = & -1.66 \times 100 - 2\\ & = & -167 \end{array}$$

So, the strategy loses $167.

The following algorithm implements a naked call Option strategy:

```C#
public class NakedCallAlgorithm : QCAlgorithm
{
    private Symbol _call, _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("IBM");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().NakedCall(30, 0));

        // use the underlying equity as the benchmark
        SetBenchmark(_symbol.Underlying);
    }

    public override void OnData(Slice slice)
    {
        if (_call != null && Portfolio[_call].Invested) return;

        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // Find ATM call with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var atmCall = chain
            .Where(x=> x.Right == OptionRight.Call && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
            .FirstOrDefault();

        if (atmCall == null) return;

        var nakedCall = OptionStrategies.NakedCall(_symbol, atmCall.Strike, expiry);
        Buy(nakedCall, 1);

        _call = atmCall.Symbol;
    }
}
```

Option Strategies

Naked Put

Introduction

A Naked Put , also known as an uncovered put , consists of selling put Options without having a corresponding short position in the underlying security. It's called "naked" because you don't have any cover or protection in the form of a short position in the underlying asset, which exposes you to potentially unlimited risk. Naked puts aim to profit from the Option premium by selling puts. At any time for American Options or at expiration for European Options, if the stock moves above the strike price, you keep the premium. If the underlying price moves below the strike, the Option buyer can exercise the Options contract , which means you need sell the underlying at market price to fulfill your obligation to buy it at the strike price and keep the premium.

Implementation

Follow these steps to implement the naked put strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("IBM");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().NakedPut(30, 0));
}
```

   The `NakedPut` filter narrows the universe down to just the one contract you need to form a naked put.

2. In the `OnData` method, select the Option contract.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

    // Find ATM put with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var atmPut = chain
        .Where(x => x.Right == OptionRight.Put && x.Expiry == expiry)
        .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
        .FirstOrDefault();
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.NakedPut` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var nakedPut = OptionStrategies.NakedPut(_symbol, atmPut.Strike, expiry);
Buy(nakedPut, 1);
```

Approach B: Call the Market Order or Limit Order method.

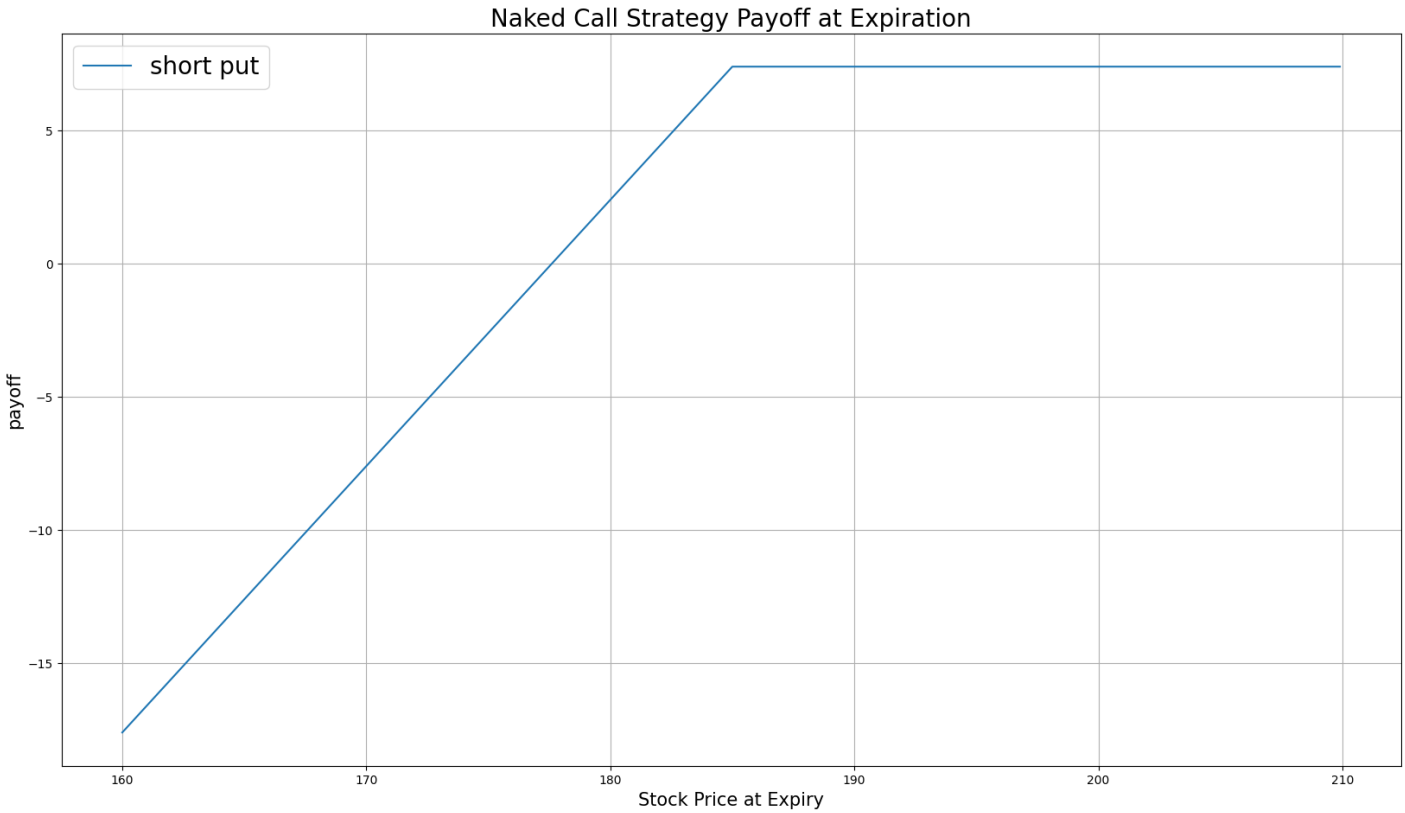
```C#
MarketOrder(atmPut.Symbol, -1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcl} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (P^{K}_0 - P^{K}_T)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is P^{K}_0, which occurs when the underlying price is at or above the strike price of the put at expiration.

The maximum loss is $K - P^{K}_0$, which ocurrs when the underlying price drops to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.37	185.00
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.01)^{+}\\ & = & 0.0\\ P_T & = & (P^{K}_0 - P^{K}_T)\times m - fee\\ & = & (1.37 - 0.0)\times m - fee\\ & = & 1.37 \times 100 - 1\\ & = & 136 \end{array}$$

So, the strategy gains $136.

The following algorithm implements a naked put Option strategy:

```C#
public class NakedPutAlgorithm : QCAlgorithm
{
    private Symbol _put, _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("IBM");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().NakedPut(30, 0));

        // use the underlying equity as the benchmark
        SetBenchmark(_symbol.Underlying);
    }

    public override void OnData(Slice slice)
    {
        if (_put != null && Portfolio[_put].Invested) return;

        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // Find ATM put with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var atmPut = chain
            .Where(x=> x.Right == OptionRight.Put && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
            .FirstOrDefault();

        if (atmPut == null) return;

        var nakedPut = OptionStrategies.NakedPut(_symbol, atmPut.Strike, expiry);
        Buy(nakedPut, 1);

        _put = atmPut.Symbol;
    }
}
```

Option Strategies

Protective Call

Introduction

A Protective Call consists of a short position in a stock and a long position in a call Option for the same amount of stock. Protective calls aim to hedge the short position of a stock with a long ATM or slightly OTM call Option. At any time for American Options or at expiration for European Options, if the stock moves below the strike price, the Option contract becomes worthless but the short position acquires an unrealized gain. If the underlying price moves above the strike, you can exercise the Options contract and receive the underlying Equity, which closes your short position.

Implementation

Follow these steps to implement the protective call strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Options universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("IBM");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().NakedCall(30, 0));
}
```

   The `NakedCall` filter narrows the universe down to just the one contract you need to form a protective call.

2. In the `OnData` method, select the Option contract.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

    // Find ATM call with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var atmCall = chain
        .Where(x => x.Right == OptionRight.Call && x.Expiry == expiry)
        .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
        .FirstOrDefault();
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ProtectiveCall` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var protectiveCall = OptionStrategies.ProtectiveCall(_symbol, atmCall.Strike, expiry);
Buy(protectiveCall, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

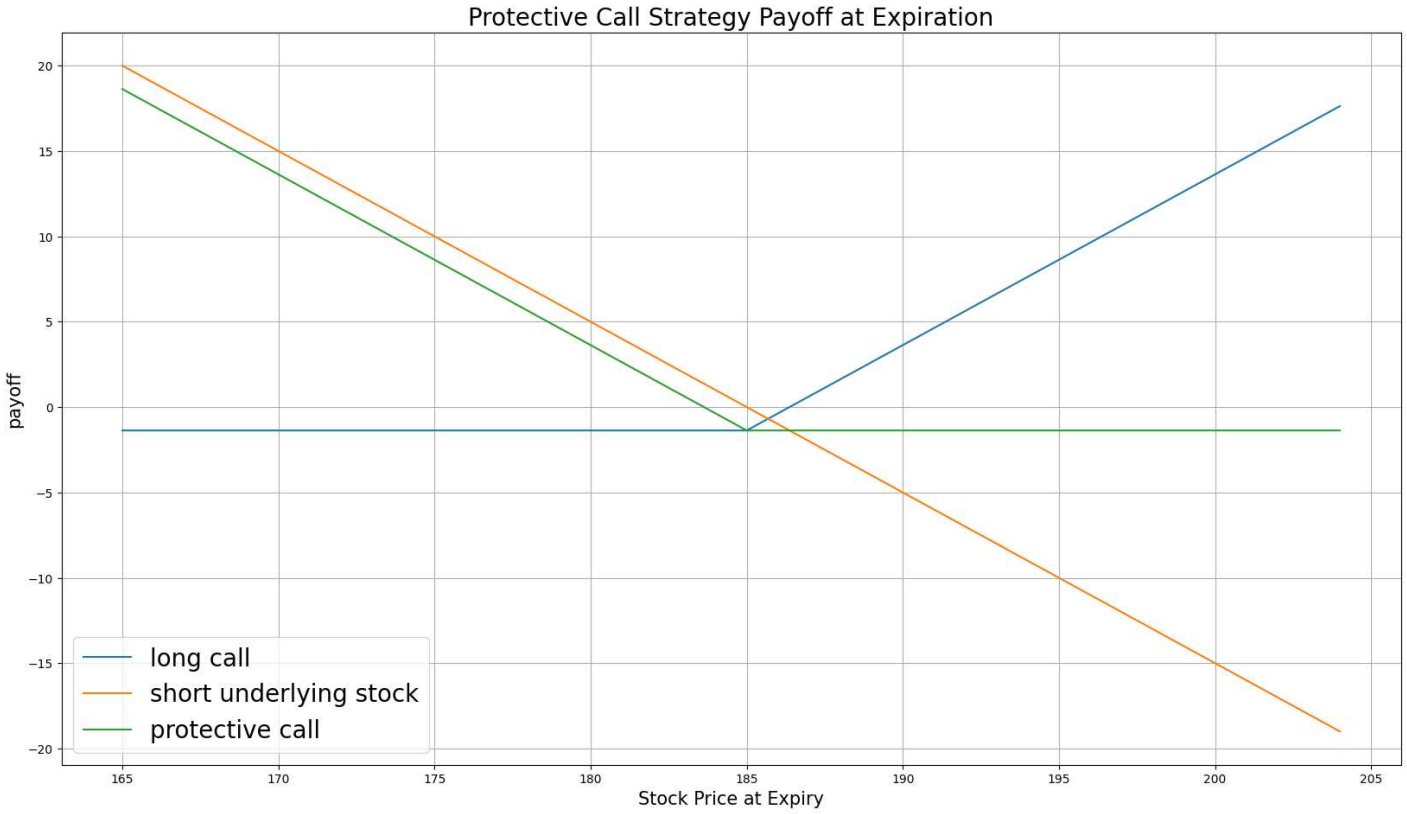
```C#
var legs = new List<Leg>()
    {
        Leg.Create(atmCall.Symbol, 1),
        Leg.Create(chain.Underlying.Symbol, -chain.Underlying.SymbolProperties.ContractMultiplier)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ P_T & = & (S_0 - S_T + C^{K}_T - C^{K}_0)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & C^{K}_T & = & \textrm{Call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Call strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C^{K}_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $S_0 - C^{K}_0$, which occurs when the underlying price is 0.

The maximum loss is $S_0 - K - C^{K}_0$, which occurs when the underlying price is above the strike price.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	3.50	185.00
Underlying Equity at start of the trade	186.94	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{K}_T & = & (S_T - K)^{+}\\ & = & (190.01 - 185)^{+}\\ & = & 5.01\\ P_T & = & (S_0 - S_T + C^{K}_T - C^{K}_0)\times m - fee\\ & = & (186.94 - 190.01 + 5.01 - 3.50)\times m - fee\\ & = & -1.56 \times 100 - 2\\ & = & -158 \end{array}$$

So, the strategy loses $158.

The following algorithm implements a protective call Option strategy:

```C#
public class ProtectiveCallAlgorithm : QCAlgorithm
{
    private Symbol _call, _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("IBM");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().NakedCall(30, 0));

        // use the underlying equity as the benchmark
        SetBenchmark(_symbol.Underlying);
    }

    public override void OnData(Slice slice)
    {
        if (_call != null && Portfolio[_call].Invested) return;

        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // Find ATM call with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var atmCall = chain
            .Where(x=> x.Right == OptionRight.Call && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
            .FirstOrDefault();

        if (atmCall == null) return;

        var protectiveCall = OptionStrategies.ProtectiveCall(_symbol, atmCall.Strike, expiry);
        Buy(protectiveCall, 1);

        _call = atmCall.Symbol;
    }
}
```

Option Strategies

Protective Put

Introduction

A Protective Put consists of buying a long position in a stock and a long position in put Options for the same amount of stock. Protective puts aim to hedge the long position of a stock with a long ATM or slightly OTM put Option. At any time for American Options or at expiration for European Options, if the stock moves above the strike price, the Option contract becomes worthless but the long stock position acquires an unrealized gain. If the underlying price moves below the strike, you can exercise the Options contract , which sells your underlying position at the put Option strike price.

Implementation

Follow these steps to implement the protective put strategy:

1. In the `Initialize` method, set the start date, end date, starting cash, and Options universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("IBM");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().NakedPut(30, 0));
}
```

   The `NakedPut` filter narrows the universe down to just the one contract you need to form a protective put.

2. In the `OnData` method, select the Option contract.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find ATM put with the farthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var atmPut = chain
        .Where(x => x.Right == OptionRight.Put && x.Expiry == expiry)
        .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
        .FirstOrDefault();
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ProtectivePut` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var protectivePut = OptionStrategies.ProtectivePut(_symbol, atmPut.Strike, expiry);
Buy(protectivePut, 1);
```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

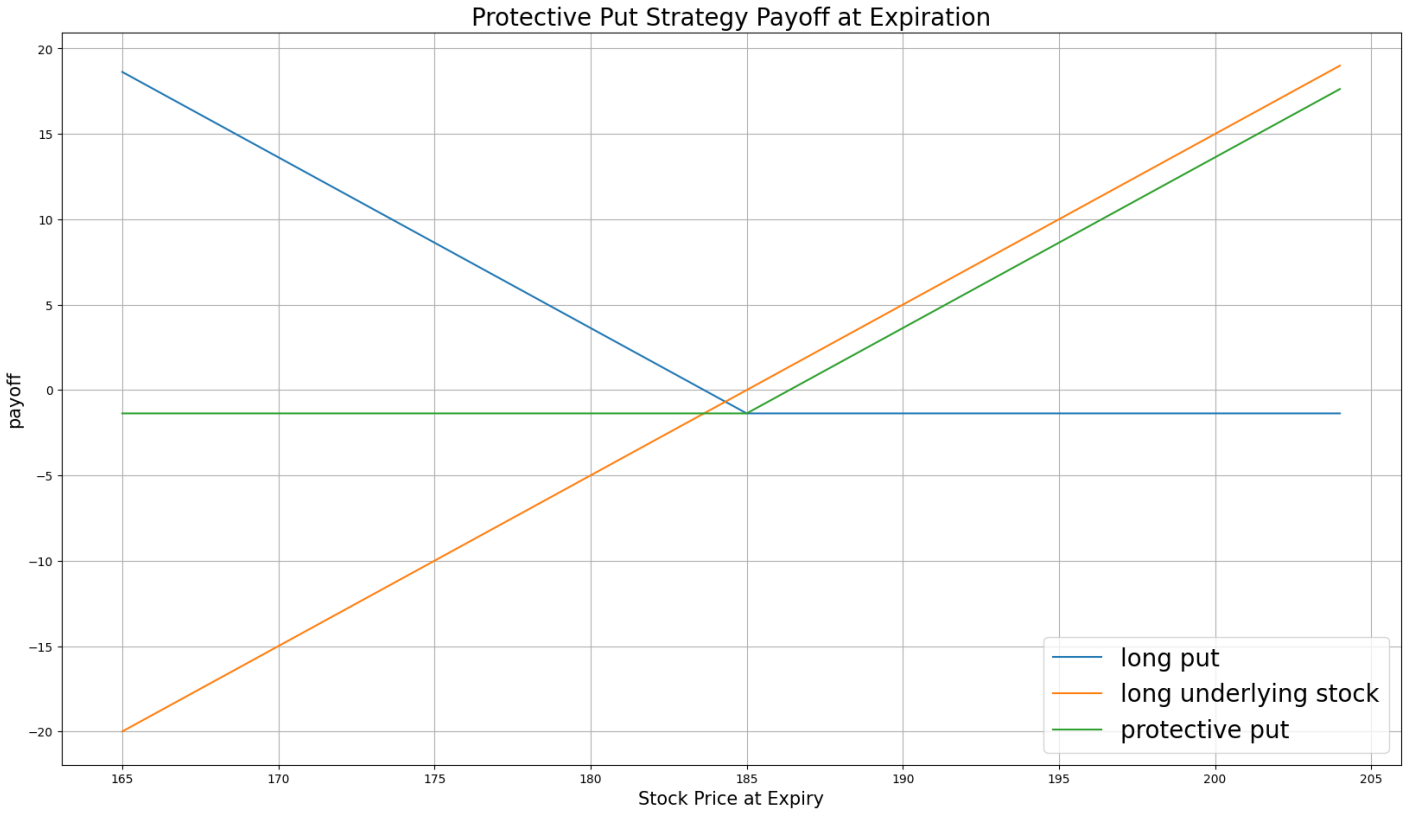
```
C#
var legs = new List<Leg>()
    {
        Leg.Create(atmPut.Symbol, 1),
        Leg.Create(chain.Underlying.Symbol, chain.Underlying.SymbolProperties.ContractMultiplier)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ P_T & = & (S_T - S_0 + P^{K}_T - P^{K}_0)\times m - fee \end{array}$$
$$\begin{array}{rcll} \textrm{where} & P^{K}_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & P^{K}_0 & = & \textrm{Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $S_T - S_0 - P^{K}_0$, which occurs when the underlying price is above the $S_0 + P^{K}_0$.

The maximum loss is P^{K}_0, which occurs when the underlying price drops.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Put	1.53	185.00
Underlying Equity at start of the trade	187.07	-
Underlying Equity at expiration	190.01	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{K}_T & = & (K - S_T)^{+}\\ & = & (185 - 190.1)^{+}\\ & = & 0\\ P_T & = & (S_T - S_0 + P^{K}_T - P^{K}_0)\times m - fee\\ & = & (190.01 - 187.07 + 0 - 1.53)\times m - fee\\ & = & 1.41 \times 100 - 2\\ & = & 139 \end{array}$$

So, the strategy gains $139.

The following algorithm implements a protective put Option strategy:

C#

```
public class ProtectivePutAlgorithm : QCAlgorithm
{
    private Symbol _put, _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("IBM");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().NakedPut(30, 0));

        // use the underlying equity as the benchmark
        SetBenchmark(_symbol.Underlying);
    }

    public override void OnData(Slice slice)
    {
        if (_put != null && Portfolio[_put].Invested) return;

        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // Find ATM put with the farthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var atmPut = chain
            .Where(x=> x.Right == OptionRight.Put && x.Expiry == expiry)
            .OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price))
            .FirstOrDefault();

        if (atmPut == null) return;

        var protectivePut = OptionStrategies.ProtectivePut(_symbol, atmPut.Strike, expiry);
        Buy(protectivePut, 1);

        _put = atmPut.Symbol;
    }
}
```

Option Strategies

Protective Collar

Introduction

A Protective Collar is an Options strategy that consists of a covered call and a long put (protective put) with a lower strike price than the short call contract. In contrast to the covered call, the protective put component limits the drawdown of the strategy when the underlying price decreases too much.

Implementation

Follow these steps to implement the protective collar strategy:

1. In the `Initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().ProtectiveCollar(30, -1, -10));
}
```

   The `ProtectiveCollar` filter narrows the universe down to just the two contracts you need to form a protective collar.

2. In the `OnData` method, select the Option contracts.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested) return;

    // Get the OptionChain
    if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

    // Select an expiry date
    var expiry = chain.Max(x => x.Expiry);

    // Select the call and put contracts that expire on the selected date
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
    if (calls.Count() == 0 || puts.Count() == 0) return;

    // Select the OTM contracts
    var call = calls.OrderBy(x => x.Strike).Last();
    var put = puts.OrderBy(x => x.Strike).First();
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.ProtectiveCollar` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var protectiveCollar = OptionStrategies.ProtectiveCollar(_symbol, call.Strike, put.Strike, expiry);
Buy(protectiveCollar, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

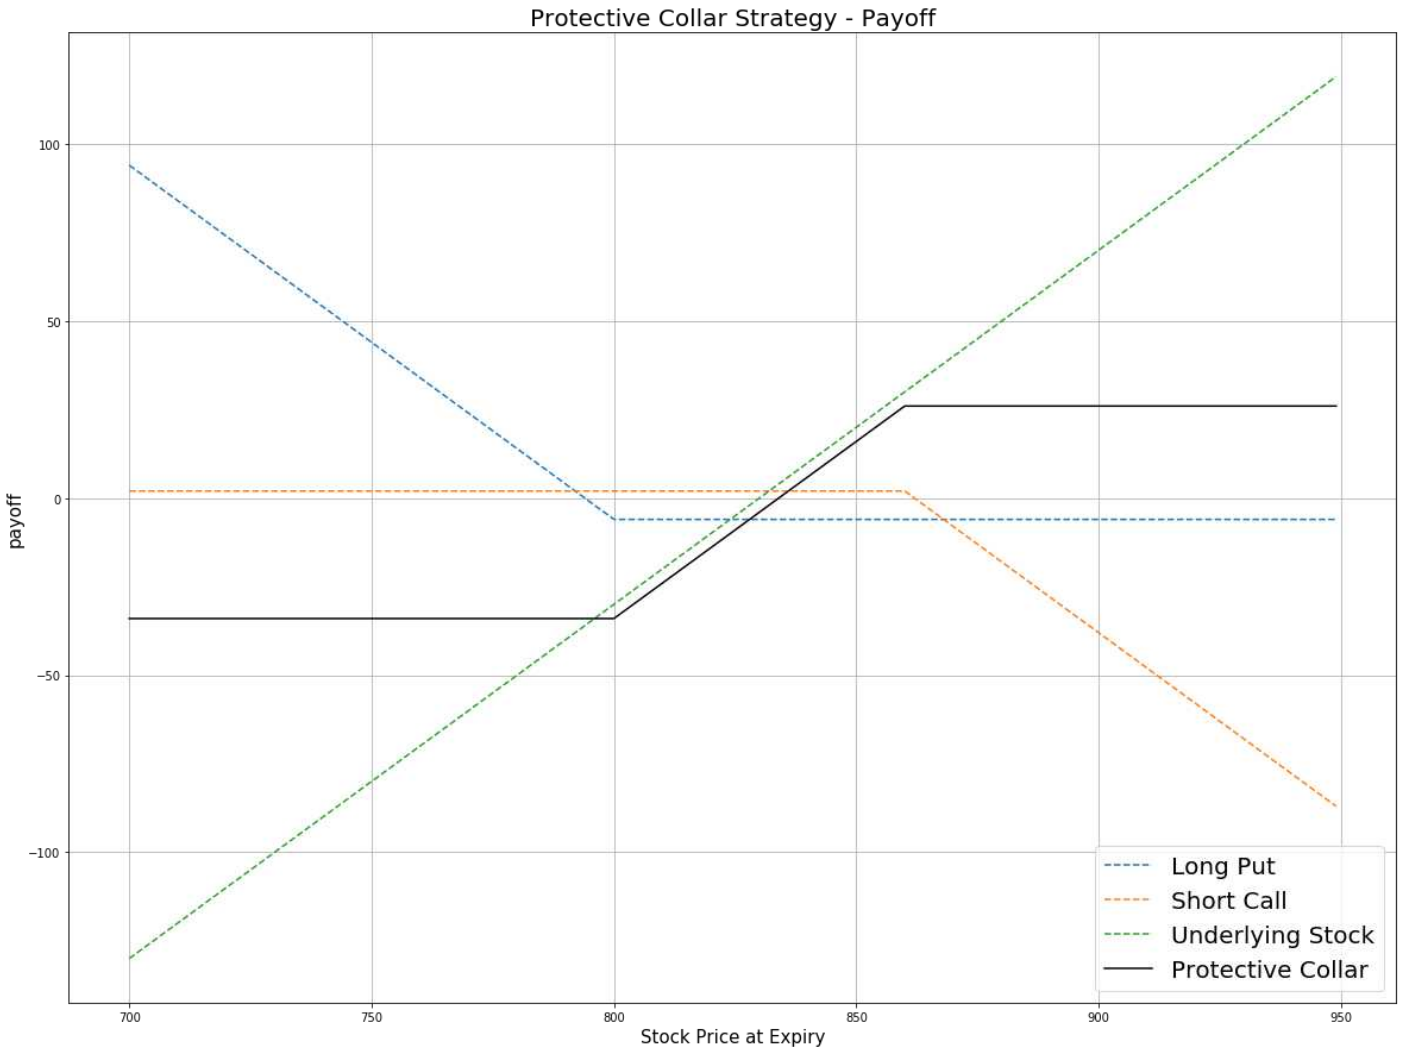
```C#
var legs = new List<Leg>()
    {
        Leg.Create(call.Symbol, -1),
        Leg.Create(put.Symbol, 1),
        Leg.Create(chain.Underlying.Symbol, chain.Underlying.SymbolProperties.ContractMultiplier)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

This is a limited-profit-limited-loss strategy. The payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K^{C})^{+}\\ P_T & = & (K^{P} - S_T)^{+}\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C_T & = & \textrm{Call value at time T}\\ & P_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{Call strike price}\\ & K^{P} & = & \textrm{Put strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & P_0 & = & \textrm{Put price when the trade opened (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K^{C} - S_T + C_0 - P_0$. It occurs when the underlying price is at or above the strike price of the call at expiration.

The maximum profit is $S_T - K^{P} + C_0 - P_0$. It occurs when the underlying price is at or below the strike price of the put at expiration.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	2.85	845.00
Put	6.00	822.50
Underlying Equity at position opens	833.17	-
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K^{C})^{+}\\ & = & (843.365 - 845.00)^{+}\\ & = & 0\\ P_T & = & (K^{P} - S_T)^{+}\\ & = & (822.50 - 843.365)^{+}\\ & = & 0\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee\\ & = & (843.25 - 833.17 - 0 + 0 + 2.85 - 6.00)\times100-1.00\times3\\ & = & 690\\ \end{array}$$

So, the strategy gains $690.

The following algorithm implements a protective collar Option strategy:

C#

```
public class ProtectiveCollarStrategy : QCAlgorithm
{
    private Symbol _equity;
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _equity = AddEquity("GOOG", Resolution.Minute).Symbol;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().ProtectiveCollar(30, -1, -10));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        var chain = slice.OptionChains.get(_symbol, null);
        if (chain == null || chain.Count() == 0) return;

        // sort the optionchain by expiration date and choose the furthest date
        var expiry = chain.OrderBy(x => x.Expiry).Last().Expiry;

        // filter the call and put options from the contracts expires on that date
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
        if (calls.Count() == 0 || puts.Count() == 0) return;

        // select the strike prices
        var callStrike = calls.OrderBy(x => x.Strike).Last().Strike;
        var putStrike = puts.OrderBy(x => x.Strike).First().Strike;

        var protectiveCollar = OptionStrategies.ProtectiveCollar(_symbol, callStrike, putStrike, expiry);
        Buy(protectiveCollar, 1);
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        if (symbol.Value == "GOOG")
        {
            Log($"{Time}::{symbol}::{Securities[symbol].Price}");
        }
    }
}
```

Option Strategies

Long Straddle

Introduction

Long Straddle is an Options trading strategy that consists of buying an ATM call and an ATM put, where both contracts have the same underlying asset, strike price, and expiration date. This strategy aims to profit from volatile movements in the underlying stock, either positive or negative.

Implementation

Follow these steps to implement the long straddle strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().Straddle(30));
}
```

   The `Straddle` filter narrows the universe down to just the two contracts you need to form a long straddle.

2. In the `OnData` method, select the expiration date and strike price of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find ATM options with the nearest expiry
    var expiry = chain.Min(contract => contract.Expiry);
    var strike = chain.OrderBy(contract => Math.Abs(contract.Strike - chain.Underlying.Price)).First().Strike;
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.Straddle` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var longStraddle = OptionStrategies.Straddle(_symbol, strike, expiry);
Buy(longStraddle, 1);
```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit

Order method.

```C#
var contracts = chain.Where(contract => contract.Expiry == expiry && contract.Strike == strike);
if (contracts.Length < 2) return;

var atmCall = contracts.Single(x => x.Right == OptionRight.Call);
var atmPut = contracts.Single(x => x.Right == OptionRight.Put);

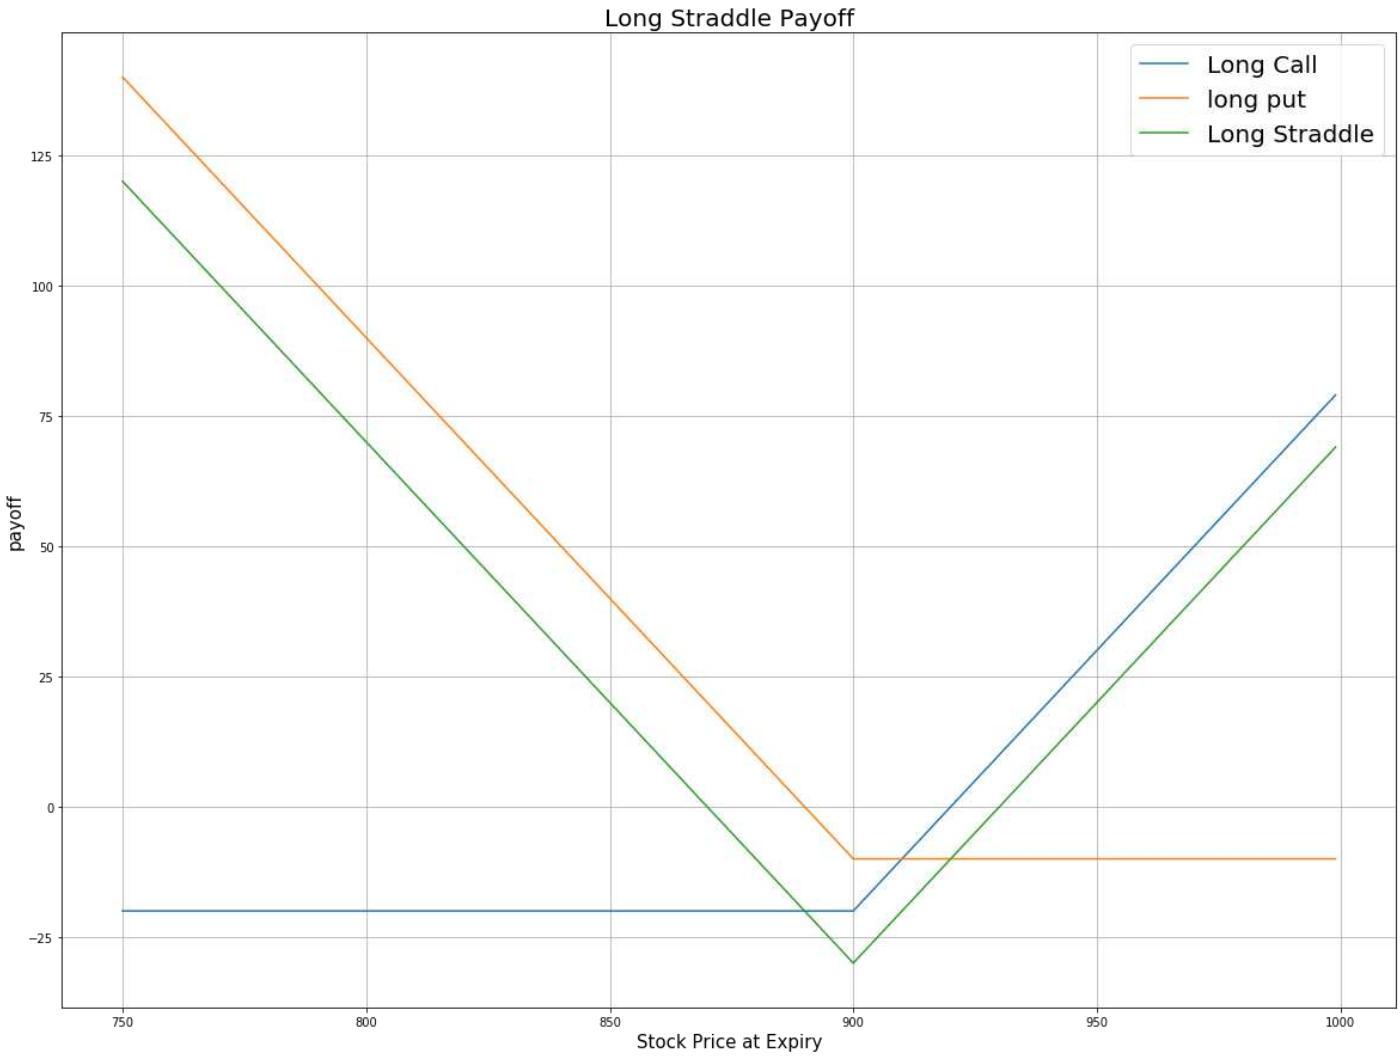
var legs = new List<Leg>()
    {
        Leg.Create(atmCall.Symbol, 1),
        Leg.Create(atmPut.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{ATM}_0 - P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{ATM call strike price}\\ & K^{P} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is unlimited if the underlying price rises to infinity or substantial, $K^{P} - C^{OTM}_0 - P^{OTM}_0$, if it drops to zero at expiration.

The maximum loss is the net debit paid, $C^{ATM}_0 + P^{ATM}_0$. It occurs when the underlying price is the same at expiration as it was when you opened the trade. In this case, both Options expire worthless.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-05-20):

Asset	**Price ($)**	**Strike ($)**
Call	22.30	835.00
Put	23.90	835.00
Underlying Equity at expiration	934.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ & = & (934.01-835.00)^{+}\\ & = & 98.99\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ & = & (835.00-934.01)^{+}\\ & = & 0\\ P_T & = & (C^{ATM}_T + P^{ATM}_T - C^{ATM}_0 - P^{ATM}_0)\times m - fee\\ & = & (98.99+0-22.3-23.9)\times100-1.00\times2\\ & = & 5277 \end{array}$$

So, the strategy gains $5,277.

The following algorithm implements a long straddle Option strategy:

```C#
public class LongStraddleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().Straddle(30));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Find ATM options with the nearest expiry
        var expiry = chain.Min(contract => contract.Expiry);
        var contracts = chain.Where(contract => contract.Expiry == expiry)
                             .OrderBy(contract => Math.Abs(contract.Strike - chain.Underlying.Price))
                             .ToArray();

        if (contracts.Length < 2) return;

        var longStraddle = OptionStrategies.Straddle(_symbol, contracts[0].Strike, expiry);
        Buy(longStraddle, 1);
    }
}
```

Option Strategies

Short Straddle

Introduction

A Short Straddle consists of selling a call and a put, where both contracts have the same underlying asset, strike price (normally at-the-money), and expiration date. If you enter a short straddle, you bet that the underlying asset will remain relatively stable and not experience significant price movements before the Option expires.

Implementation

Follow these steps to implement the short straddle strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().Straddle(30));
}
```

   The `Straddle` filter narrows the universe down to just the two contracts you need to form a short straddle.

2. In the `OnData` method, select the expiration date and strike price of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find ATM options with the nearest expiry
    var expiry = chain.Min(contract => contract.Expiry);
    var strike = chain.OrderBy(contract => Math.Abs(contract.Strike - chain.Underlying.Price)).First().Strike;
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.ShortStraddle` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var shortStraddle = OptionStrategies.ShortStraddle(_symbol, contracts[0].Strike, expiry);
Buy(shortStraddle, 1);
```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit

Order method.

```C#
var contracts = chain.Where(contract => contract.Expiry == expiry && contract.Strike == strike);
if (contracts.Length < 2) return;

var atmCall = contracts.Single(x => x.Right == OptionRight.Call);
var atmPut = contracts.Single(x => x.Right == OptionRight.Put);

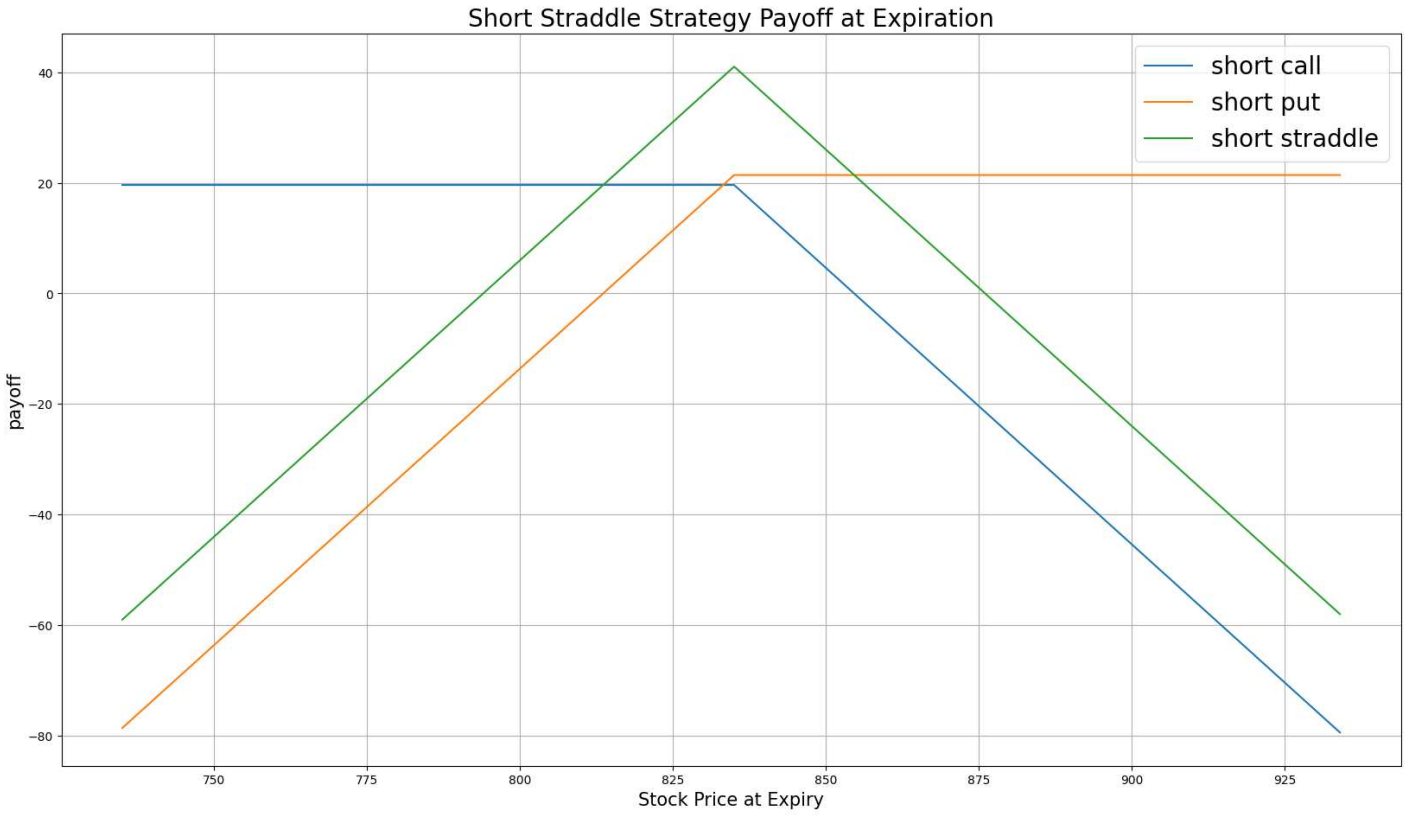
var legs = new List<Leg>()
    {
        Leg.Create(atmCall.Symbol, -1),
        Leg.Create(atmPut.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcl} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (-C^{ATM}_T - P^{ATM}_T + C^{ATM}_0 + P^{ATM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{ATM}_T & = & \textrm{ATM call value at time T}\\ & P^{ATM}_T & = & \textrm{ATM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{ATM call strike price}\\ & K^{P} & = & \textrm{ATM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{ATM}_0 & = & \textrm{ATM call value at position opening (debit paid)}\\ & P^{ATM}_0 & = & \textrm{ATM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $C^{ATM}_0 + P^{ATM}_0$. It occurs when the price of the underlying asset remains exactly at the strike price upon expiration.

The maximum loss is unlimited if the underlying price rises to infinity or drops to zero at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-05-20):

Asset	Price ($)	Strike ($)
Call	19.6	835.00
Put	21.4	835.00
Underlying Equity at early (2017-05-15) call assignment	932.22	-
Underlying Equity at expiration	934.01	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{ATM}_T & = & (S_T - K^{C})^{+}\\ & = & (934.01-835.00)^{+}\\ & = & 99.01\\ P^{ATM}_T & = & (K^{P} - S_T)^{+}\\ & = & (835.00-934.01)^{+}\\ & = & 0\\ P_T & = & (-C^{ATM}_T - P^{ATM}_T + C^{ATM}_0 + P^{ATM}_0)\times m - fee\\ & = & (-99.01-0+19.6+21.4)\times 100 - 2.00\\ & = & -5803 \end{array}$$

So, the strategy loses $5,277. The early assigment doesn't influence the payoff.

The following algorithm implements a short straddle Option strategy:

C#

```
public class ShortStraddleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().Straddle(30));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Find ATM options with the nearest expiry
        var expiry = chain.Min(contract => contract.Expiry);
        var contracts = chain.Where(contract => contract.Expiry == expiry)
                             .OrderBy(contract => Math.Abs(contract.Strike - chain.Underlying.Price))
                             .ToArray();

        if (contracts.Length < 2) return;

        var shortStraddle = OptionStrategies.ShortStraddle(_symbol, contracts[0].Strike, expiry);
        Buy(shortStraddle, 1);
    }
}
```

Option Strategies

Long Strangle

Introduction

Long Strangle is an Options trading strategy that consists of simultaneously buying an OTM put and an OTM call, where both contracts have the same underlying asset and expiration date. This strategy aims to profit from volatile movements in the underlying stock, either positive or negative.

Compared to a long straddle , the net debit of a long strangle is lower since OTM Options are cheaper. Additionally, the losing range of a long straddle is wider and the strike spread is wider.

Implementation

Follow these steps to implement the long strangle strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().Strangle(30, 5, -10));
}
```

   The `Strangle` filter narrows the universe down to just the two contracts you need to form a long strangle.

2. In the `OnData` method, select the contracts of the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find options with the farthest expiry
    var expiry = chain.Max(contract => contract.Expiry);
    var contracts = chain.Where(contract => contract.Expiry == expiry).ToList();

    // Order the OTM calls by strike to find the nearest to ATM
    var callContracts = contracts
        .Where(contract => contract.Right == OptionRight.Call &&
            contract.Strike > chain.Underlying.Price)
        .OrderBy(contract => contract.Strike).ToArray();
    if (callContracts.Length == 0) return;

    // Order the OTM puts by strike to find the nearest to ATM
    var putContracts = contracts
        .Where(contract => contract.Right == OptionRight.Put &&
            contract.Strike < chain.Underlying.Price)
        .OrderByDescending(contract => contract.Strike).ToArray();
    if (putContracts.Length == 0) return;

    var call = callContracts[0];
    var put = putContracts[0];
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.Strangle` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var longStrangle = OptionStrategies.Strangle(_symbol, call.Strike, put.Strike, expiry);
Buy(longStrangle, 1);
```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

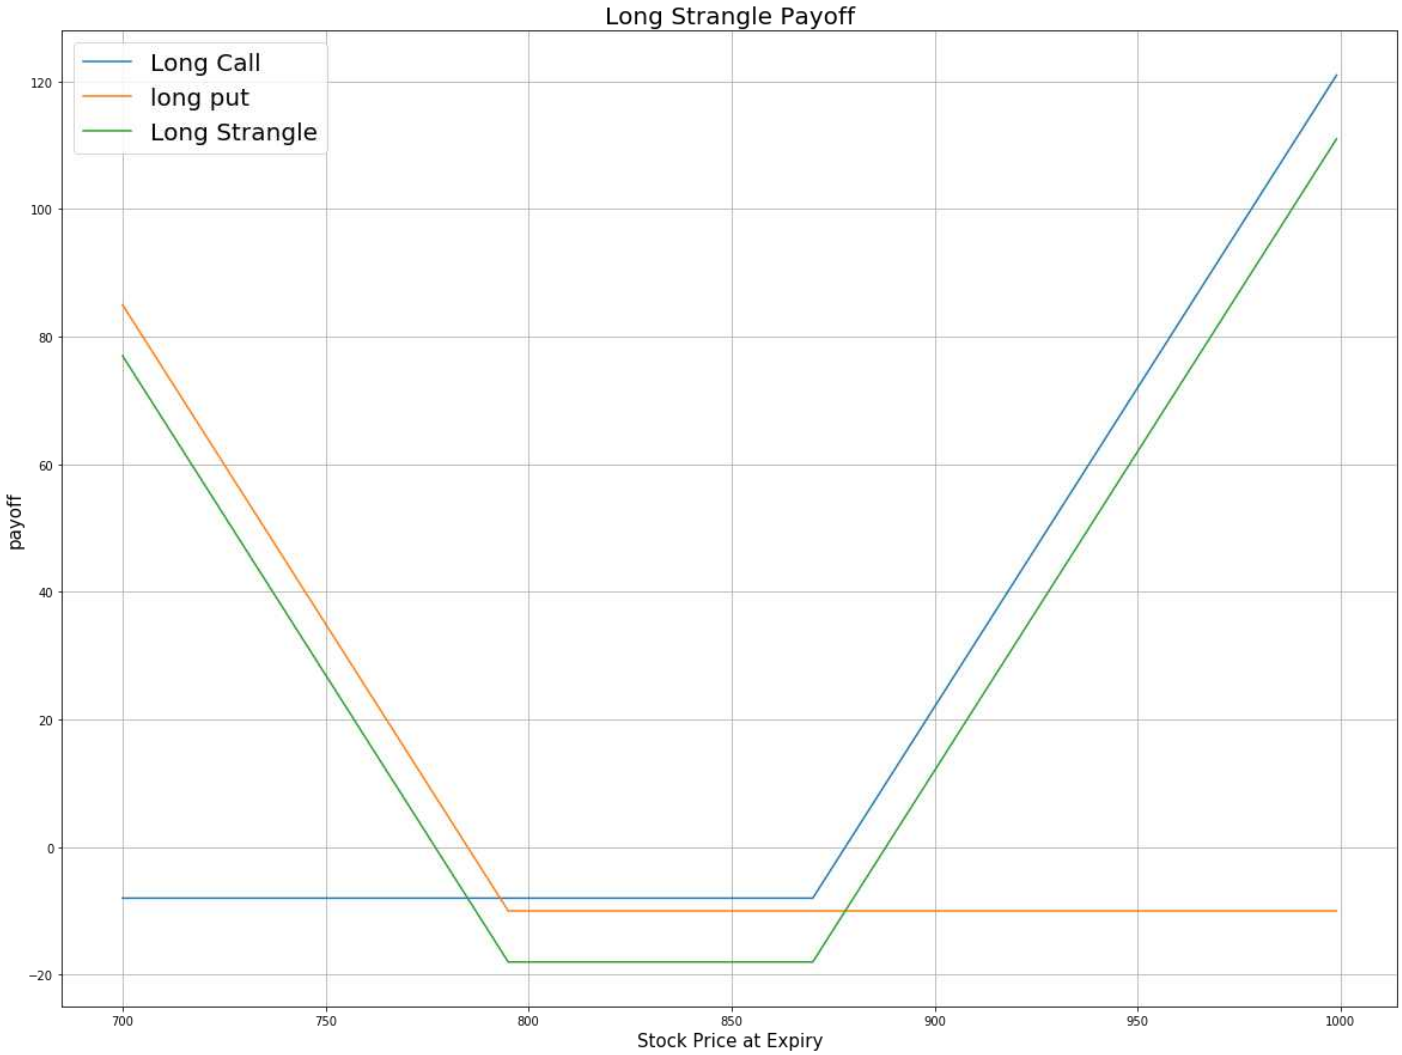
```
C#
var legs = new List<Leg>()
    {
        Leg.Create(call.Symbol, 1),
        Leg.Create(put.Symbol, 1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{OTM}_0 - P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{OTM call strike price}\\ & K^{P} & = & \textrm{OTM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is unlimited if the underlying price rises to infinity at expiration.

The maximum loss is the net debit paid, C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price at expiration is the same as when you opened the trade. In this case, both Options expire worthless.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (04/22/2017):

Asset	**Price ($)**	**Strike ($)**
Call	8.80	835.00
Put	9.50	832.50
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ & = & (832.50-843.19)^{+}\\ & = & 0\\ P_T & = & (C^{OTM}_T + P^{OTM}_T - C^{OTM}_0 - P^{OTM}_0)\times m - fee\\ & = & (8.19+0-8.80-9.50)\times100-2.00\times2\\ & = & -1013 \end{array}

So, the strategy loses $1,013.

The following algorithm implements a long strangle Option strategy:

C#

```
public class LongStrangleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().Strangle(30, 5, -10));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Find options with the farthest expiry
        var expiry = chain.Max(contract => contract.Expiry);
        var contracts = chain.Where(contract => contract.Expiry == expiry).ToList();

        // Order the OTM calls by strike to find the nearest to ATM
        var callContracts = contracts
            .Where(contract => contract.Right == OptionRight.Call &&
                contract.Strike > chain.Underlying.Price)
            .OrderBy(contract => contract.Strike).ToArray();
        if (callContracts.Length == 0) return;

        // Order the OTM puts by strike to find the nearest to ATM
        var putContracts = contracts
            .Where(contract => contract.Right == OptionRight.Put &&
                contract.Strike < chain.Underlying.Price)
            .OrderByDescending(contract => contract.Strike).ToArray();
        if (putContracts.Length == 0) return;

        var callStrike = callContracts[0].Strike;
        var putStrike = putContracts[0].Strike;

        var longStrangle = OptionStrategies.Strangle(_symbol, callStrike, putStrike, expiry);
        Buy(longStrangle, 1);
    }
}
```

Option Strategies

Short Strangle

Introduction

Short Strangle is an Options trading strategy that consists of simultaneously selling an OTM put and an OTM call, where both contracts have the same underlying asset and expiration date. By doing so, the trader is essentially betting that the underlying asset will remain relatively stable and not experience significant price movements before the Options' expiration.

Compared to a short straddle , the net debit of a short strangle is lower since OTM Options are cheaper. Additionally, the winning range of a short straddle is wider and the strike spread is wider.

Implementation

Follow these steps to implement the short strangle strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG");
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().Strangle(30, 5, -10));
}
```

   The `Strangle` filter narrows the universe down to just the two contracts you need to form a short strangle.

2. In the `OnData` method, select the contracts of the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Find options with the farthest expiry
    var expiry = chain.Max(contract => contract.Expiry);
    var contracts = chain.Where(contract => contract.Expiry == expiry).ToList();

    // Order the OTM calls by strike to find the nearest to ATM
    var callContracts = contracts
        .Where(contract => contract.Right == OptionRight.Call &&
            contract.Strike > chain.Underlying.Price)
        .OrderBy(contract => contract.Strike).ToArray();
    if (callContracts.Length == 0) return;

    // Order the OTM puts by strike to find the nearest to ATM
    var putContracts = contracts
        .Where(contract => contract.Right == OptionRight.Put &&
            contract.Strike < chain.Underlying.Price)
        .OrderByDescending(contract => contract.Strike).ToArray();
    if (putContracts.Length == 0) return;

    var call = callContracts[0];
    var put = putContracts[0];
```

3. In the `OnData` method, place the orders.

   Approach A: Call the `OptionStrategies.ShortStrangle` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var shortStrangle = OptionStrategies.ShortStrangle(_symbol, call.Strike, put.Strike, expiry);
Buy(shortStrangle, 1);
```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

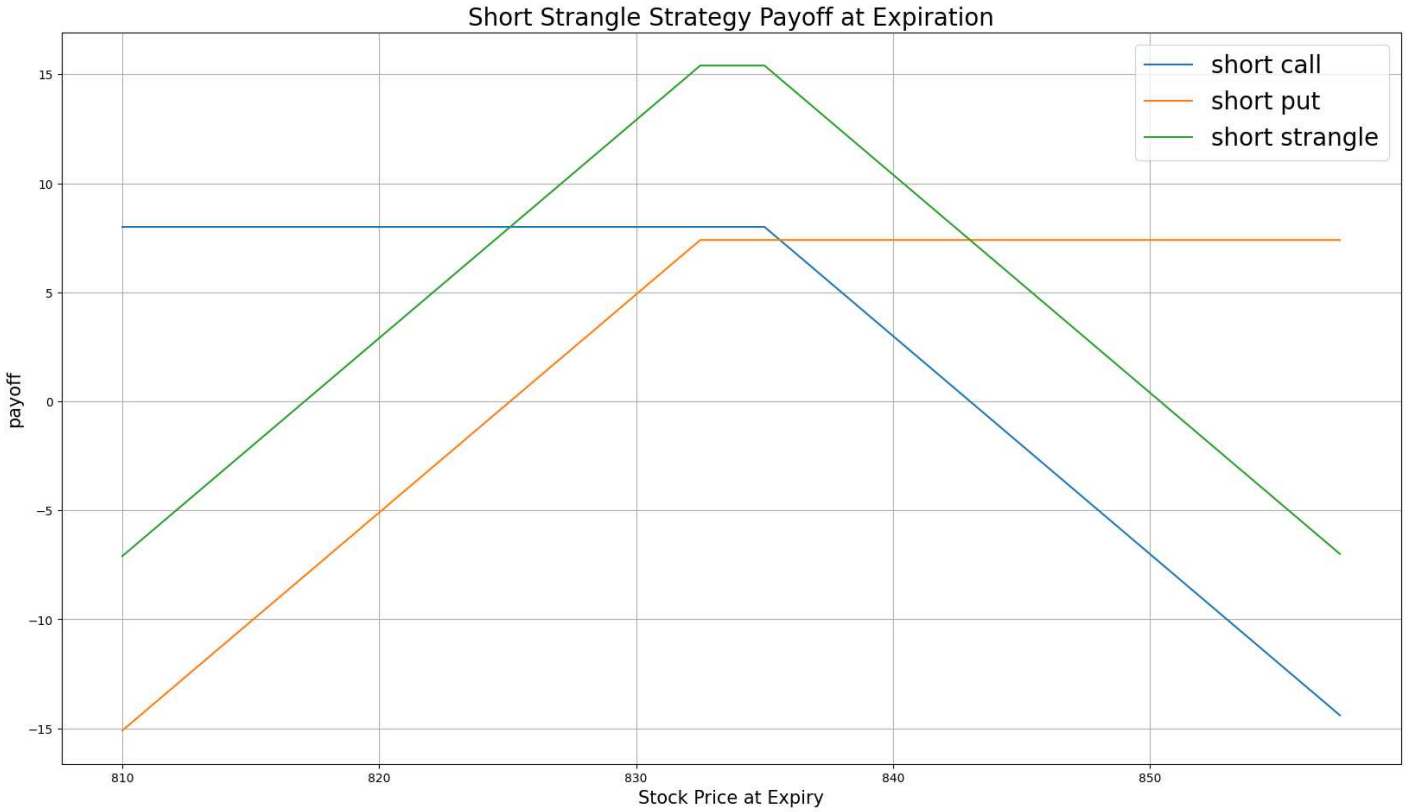
```
C#
var legs = new List<Leg>()
    {
        Leg.Create(call.Symbol, -1),
        Leg.Create(put.Symbol, -1)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

The payoff of the strategy is

$$\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ P_T & = & (-C^{OTM}_T - P^{OTM}_T + C^{OTM}_0 + P^{OTM}_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C^{OTM}_T & = & \textrm{OTM call value at time T}\\ & P^{OTM}_T & = & \textrm{OTM put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{C} & = & \textrm{OTM call strike price}\\ & K^{P} & = & \textrm{OTM put strike price}\\ & P_T & = & \textrm{Payout total at time T}\\ & C^{OTM}_0 & = & \textrm{OTM call value at position opening (debit paid)}\\ & P^{OTM}_0 & = & \textrm{OTM put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit C^{OTM}_0 + P^{OTM}_0. It occurs when the underlying price at expiration remains within the range of the strike prices. In this case, both Options expire worthless.

The maximum loss is unlimited if the underlying price rises to infinity or substantial, C^{OTM}_0 + P^{OTM}_0 - K^{P}, if it drops to zero at expiration.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm at Option expiration (2017-04-22):

Asset	**Price ($)**	**Strike ($)**
Call	8.00	835.00
Put	7.40	832.50
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

\begin{array}{rcll} C^{OTM}_T & = & (S_T - K^{C})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ P^{OTM}_T & = & (K^{P} - S_T)^{+}\\ & = & (832.50-843.19)^{+}\\ & = & 0\\ P_T & = & (-C^{OTM}_T - P^{OTM}_T + C^{OTM}_0 + P^{OTM}_0)\times m - fee\\ & = & (-8.19-0+8.00+7.40)\times100-2.00\times2\\ & = & 719 \end{array}

So, the strategy gains $719.

The following algorithm implements a short strangle Option strategy:

C#

```
public class ShortStrangleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG");
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().Strangle(30, 5, -10));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Find options with the farthest expiry
        var expiry = chain.Max(contract => contract.Expiry);
        var contracts = chain.Where(contract => contract.Expiry == expiry).ToList();

        // Order the OTM calls by strike to find the nearest to ATM
        var callContracts = contracts
            .Where(contract => contract.Right == OptionRight.Call &&
                contract.Strike > chain.Underlying.Price)
            .OrderBy(contract => contract.Strike).ToArray();
        if (callContracts.Length == 0) return;

        // Order the OTM puts by strike to find the nearest to ATM
        var putContracts = contracts
            .Where(contract => contract.Right == OptionRight.Put &&
                contract.Strike < chain.Underlying.Price)
            .OrderByDescending(contract => contract.Strike).ToArray();
        if (putContracts.Length == 0) return;

        var callStrike = callContracts[0].Strike;
        var putStrike = putContracts[0].Strike;

        var shortStrangle = OptionStrategies.ShortStrangle(_symbol, callStrike, putStrike, expiry);
        Buy(shortStrangle, 1);
    }
}
```

Option Strategies

Conversion

Introduction

A Conversion is a special case of a protective collar . It consist of holding one lot of the underlying security, shorting a call, and longing a put with lower strike price. However, the strategy now serves as an delta-neutral arbitration from Option mispricing instead of a hedge strategy. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the conversion strategy:

1. In the `Initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

   ```C#
   private Symbol _symbol;

   public override void Initialize()
   {
       SetStartDate(2024, 9, 1);
       SetEndDate(2024, 12, 31);
       SetCash(100000);

       UniverseSettings.Asynchronous = true;
       var option = AddOption("GOOG", Resolution.Minute);
       _symbol = option.Symbol;
       option.SetFilter(universe => universe.IncludeWeeklys().Conversion(30, -5));
   }
   ```

   The `Conversion` filter narrows the universe down to just the two contracts you need to form a conversion.

2. In the `OnData` method, select the strike and expiry of the contracts in the strategy legs.

   ```C#
   public override void OnData(Slice slice)
   {
       if (Portfolio.Invested) return;

       // Get the OptionChain
       if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

       // Select an expiry date and ATM strike price
       var expiry = chain.Max(x => x.Expiry);
       var strike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;
   ```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.Conversion` method with the details of each leg and then pass the result to the `Buy` method.

   ```C#
   var conversion = OptionStrategies.Conversion(_symbol, strike, expiry);
   Buy(conversion, 1);
   ```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
// Select the call and put contracts
var call = chain.Single(x => x.Expiry == expiry && x.Strike == strike && x.Right == OptionRight.Call);
var put = chain.Single(x => x.Expiry == expiry && x.Strike == strike && x.Right == OptionRight.Put);

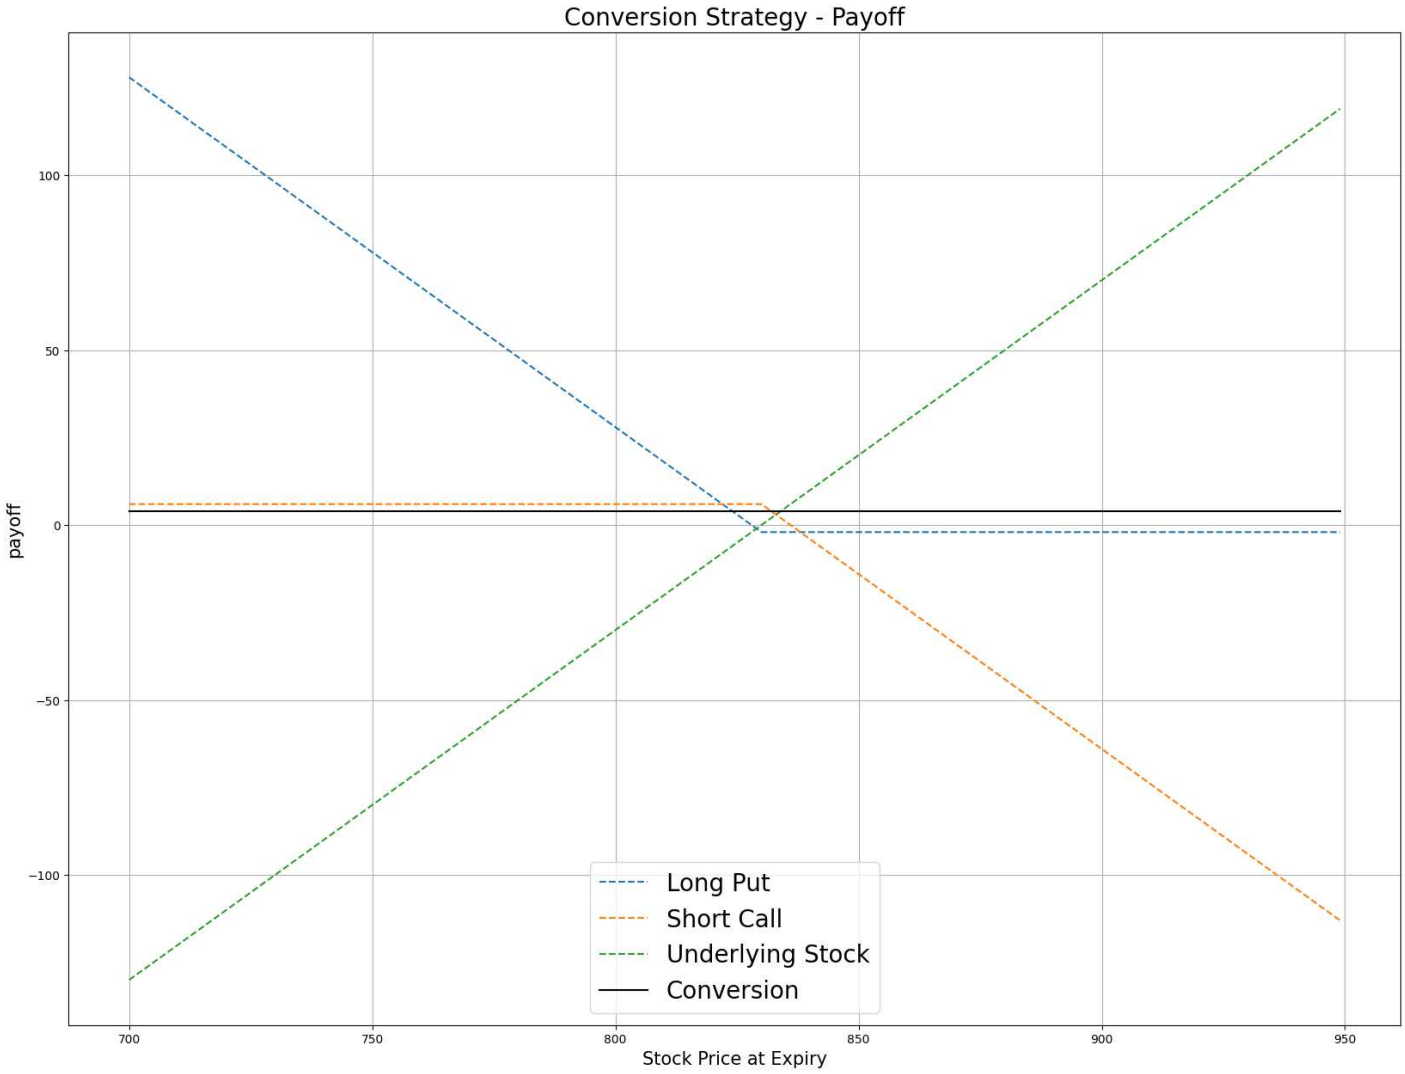
var legs = new List<Leg>()
    {
        Leg.Create(call.Symbol, -1),
        Leg.Create(put.Symbol, 1),
        Leg.Create(chain.Underlying.Symbol, chain.Underlying.SymbolProperties.ContractMultiplier)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K)^{+}\\ P_T & = & (K - S_T)^{+}\\ Payoff_T & = & (S_T - S_0 - C_T + P_T + C_0 - P_0)\times m - fee\\ & = & (K - S_0 + C_0 - P_0)\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C_T & = & \textrm{Call value at time T}\\ & P_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & P_0 & = & \textrm{Put price when the trade opened (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	8.10	832.50
Put	9.50	832.50
Underlying Equity at position opens	833.17	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (K - S_0 + C_0 - P_0)\times m - fee\\ & = & (832.50 - 833.17 + 8.10 - 9.50)\times100-1.00\times3\\ & = & -210.00\\ \end{array}$$

So, the strategy loses $210.

The following algorithm implements a conversion Option strategy:

```C#
public class ConversionStrategy : QCAlgorithm
{
    private Symbol _equity;
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _equity = AddEquity("GOOG", Resolution.Minute).Symbol;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().Conversion(30, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // sort the optionchain by expiration date and choose the furthest date
        var expiry = chain.OrderBy(x => x.Expiry).Last().Expiry;

        // select ATM strike price
        var strike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // Order Strategy
        var conversion = OptionStrategies.Conversion(_symbol, strike, expiry);
        Buy(conversion, 1);
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        if (symbol.Value == "GOOG")
        {
            Log($"{Time}::{symbol}::{Securities[symbol].Price}");
        }
    }
}
```

Option Strategies

Reverse Conversion

Introduction

A Reverse Conversion , or Reversal , is the inverse of a conversion and also a special case of a protective collar . It consist of shorting one lot of the underlying security, buying a call, and selling a put with lower strike price. However, the strategy now serves as an delta-neutral arbitration from Option mispricing instead of a hedge strategy. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the reverse conversion strategy:

1. In the `Initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

   ```C#
   private Symbol _symbol;

   public override void Initialize()
   {
       SetStartDate(2024, 9, 1);
       SetEndDate(2024, 12, 31);
       SetCash(100000);

       UniverseSettings.Asynchronous = true;
       var option = AddOption("GOOG", Resolution.Minute);
       _symbol = option.Symbol;
       option.SetFilter(universe => universe.IncludeWeeklys().Conversion(30, -5));
   }
   ```

   The `Conversion` filter narrows the universe down to just the two contracts you need to form a reverse conversion.

2. In the `OnData` method, select the strike and expiry of the contracts in the strategy legs.

   ```C#
   public override void OnData(Slice slice)
   {
       if (Portfolio.Invested) return;

       // Get the OptionChain
       if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

       // Select an expiry date and ATM strike price
       var expiry = chain.Max(x => x.Expiry);
       var strike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;
   ```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.ReverseConversion` method with the details of each leg and then pass the result to the `Buy` method.

   ```C#
   var reverseConversion = OptionStrategies.ReverseConversion(_symbol, strike, expiry);
   Buy(reverseConversion, 1);
   ```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
// Select the call and put contracts
var call = chain.Single(x => x.Expiry == expiry && x.Strike == strike && x.Right == OptionRight.Call);
var put = chain.Single(x => x.Expiry == expiry && x.Strike == strike && x.Right == OptionRight.Put);

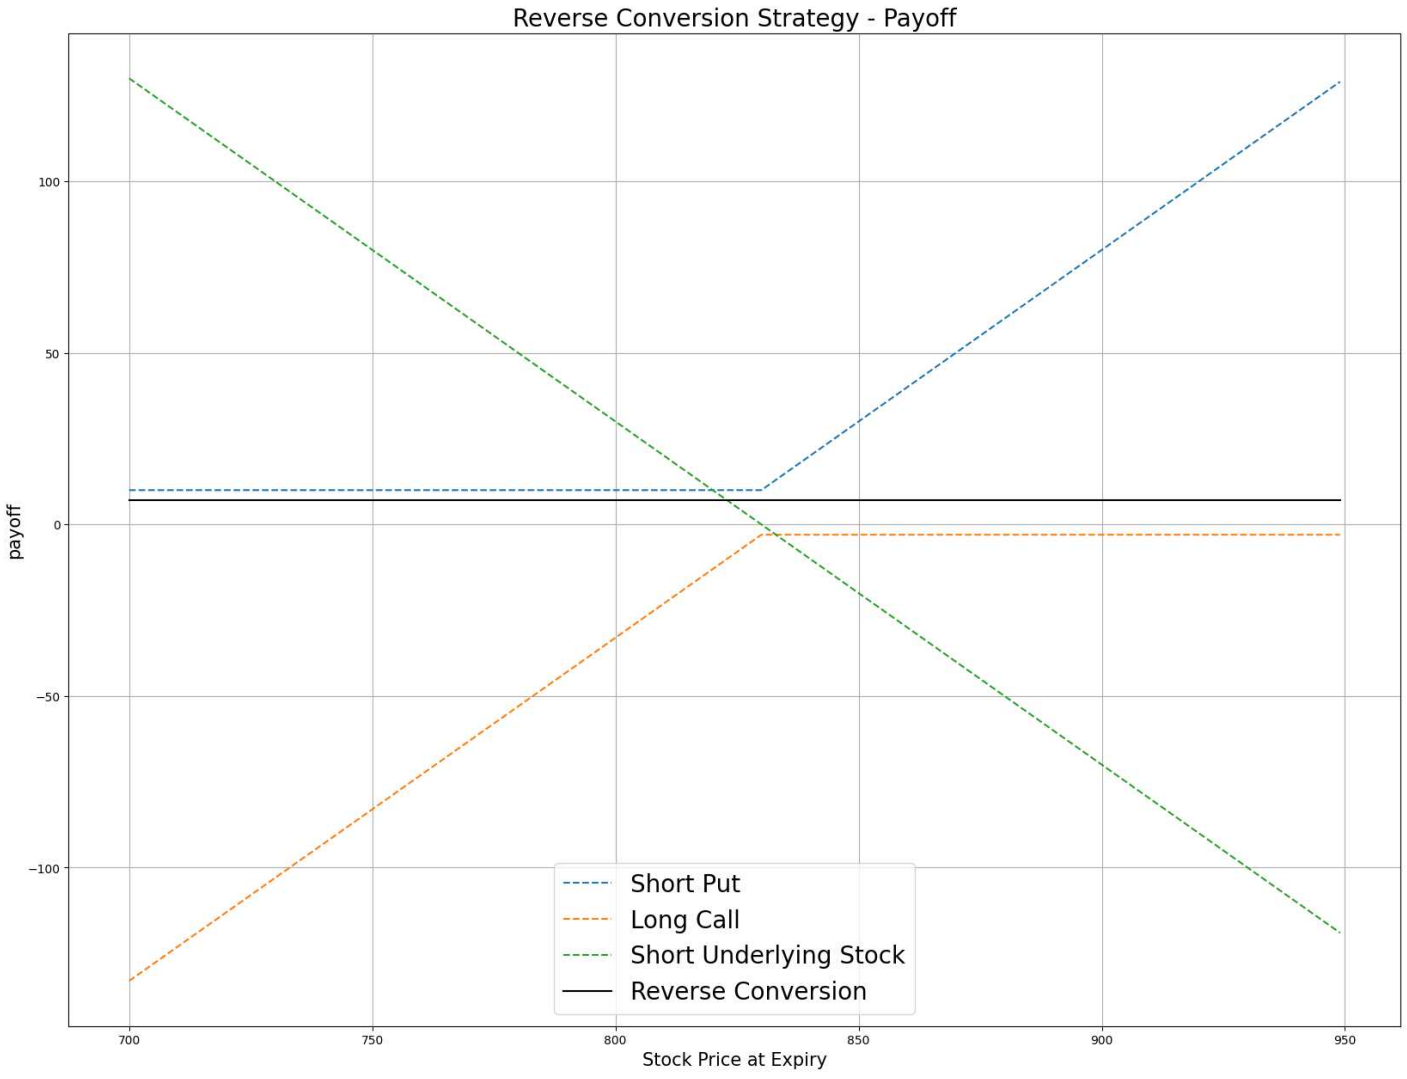
var legs = new List<Leg>()
    {
        Leg.Create(call.Symbol, 1),
        Leg.Create(put.Symbol, -1),
        Leg.Create(chain.Underlying.Symbol, -chain.Underlying.SymbolProperties.ContractMultiplier)
    };
ComboMarketOrder(legs, 1);
```

Strategy Payoff

This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_T & = & (S_T - K)^{+}\\ P_T & = & (K - S_T)^{+}\\ Payoff_T & = & (S_0 - S_T + C_T - P_T - C_0 + P_0)\times m - fee\\ & = & (S_0 - K - C_0 + P_0)\times m - fee \end{array} \begin{array}{rcl} \textrm{where} & C_T & = & \textrm{Call value at time T}\\ & P_T & = & \textrm{Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K & = & \textrm{Strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & S_0 & = & \textrm{Underlying asset price when the trade opened}\\ & C_0 & = & \textrm{Call price when the trade opened (credit received)}\\ & P_0 & = & \textrm{Put price when the trade opened (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Call	10.30	832.50
Put	7.40	832.50
Underlying Equity at position opens	832.26	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (S_0 - K - C_0 + P_0)\times m - fee\\ & = & (832.26 - 832.50 - 10.30 + 7.40)\times100-1.00\times3\\ & = & -317.00\\ \end{array}$$

So, the strategy loses $317.

The following algorithm implements a reverse conversion Option strategy:

```C#
public class ReverseConversionStrategy : QCAlgorithm
{
    private Symbol _equity;
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _equity = AddEquity("GOOG", Resolution.Minute).Symbol;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().Conversion(30, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain of the symbol
        if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

        // sort the optionchain by expiration date and choose the furthest date
        var expiry = chain.OrderBy(x => x.Expiry).Last().Expiry;

        // select ATM strike price
        var strike = chain.OrderBy(x => Math.Abs(x.Strike - chain.Underlying.Price)).First().Strike;

        // Order Strategy
        var reverseConversion = OptionStrategies.ReverseConversion(_symbol, strike, expiry);
        Buy(reverseConversion, 1);
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        if (symbol.Value == "GOOG")
        {
            Log($"{Time}::{symbol}::{Securities[symbol].Price}");
        }
    }
}
```

Option Strategies

Long Box Spread

Introduction

A long Box Spread is the combination of a bull call spread and a bear put spread . It consist of buying an ITM call at strike A, selling an OTM put at strike A, buying an ITM put at strike B < A, and selling an OTM call at strike B, where all of the contracts have the same expiry date. This strategy serves as an delta-neutral arbitration from Option mispricing. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the long box spread strategy:

1. In the `Initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().BoxSpread(30, 5));
}
```

   The `BoxSpread` filter narrows the universe down to just the four contracts you need to form a box spread.

2. In the `OnData` method, select the expiry and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested) return;

    // Get the OptionChain
    if (!slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select an expiry date and ITM & OTM strike prices
    var expiry = chain.Max(x => x.Expiry);
    var contracts = chain.Where(x => x.Expiry == expiry).ToList();
    var higherStrike = contracts.Max(x => x.Strike);
    var lowerStrike = contracts.Min(x => x.Strike);
```

3. In the `OnData` method, select the contracts and place the order.

   Approach A: Call the `OptionStrategies.BoxSpread` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var boxSpread = OptionStrategies.BoxSpread(_symbol, higherStrike, lowerStrike, expiry);
Buy(boxSpread, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
// Select the call and put contracts
var itmCall = contracts.Single(x => x.Strike == lowerStrike && x.Right == OptionRight.Call);
var otmCall = contracts.Single(x => x.Strike == higherStrike && x.Right == OptionRight.Call);
var itmPut = contracts.Single(x => x.Strike == higherStrike && x.Right == OptionRight.Put);
var otmPut = contracts.Single(x => x.Strike == lowerStrike && x.Right == OptionRight.Put);

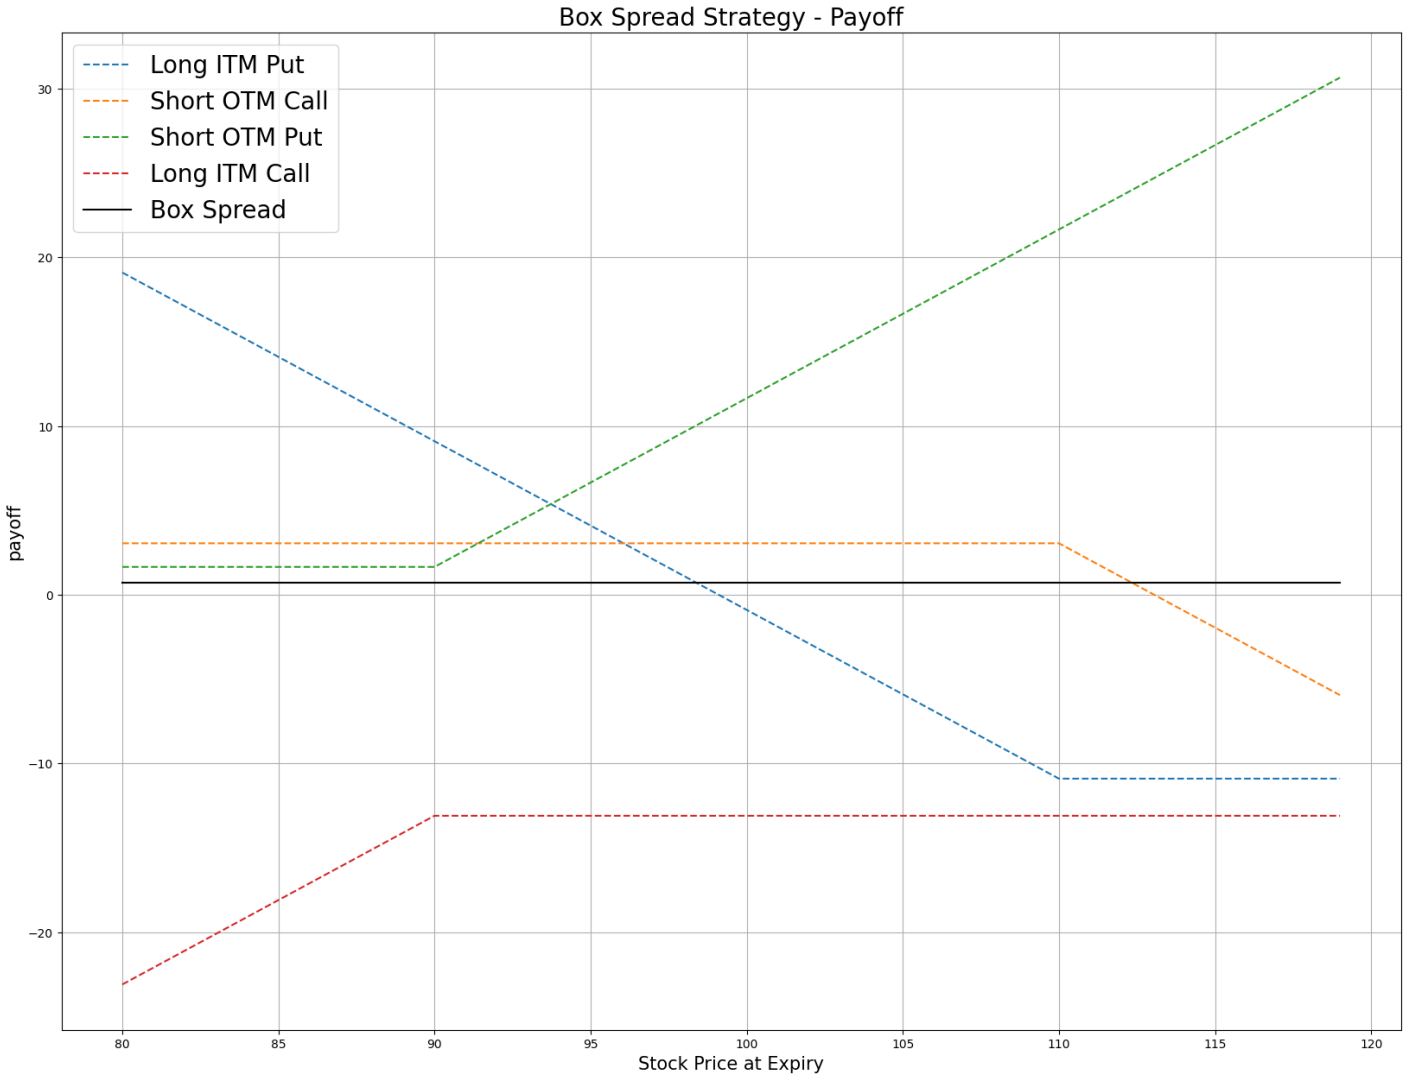
var legs = new List<Leg>()
{
    Leg.Create(itmCall.Symbol, 1),
    Leg.Create(itmPut.Symbol, 1),
    Leg.Create(otmCall.Symbol, -1),
    Leg.Create(otmPut.Symbol, -1),
};
ComboMarketOrder(legs, 1);
```

Strategy Payoff

This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_T^{ITM} & = & (S_T - K_{-})^{+}\\ C_T^{OTM} & = & (S_T - K_{+})^{+}\\ P_T^{ITM} & = & (K_{+} - S_T)^{+}\\ P_T^{OTM} & = & (K_{-} - S_T)^{+}\\ Payoff_T & = & (C_T^{ITM} - C_{T_0}^{ITM} + P_T^{ITM} - P_{T_0}^{ITM} - C_T^{OTM} + C_{T_0}^{OTM} - P_T^{OTM} + P_{T_0}^{OTM})\times m - fee\\ & = & (K_{+} - K_{-} + C_{T_0}^{OTM} + P_{T_0}^{OTM} - C_{T_0}^{ITM} - P_{T_0}^{ITM})\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C_T^{ITM} & = & \textrm{ITM Call value at time T}\\ & C_T^{OTM} & = & \textrm{OTM Call value at time T}\\ & P_T^{ITM} & = & \textrm{ITM Put value at time T}\\ & P_T^{OTM} & = & \textrm{OTM Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K_{+} & = & \textrm{Higher strike price}\\ & K_{-} & = & \textrm{Lower strike price}\\ & Payoff_{T_1} & = & \textrm{Payout total at time T1}\\ & C_{T_0}^{ITM} & = & \textrm{ITM Call price when the trade opened (debit paid)}\\ & C_{T_0}^{OTM} & = & \textrm{OTM Call price when the trade opened (credit received)}\\ & P_{T_0}^{ITM} & = & \textrm{ITM Put price when the trade opened (debit paid)}\\ & P_{T_0}^{OTM} & = & \textrm{OTM Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
ITM Call	27.30	810.00
ITM Put	28.00	857.50
OTM Call	1.05	857.50
OTM Put	1.50	810.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (K_{+} - K_{-} + C_0^{OTM} + P_0^{OTM} - C_0^{ITM} - P_0^{ITM})\times m - fee\\ & = & (857.50 - 810.00 + 1.05 + 1.50 - 27.30 - 28.00)\times100 - 1.00\times4\\ & = & -529.00\\ \end{array}$$

So, the strategy loses $529.

The following algorithm implements a long box spread Option strategy:

```C#
public class BoxSpreadStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        UniverseSettings.Asynchronous = true;

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().BoxSpread(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested) return;

        // Get the OptionChain
        if (!slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select an expiry date
        var expiry = chain.Max(x => x.Expiry);

        // Select the strike prices of the contracts
        var contracts = chain.Where(x => x.Expiry == expiry).ToList();
        var higherStrike = contracts.Max(x => x.Strike);
        var lowerStrike = contracts.Min(x => x.Strike);
        var boxSpread = OptionStrategies.BoxSpread(_symbol, higherStrike, lowerStrike, expiry);
        Buy(boxSpread, 1);
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        if (symbol == _symbol.Underlying)
        {
            Log($"{Time}::{symbol}::{Securities[symbol].Price}");
        }
    }
}
```

Option Strategies

Short Box Spread

Introduction

A Short Box Spread is the inverse of a box spread , as well as the combination of a bear call spread and a bull put spread . It consists of buying an OTM call at strike A, selling an ITM put at strike A, buying an OTM put and strike B < A, and selling an ITM call at strike B, where all of the contracts have the same expiry date. This strategy serves as an delta-neutral arbitration from Option mispricing. Note that it only attains a true profit when the risk-free return is greater than the risk-free interest rate .

Implementation

Follow these steps to implement the short box spread strategy:

1. In the `Initialize` method, set the start date, set the end date, subscribe to the underlying Equity , and create an Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().BoxSpread(30, 5));
}
```

   The `BoxSpread` filter narrows the universe down to just the four contracts you need to form a short box spread.

2. In the `OnData` method, select the strike and expiry of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested) return;

    // Get the OptionChain
    if (!slice.OptionChains.TryGetValue(_symbol, out var chain)) return;

    // Select an expiry date and ITM & OTM strike prices
    var expiry = chain.Max(x => x.Expiry);
    var contracts = chain.Where(x => x.Expiry == expiry).ToList();
    var higherStrike = contracts.Max(x => x.Strike);
    var lowerStrike = contracts.Min(x => x.Strike);
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.ShortBoxSpread` method with the details of each leg and then pass the result to the `Buy` method.

   ```
   C#
   var shortBoxSpread = OptionStrategies.ShortBoxSpread(_symbol, higherStrike, lowerStrike, expiry);
   Buy(shortBoxSpread, 1);
   ```

   Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

   ```
   C#
   // Select the call and put contracts
   var itmCall = chain.Single(x => x.Expiry == expiry && x.Strike == lowerStrike && x.Right == OptionRight.Call);
   var otmCall = chain.Single(x => x.Expiry == expiry && x.Strike == higherStrike && x.Right == OptionRight.Call);
   var itmPut = chain.Single(x => x.Expiry == expiry && x.Strike == higherStrike && x.Right == OptionRight.Put);
   var otmPut = chain.Single(x => x.Expiry == expiry && x.Strike == lowerStrike && x.Right == OptionRight.Put);

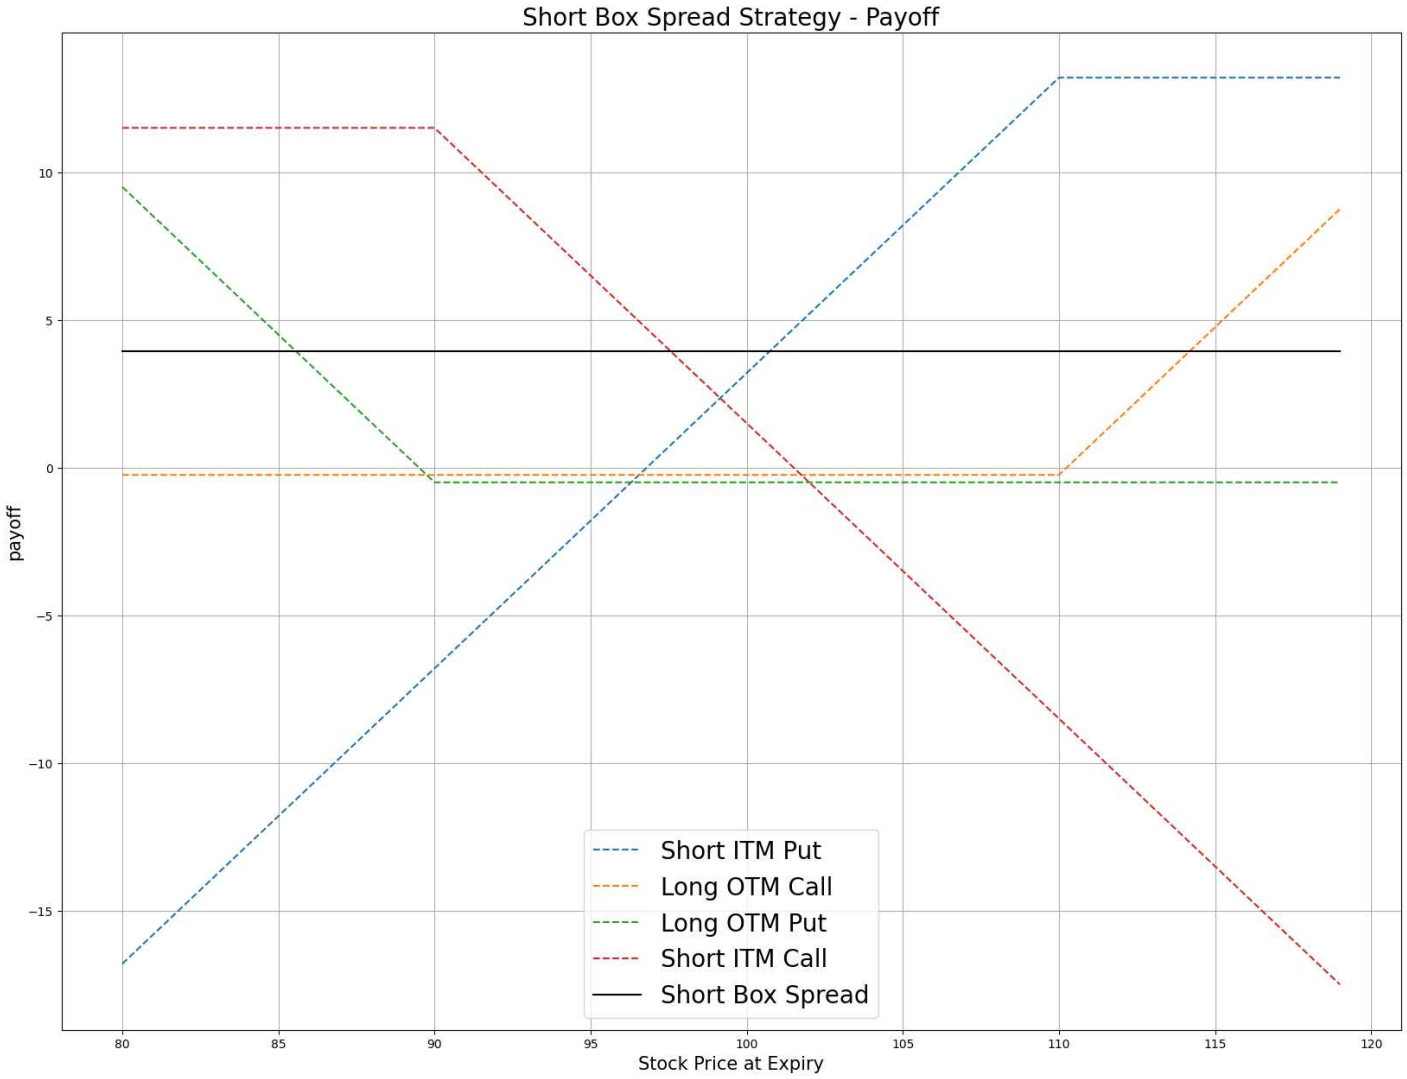
   var legs = new List<Leg>()
       {
           Leg.Create(itmCall.Symbol, -1),
           Leg.Create(itmPut.Symbol, -1),
           Leg.Create(otmCall.Symbol, 1),
           Leg.Create(otmPut.Symbol, 1),
       };
   ComboMarketOrder(legs, 1);
   ```

Strategy Payoff

This is a fixed payoff, delta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_T^{ITM} & = & (S_T - K_{-})^{+}\\ C_T^{OTM} & = & (S_T - K_{+})^{+}\\ P_T^{ITM} & = & (K_{+} - S_T)^{+}\\ P_T^{OTM} & = & (K_{-} - S_T)^{+}\\ Payoff_T & = & (C_{T_0}^{ITM} - C_T^{ITM} + P_{T_0}^{ITM} - P_T^{ITM} - C_{T_0}^{OTM} + C_T^{OTM} - P_{T_0}^{OTM} + P_T^{OTM})\times m - fee\\ & = & (K_{-} - K_{+} + C_{T_0}^{ITM} + P_{T_0}^{ITM} - C_{T_0}^{OTM} - P_{T_0}^{OTM})\times m - fee \end{array} \begin{array}{rcll} \textrm{where} & C_T^{ITM} & = & \textrm{ITM Call value at time T}\\ & C_T^{OTM} & = & \textrm{OTM Call value at time T}\\ & P_T^{ITM} & = & \textrm{ITM Put value at time T}\\ & P_T^{OTM} & = & \textrm{OTM Put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K_{+} & = & \textrm{Higher strike price}\\ & K_{-} & = & \textrm{Lower strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & C_{T_0}^{ITM} & = & \textrm{ITM Call price when the trade opened (debit paid)}\\ & C_{T_0}^{OTM} & = & \textrm{OTM Call price when the trade opened (credit received)}\\ & P_{T_0}^{ITM} & = & \textrm{ITM Put price when the trade opened (debit paid)}\\ & P_{T_0}^{OTM} & = & \textrm{OTM Put price when the trade opened (credit received)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The payoff is only dependent on the strike price and the initial asset prices.

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
ITM Call	23.00	810.00
ITM Put	23.80	857.50
OTM Call	1.85	857.50
OTM Put	2.75	810.00
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_T & = & (K_{-} - K_{+} + C_0^{ITM} + P_0^{ITM} - C_0^{OTM} - P_0^{OTM})\times m - fee\\ & = & (810.00 - 857.50 + 23.00 + 23.80 - 1.85 - 2.75)\times100 - 1.00\times4\\ & = & -534.00\\ \end{array}$$

So, the strategy loses $534.

The following algorithm implements a short box spread Option strategy:

```C#
public class ProtectiveCollarStrategy : QCAlgorithm
{
    private Symbol _equitySymbol;
    private Symbol _optionSymbol;
    private bool _investEver = false;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        UniverseSettings.Asynchronous = true;
        _equitySymbol = AddEquity("GOOG").Symbol;

        var option = AddOption("GOOG", Resolution.Minute);
        _optionSymbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().BoxSpread(30, 5));
    }

    public override void OnData(Slice slice)
    {
        if (_investEver) return;

        // Get the OptionChain
        var chain = slice.OptionChains.get(_optionSymbol, null);
        if (chain == null || chain.Count() == 0) return;

        // Select an expiry date
        var expiry = chain.OrderBy(x => x.Expiry).Last().Expiry;

        // Select the strike prices of the contracts
        var orderedContracts = chain.OrderBy(x => x.Strike);
        var higherStrike = orderedContracts.Last().Strike;
        var lowerStrike = orderedContracts.First().Strike;
        var boxSpread = OptionStrategies.ShortBoxSpread(_optionSymbol, higherStrike, lowerStrike, expiry);
        Buy(boxSpread, 1);

        _investEver = true;
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        if (symbol == _equitySymbol)
        {
            Log($"{Time}::{symbol}::{Securities[symbol].Price}");
        }
    }
}
```

Option Strategies

Long Jelly Roll

Introduction

A long Jelly Roll , or simply Roll , is a combination of a long call calendar spread and a short put calendar spread . It consists of buying a put and selling a call of the same expiry, as well as buying a call and selling a put with a further expiry, where all of the contracts have the same strike price. This strategy serves as an arbitrage on Option mispricing due to the temporary disparity between the call spread and the put spread synthetic portfolios. It is a delta -, gamma -, vega -, and theta -neutral strategy, but sensitive to rho (interest rate) and phi (dividend yield).

Implementation

Follow these steps to implement the long jelly roll strategy:

1. In the `Initialize` method, set the start date, set the end date, and create an Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(x => x.IncludeWeeklys().JellyRoll(5m, 30, 60));
}
```

2. In the `OnData` method, select the expiry and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested) return;

    // Get the OptionChain
    if (!slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select expiry dates and strike price
    var strike = chain.OrderBy(x => Math.Abs(chain.Underlying.Price - x.Strike)).First().Strike;
    var contracts = chain.Where(x => x.Strike == strike).ToList();
    var farExpiry = contracts.Max(x => x.Expiry);
    var nearExpiry = contracts.Min(x => x.Expiry);
```

3. In the `OnData` method, select the contracts and place the order.

   Approach A: Call the `OptionStrategies.JellyRoll` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var jellyRoll = OptionStrategies.JellyRoll(_symbol, strike, nearExpiry, farExpiry);
Buy(jellyRoll, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
// Select the call and put contracts
var nearCall = contracts.Single(x => x.Expiry == nearExpiry && x.Right == OptionRight.Call);
var farCall = contracts.Single(x => x.Expiry == farExpiry && x.Right == OptionRight.Call);
var nearPut = contracts.Single(x => x.Expiry == nearExpiry && x.Right == OptionRight.Put);
var farPut = contracts.Single(x => x.Expiry == farExpiry && x.Right == OptionRight.Put);

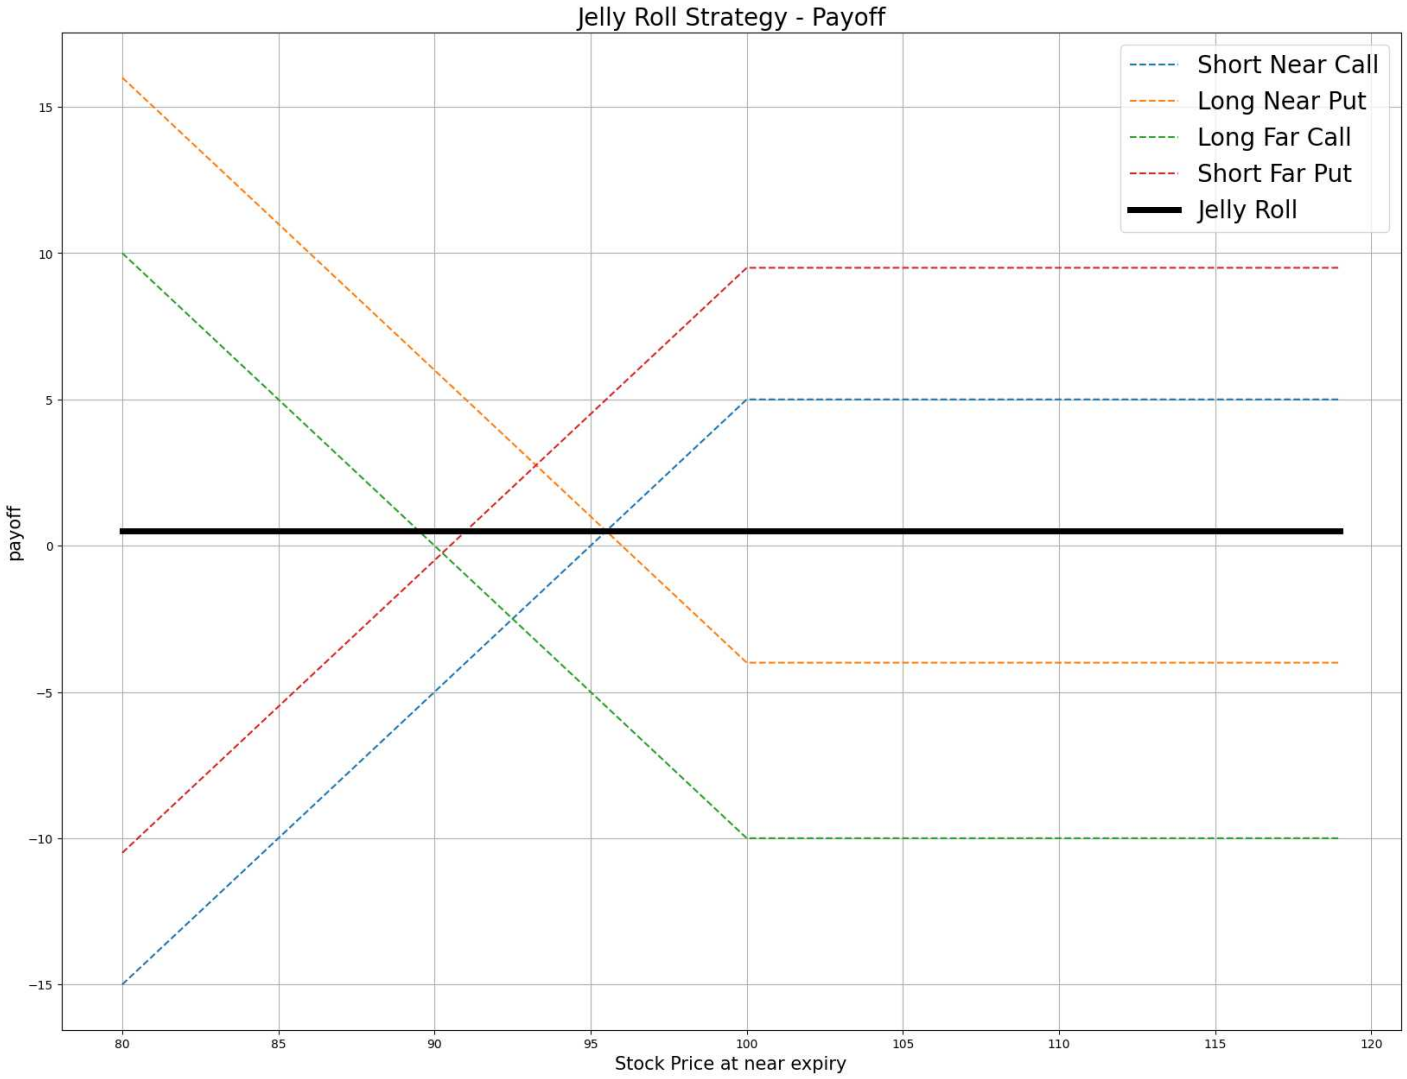
var legs = new List<Leg>()
{
    Leg.Create(nearCall.Symbol, -1),
    Leg.Create(farCall.Symbol, 1),
    Leg.Create(nearPut.Symbol, 1),
    Leg.Create(farPut.Symbol, -1),
};
ComboMarketOrder(legs, 1);
```

Strategy Payoff

This is a delta-, gamma-, vega-, and theta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_{T_1}^{T_1} & = & (S_{T_1} - K)^{+}\\ P_{T_1}^{T_1} & = & (K - S_{T_1})^{+}\\ Payoff_{T_1} & = & (P_{T_1}^{T_1} - P_{T_0}^{T_1} - C_{T_1}^{T_1} + C_{T_0}^{T_1} + C_{T_1}^{T_2} - C_{T_0}^{T_2} - P_{T_1}^{T_2} + P_{T_0}^{T_2})\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & C_{T_1}^{T_1} & = & \textrm{Market value of Call with expiry at T1 at time T1}\\ & C_{T_1}^{T_2} & = & \textrm{Market value of Call with expiry at T2 at time T1}\\ & P_{T_1}^{T_1} & = & \textrm{Market value of Put with expiry at T1 at time T1}\\ & P_{T_1}^{T_2} & = & \textrm{Market value of Put with expiry at T2 at time T1}\\ & S_{T_1} & = & \textrm{Underlying asset price at time T1}\\ & K & = & \textrm{Strike price}\\ & Payoff_T & = & \textrm{Payout total at time T}\\ & C_{T_0}^{T_1} & = & \textrm{Market value of Call with expiry at T1 when the trade opened}\\ & C_{T_0}^{T_2} & = & \textrm{Market value of Call with expiry at T2 when the trade opened}\\ & P_{T_0}^{T_1} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ & P_{T_0}^{T_2} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ & m & = & \textrm{Contract multiplier}\\ & T_1 & = & \textrm{Time T1 as the near expiration}\\ & T_2 & = & \textrm{Time T2 as the far expiration} \end{array}$$

The following chart shows the payoff at expiration:



The payoff is dependent on the market prices of the Options, but in theory, if assuming call-put parity exists, the expected payoff would be

$$\begin{array}{rcll} Payoff_{T_1} & = & Payoff_{\textrm{call calendar spread}} - Payoff_{\textrm{put calendar spread}}\\ & = & K \times (T_2 - T_1) \times r - D \end{array} \begin{array}{rcl} \textrm{where} & r & = & \textrm{Continuous compounding interest rate}\\ & D & = & \textrm{Dividend payment during the life of the option} \end{array}$$

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price at position open ($)	Price at the first expiry ($)	Strike ($)
Near-expiry Call	18.50	23.75	832.50
Near-expiry Put	22.50	12.85	832.50
Far-expiry Call	23.90	24.45	832.50
Far-expiry Put	19.00	13.70	832.50
Underlying Equity	-	843.2500	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_{T_1} & = & (P_{T_1}^{T_1} - P_0^{T_1} - C_{T_1}^{T_1} + C_0^{T_1} + C_{T_1}^{T_2} - C_0^{T_2} - P_{T_1}^{T_2} + P_0^{T_2})\times m - fee\\ & = & (12.85 - 22.50 - 23.75 + 18.50 + 24.45 - 23.90 - 13.70 + 19.00)\times100 - 1.00\times4\\ & = & -909.00\\ \end{array}$$

So, the strategy loses $909.

The following algorithm implements a long jelly roll Option strategy:

```C#
public class JellyRollStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().JellyRoll(5m, 30, 60));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select expiry dates and strike price
        var strike = chain.OrderBy(x => Math.Abs(chain.Underlying.Price - x.Strike)).First().Strike;
        var contracts = chain.Where(x => x.Strike == strike).ToList();
        var farExpiry = contracts.Max(x => x.Expiry);
        var nearExpiry = contracts.Min(x => x.Expiry);

        // Order Strategy
        var jellyRoll = OptionStrategies.JellyRoll(_symbol, strike, nearExpiry, farExpiry);
        Buy(jellyRoll, 1);
    }
}
```

Option Strategies

Short Jelly Roll

Introduction

A Short Jelly Roll , or simply Short Roll , is a combination of a short call calendar spread and a long put calendar spread . It is the inverse of a jelly roll . It consist of selling a put and buying a call of the same expiry, as well as buying a put and selling a call with a further expiry, where all of the contracts have the same strike prices. This strategy serves as an arbitrage on Option mispricing due to the temporary disparity between the call spread and the put spread synthetic portfolios. It is a delta -, gamma - , vega -, and theta -neutral strategy, but sensitive to rho (interest rate) and phi (dividend yield).

Implementation

Follow these steps to implement the short jelly roll strategy:

1. In the `Initialize` method, set the start date, set the end date, and create an Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(100000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(x => x.IncludeWeeklys().JellyRoll(5m, 30, 60));
}
```

2. In the `OnData` method, select the expiry and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested) return;

    // Get the OptionChain
    if (!slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select expiry dates and strike price
    var strike = chain.OrderBy(x => Math.Abs(chain.Underlying.Price - x.Strike)).First().Strike;
    var contracts = chain.Where(x => x.Strike == strike).ToList();
    var farExpiry = contracts.Max(x => x.Expiry);
    var farExpiry = contracts.Max(x => x.Expiry);
    var nearerExpiries = contracts.Where(x => x.Expiry < farExpiry);
    if (!nearerExpiries.Any()) return;
    var nearExpiry = nearerExpiries.Min(x => x.Expiry);
```

3. In the `OnData` method, select the contracts and place the order.

   Approach A: Call the `OptionStrategies.ShortJellyRoll` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var shortJellyRoll = OptionStrategies.ShortJellyRoll(_symbol, strike, nearExpiry, farExpiry);
Buy(shortJellyRoll, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
// Select the call and put contracts
var nearCall = contracts.Single(x => x.Expiry == nearExpiry && x.Right == OptionRight.Call);
var farCall = contracts.Single(x => x.Expiry == farExpiry && x.Right == OptionRight.Call);
var nearPut = contracts.Single(x => x.Expiry == nearExpiry && x.Right == OptionRight.Put);
var farPut = contracts.Single(x => x.Expiry == farExpiry && x.Right == OptionRight.Put);

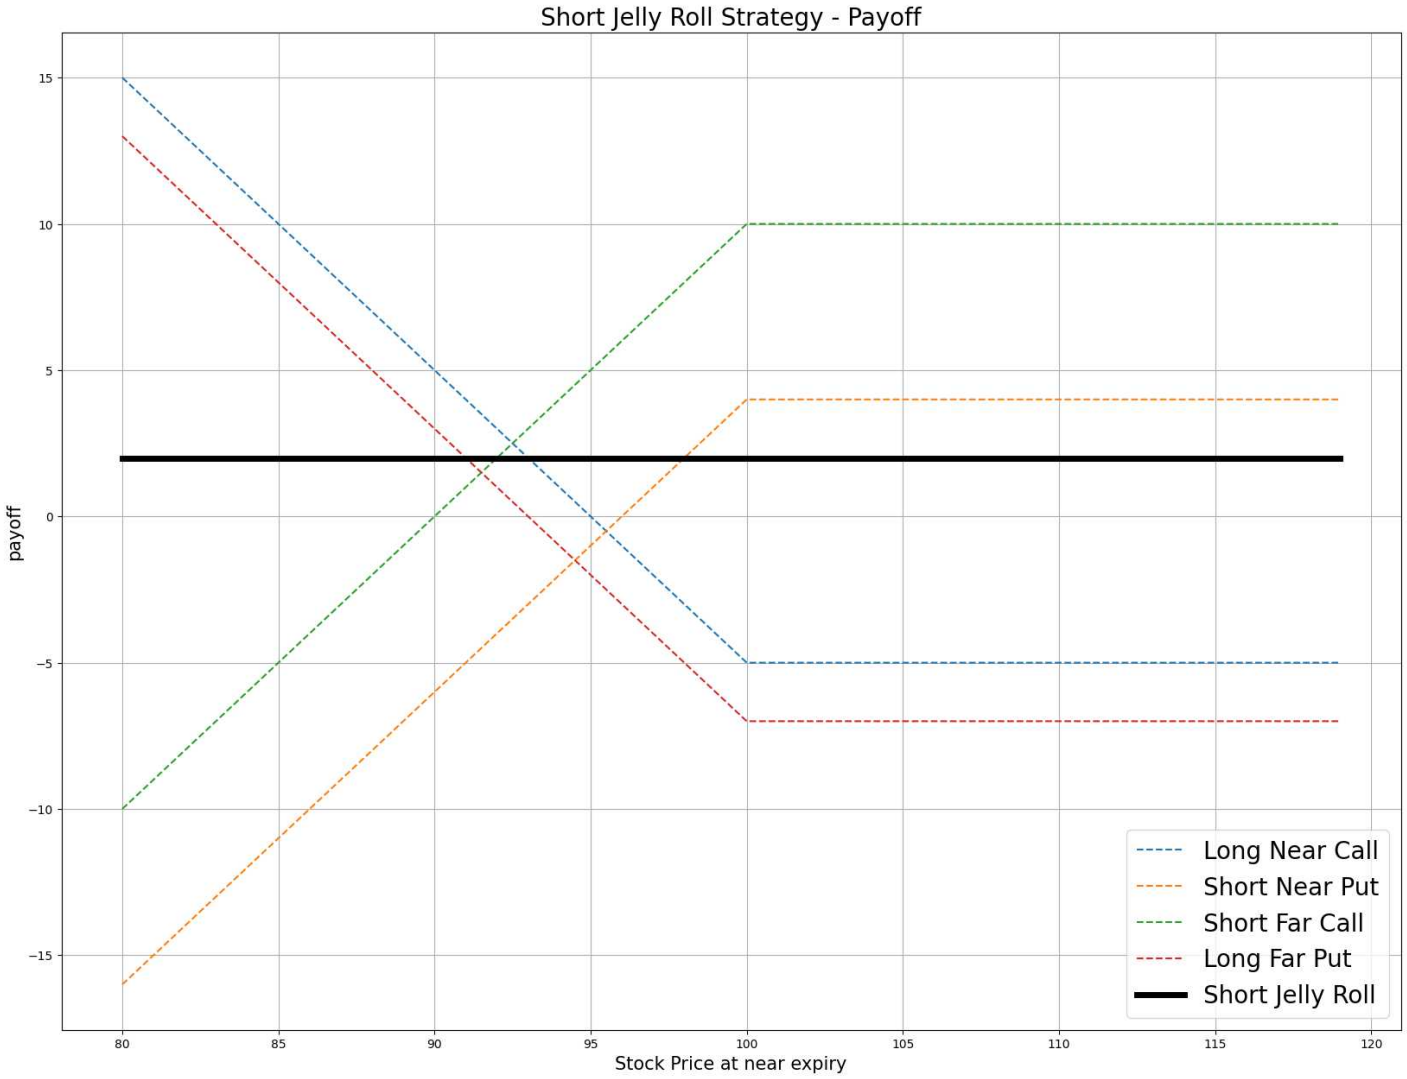
var legs = new List<Leg>()
{
    Leg.Create(nearCall.Symbol, 1),
    Leg.Create(farCall.Symbol, -1),
    Leg.Create(nearPut.Symbol, -1),
    Leg.Create(farPut.Symbol, 1),
};
ComboMarketOrder(legs, 1);
```

Strategy Payoff

This is a delta-, gamma-, vega-, and theta-neutral strategy. The payoff is

$$\begin{array}{rcll} C_{T_1}^{T_1} & = & (S_{T_1} - K)^{+}\\ P_{T_1}^{T_1} & = & (K - S_{T_1})^{+}\\ Payoff_{T_1} & = & (C_{T_1}^{T_1} - C_{T_0}^{T_1} - P_{T_1}^{T_1} + P_{T_0}^{T_1} + P_{T_1}^{T_2} - P_{T_0}^{T_2} - C_{T_1}^{T_2} + C_{T_0}^{T_2})\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & C_{T_1}^{T_1} & = & \textrm{Market value of Call with expiry at T1 at time T1}\\ & C_{T_1}^{T_2} & = & \textrm{Market value of Call with expiry at T2 at time T1}\\ & P_{T_1}^{T_1} & = & \textrm{Market value of Put with expiry at T1 at time T1}\\ & P_{T_1}^{T_2} & = & \textrm{Market value of Put with expiry at T2 at time T1}\\ & S_{T_1} & = & \textrm{Underlying asset price at time T1}\\ & K & = & \textrm{Strike price}\\ & Payoff_{T_1} & = & \textrm{Payout total at time T1}\\ & C_{T_0}^{T_1} & = & \textrm{Market value of Call with expiry at T1 when the trade opened}\\ & C_{T_0}^{T_2} & = & \textrm{Market value of Call with expiry at T2 when the trade opened}\\ & P_{T_0}^{T_1} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ & P_{T_0}^{T_2} & = & \textrm{Market value of Put with expiry at T2 when the trade opened}\\ & m & = & \textrm{Contract multiplier}\\ & T_1 & = & \textrm{Time T1 as the near expiration}\\ & T_2 & = & \textrm{Time T2 as the far expiration} \end{array}$$

The following chart shows the payoff at expiration:



The payoff is dependent on the market prices of the options, but in theory, if assuming call-put parity exists, the expected payoff would be

$$\begin{array}{rcll} Payoff_{T_1} & = & Payoff_{\textrm{put calendar spread}} - Payoff_{\textrm{call calendar spread}}\\ & = & D - K \times (T_2 - T_1) \times r \end{array} \begin{array}{rcl} \textrm{where} & r & = & \textrm{Continuous compounding interest rate}\\ & D & = & \textrm{Dividend payment during the life of the option} \end{array}$$

If the Option is American Option, there is a risk of early assignment on the contracts you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price at position open ($)	Price at the first expiry ($)	Strike ($)
Near-expiry Call	22.80	23.75	832.50
Near-expiry Put	18.10	12.85	832.50
Far-expiry Call	19.50	24.45	832.50
Far-expiry Put	23.50	13.70	832.50
Underlying Equity	-	843.2500	-

Therefore, the payoff is

$$\begin{array}{rcll} Payoff_{T_1} & = & (C_{T_1}^{T_1} - C_0^{T_1} - P_{T_1}^{T_1} + P_0^{T_1} + P_{T_1}^{T_2} - P_0^{T_2} - C_{T_1}^{T_2} + C_0^{T_2})\times m - fee\\ & = & (23.75 - 22.80 - 12.85 + 18.10 + 13.70 - 23.50 - 24.45 + 19.50)\times100 - 1.00\times4\\ & = & -859.00\\ \end{array}$$

So, the strategy loses $859.

The following algorithm implements a short jelly roll Option strategy:

```C#
public class ShortJellyRollStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(x => x.IncludeWeeklys().JellyRoll(5m, 30, 60));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select expiry dates and strike price
        var strike = chain.OrderBy(x => Math.Abs(chain.Underlying.Price - x.Strike)).First().Strike;
        var contracts = chain.Where(x => x.Strike == strike).ToList();
        var farExpiry = contracts.Max(x => x.Expiry);
        var nearExpiry = contracts.Min(x => x.Expiry);

        // Order Strategy
        var shortJellyRoll = OptionStrategies.ShortJellyRoll(_symbol, strike, nearExpiry, farExpiry);
        Buy(shortJellyRoll, 1);
    }
}
```

Option Strategies

Bear Call Ladder

Introduction

Bear call ladder , also known as short call ladder , is a combination of a bear call spread and a long call with a higher strike price than the 2 legs of the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the bear call ladder strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallLadder(30, 5, 0, -5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 3)
    {
        return;
    }

    var lowStrike = strikes[0];
    var middleStrike = strikes[1];
    var highStrike = strikes[2];
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Call the `OptionStrategies.BearCallLadder` method with the details of each leg and then pass the result to the `Buy` method.

```
var optionStrategy = OptionStrategies.BearCallLadder(_symbol, lowStrike, middleStrike, highStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
var lowStrikeCall = calls.Single(x => x.Strike == lowStrike);
var middleStrikeCall = calls.Single(x => x.Strike == middleStrike);
var highStrikeCall = calls.Single(x => x.Strike == highStrike);

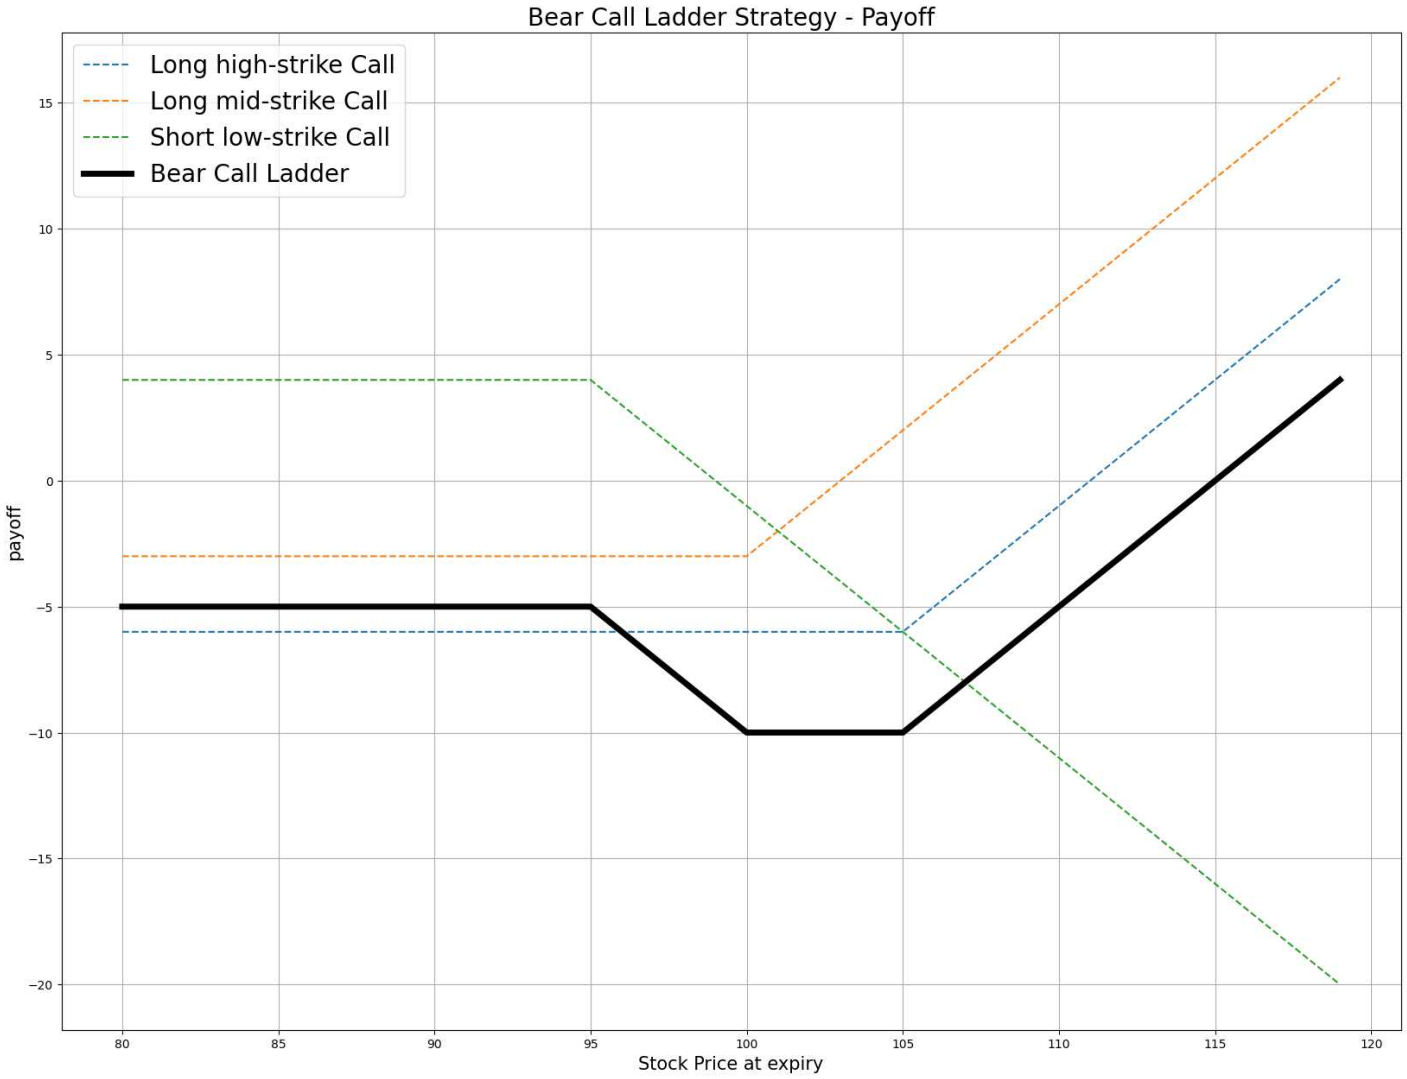
var legs = new List<Leg>()
{
    Leg.Create(lowStrikeCall.Symbol, -1),
    Leg.Create(middleStrikeCall.Symbol, 1),
    Leg.Create(highStrikeCall.Symbol, 1)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The bear call ladding is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ C^{mid}_T & = & (S_T - K^{mid})^{+}\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{mid}_T - C^{mid}_0 + C^{high}_T - C^{high}_0)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & C^{low}_T & = & \textrm{Lower-strike call value at time T}\\ & C^{mid}_T & = & \textrm{Middle-strike call value at time T}\\ & C^{high}_T & = & \textrm{Higher-strike call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{low} & = & \textrm{Lower-strike call strike price}\\ & K^{mid} & = & \textrm{Middle-strike call strike price}\\ & K^{high} & = & \textrm{Higher-strike call strike price}\\ & C^{low}_0 & = & \textrm{Lower-strike call value at position opening (credit received)}\\ & C^{mid}_0 & = & \textrm{Middle-strikeTM call value at position opening (debit paid)}\\ & C^{high}_0 & = & \textrm{Higher-strike call value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is unlimited, which occurs when the underlying price increases indefinitely.

The maximum loss is K^{low} - K^{mid} + C^{low}_0 - C^{mid}_0 - C^{high}_0, which occurs when the underlying price is between the two higher strike prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
Lower-Strike call	13.80	822.50
Middle-strike call	15.10	825.00
Higher-strike call	13.10	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.25-822.50)^{+}\\ & = & 20.75\\ C^{mid}_T & = & (S_T - K^{mid})^{+}\\ & = & (843.25-825.00)^{+}\\ & = & 18.25\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.25-827.50)^{+}\\ & = & 15.75\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{mid}_T - C^{mid}_0 + C^{high}_T - C^{high}_0)\times m - fee\\ & = & (13.80 - 20.75 + 18.25 - 15.10 + 15.75 - 13.10)\times100-1.00\times3\\ & = & -118\\ \end{array}

So, the strategy loses $118.

The following algorithm implements a bear call ladder Option strategy:

```C#
public class BearCallLadderStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallLadder(30, 5, 0, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 3)
        {
            return;
        }

        var lowStrike = strikes[0];
        var middleStrike = strikes[1];
        var highStrike = strikes[2];

        // Order Strategy
        var optionStrategy = OptionStrategies.BearCallLadder(_symbol, lowStrike, middleStrike, highStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Bear Put Ladder

Introduction

Bear put ladder , also known as long put ladder , is a combination of a bear put spread and short put with a lower strike price than the 2 legs of the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from low volatility of the underlying asset. For instance, the underlying price stays similar to its current price.

Implementation

Follow these steps to implement the bear put ladder strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutLadder(30, 5, 0, -5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the put Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 3)
    {
        return;
    }

    var lowStrike = strikes[0];
    var middleStrike = strikes[1];
    var highStrike = strikes[2];
```

3. In the `OnData` method, select the contracts and place the orders.

    Approach A: Put the `OptionStrategies.BearPutLadder` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var optionStrategy = OptionStrategies.BearPutLadder(_symbol, highStrike, middleStrike, lowStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then put the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
var lowStrikePut = puts.Single(x => x.Strike == lowStrike);
var middleStrikePut = puts.Single(x => x.Strike == middleStrike);
var highStrikePut = puts.Single(x => x.Strike == highStrike);

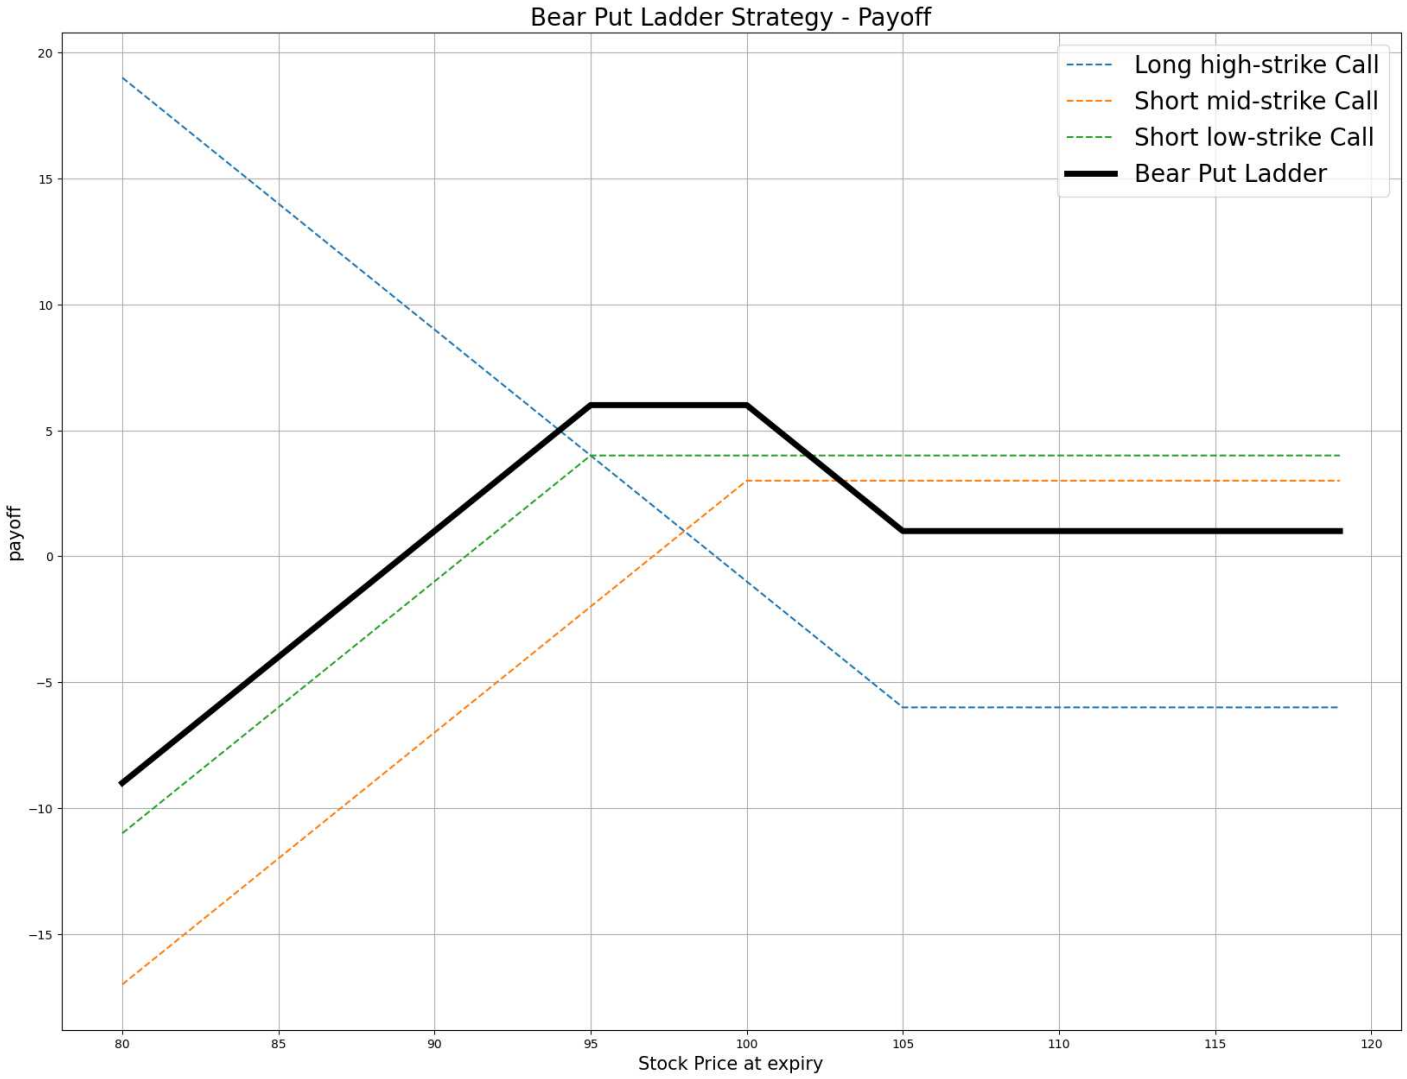
var legs = new List<Leg>()
{
    Leg.Create(lowStrikePut.Symbol, -1),
    Leg.Create(middleStrikePut.Symbol, -1),
    Leg.Create(highStrikePut.Symbol, 1)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The bear put ladding is an limited-profit strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ P^{mid}_T & = & (K^{mid} - S_T)^{+}\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ Payoff_T & = & (P^{low}_0 - P^{low}_T + P^{mid}_0 - P^{mid}_T + P^{high}_T - P^{high}_0)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & P^{low}_T & = & \textrm{Lower-strike put value at time T}\\ & P^{mid}_T & = & \textrm{Middle-strike put value at time T}\\ & P^{high}_T & = & \textrm{Higher-strike put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{low} & = & \textrm{Lower-strike put strike price}\\ & K^{mid} & = & \textrm{Middle-strike put strike price}\\ & K^{high} & = & \textrm{Higher-strike put strike price}\\ & P^{low}_0 & = & \textrm{Lower-strike put value at position opening (credit received)}\\ & P^{mid}_0 & = & \textrm{Middle-strikeTM put value at position opening (debit paid)}\\ & P^{high}_0 & = & \textrm{Higher-strike put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K^{high} - K^{mid} + P^{low}_0 + P^{mid}_0 - P^{high}_0$, which occurs when the underlying price is between the two lower strike prices.

The maximum loss is $K^{high} - K^{mid} - K^{low} + P^{low}_0 + P^{mid}_0 - P^{high}_0$, which occurs when the underlying price decreases to $0.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike put	3.80	822.50
Middle-strike put	4.70	825.00
Higher-strike put	7.80	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{low}_T &=& (K^{low} - S_T)^{+}\\ &=& (822.50-843.25)^{+}\\ &=& 0\\ P^{mid}_T &=& (K^{mid} - S_T)^{+}\\ &=& (825.00-843.25)^{+}\\ &=& 0\\ P^{high}_T &=& (K^{high} - S_T)^{+}\\ &=& (827.50-843.25)^{+}\\ &=& 0\\ Payoff_T &=& (P^{low}_0 - P^{low}_T + P^{mid}_0 - P^{mid}_T + P^{high}_T - P^{high}_0)\times m - fee\\ &=& (3.80 - 0 + 4.70$$

- 0 + 0 - 7.80)\times100-1.00\times3\\ & = & 67\\ \end{array}

So, the strategy gains $67.

The following algorithm implements a bear put ladder Option strategy:

```C#
public class BearPutLadderStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutLadder(30, 5, 0, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 3)
        {
            return;
        }

        var lowStrike = strikes[0];
        var middleStrike = strikes[1];
        var highStrike = strikes[2];

        // Order Strategy
        var optionStrategy = OptionStrategies.BearPutLadder(_symbol, highStrike, middleStrike, lowStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Bull Call Ladder

Introduction

Bull call ladder , also known as long call ladder , is a combination of a bull call spread and a short call with a higher strike price than the 2 legs of the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from low volatility of the underlying asset. For instance, the underlying price stays similar to its current price.

Implementation

Follow these steps to implement the bull call ladder strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallLadder(30, 5, 0, -5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 3)
    {
        return;
    }

    var lowStrike = strikes[0];
    var middleStrike = strikes[1];
    var highStrike = strikes[2];
```

3. In the `OnData` method, select the contracts and place the orders.

    Approach A: Call the `OptionStrategies.BullCallLadder` method with the details of each leg and then pass the result to the `Buy` method.

```
var optionStrategy = OptionStrategies.BullCallLadder(_symbol, lowStrike, middleStrike, highStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
var lowStrikeCall = calls.Single(x => x.Strike == lowStrike);
var middleStrikeCall = calls.Single(x => x.Strike == middleStrike);
var highStrikeCall = calls.Single(x => x.Strike == highStrike);

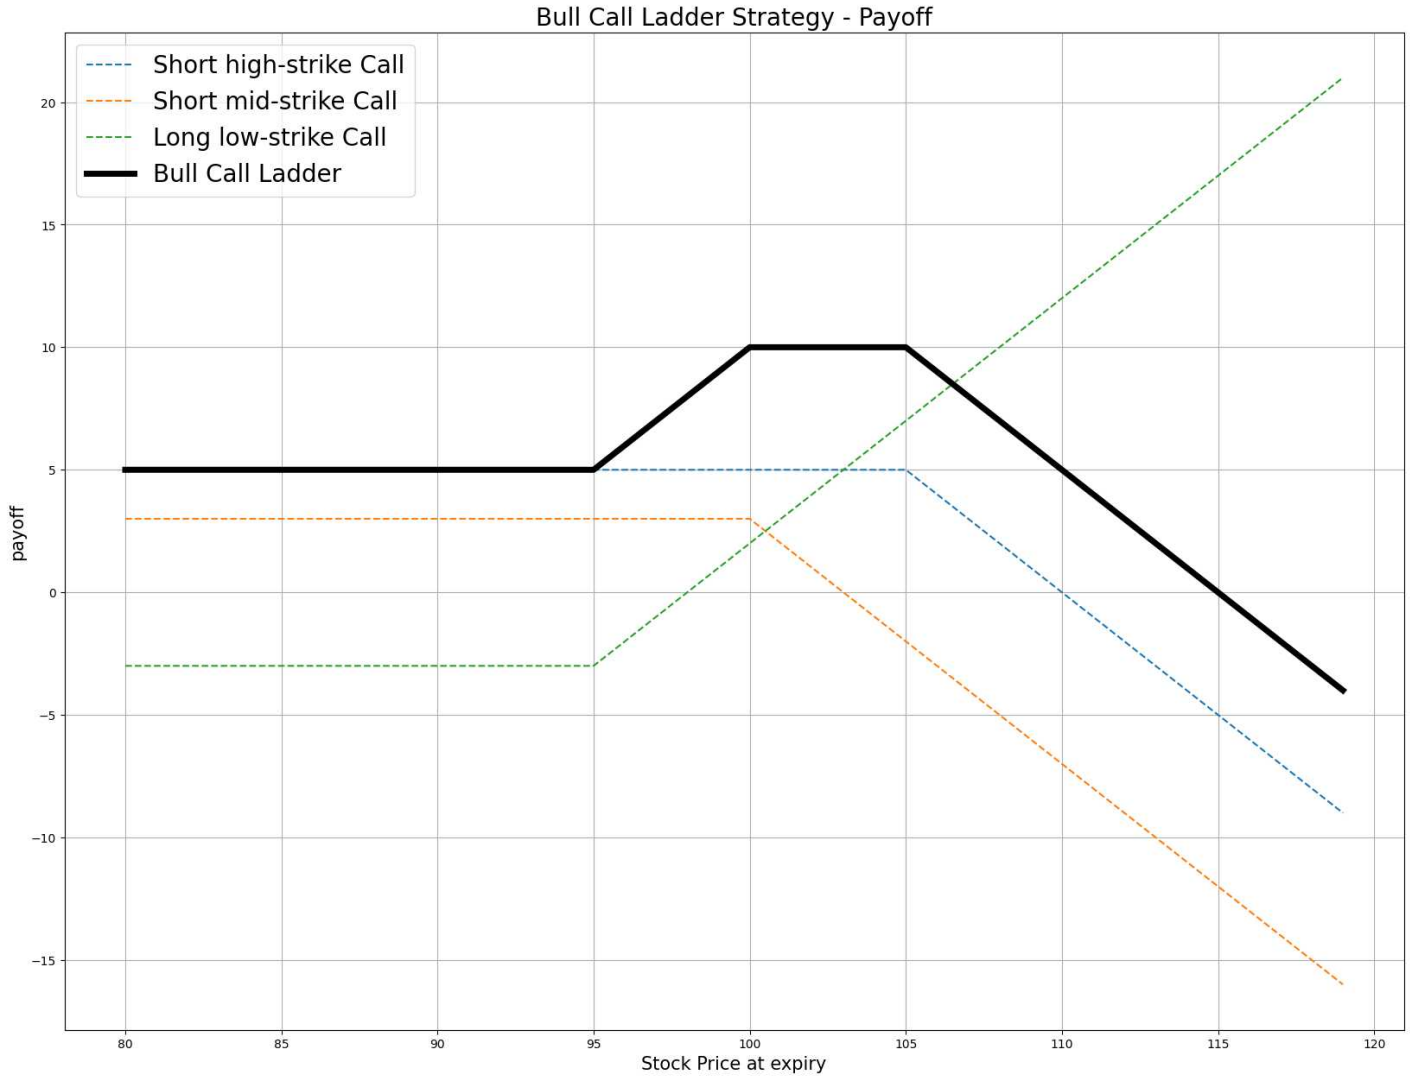
var legs = new List<Leg>()
{
    Leg.Create(lowStrikeCall.Symbol, 1),
    Leg.Create(middleStrikeCall.Symbol, -1),
    Leg.Create(highStrikeCall.Symbol, -1)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The bull call spread is an limited-profit strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ C^{mid}_T & = & (S_T - K^{mid})^{+}\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ Payoff_T & = & (C^{low}_T - C^{low}_0 + C^{mid}_0 - C^{mid}_T + C^{high}_0 - C^{high}_T)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & C^{low}_T & = & \textrm{Lower-strike call value at time T}\\ & C^{mid}_T & = & \textrm{Middle-strike call value at time T}\\ & C^{high}_T & = & \textrm{Higher-strike call value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{low} & = & \textrm{Lower-strike call strike price}\\ & K^{mid} & = & \textrm{Middle-strike call strike price}\\ & K^{high} & = & \textrm{Higher-strike call strike price}\\ & C^{low}_0 & = & \textrm{Lower-strike call value at position opening (credit received)}\\ & C^{mid}_0 & = & \textrm{Middle-strikeTM call value at position opening (debit paid)}\\ & C^{high}_0 & = & \textrm{Higher-strike call value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is K^{mid} - K^{low} - C^{low}_0 + C^{mid}_0 + C^{high}_0, which occurs when the underlying price is between the two higher strike prices.

The maximum loss is unlimited, which occurs when the underlying price increases indefinitely.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
Lower-Strike call	17.10	822.50
Middle-strike call	12.00	825.00
Higher-strike call	10.90	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.25-822.50)^{+}\\ & = & 20.75\\ C^{mid}_T & = & (S_T - K^{mid})^{+}\\ & = & (843.25-825.00)^{+}\\ & = & 18.25\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.25-827.50)^{+}\\ & = & 15.75\\ Payoff_T & = & (C^{low}_T - C^{low}_0 + C^{mid}_0 - C^{mid}_T + C^{high}_0 - C^{high}_T)\times m - fee\\ & = & (20.75 - 17.10 + 12.00 - 18.25 + 10.90 - 15.75)\times100-1.00\times3\\ & = & -748\\ \end{array}

So, the strategy loses $748.

The following algorithm implements a bull call ladder Option strategy:

```C#
public class BullCallLadderStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallLadder(30, 5, 0, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 3)
        {
            return;
        }

        var lowStrike = strikes[0];
        var middleStrike = strikes[1];
        var highStrike = strikes[2];

        // Order Strategy
        var optionStrategy = OptionStrategies.BullCallLadder(_symbol, lowStrike, middleStrike, highStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Bull Put Ladder

Introduction

Bull put ladder , also known as short put ladder , is a combination of a bull put spread and short put with a lower strike price than the 2 legs of the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the bull put ladder strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe .

```
C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutLadder(30, 5, 0, -5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```
C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the put Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
    if (puts.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 3)
    {
        return;
    }

    var lowStrike = strikes[0];
    var middleStrike = strikes[1];
    var highStrike = strikes[2];
```

3. In the `OnData` method, select the contracts and place the orders.

   Approach A: Put the `OptionStrategies.BullPutLadder` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var optionStrategy = OptionStrategies.BullPutLadder(_symbol, highStrike, middleStrike, lowStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then put the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
var lowStrikePut = puts.Single(x => x.Strike == lowStrike);
var middleStrikePut = puts.Single(x => x.Strike == middleStrike);
var highStrikePut = puts.Single(x => x.Strike == highStrike);

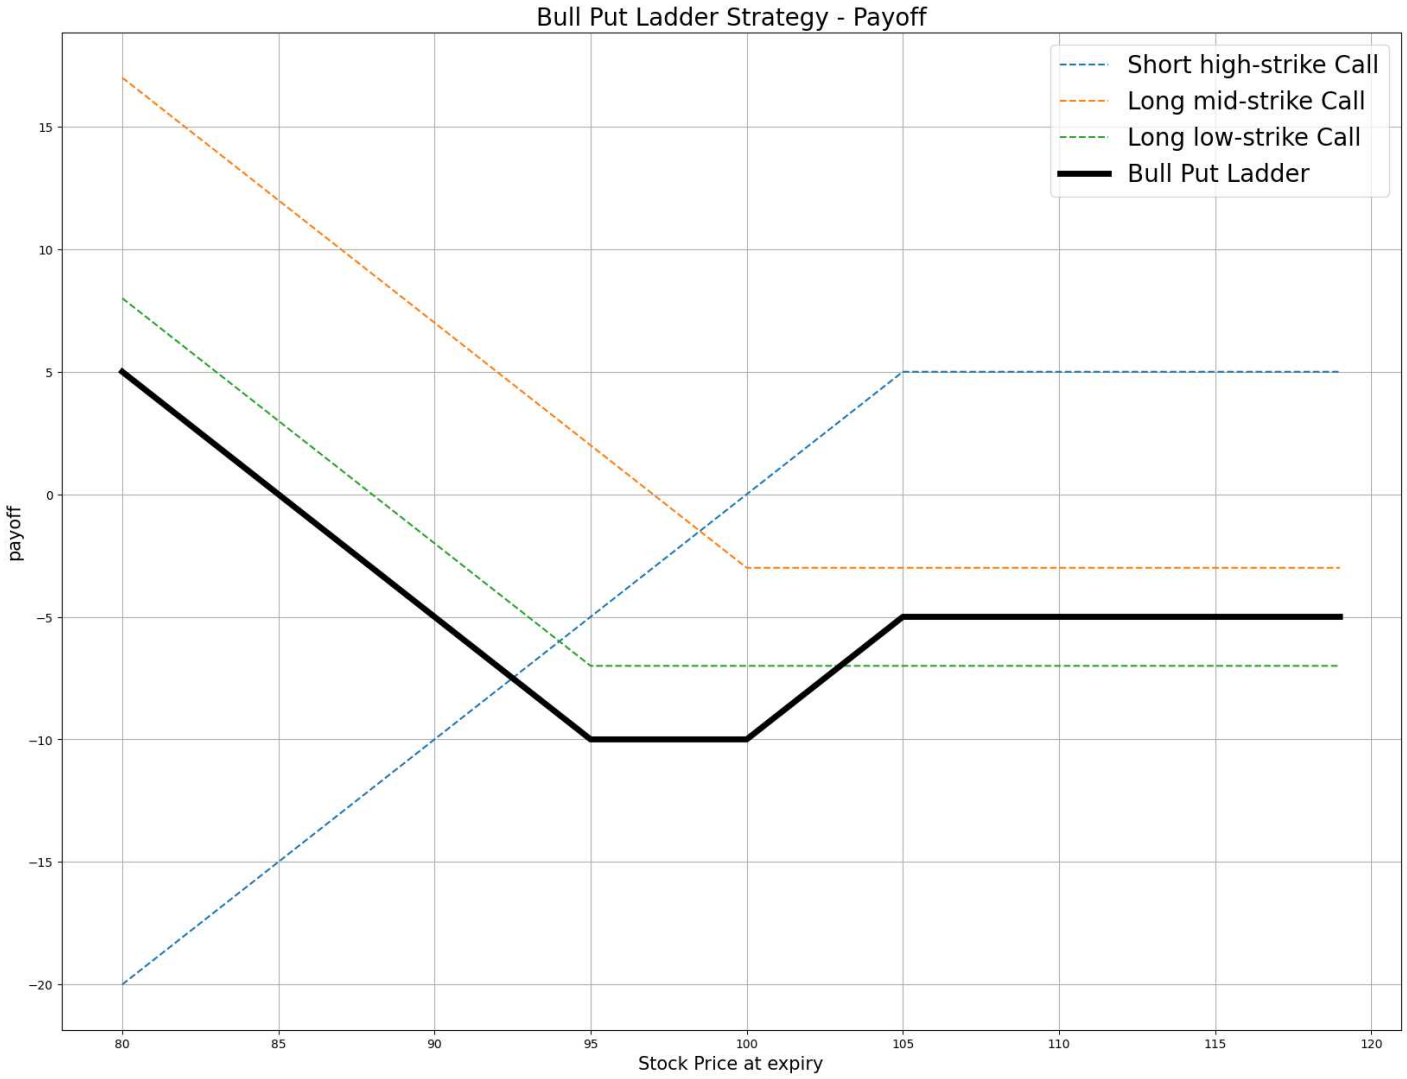
var legs = new List<Leg>()
{
    Leg.Create(lowStrikePut.Symbol, 1),
    Leg.Create(middleStrikePut.Symbol, 1),
    Leg.Create(highStrikePut.Symbol, -1)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The bull put spread is an limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ P^{mid}_T & = & (K^{mid} - S_T)^{+}\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ Payoff_T & = & (P^{low}_T - P^{low}_0 + P^{mid}_T - P^{mid}_0 + P^{high}_0 - P^{high}_T)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & P^{low}_T & = & \textrm{Lower-strike put value at time T}\\ & P^{mid}_T & = & \textrm{Middle-strike put value at time T}\\ & P^{high}_T & = & \textrm{Higher-strike put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{low} & = & \textrm{Lower-strike put strike price}\\ & K^{mid} & = & \textrm{Middle-strike put strike price}\\ & K^{high} & = & \textrm{Higher-strike put strike price}\\ & P^{low}_0 & = & \textrm{Lower-strike put value at position opening (credit received)}\\ & P^{mid}_0 & = & \textrm{Middle-strikeTM put value at position opening (debit paid)}\\ & P^{high}_0 & = & \textrm{Higher-strike put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is K^{mid} + K^{low} - K^{high} - P^{low}_0 - P^{mid}_0 + P^{high}_0, which occurs when the underlying price decreases to $0.

The maximum loss is K^{mid} - K^{high} - P^{low}_0 - P^{mid}_0 + P^{high}_0, which occurs when the underlying price is between the two lower strike prices.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike put	6.00	822.50
Middle-strike put	4.70	825.00
Higher-strike put	5.60	827.50
Underlying Equity at expiration	843.25	-

Therefore, the payoff is

\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ & = & (822.50-843.25)^{+}\\ & = & 0\\ P^{mid}_T & = & (K^{mid} - S_T)^{+}\\ & = & (825.00-843.25)^{+}\\ & = & 0\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ & = & (827.50-843.25)^{+}\\ & = & 0\\ Payoff_T & = & (P^{low}_T - P^{low}_0 + P^{mid}_T - P^{mid}_0 + P^{high}_0 - P^{high}_T)\times m - fee\\ & = & (0 - 6.00 + 0 -

4.70 + 5.60 - 0)\times100-1.00\times3\\ & = & -513\\ \end{array}

So, the strategy loses $513.

The following algorithm implements a bull put ladder Option strategy:

```C#
public class BullPutLadderStrategy : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutLadder(30, 5, 0, -5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var puts = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Put);
        if (puts.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 3)
        {
            return;
        }

        var lowStrike = strikes[0];
        var middleStrike = strikes[1];
        var highStrike = strikes[2];

        // Order Strategy
        var optionStrategy = OptionStrategies.BullPutLadder(_symbol, highStrike, middleStrike, lowStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Long Call Backspread

Introduction

Long Call Backspread , consists of short 1 lower-strike call and long 2 higher strike calls. It is a combination of a bear call spread and a long call with the same strike price as the higher-strike leg the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the long call backspread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe . You can use the `CallSpread` helper method in option universe filtering, since a call backspread consists of the same contracts as a call spread.

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(20, 5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 2)
    {
        return;
    }

    var lowStrike = strikes[0];
    var highStrike = strikes[1];
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.CallBackspread` method with the details of each leg and then pass the result to the `Buy` method.

```C#
var optionStrategy = OptionStrategies.CallBackspread(_symbol, lowStrike, highStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```C#
var lowStrikeCall = calls.Single(x => x.Strike == lowStrike);
var highStrikeCall = calls.Single(x => x.Strike == highStrike);

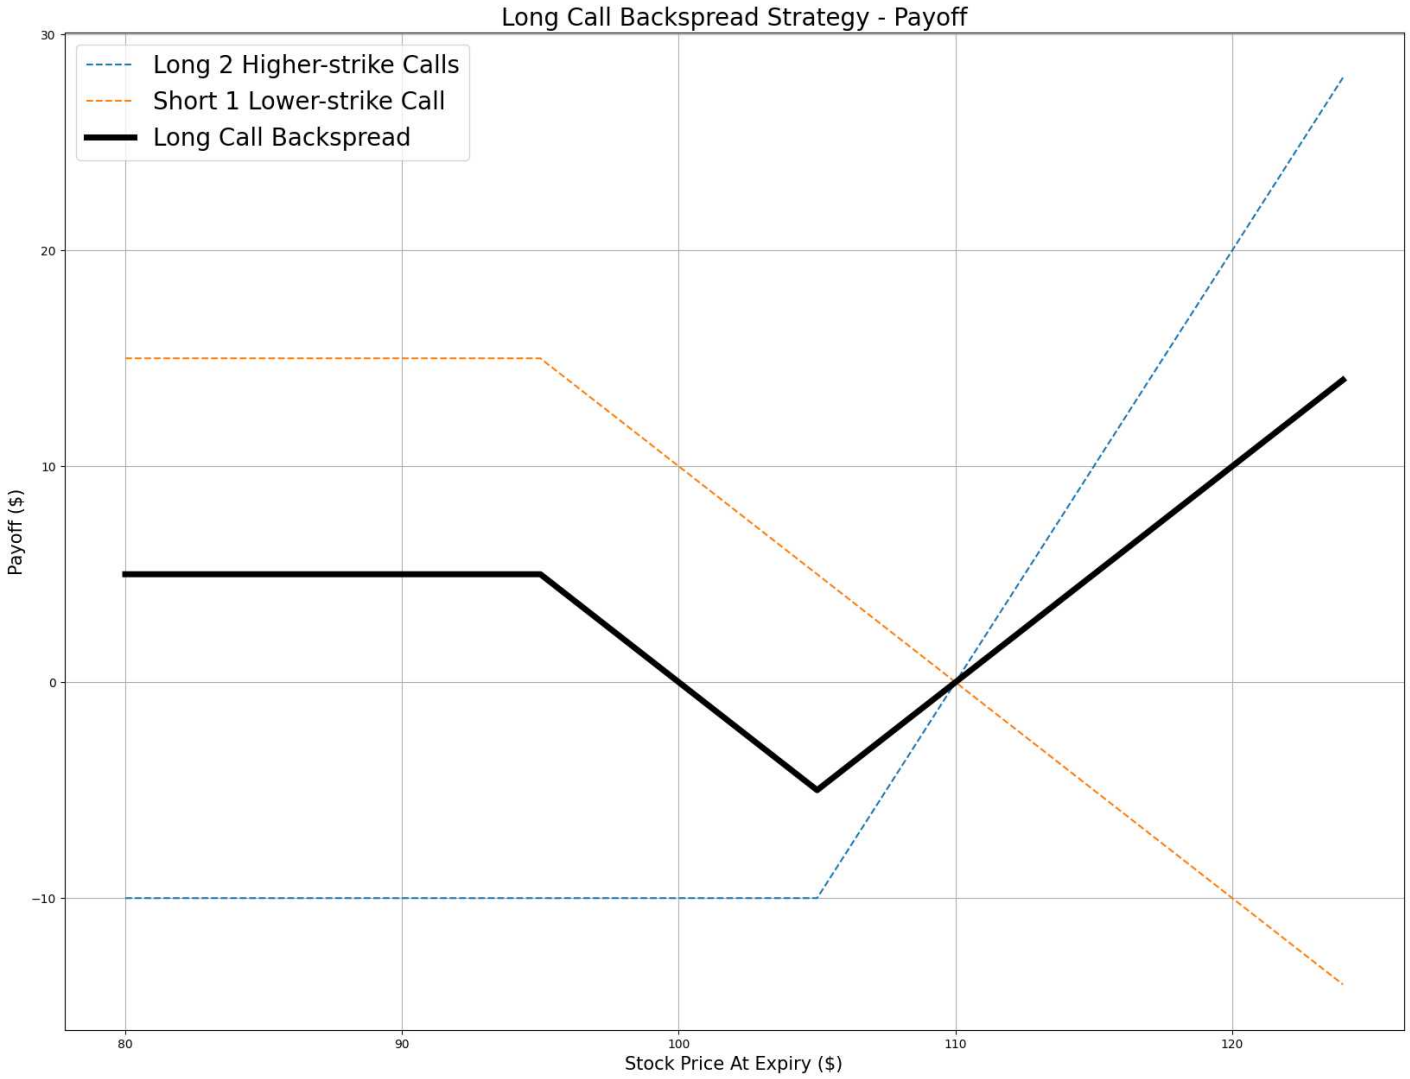
var legs = new List<Leg>()
{
    Leg.Create(lowStrikeCall.Symbol, -1),
    Leg.Create(highStrikeCall.Symbol, 2)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The long call backspread is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{high}_T \times 2 - C^{high}_0 \times 2)\times m - fee\\ \end{array} \begin{array}{rcl} \textrm{where} & & \\ C^{low}_T & = & \textrm{Lower-strike call value at time T}\\ C^{high}_T & = & \textrm{Higher-strike call value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{low} & = & \textrm{Lower-strike call strike price}\\ K^{high} & = & \textrm{Higher-strike call strike price}\\ C^{low}_0 & = & \textrm{Lower-strike call value at position opening (credit received)}\\ C^{high}_0 & = & \textrm{Higher-strike call value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is unlimited, which occurs when the underlying price increases indefinitely.

The maximum loss is K^{low} - K^{high} + C^{low}_0 - C^{high}_0 \times 2, which occurs when the underlying price is exactly at the higher strike at expiry.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
Lower-Strike call	12.00	825.00
Higher-strike call	8.80	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.19-825.00)^{+}\\ & = & 18.19\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ Payoff_T & = & (C^{low}_0 - C^{low}_T + C^{high}_T \times 2 - C^{high}_0 \times 2)\times m - fee\\ & = & (12.00 - 18.19 + 8.19\times2 - 8.80\times2)\times100-2.30\\ & = & -743.30\\ \end{array}

So, the strategy loses $743.30.

The following algorithm implements a long call backspread Option strategy:

```C#
public class BackspreadOptionStrategyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        UniverseSettings.Asynchronous = true;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(20, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 2)
        {
            return;
        }

        var lowStrike = strikes[0];
        var highStrike = strikes[1];

        var optionStrategy = OptionStrategies.CallBackspread(_symbol, lowStrike, highStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Short Call Backspread

Introduction

Short Call Backspread , consists of long 1 lower-strike call and short 2 higher strike calls. It is a combination of a bull call spread and a short call with the same strike price as the higher-strike leg the call spread. All calls have the same underlying Equity and expiration date. This strategy profits from stable, consistent price of the underlying asset. For instance, the underlying price stays at its current price.

Implementation

Follow these steps to implement the short call backspread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe . You can use the `CallSpread` helper method in option universe filtering, since a call backspread consists of the same contracts as a call spread.

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(20, 5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the call Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
    if (calls.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 2)
    {
        return;
    }

    var lowStrike = strikes[0];
    var highStrike = strikes[1];
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.ShortCallBackspread` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var optionStrategy = OptionStrategies.ShortCallBackspread(_symbol, lowStrike, highStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var lowStrikeCall = calls.Single(x => x.Strike == lowStrike);
var highStrikeCall = calls.Single(x => x.Strike == highStrike);

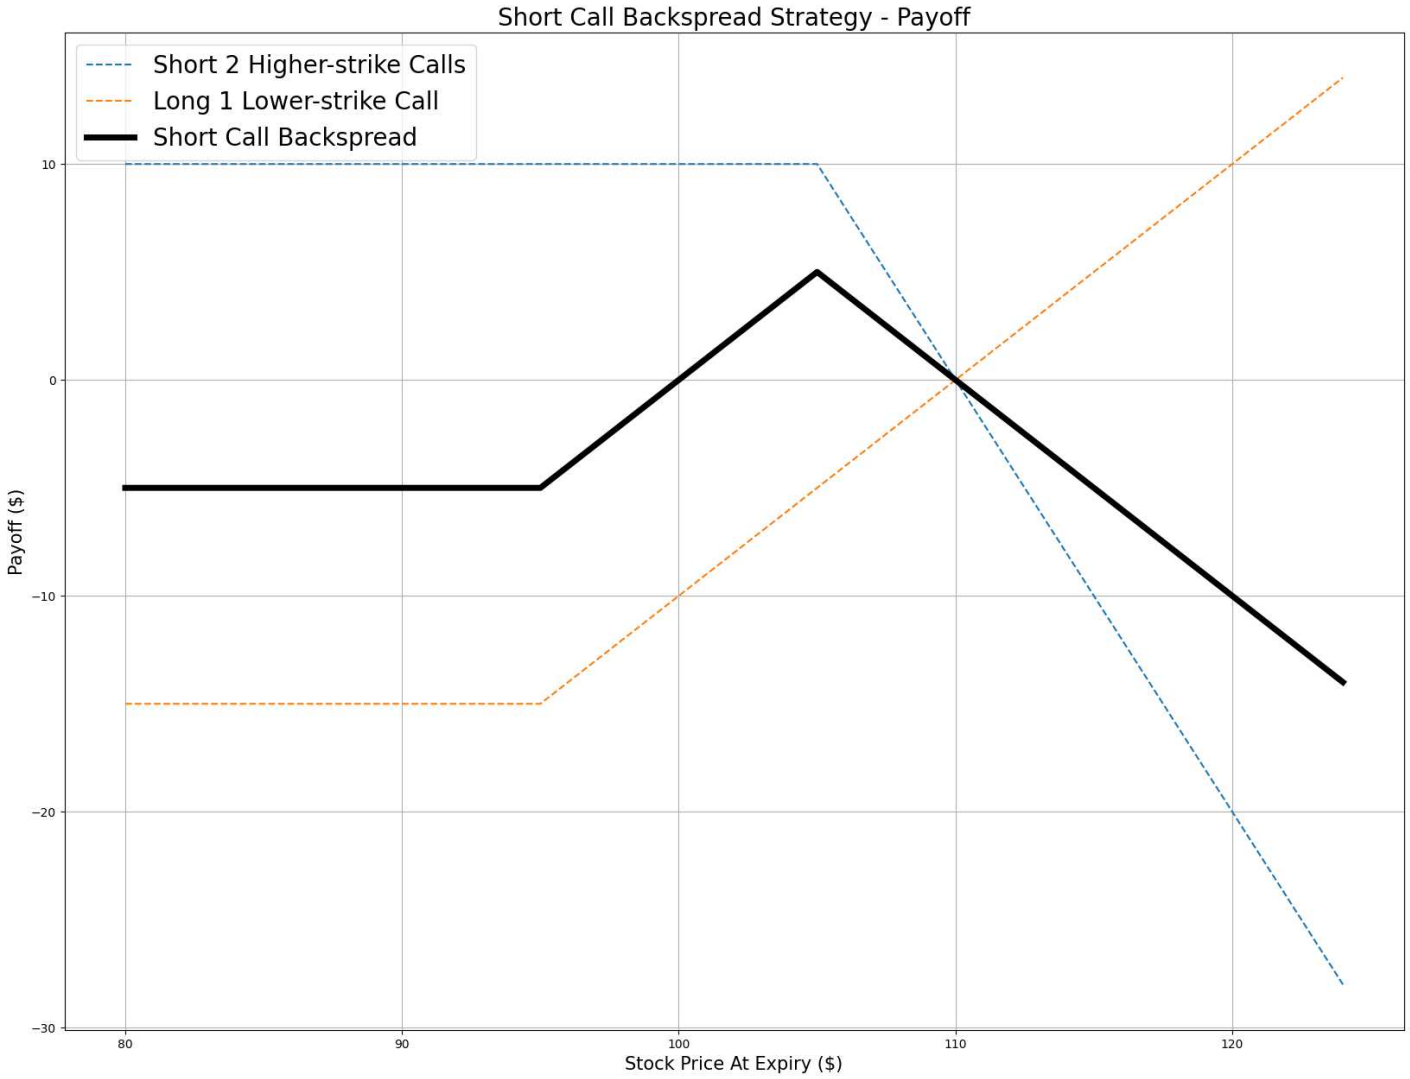
var legs = new List<Leg>()
{
    Leg.Create(lowStrikeCall.Symbol, 1),
    Leg.Create(highStrikeCall.Symbol, -2)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The short call backspread is an limited-profit-unlimited-risk strategy. The payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ Payoff_T & = & (C^{low}_T - C^{low}_0 + C^{high}_0 \times 2 - C^{high}_T \times 2)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & & & \\ C^{low}_T & = & \textrm{Lower-strike call value at time T}\\ C^{high}_T & = & \textrm{Higher-strike call value at time T}\\ S_T & = & \textrm{Underlying asset price at time T}\\ K^{low} & = & \textrm{Lower-strike call strike price}\\ K^{high} & = & \textrm{Higher-strike call strike price}\\ C^{low}_0 & = & \textrm{Lower-strike call value at position opening (credit received)}\\ C^{high}_0 & = & \textrm{Higher-strike call value at position opening (debit paid)}\\ m & = & \textrm{Contract multiplier}\\ T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K^{high} - K^{low} - C^{low}_0 + C^{high}_0 \times 2$, which occurs when the underlying price is exactly at the higher strike at expiry.

The maximum loss is unlimited, which occurs when the underlying price increases indefinitely.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
Lower-Strike call	15.10	825.00
Higher-strike call	8.00	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} C^{low}_T & = & (S_T - K^{low})^{+}\\ & = & (843.19-825.00)^{+}\\ & = & 18.19\\ C^{high}_T & = & (S_T - K^{high})^{+}\\ & = & (843.19-835.00)^{+}\\ & = & 8.19\\ Payoff_T & = & (C^{low}_T - C^{low}_0 - C^{high}_T \times 2 + C^{high}_0 \times 2)\times m - fee\\ & = & (18.19 - 15.10 - 8.19\times2 + 8.00\times2)\times100-2.30\\ & = & 268.70\\ \end{array}$$

So, the strategy gains $268.70.

The following algorithm implements a short call backspread Option strategy:

```C#
public class BackspreadOptionStrategyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        UniverseSettings.Asynchronous = true;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().CallSpread(20, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var calls = chain.Where(x => x.Expiry == expiry && x.Right == OptionRight.Call);
        if (calls.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = calls.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 2)
        {
            return;
        }

        var lowStrike = strikes[0];
        var highStrike = strikes[1];

        var optionStrategy = OptionStrategies.ShortCallBackspread(_symbol, lowStrike, highStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Long Put Backspread

Introduction

Long Put Backspread , consists of short 1 higher-strike put and long 2 lower-strike puts. It is a combination of a bull put spread and a long put with the same strike price as the lower-strike leg the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from increasing volatility of the underlying asset. For instance, the underlying price moves away from its current price.

Implementation

Follow these steps to implement the long put backspread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe . You can use the `PutSpread` helper method in option universe filtering, since a put backspread consists of the same contracts as a put spread.

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(20, 5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the put Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry);
    if (puts.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 2)
    {
        return;
    }

    var lowStrike = strikes[0];
    var highStrike = strikes[1];
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.PutBackspread` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var optionStrategy = OptionStrategies.PutBackspread(_symbol, highStrike, lowStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var lowStrikePut = puts.Single(x => x.Strike == lowStrike);
var highStrikePut = puts.Single(x => x.Strike == highStrike);

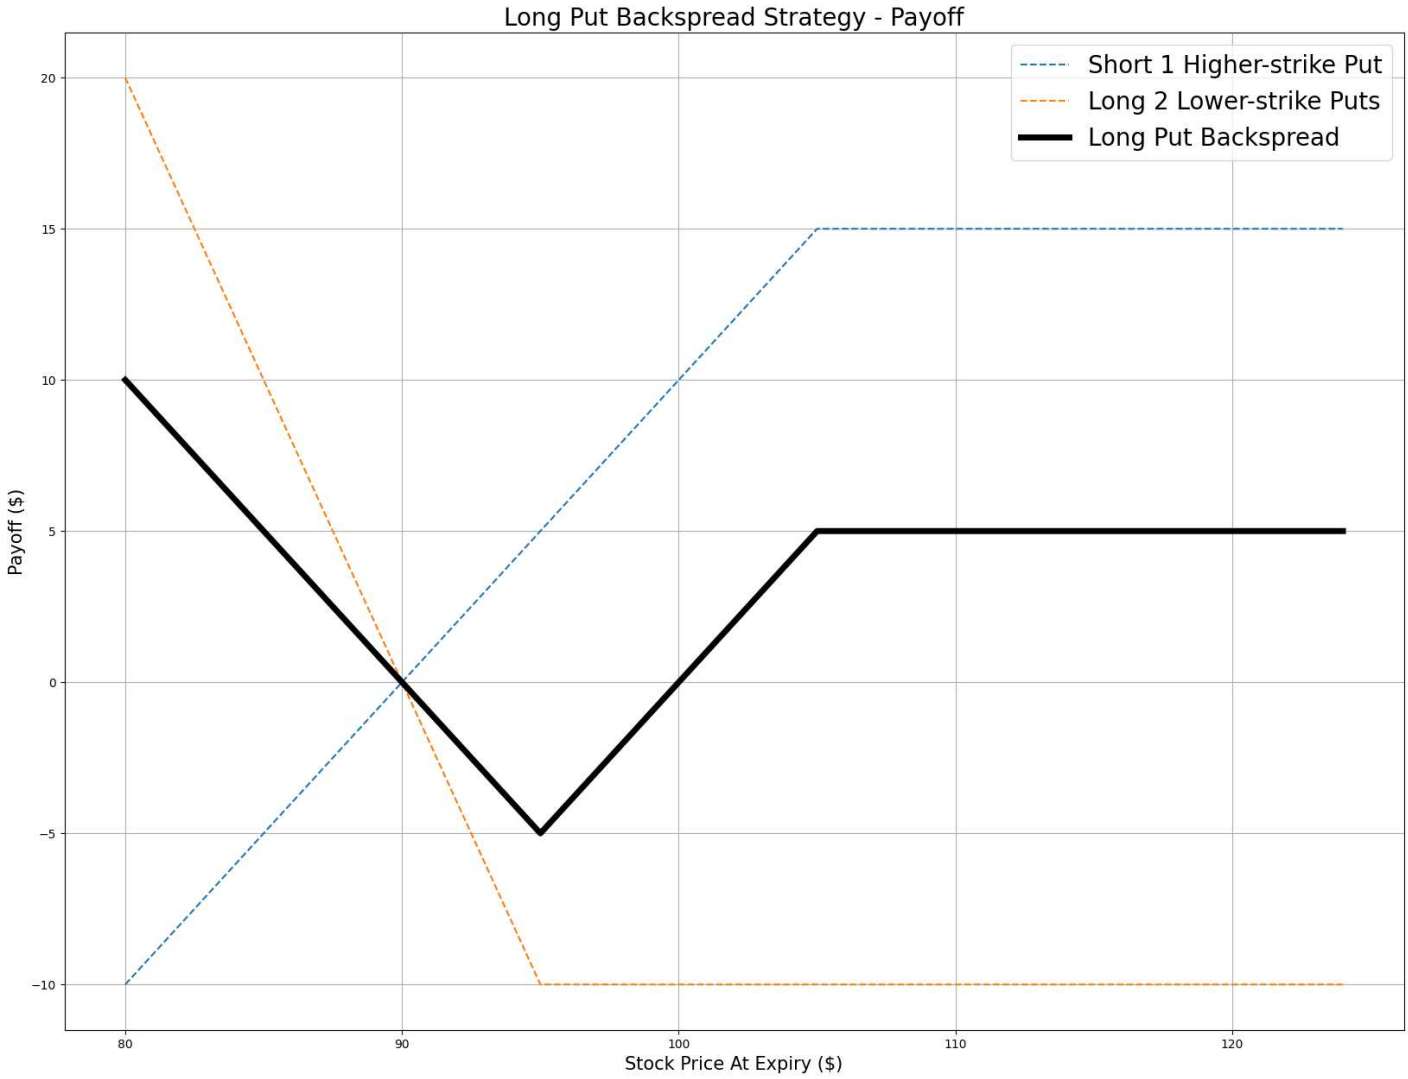
var legs = new List<Leg>()
{
    Leg.Create(lowStrikePut.Symbol, 2),
    Leg.Create(highStrikePut.Symbol, -1)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The long put backspread is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ Payoff_T & = & (P^{high}_0 - P^{high}_T + P^{low}_T \times 2 - P^{low}_0 \times 2)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & P^{low}_T & = & \textrm{Lower-strike put value at time T}\\ & P^{high}_T & = & \textrm{Higher-strike put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{low} & = & \textrm{Lower-strike put strike price}\\ & K^{high} & = & \textrm{Higher-strike put strike price}\\ & P^{low}_0 & = & \textrm{Lower-strike put value at position opening (credit received)}\\ & P^{high}_0 & = & \textrm{Higher-strike put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is unlimited, which occurs when the underlying price increases indefinitely.

The maximum loss is $K^{low} - K^{high} + P^{high}_0 - P^{low}_0 \times 2$, which occurs when the underlying price is exactly at the lower strike at expiry.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	**Price ($)**	**Strike ($)**
Lower-Strike put	6.90	825.00
Higher-strike put	8.50	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ & = & (825.00-843.19)^{+}\\ & = & 0.00\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ & = & (835.00-843.19)^{+}\\ & = & 0.00\\ Payoff_T & = & (P^{high}_0 - P^{high}_T + P^{low}_T \times 2 - P^{low}_0 \times 2)\times m - fee\\ & = & (8.50 - 0.00 + 0.00\times2 - 6.90\times2)\times100-2.30\\ & = & -532.30\\ \end{array}$$

So, the strategy loses $532.30.

The following algorithm implements a long put backspread Option strategy:

```C#
public class BackspreadOptionStrategyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        UniverseSettings.Asynchronous = true;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(20, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var puts = chain.Where(x => x.Expiry == expiry);
        if (puts.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 2)
        {
            return;
        }

        var lowStrike = strikes[0];
        var highStrike = strikes[1];

        var optionStrategy = OptionStrategies.PutBackspread(_symbol, highStrike, lowStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Option Strategies

Short Put Backspread

Introduction

Short Put Backspread , consists of short 1 higher-strike put and short 2 lower-strike puts. It is a combination of a bear put spread and a short put with the same strike price as the lower-strike leg the put spread. All puts have the same underlying Equity and expiration date. This strategy profits from stable, consistent price of the underlying asset. For instance, the underlying price stays at its current price.

Implementation

Follow these steps to implement the short put backspread strategy:

1. In the `Initialize` method, set the start date, end date, cash, and Option universe . You can use the `PutSpread` helper method in option universe filtering, since a put backspread consists of the same contracts as a put spread.

```C#
private Symbol _symbol;

public override void Initialize()
{
    SetStartDate(2024, 9, 1);
    SetEndDate(2024, 12, 31);
    SetCash(1000000);

    UniverseSettings.Asynchronous = true;
    var option = AddOption("GOOG", Resolution.Minute);
    _symbol = option.Symbol;
    option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(20, 5));
}
```

2. In the `OnData` method, select the expiration and strikes of the contracts in the strategy legs.

```C#
public override void OnData(Slice slice)
{
    if (Portfolio.Invested ||
        !slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    // Select the put Option contracts with the furthest expiry
    var expiry = chain.Max(x => x.Expiry);
    var puts = chain.Where(x => x.Expiry == expiry);
    if (puts.Count() == 0) return;

    // Select the strike prices from the remaining contracts
    var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
    if (strikes.Count < 2)
    {
        return;
    }

    var lowStrike = strikes[0];
    var highStrike = strikes[1];
```

3. In the `OnData` method, select the contracts and place the orders.

Approach A: Call the `OptionStrategies.ShortPutBackspread` method with the details of each leg and then pass the result to the `Buy` method.

```
C#
var optionStrategy = OptionStrategies.ShortPutBackspread(_symbol, highStrike, lowStrike, expiry);
Buy(optionStrategy, 1);
```

Approach B: Create a list of `Leg` objects and then call the Combo Market Order , Combo Limit Order , or Combo Leg Limit Order method.

```
C#
var lowStrikePut = puts.Single(x => x.Strike == lowStrike);
var highStrikePut = puts.Single(x => x.Strike == highStrike);

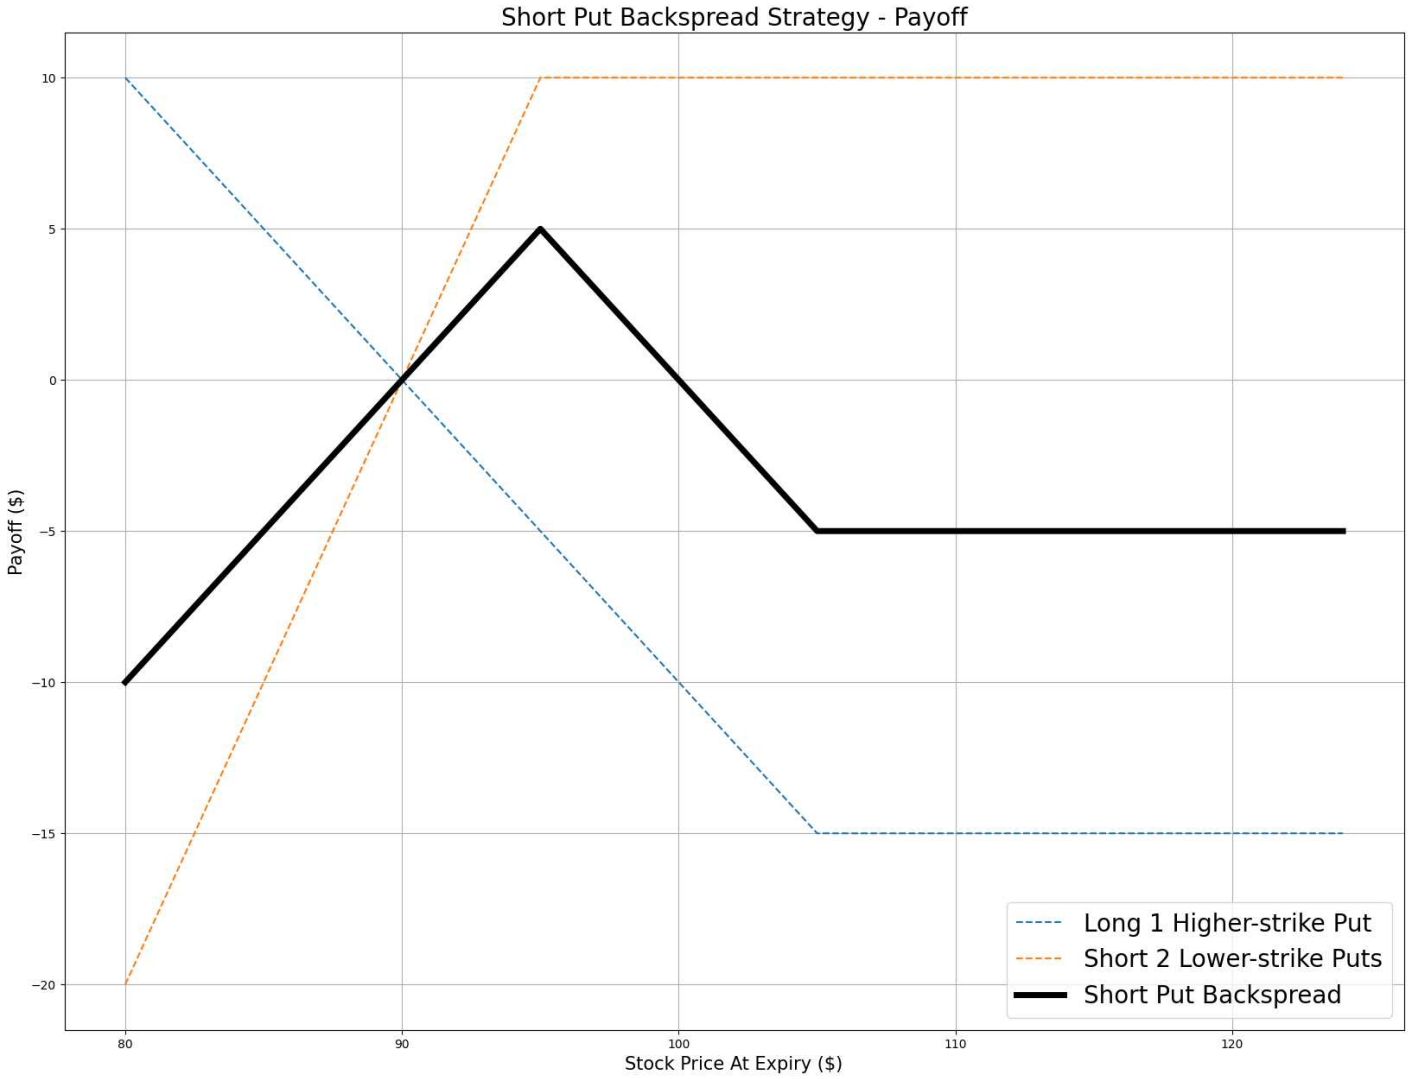
var legs = new List<Leg>()
{
    Leg.Create(lowStrikePut.Symbol, -2),
    Leg.Create(highStrikePut.Symbol, 1)
};
ComboMarketOrder(legs, 1, true);
```

Strategy Payoff

The short put backspread is an unlimited-profit-limited-risk strategy. The payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ Payoff_T & = & (P^{high}_T - P^{high}_0 - P^{low}_T \times 2 + P^{low}_0 \times 2)\times m - fee\\ \end{array} \begin{array}{rcll} \textrm{where} & P^{low}_T & = & \textrm{Lower-strike put value at time T}\\ & P^{high}_T & = & \textrm{Higher-strike put value at time T}\\ & S_T & = & \textrm{Underlying asset price at time T}\\ & K^{low} & = & \textrm{Lower-strike put strike price}\\ & K^{high} & = & \textrm{Higher-strike put strike price}\\ & P^{low}_0 & = & \textrm{Lower-strike put value at position opening (credit received)}\\ & P^{high}_0 & = & \textrm{Higher-strike put value at position opening (debit paid)}\\ & m & = & \textrm{Contract multiplier}\\ & T & = & \textrm{Time of expiration} \end{array}$$

The following chart shows the payoff at expiration:



The maximum profit is $K^{high} - K^{low} - P^{high}_0 + P^{low}_0 \times 2$, which occurs when the underlying price is exactly at the lower strike at expiry.

The maximum loss is $P^{low}_0 \times 2 - P^{high}_0 - S_T$, which occurs when the underlying price drops to zero.

If the Option is American Option, there is a risk of early assignment on the contract you sell.

Example

The following table shows the price details of the assets in the algorithm:

Asset	Price ($)	Strike ($)
Lower-Strike put	4.70	825.00
Higher-strike put	10.90	835.00
Underlying Equity at expiration	843.19	-

Therefore, the payoff is

$$\begin{array}{rcll} P^{low}_T & = & (K^{low} - S_T)^{+}\\ & = & (825.00-843.19)^{+}\\ & = & 0.00\\ P^{high}_T & = & (K^{high} - S_T)^{+}\\ & = & (835.00-843.19)^{+}\\ & = & 0.00\\ Payoff_T & = & (P^{high}_T - P^{high}_0 - P^{low}_T \times 2 + P^{low}_0 \times 2)\times m - fee\\ & = & (0 - 10.90 - 0.00\times2 + 4.70\times2)\times100-2.30\\ & = & -152.30\\ \end{array}$$

So, the strategy loses $152.30.

The following algorithm implements a short put backspread Option strategy:

```C#
public class BackspreadOptionStrategyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        UniverseSettings.Asynchronous = true;
        var option = AddOption("GOOG", Resolution.Minute);
        _symbol = option.Symbol;
        option.SetFilter(universe => universe.IncludeWeeklys().PutSpread(20, 5));
    }

    public override void OnData(Slice slice)
    {
        if (Portfolio.Invested ||
            !slice.OptionChains.TryGetValue(_symbol, out var chain))
        {
            return;
        }

        // Select the call Option contracts with the furthest expiry
        var expiry = chain.Max(x => x.Expiry);
        var puts = chain.Where(x => x.Expiry == expiry);
        if (puts.Count() == 0) return;

        // Select the strike prices from the remaining contracts
        var strikes = puts.Select(x => x.Strike).Distinct().OrderBy(x => x).ToList();
        if (strikes.Count < 2)
        {
            return;
        }

        var lowStrike = strikes[0];
        var highStrike = strikes[1];

        var optionStrategy = OptionStrategies.ShortPutBackspread(_symbol, highStrike, lowStrike, expiry);
        Buy(optionStrategy, 1);
    }
}
```

Trading and Orders

Order Properties

Introduction

Order properties enable you to customize how the brokerage executes your orders. The `DefaultOrderProperties` of your algorithm sets the order properties for all of your orders. To adjust the order properties of an order, you can change the `DefaultOrderProperties` or pass an order properties object to the order method.

Time In Force

The `TimeInForce` property determines how long an order should remain open if it doesn't fill. This property doesn't apply to market orders since they usually fill immediately. Time in force is useful to automatically cancel old trades. The following table describes the available TimeInForce options:

Member	Example	Description
`GoodTilCanceled`	`TimeInForce.GoodTilCanceled`	Order is valid until filled (default)
`Day`	`TimeInForce.Day`	Order is valid until filled or the market closes
`GoodTilDate(DateTime expiry)`	`TimeInForce.GoodTilDate(new DateTime(2019, 6, 19, 12, 0, 0))`	Order is valid until filled or the specified expiration time

By default, orders remain open until they are canceled (`TimeInForce.GoodTilCanceled`). To update the value, set the `DefaultOrderProperties.TimeInForce` before you place an order or pass an `orderProperties` argument to the order method.

```C#
// Set a Limit Order to be good until market close
DefaultOrderProperties.TimeInForce = TimeInForce.Day;
LimitOrder("IBM", 100, 120);

// Set a Limit Order to be good until noon
LimitOrder("IBM", 100, 120, orderProperties: new OrderProperties
{
    TimeInForce = TimeInForce.GoodTilDate(new DateTime(2019, 6, 19, 12, 0, 0))
});
```

If you trade a market that's open 24 hours a day with daily data, `TimeInForce.Day` won't work because the order cancels at the market close time but your algorithm receives daily data at midnight.

Market on open (MOO) and market on close (MOC) orders don't support the `GoodTilDate` time in force. If you submit a MOO or MOC order with the `GoodTilDate` time in force, LEAN automatically adjusts the time in force to be `GoodTilCanceled` .

The brokerage you use may not support all of the `TimeInForce` options. To see the options that your brokerage supports, see the Orders section of the brokerage model documentation .

Brokerage-Specific Properties

Some brokerages support additional order properties so you can customize how your orders execute. Some examples include the following order properties:

- Financial Advisor group orders
- An `OutsideRegularTradingHours` property to let orders fill during pre-market and post-market trading hours
- A `PostOnly` property to force an order to only add liquidity to a market
- A `Hidden` property to make an order not show on the order book
- A `ReduceOnly` property to signal the order must only decrease your position size
- `FeeInBase` and `FeeInQuote` properties to set which currency you pay fees in for a Crypto trade

To view the order properties your brokerage supports, see the Orders section of the brokerage model documentation .

Tags

You can tag orders to aid your strategy development. Tags can be any string of up to 100 characters. Tags aren't part of the `OrderProperties` object, but they are a property of the `Order` class you can set. To set an order tag, pass it as an argument when you create the order or use the order update methods.

```
C#

// Tag an order on creation
var ticket = LimitOrder("SPY", 100, 221.05, tag: "Original tag");

// Update the tag with UpdateTag
ticket.UpdateTag("Updated tag");

// Update the tag with UpdateOrderFields
ticket.Update(new() { Tag = "Another tag" });
```

Examples

The following examples demonstrate some common practices for utilizing order properties.

Example 1: Extended Market Hour Orders

The following algorithm trades buys or sells SPY during pre-market to capture momentum in the overnight gap. It exits the positions at 15 minutes after the market opens. To trade in the extended market hours without stale fills, it set the respective order properties.

```C#
public class OrderPropertiesAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private decimal _lastPrice = 0m;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add extended market hour SPY data for trading.
        _spy = AddEquity("SPY", extendedMarketHours: true).Symbol;

        // Add a Scheduled Event to trade 2 hours enter a position during pre-market.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.BeforeMarketOpen(_spy, 120), OpenPosition);
        // Add a Scheduled Event to exit the position 15 minutes after market open.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.AfterMarketOpen(_spy, 15), () => Liquidate());
        // Add a Scheduled Event to cache the daily close price so you can generate signals the next day.
        Schedule.On(DateRules.EveryDay(_spy), TimeRules.BeforeMarketClose(_spy), GetLastPrice);
        // Add a warm-up period so the algorithm trades on the first day in live mode.
        SetWarmUp(TimeSpan.FromDays(1));
    }

    private void OpenPosition()
    {
        if (_lastPrice > 0m)
        {
            var currentPrice = Securities[_spy].Price;

            // Define the order properties to trade in pre-market. The order will only valid for 3 minutes to avoid
            // stale fills.
            var orderProperties = new InteractiveBrokersOrderProperties
            {
                TimeInForce = TimeInForce.GoodTilDate(Time.AddMinutes(3)),
                OutsideRegularTradingHours = true
            };

            // Buy if the overnight direction is upward, indicating positive market sentiment.
            // Sell if the overnight direction is downward, indicating negative market sentiment.
            // Note that pre-market orders do not accept market order.
            LimitOrder(_spy, currentPrice > _lastPrice ? 10 : -10, currentPrice, orderProperties: orderProperties);
        }
    }

    private void GetLastPrice()
    {
        _lastPrice = Securities[_spy].Price;
    }
}
```

Example 2: Financial Advisor Managing Client Funds

The following algorithm forms an equal-weight portfolio at the start of each week with the 10 most liquid US Equities. It demonstrates how order properties can give financial advisors easy control over client funds.

C#

```
public class OrderPropertiesAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Define the order properties to trade with an FA group.
        DefaultOrderProperties = new InteractiveBrokersOrderProperties
        {
            FaGroup = "TestGroupEQ",        // FA group
            FaMethod = "NetLiq",            // Allocation by net liquidation
            Account = "FA123456"            // FA account
        };

        // Add a universe that selects the 10 most liquid US Equities at the start of each week.
        var spy = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);
        UniverseSettings.Schedule.On(DateRules.WeekStart(spy));
        var universe = AddUniverse(Universe.Top(10));

        // Add a Scheduled Event to rebalance at the start of each week.
        Schedule.On(
            DateRules.WeekStart(spy),
            TimeRules.At(10, 0),
            // Form an equal-weighted portfolio of the universe constituents.
            () => SetHoldings(
                universe.Selected.Select(symbol => new PortfolioTarget(symbol, 0.1m)).ToList(),
                // Liquidate the assets that aren't in the universe anymore.
                liquidateExistingHoldings: true
            )
        );
    }
}
```

Trading and Orders

Order Events

Introduction

An `OrderEvent` object represents an update to the state of an order. As the state of your orders change, we notify your algorithm with `OrderEvent` objects through the `OnOrderEvent` and `OnAssignmentOrderEvent` event handlers.

Track Order Events

Each order generates events over its life as its status changes. Your algorithm receives these events through the `OnOrderEvent` and `OnAssignmentOrderEvent` methods. The `OnOrderEvent` event handler receives all order events. The `OnAssignmentOrderEvent` receives order events for Option assignments. The event handlers receive an `OrderEvent` object, which contains information about the order status.

```C#
public override void OnOrderEvent(OrderEvent orderEvent)
{
    var order = Transactions.GetOrderById(orderEvent.OrderId);
    if (orderEvent.Status == OrderStatus.Filled)
    {
        Debug($"{Time}: {order.Type}: {orderEvent}");
    }
}

public override void OnAssignmentOrderEvent(OrderEvent assignmentEvent)
{
    Log(assignmentEvent.ToString());
}
```

To get a list of all `OrderEvent` objects for an order, call the `OrderEvents` method of the order ticket .

```C#
var orderEvents = orderTicket.OrderEvents();
```

If you don't have the order ticket, get the order ticket from the TransactionManager .

Order States

Orders can have any of the following states:

Event Attributes

The `OnOrderEvent` and `OnAssignmentOrderEvent` event handlers in your algorithm receive `OrderEvent` objects, which have the following attributes:

Examples

The following examples demonstrate some common practices for using order events.

Example 1: Illiquid Stock Partial Fill

The following algorithm trades EMA cross on CARZ, an illiquid ETF. To realistically simulate the fill behavior, we set a fill model to partially fill the orders with at most 50% of the previous bar's volume per fill. We cancel the remaining open order after the

partial fill since we only trade on the updated information.

C#

```
public class OrderEventsAlgorithm : QCAlgorithm
{
    private Symbol _carz;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request CARZ data to feed indicator and trade.
        var equity = AddEquity("CARZ");
        _carz = equity.Symbol;
        // Set a custom partial fill model for the illiquid CARZ stock since it is more realistic.
        equity.SetFillModel(new CustomPartialFillModel(this));

        // Create EMA indicator to generate trade signals.
        _ema = EMA(_carz, 60, Resolution.Daily);
        // Warm up indicator for immediate readiness to use.
        WarmUpIndicator(_carz, _ema, Resolution.Daily);
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_carz, out var bar))
        {
            // Trade EMA cross on CARZ for trend-following strategy.
            if (bar.Close > _ema && !Portfolio[_carz].IsLong)
            {
                SetHoldings(_carz, 0.5m);
            }
            else if (bar.Close < _ema && !Portfolio[_carz].IsShort)
            {
                SetHoldings(_carz, -0.5m);
            }
        }
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        // If an order is only partially filled, we cancel the rest to avoid trade on non-updated information.
        if (orderEvent.Status == OrderStatus.PartiallyFilled)
        {
            Transactions.CancelOpenOrders();
        }
    }

    /// Implements a custom fill model that partially fills each order with a ratio of the previous trade bar.
    private class CustomPartialFillModel : FillModel
    {
        private readonly QCAlgorithm _algorithm;
        private readonly Dictionary<int, decimal> _absoluteRemainingByOrderId;
        // Save the ratio of the volume of the previous bar to fill the order.
        private decimal _ratio;

        public CustomPartialFillModel(QCAlgorithm algorithm, decimal ratio = 0.5m)
            : base()
        {
            _algorithm = algorithm;
            _absoluteRemainingByOrderId = new Dictionary<int, decimal>();
            _ratio = ratio;
        }

        public override OrderEvent MarketFill(Security asset, MarketOrder order)
        {
            decimal absoluteRemaining;
            if (!_absoluteRemainingByOrderId.TryGetValue(order.Id, out absoluteRemaining))
            {
                absoluteRemaining = order.AbsoluteQuantity;
            }

            var fill = base.MarketFill(asset, order);

            // Partially filled each order with at most 50% of the previous bar.
            fill.FillQuantity = Math.Sign(order.Quantity) * asset.Volume * _ratio;
            if (Math.Min(Math.Abs(fill.FillQuantity), absoluteRemaining) == absoluteRemaining)
            {
```

```
                fill.FillQuantity = Math.Sign(order.Quantity) * absoluteRemaining;
                fill.Status = OrderStatus.Filled;
                _absoluteRemainingByOrderId.Remove(order.Id);
            }
            else
            {
                fill.Status = OrderStatus.PartiallyFilled;
                // Save the remaining quantity after it is partially filled.
                _absoluteRemainingByOrderId[order.Id] = absoluteRemaining - Math.Abs(fill.FillQuantity);
                var price = fill.FillPrice;
            }
            return fill;
        }
    }
}
```

Example 2: Price Actions

The following algorithm saves the trailing 3 `TradeBar` objects into a `RollingWindow` . When it identifies a volume contraction breakout price action pattern on the SPY, it buys to ride on the capital inflow. To exit positions, it places a 2% take profit and 1% stop loss order in the `OnOrderEvent` method.

C#

```
public class RollingWindowAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    // Set up a rolling window to hold the last 3 trade bars for price action detection as the trade signal.
    private RollingWindow<TradeBar> _windows = new(3);

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Add SPY data for signal generation and trading.
        _spy = AddEquity("SPY", Resolution.Minute).Symbol;

        // Warm up the rolling window.
        var history = History<TradeBar>(_spy, 3, Resolution.Minute);
        foreach (var bar in history)
        {
            _windows.Add(bar);
        }
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trade the price action if the previous bars fulfill a contraction breakout.
            if (ContractionAction() && BreakoutAction(bar.Close))
            {
                SetHoldings(_spy, 0.5m);
            }

            // Add the current bar to the window.
            _windows.Add(bar);
        }
    }

    private bool ContractionAction()
    {
        // We trade contraction type price action, where the buying preesure is increasing.
        // 1. The last 3 bars are green.
        // 2. The price is increasing in trend.
        // 3. The trading Volume is increasing as well.
        // 4. The range of the bars are decreasing.
        return _windows[2].Close > _windows[2].Open &&
            _windows[1].Close > _windows[1].Open &&
            _windows[0].Close > _windows[0].Open &&
            _windows[0].Close > _windows[1].Close && _windows[1].Close > _windows[2].Close &&
            _windows[0].Volume > _windows[1].Volume && _windows[1].Volume > _windows[2].Volume &&
            _windows[2].Close - _windows[2].Open > _windows[1].Close - _windows[1].Open &&
            _windows[1].Close - _windows[1].Open > _windows[0].Close - _windows[0].Open;
    }
```

```
    private bool BreakoutAction(decimal currentPrice)
    {
        // Trade breakout from contraction: the breakout should be much greater than the contracted range of the last
bar.
        return currentPrice - _windows[0].Close > (_windows[0].Close - _windows[0].Open) * 2m;
    }

    public override void OnOrderEvent(OrderEvent orderEvent)
    {
        if (orderEvent.Status == OrderStatus.Filled)
        {
            if (orderEvent.Ticket.OrderType == OrderType.Market)
            {
                // Stop loss order at 1%.
                var stopPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 0.99m : orderEvent.FillPrice *
1.01m;
                StopMarketOrder(_spy, -Portfolio[_spy].Quantity, stopPrice);
                // Take profit order at 2%.
                var takeProfitPrice = orderEvent.FillQuantity > 0m ? orderEvent.FillPrice * 1.02m :
orderEvent.FillPrice * 0.98m;
                LimitOrder(_spy, -Portfolio[_spy].Quantity, takeProfitPrice);
            }
            else if (orderEvent.Ticket.OrderType == OrderType.StopMarket || orderEvent.Ticket.OrderType ==
OrderType.Limit)
            {
                // Cancel open orders if the stop loss or take profit order fills.
                Transactions.CancelOpenOrders();
            }
        }
    }
}
```

Trading and Orders

Order Errors

Introduction

If an error occurs with one of your orders, LEAN logs the error message and stops executing.

Types of Order Errors

Errors can occur when you place orders or after you place them.

Errors at Order Submission

The following errors can occur when you submit an order:

- `AlgorithmWarmingUp`
- `BrokerageFailedToSubmitOrder`
- `BrokerageModelRefusedToSubmitOrder`
- `ConversionRateZero`
- `EuropeanOptionNotExpiredOnExercise`
- `ExceededMaximumOrders`
- `ExceedsShortableQuantity`
- `ExchangeNotOpen`
- `ForexBaseAndQuoteCurrenciesRequired`
- `ForexConversionRateZero`
- `InsufficientBuyingPower`
- `MarketOnCloseOrderTooLate`
- `MissingSecurity`
- `NonExercisableSecurity`
- `NonTradableSecurity`
- `OptionOrderOnStockSplit`
- `OrderAlreadyExisits`
- `OrderQuantityLessThanLotSize`
- `OrderQuantityZero`
- `PreOrderChecksError`
- `QuoteCurrencyRequired`
- `SecurityHasNoData`
- `UnsupportedRequestType`

Errors After Order Submission

The following errors can occur for active orders:

- `BrokerageFailedToUpdateOrder`
- `BrokerageModelRefusedToUpdateOrder`
- `InvalidNewOrderStatus`
- `InvalidOrderStatus`

- `InvalidRequest`
- `RequestCanceled`
- `UnableToFindOrder`

Common Errors

There are a few common order errors you may experience.

Why is my order converted to a market on open order?

If you place a market order when the market is closed, LEAN automatically converts the order into market on open order. This most commonly happens when you use daily or hourly data, which your algorithm can receive when the market is closed. With the `DailyPreciseEndTime` setting enabled, your algorithm receives daily bars and the last hourly bar of each day at 4 PM Eastern Time (ET). To avoid LEAN from converting your market order to market on open orders, submit your market orders when the market is open. To check if the market is open, call the `IsMarketOpen` method.

```C#
// Check the market status before placing an order to avoid unintended market-on-open trades
if (IsMarketOpen(_symbol))
{
    MarketOrder(symbol, quantity);
}
```

Why am I seeing the "stale price" warning?

Stale fills occur when you fill an order with price data that is timestamped an hour or more into the past. Stale fills usually only occur if you trade illiquid assets or if your algorithm uses daily data but you trade intraday with Scheduled Events. If your order is filled with stale data, the fill price may not be realistic. The pre-built fill models can only fill market orders with stale data. To adjust the length of time that needs to pass before an order is considered stale, set the `StalePriceTimeSpan` setting.

```C#
public override void Initialize()
{
    // Adjust the stale price time span to be 10 minutes.
    Settings.StalePriceTimeSpan = TimeSpan.FromMinutes(10);
}
```

Why do I get "Backtest Handled Error: The security with symbol '/ES' is marked as non-tradable"?

This error occurs when you place an order for a continuous Futures contract, which isn't a tradable security. To fix the issue, place the order for a specific Futures contract. To access the currently selected contract in the continuous contract series, use the `Mapped` property of the `Future` object.

Why do I get "Backtest Handled Error: Order Error: ids: [1], Insufficient buying power to complete orders" from a Crypto order?

When you place Crypto trades, ensure you have a sufficient balance of the base or quote currency before each trade. If you hold multiple assets and you want to put all of your capital into BTCUSDT, you need to first convert all your non-BTC assets into USDT and then purchase BTCUSDT.

By default, the account currency is USD and your starting cash is 100,000. Some Crypto exchanges don't support fiat currencies, which means you can't convert the 100,000 USD to the pair's quote currency . In this case, set your account currency to the quote currency with a positive quantity.

```C#
SetAccountCurrency("USDT", 1000);   // Set the account currency to Tether and its quantity to 1,000 USDT
```

Error Code Reference

The `OrderError` enumeration has the following members:

Order Response Error Reference

The following sections explain why each `OrderResponseErrorCode` occurs and how to avoid it.

None

The `OrderResponseErrorCode.None` (0) error means there is no order response error.

Processing Error

The `OrderResponseErrorCode.ProcessingError` (-1) error occurs in the following situations:

- When you submit a new order, but LEAN throws an exception while checking if you have sufficient buying power for the order.
- When you try to update or cancel an order, but LEAN throws an exception.

To investigate this order response error further, see the `HandleSubmitOrderRequest` , `UpdateOrder` , and `CancelOrder` methods of the BrokerageTransactionHandler in the LEAN GitHub repository.

Order Already Exists

The `OrderResponseErrorCode.OrderAlreadyExists` (-2) error occurs when you submit a new order but you already have an open order or a completed order with the same order ID. This order response error usually comes from a concurrency issue.

To avoid this order response, don't place two asynchronous orders at the same time.

Insufficient Buying Power

The `OrderResponseErrorCode.InsufficientBuyingPower` (-3) error occurs when you place an order but the buying power model determines you can't afford it.

To avoid this order response error, ensure you have enough margin remaining to cover the initial margin requirements of the order before placing it.

This error also commonly occurs when you place a market on open order with daily data. If you place the order with `SetHoldings` or use `CalculateOrderQuantity` to determine the order quantity, LEAN calculates the order quantity based on the market close price. If the open price on the following day makes your order more expensive, then you may have insufficient buying power. To avoid the order response error in this case, either use intraday data and place trades when the market is open or adjust your buying power buffer .

```C#
Settings.FreePortfolioValuePercentage = 0.05m;
```

Brokerage Model Refused to Submit Order

The `OrderResponseErrorCode.BrokerageModelRefusedToSubmitOrder` (-4) error occurs when you place an order but the brokerage model determines it's invalid. The brokerage model usually checks your order meets the following requirements before sending it to the brokerage:

- Supported security types
- Supported order types and their respective requirements
- Supported time in force options
- The order size is larger than the minimum order size

Each brokerage model can have additional order requirements that the brokerage declares. To avoid this order response error, see the Orders section of the brokerage model documentation .

To investigate this order response error further, see the `CanSubmitOrder` method definition of your brokerage model . This order response error occurs when the `CanSubmitOrder` method returns `false` .

Brokerage Failed to Submit Order

The `OrderResponseErrorCode.BrokerageFailedToSubmitOrder` (-5) error occurs when you place an order but the brokerage implementation fails to submit the order to your brokerage.

To investigate this order response error further, see the `PlaceOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when the `PlaceOrder` method throws an error or returns `false` .

Brokerage Failed to Update Order

The `OrderResponseErrorCode.BrokerageFailedToUpdateOrder` (-6) error occurs when you try to update an order but the brokerage implementation fails to submit the order update request to your brokerage.

To avoid this order response error, see the Orders section of the brokerage model documentation .

To investigate this order response error further, see the `UpdateOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when the `UpdateOrder` method throws an error or returns `false` .

Brokerage Failed to Cancel Order

The `OrderResponseErrorCode.BrokerageFailedToCancelOrder` (-8) error occurs when you try to cancel an order but the brokerage implementation fails to submit the cancel request to your brokerage.

To investigate this order response error further, see the `CancelOrder` method definition of your brokerage or the BacktestingBrokerage in the LEAN GitHub repository. This order response error occurs when `CancelOrder` method throws an error or returns `false` .

Invalid Order Status

The `OrderResponseErrorCode.InvalidOrderStatus` (-9) error occurs when you try to update or cancel an order but the order is already complete. An order is complete if it has `OrderStatus.Filled` , `OrderStatus.Canceled` , or `OrderStatus.Invalid` .

To avoid this order response error, check the `Status` of an order ticket or order event before you update or cancel the order.

```C#
if (!_orderTicket.Status.IsClosed())
{
    _orderTicket.Cancel();
}
```

Unable to Find Order

The `OrderResponseErrorCode.UnableToFindOrder` (-10) error occurs when you try to place, update, or cancel an order, but the `BrokerageTransactionHandler` doesn't have a record of the order ID.

To investigate this order response error further, see BrokerageTransactionHandler.cs in the LEAN GitHub repository. This order response error occurs when the `BrokerageTransactionHandler` can't find the order ID in it's `_completeOrders` or `_completeOrderTickets` dictionaries.

Order Quantity Zero

The `OrderResponseErrorCode.OrderQuantityZero` (-11) error occurs when you place an order that has zero quantity or when you update an order to have a zero quantity. This error commonly occurs if you use the SetHoldings method but the portfolio weight you provide to the method is too small to translate into a non-zero order quantity.

To avoid this order response error, check if the quantity of the order is non-zero before you place the order. If you use the `SetHoldings` method, replace it with a combination of the CalculateOrderQuantity and MarketOrder methods.

```
C#

var quantity = CalculateOrderQuantity(_symbol, 0.05);
if (quantity != 0)
{
    MarketOrder(_symbol, quantity);
}
```

Unsupported Request Type

The `OrderResponseErrorCode.UnsupportedRequestType` (-12) error occurs in the following situations:

- When you try to exercise an Option contract for which you hold a short position
- When you try to exercise more Option contracts than you hold

To avoid this order response error, check the quantity of your holdings before you try to exercise an Option contract.

```
C#

var holdingQuantity = Portfolio[_contractSymbol].Quantity;
if (holdingQuantity > 0)
{
    ExerciseOption(_contractSymbol, Math.Max(holdingQuantity, exerciseQuantity));
}
```

Missing Security

The `OrderResponseErrorCode.MissingSecurity` (-14) error occurs when you place an order for a security but you don't have a subscription for the security in your algorithm.

To avoid this order response error, create a subscription for each security you want to trade. To create subscriptions, see the Requesting Data page of the documentation for each asset class .

Exchange Not Open

The `OrderResponseErrorCode.ExchangeNotOpen` (-15) error occurs in the following situations:

- When you try to exercise an Option while the exchange is not open

  To avoid the order response error in this case, check if the exchange is open before you exercise an Option contract.

```
if (IsMarketOpen(_contractSymbol))
{
    ExerciseOption(_contractSymbol, quantity);
}
```

- When you try to place a market on open order for a Futures contract or a Future Option contract

Security Price Zero

The `OrderResponseErrorCode.SecurityPriceZero` (-16) error occurs when you place an order or exercise an Option contract while the security price is 0. The security price can be 0 for the following reasons:

- The data is missing

  Investigate if it's a data issue. If it is a data issue, report it .

- The algorithm hasn't received data for the security yet

  If you subscribe to a security and place an order for the security in the same time step , you'll get this error. To avoid this order response error, enable the `SeedInitialPrices` setting to seed new assets with their last known price.

  ```
  Settings.SeedInitialPrices = true;
  ```

Forex Base and Quote Currencies Required

The `OrderResponseErrorCode.ForexBaseAndQuoteCurrenciesRequired` (-17) error occurs when you place a trade for a Forex or Crypto pair but you don't have the base currency and quote currency in your cash book . This error should never occur. If it does, create a bug report.

Forex Conversion Rate Zero

The `OrderResponseErrorCode.ForexConversionRateZero` (-18) error occurs when you place a trade for a Forex or Crypto pair and LEAN can't convert the value of the base currency to your account currency. This error usually indicates a lack of data. Investigate the data and if there is some missing, report it .

Security Has No Data

The `OrderResponseErrorCode.SecurityHasNoData` (-19) error occurs when you place an order for a security before your algorithm receives any data for it. If you subscribe to a security and place an order for the security in the same time step , you'll get this error. To avoid this order response error, enable the `SeedInitialPrices` setting to seed new assets with their last known price.

```
Settings.SeedInitialPrices = true;
```

Exceeded Maximum Orders

The `OrderResponseErrorCode.ExceededMaximumOrders` (-20) error occurs when exceed your order quota in a backtest. The number of orders you can place in a single backtest depends on the tier of your organization . The following table shows the number of orders you can place on each tier:

Tier	Orders Quota
Free	10K
Quant Researcher	10M
Team	Unlimited
Trading Firm	Unlimited
Institution	Unlimited

To avoid this order response error, reduce the number of orders in your backtest or upgrade your organization .

Market on Close Order Too Late

The `OrderResponseErrorCode.MarketOnCloseOrderTooLate` (-21) error occurs when you try to place a market on close (MOC) order too early in the trading day.

To avoid this order response error, place the MOC order closer to the market close or adjust the submission time buffer. By default, you must place MOC orders at least 15.5 minutes before the close, but some exchanges let you submit them closer to the market closing time. To adjust the buffer period that's required, set the `MarketOnCloseOrder.SubmissionTimeBuffer` property.

```
C#
Orders.MarketOnCloseOrder.SubmissionTimeBuffer = TimeSpan.FromMinutes(10);
```

Invalid Request

The `OrderResponseErrorCode.InvalidRequest` (-22) error occurs when you try to cancel an order multiple times.

To avoid this order response error, only try to cancel an order one time.

Request Canceled

The `OrderResponseErrorCode.RequestCanceled` (-23) error occurs when you try to cancel an order multiple times.

To avoid this order response error, only try to cancel an order one time.

Algorithm Warming Up

The `OrderResponseErrorCode.AlgorithmWarmingUp` (-24) error occurs in the following situations:

- When you try to place, update, or cancel an order during the warm-up period
- When the Option assignment simulator assigns you to an Option during the warm-up period

To avoid this order response error, only manage orders after the warm-up period ends. To avoid trading during the warm-up period, add an `IsWarmingUp` guard to the top of the `OnData` method.

```
C#
if (IsWarmingUp) return;
```

Brokerage Model Refused to Update Order

The `OrderResponseErrorCode.BrokerageModelRefusedToUpdateOrder` (-25) error occurs in backtests when you try to update

an order in a way that the brokerage model doesn't support.

To avoid this issue, see the Orders section of the brokerage model documentation to check its order requirements.

To investigate this order response error further, see the `CanUpdateOrder` method definition of your brokerage model .

Quote Currency Required

The `OrderResponseErrorCode.QuoteCurrencyRequired` (-26) error occurs when you place an order for a Forex or Crypto pair and don't have the quote currency of the pair in your cash book . This error should never occur. If it does, create a bug report.

Conversion Rate Zero

The `OrderResponseErrorCode.ConversionRateZero` (-27) error occurs when you place an order for a Forex or Crypto pair and LEAN can't convert the value of the quote currency in the pair to your account currency. This order response error usually indicates a lack of data. Investigate the data and if there is data missing, report it .

Non-Tradable Security

The `OrderResponseErrorCode.NonTradableSecurity` (-28) error occurs when you place an order for a security that's not tradable . To avoid this order response error, check if a security is tradable before you trade it.

```
C#
if (Securities[_symbol].IsTradable)
{
    MarketOrder(_symbol, quantity);
}
```

Non-Exercisable Security

The `OrderResponseErrorCode.NonExercisableSecurity` (-29) error occurs when you call the ExerciseOption method with a `Symbol` that doesn't reference an Option contract.

Order Quantity Less Than Lot Size

The `OrderResponseErrorCode.OrderQuantityLessThanLotSize` (-30) error occurs when you place an order with a quantity that's less than the lot size of the security.

To avoid this order response error, check if the order quantity is greater than or equal to the security lot size before you place an order.

```
C#
var lotSize = Securities[_symbol].SymbolProperties.LotSize;
if (quantity >= lotSize)
{
    MarketOrder(_symbol, quantity);
}
```

Exceeds Shortable Quantity

The `OrderResponseErrorCode.ExceedsShortableQuantity` (-31) error occurs when you place an order to short a security but the shortable provider of the brokerage model states there isn't enough shares to borrow. For a full example of this error, clone and run this backtest .

To avoid this order response error, check if there are enough shares available before you place an order to short a security.

```
if (quantityToBorrow <= ShortableQuantity(_symbol))
{
    MarketOrder(_symbol, -quantityToBorrow);
}
```

Invalid New Order Status

The `OrderResponseErrorCode.InvalidNewOrderStatus` (-32) error occurs in live trading when you try to update or cancel an order while it still has `OrderStatus.New` status.

To avoid this order response error, check the `Status` property of the order ticket or order event before you update or cancel an order.

```
if (_orderTicket.Status != OrderStatus.New)
{
    _orderTicket.Cancel();
}
```

European Option Not Expired on Exercise

The `OrderResponseErrorCode.EuropeanOptionNotExpiredOnExercise` (-33) error occurs when you try to exercise a European Option contract before its expiry date.

To avoid this order response error, check the type and expiry date of the contract before you exercise it.

```
if (_contractSymbol.ID.OptionStyle == OptionStyle.European && _contractSymbol.ID.Date == Time.Date)
{
    ExerciseOption(_contractSymbol, quantity);
}
```

Option Order on Stock Split

The `OrderResponseErrorCode.OptionOrderOnStockSplit` (-34) error occurs when you try to submit an order for an Equity Option contract when the current time slice contains a split for the underlying Equity.

To avoid this order response error, check if the time slice has a split event for the underlying Equity of the contract before you place an order for the contract.

```
if (!slice.Splits.ContainsKey(_contractSymbol.Underlying))
{
    MarketOrder(_contractSymbol, quantity);
}
```

Market on Open Not Allowed During Regular Hours

The `OrderResponseErrorCode.MarketOnOpenNotAllowedDuringRegularHours` (-35) error occurs when you try to place a market on open order for an asset when it's during regular trading hours.

To avoid this order response error, place the order when the market is closed.

```C#
if (!IsMarketOpen(_symbol))
{
    MarketOnOpenOrder(_symbol, quantity);
}
```

Warnings

The following sections explain why each some warnings occur and how to avoid them.

Limit Price Exceeds Precision Requirements

Limit prices must be a multiple of the security's `MinimumPriceVariation` property . Otherwise, LEAN rounds the limit price for you and throws the following warning message:

Backtest Handled Error: Warning: To meet brokerage precision requirements, order LimitPrice was rounded to 6136.00 from 6136.125

To avoid the warning, round the limit price to the nearest value that respects the `MinimumPriceVariation` before you place the order.

```C#
private decimal AdjustLimitPrice(Security security, decimal price, bool roundUp = true)
{
    decimal pip = security.PriceVariationModel.GetMinimumPriceVariation(
        new GetMinimumPriceVariationParameters(security, price)
    );
    return ((int)(price / pip) + (roundUp ? 1 : 0)) * pip;
}
```

Examples

The following examples demonstrate common practices for handling order errors.

Example 1: Pre-Open Order Error

The following algorithm simulate extended market hour trading on Tradier Brokerage . We place a market-on-open order at 7:30am and expect the order cannot submit to the broker since it is not supported, resulting into an error.

C#

```
public class OrderErrorsAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 9, 5);
        // Simulate Tradier brokerage, which does not support the market-on-open orders.
        SetBrokerageModel(BrokerageName.TradierBrokerage, AccountType.Cash);

        // Request extended market hour SPY data for trading.
        _spy = AddEquity("SPY", extendedMarketHours: true).Symbol;

        // Set a scheduled event to trade 2 hours pre-open to place the market-on-open-order.
        Schedule.On(
            DateRules.EveryDay(_spy),
            TimeRules.BeforeMarketOpen(_spy, 120),
            OpenPosition
        );
    }

    private void OpenPosition()
    {
        // Buy on market open will result in an error since Tradier does not support it.
        MarketOnOpenOrder(_spy, 10);
    }

    // It will be triggered on live trading.
    public override void OnBrokerageMessage(BrokerageMessageEvent message)
    {
        if (message.Type == BrokerageMessageType.Error)
        {
            Log($"{Time}: {message.Type}: Message: {message.Message}");
        }
    }
}
```

Trading and Orders

Trade Statistics

Introduction

The `TradeBuilder` tracks the trades of your algorithm and calculates some statistics. Some of these statistics are a function of the risk free interest rate and the number of trading days per year . You can adjust how the `TradeBuilder` defines a trade and how it matches offsetting order fills.

Set Trade Builder

To set the `TradeBuilder` , in the `Initialize` method, call the `SetTradeBuilder` method.

```
C#
SetTradeBuilder(new TradeBuilder(groupingMethod, matchingMethod));
```

The following table describes the arguments the `TradeBuilder` constructor accepts:

Argument	Data Type	Description	Default Value
`groupingMethod`	`FillGroupingMethod`	The method used to group order fills into trades	
`matchingMethod`	`FillMatchingMethod`	The method used to match offsetting order fills	

The `FillGroupingMethod` enumeration has the following members:

The `FillMatchingMethod` enumeration has the following members:

Default Behavior

The default `TradeBuilder` uses `FillGroupingMethod.FillToFill` and `FillMatchingMethod.FIFO` .

Check Open Positions

To check if you have a position open for a security as defined by the `FillGroupingMethod` , call the `HasOpenPosition` method.

```
C#
// Check if the trade builder has recorded any active trades (unclosed positions)
// for a security.
var hasOpenPosition = TradeBuilder.HasOpenPosition(_symbol);
```

Get Closed Trades

To get your closed trades, use the `ClosedTrades` property.

```
C#
var trades = TradeBuilder.ClosedTrades;
```

This property returns a list of `Trade` objects, which have the following attributes:

Examples

The following examples demonstrate some common practices for making use of trade statistics.

Example 1: Kelly Criterion Sizing Using Previous Trades

The following algorithm uses the previous trades to update the win probability and expected return of each trade of the EMA cross strategy of SPY, by the concept of Bayes Theorem. The updated figures are used for position sizing through Kelly Criterion.

```C#
public class TradeStatisticsAlgorithm : QCAlgorithm
{
    private Symbol _spy;
    private ExponentialMovingAverage _ema;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 12);
        SetEndDate(2024, 10, 1);
        SetCash(1000000);

        // Request SPY data to trade.
        _spy = AddEquity("SPY").Symbol;
        // Create an EMA indicator to generate trade signals.
        _ema = EMA(_spy, 20, Resolution.Daily);
        // Warm-up indicator for immediate readiness.
        WarmUpIndicator(_spy, _ema, Resolution.Daily);

        // Set up a trade builder to track the trade statistics; we are interested in open-to-close round trade.
        SetTradeBuilder(new TradeBuilder(FillGroupingMethod.FlatToFlat, FillMatchingMethod.FIFO));
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_spy, out var bar))
        {
            // Trend-following strategy using price and EMA.
            // If the price is above EMA, SPY is in an uptrend, and we buy it.
            var sign = 0m;
            if (bar.Close > _ema && !Portfolio[_spy].IsLong)
            {
                sign = 1m;
            }
            else if (bar.Close < _ema && !Portfolio[_spy].IsShort)
            {
                sign = -1m;
            }
            else
            {
                return;
            }

            var size = 1m;
            var trades = TradeBuilder.ClosedTrades;

            if (trades.Count > 4)
            {
                // Use the trade builder to obtain the win rate and % return of the last five trades to calculate
position size.
                var lastFiveTrades = trades.OrderBy(x => x.ExitTime).TakeLast(5);
                var probWin = lastFiveTrades.Count(x => x.IsWin) / 5m;
                var winSize = lastFiveTrades.Average(x => x.ProfitLoss / x.EntryPrice);
                // Use the Kelly Criterion to calculate the order size.
                size = probWin - (1 - probWin) / winSize;
            }

            SetHoldings(_spy, sign * size);
        }
    }
}
```

Trading and Orders

Trading Calendar

Introduction

The `TradingCalendar` contains a variety of events relevant to the assets in your algorithm.

Trading Day Properties

`TradingDay` objects represent the trading events of a single day. They have the following properties:

Get a Single Trading Day

To get the trading events of the current day, call the `GetTradingDay` method with no arguments.

```C#
var tradingDay = TradingCalendar.GetTradingDay();
```

To get the trading events of a specific day, pass a `DateTime` object to the `GetTradingDay` method.

```C#
var tradingDay = TradingCalendar.GetTradingDay(new DateTime(2022, 6, 1));
```

Get Trading Days

To get all the trading events across a range of dates, pass start and end `DateTime` objects to the `GetTradingDays` method.

```C#
var startDate = new DateTime(2022, 6, 1);
var endDate = new DateTime(2022, 7, 1);
var tradingDays = TradingCalendar.GetTradingDays(startDate, endDate);
```

To get specific trading events across a range of dates, pass a `TradingDayType` enumeration member and the dates to the `GetDaysByType` method.

```C#
var tradingDays = TradingCalendar.GetDaysByType(TradingDayType.OptionExpiration, startDate, endDate);
```

The `TradingDayType` enumeration has the following members:

Trading and Orders

Financial Advisors

Introduction

Financial Advisor accounts enable certified professionals to use a single trading algorithm to manage several client accounts. Our Interactive Brokers integration enables you to place FA group orders if your IB account code starts with F, FA, or I.

Group Routing

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```C#
DefaultOrderProperties = new InteractiveBrokersOrderProperties
{
    FaGroup = "TestGroupEQ",
    FaMethod = "Equal",
    Account = "DU123456"
};
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `Portfolio["SPY"].Quantity` is zero.

Allocation Methods

LEAN supports several allocation methods for FA group orders. If you intend to use the same group allocation method for every order, set the `DefaultOrderProperties` of your algorithm, which sets the order properties for all of your orders.

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new InteractiveBrokersOrderProperties()
    {
        FaGroup = "TestGroupEQ",
        FaMethod = "Equal",
        Account = "DU123456"
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);
}
```

To adjust the order properties of an order, change the `DefaultOrderProperties` or pass an order properties object to the order method . The following sections explain the FA group allocation methods.

Equal

This group allocation method distributes shares equally between all accounts in the group. When you use this method, you need to specify an order quantity.

For example, say your Account Group includes four accounts and you place an order to buy 400 shares of a stock. In this case,

each account receives 100 shares. If your Account Group includes six accounts, each account receives 66 shares, and then 1 share is allocated to each account until all are distributed. After you submit the order, your algorithm receives order events to track the order progress. When all the shares are bought, the order status is `OrderStatus.Filled`. If one of the accounts in the group can't afford 10 of the shares it needs to buy, 10 shares are cancelled and you'll only end up buying 390 shares in total.

```
C#
LimitOrder(
    _symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "Equal"
    }
);
```

Net Liquidation Value

This group allocation method distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net liquidation value in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with Net Liquidation values of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```
C#
LimitOrder(_symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "NetLiq"
    }
);
```

Available Equity

This group allocation method distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with available equity of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```
C#
LimitOrder(_symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "AvailableEquity"
    }
);
```

Subscription Requirements

To use FA group orders through our Interactive Brokers integration, you need to connect as a member of a Trading Firm and Institution organization. If you aren't currently on either of these tiers, upgrade your organization .

Key Concepts

Introduction

Reality models make backtests as realistic as possible to how the strategy would perform in live trading. These reality models model the behavior of things like the portfolio, brokerage, fills, slippage, options, and strategy capacity . Some reality models are set on a security basis and some are set at the portfolio level. The default models assume you trade highly liquid assets. If you trade high volumes or on illiquid assets, you should create custom reality models to be more realistic.

Security Level Models

LEAN's philosophy is to make the models customizable per security as much as possible. The following models are security-level models:

- Fill
- Slippage
- Fee
- Brokerages
- Buying Power
- Settlement
- Short availability
- Option models
  - Pricing
  - Volatility
  - Exercise
  - Assignment
- Margin Interest Rate
- Dividend Yield

To set a security-level reality model, call the set reality model method on the `Security` object. To get the correct method, see the preceding documentation page for each type of model.

```C#
// Set IBM to have a constant $1 transaction fee
Securities["IBM"].SetFeeModel(new ConstantFeeModel(1));
```

You can also set the security-specific models inside a security initializer .

```C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetFeeModel(new ConstantFeeModel(1));
    }
}
```

Portfolio Level Models

A portfolio is a semi-closed system where the state updates over time as the value and quantity of assets in the portfolio fluctuate. It's a semi-closed system because the portfolio usually incurs transaction fees and you can add and deposit capital from the portfolio. LEAN models the portfolio holdings to track and update the average price of each asset with every transaction.

You can set the following portfolio-level models:

- Margin call model

  ```C#
  Portfolio.SetMarginCallModel(new DefaultMarginCallModel(Portfolio, DefaultOrderProperties));
  ```

- Risk free interest rate model

  ```C#
  SetRiskFreeInterestRateModel(new InterestRateProvider());
  ```

Reality Modeling

Trade Fills

Trade Fills

Key Concepts

Introduction

A trade fill is the quantity and price at which your brokerage executes your order in the market. Fill models model how each type of order fills to accurately simulate the behavior of a real brokerage. Fill models determine the price and quantity of your fills, can incorporate spread costs, and work with the slippage model to add slippage into the fill price. If you trade US Equities, our built-in fill models can fill your orders at the official opening and closing auction prices .

Set Models

The brokerage model of your algorithm automatically sets the fill model for each security, but you can override it. To manually set the fill model of a security, call the `SetFillModel` method on the Security object.

C#

```
public override void Initialize()
{
    var security = AddEquity("SPY");
    // Set the fill model for the requested security to backtest with the most realistic scenario
    // ImmediateFillModel provide no delay from network issue or brokerage rules
    security.SetFillModel(new ImmediateFillModel());
}
```

You can also set the fill model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

C#

```
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetFillModel(new ImmediateFillModel());
    }
}
```

To view all the pre-built fill models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the fill model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the EquityFillModel for Equities, the FutureFillModel for Futures, the FutureOptionFillModel for Future Options, and the ImmediateFillModel for all other asset classes.

Model Structure

Fill Models should extend the `FillModel` class. To implement your own fill model, override the methods in the `FillModel` class you wish to change. The class has a dedicated method for each order type. Most of the methods receive a `Security` and `Order` object and return an `OrderEvent` object that contains information about the order status, fill quantity, and errors.

C#

```
public class CustomFillModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
     SetStartDate(2024, 9, 1);
     SetEndDate(2024, 12, 31);
        // In the Initialize method, set the custom fill model for an added security to use the custom model
        var security = AddEquity("SPY");
        security.SetFillModel(new MyFillModel());
    }
}

// Define the custom fill model outside of the algorithm
public class MyFillModel : FillModel {

    public override OrderEvent MarketFill(Security asset, MarketOrder order) {
        return base.MarketFill(asset, order);
    }

    public override OrderEvent LimitFill(Security asset, LimitOrder order) {
        return base.LimitFill(asset, order);
    }

    public override OrderEvent LimitIfTouchedFill(Security asset, LimitIfTouchOrder order) {
        return base.LimitIfTouchedFill(asset, order);
    }

    public override OrderEvent StopMarketFill(Security asset, StopMarketOrder order) {
        return base.StopMarketFill(asset, order);
    }

    public override OrderEvent StopLimitFill(Security asset, StopLimitOrder order) {
        return base.StopLimitFill(asset, order);
    }

    public override OrderEvent TrailingStopFill(Security asset, TrailingStopOrder order) {
     return TrailingStopFill(asset, order);
    }

    public override OrderEvent MarketOnOpenFill(Security asset, MarketOnOpenOrder order) {
        return base.MarketOnOpenFill(asset, order);
    }

    public override OrderEvent MarketOnCloseFill(Security asset, MarketOnCloseOrder order) {
        return base.MarketOnCloseFill(asset, order);
    }

    public override List<OrderEvent> ComboMarketFill(Order order, FillModelParameters parameters) {
        return base.ComboMarketFill(order, parameters);
    }

    public override List<OrderEvent> ComboLimitFill(Order order, FillModelParameters parameters) {
        return base.ComboLimitFill(order, parameters);
    }

    public override List<OrderEvent> ComboLegLimitFill(Order order, FillModelParameters parameters) {
        return base.ComboLegLimitFill(order, parameters);
    }
}
```

The `FillModelParameters` class has the following properties:

Partial Fills

In live trading, your orders can partially fill. For example, if you have a buy limit order at the bid price for 100 shares and someone sells 10 shares with a market order, your order is partially filled. In backtests, the pre-built fill models assume orders completely fill. To simulate partial fills in backtests, create a custom fill model.

Stale Fills

Stale fills occur when you fill an order with price data that is timestamped an hour or more into the past. Stale fills usually only occur if you trade illiquid assets or if your algorithm uses daily data but you trade intraday with Scheduled Events. If your order is filled with stale data, the fill price may not be realistic. The pre-built fill models can only fill market orders with stale data. To adjust the length of time that needs to pass before an order is considered stale, set the `StalePriceTimeSpan` setting.

```C#
public override void Initialize()
{
    // Adjust the stale price time span to be 10 minutes.
    Settings.StalePriceTimeSpan = TimeSpan.FromMinutes(10);
}
```

Examples

The following examples demonstrate common practices for implementing a custom fill model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the default `FillModel` and overrides its built-in members so you can easily customize the parts you need.

C#

```
public class CustomFillModelAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 10, 15);
        SetCash(100000);

        var security = AddEquity("SPY", Resolution.Daily);
        security.SetFillModel(new MyFillModel());
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }
}

public class MyFillModel : FillModel {

    public override OrderEvent MarketFill(Security asset, MarketOrder order) {
        return base.MarketFill(asset, order);
    }

    public override OrderEvent LimitFill(Security asset, LimitOrder order) {
        return base.LimitFill(asset, order);
    }

    public override OrderEvent LimitIfTouchedFill(Security asset, LimitIfTouchedOrder order) {
        return base.LimitIfTouchedFill(asset, order);
    }

    public override OrderEvent StopMarketFill(Security asset, StopMarketOrder order) {
        return base.StopMarketFill(asset, order);
    }

    public override OrderEvent StopLimitFill(Security asset, StopLimitOrder order) {
        return base.StopLimitFill(asset, order);
    }

    public override OrderEvent TrailingStopFill(Security asset, TrailingStopOrder order) {
        return TrailingStopFill(asset, order);
    }

    public override OrderEvent MarketOnOpenFill(Security asset, MarketOnOpenOrder order) {
        return base.MarketOnOpenFill(asset, order);
    }

    public override OrderEvent MarketOnCloseFill(Security asset, MarketOnCloseOrder order) {
        return base.MarketOnCloseFill(asset, order);
    }

    public override List<OrderEvent> ComboMarketFill(Order order, FillModelParameters parameters) {
        return base.ComboMarketFill(order, parameters);
    }

    public override List<OrderEvent> ComboLimitFill(Order order, FillModelParameters parameters) {
        return base.ComboLimitFill(order, parameters);
    }

    public override List<OrderEvent> ComboLegLimitFill(Order order, FillModelParameters parameters) {
        return base.ComboLegLimitFill(order, parameters);
    }
}
```

Example 2: Volume Share Fill

The following algorithm longs the top 10 liquid constituents and short the bottom 10 liquid constituents of QQQ. To realistically fill the less liquid stocks, we implement a fill model that only fills with at most 30% of the previous second bar.

C#

```
public class VolumeShareSlippageModelAlgorithm : QCAlgorithm
{
    private List<Symbol> _longs = new();
    private List<Symbol> _shorts = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // The security initializer applies the VolumeShareFillModel to all assets.
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =>
        {
            // Create a slippage model to fill only 30% of the volume of the previous second bar to fill illiquid
stocks realistically.
            security.SetFillModel(new VolumeShareFillModel(this, 0.3m));
        });

        // Request extended market hour SPY data for trading.
        var qqq = AddEquity("QQQ").Symbol;

        // Weekly portfolio updating to allow time to capitalize on the popularity gap.
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        // Add universe to trade on the most and least liquid stocks among QQQ constituents.
        AddUniverse(
            // First, we select all QQQ constituents for the next filter on liquidity.
            Universe.ETF(qqq, Market.USA, UniverseSettings, (constituents) => constituents.Select(c => c.Symbol)),
            FundamentalSelection
        );

        // Set a scheduled event to rebalance the portfolio at the start of every week.
        Schedule.On(
            DateRules.WeekStart(qqq),
            TimeRules.AfterMarketOpen(qqq),
            Rebalance
        );
    }

    private IEnumerable<Symbol> FundamentalSelection(IEnumerable<Fundamental> fundamentals)
    {
        var sortedByDollarVolume = fundamentals.OrderBy(x => x.DollarVolume).ToList();
        // Add the 10 most liquid stocks to the universe to long later.
        _longs = sortedByDollarVolume.TakeLast(10)
            .Select(x => x.Symbol)
            .ToList();
        // Add the 10 least liquid stocks to the universe to short later.
        _shorts = sortedByDollarVolume.Take(10)
            .Select(x => x.Symbol)
            .ToList();

        return _longs.Union(_shorts);
    }

    private void Rebalance()
    {
        // Equally invest in the selected stocks to dissipate capital risk evenly.
        // Dollar neutral of long and short stocks to eliminate systematic risk, only capitalize the popularity gap.
        var targets = _longs.Select(symbol => new PortfolioTarget(symbol, 0.05m)).ToList();
        targets.AddRange(_shorts.Select(symbol => new PortfolioTarget(symbol, -0.05m)).ToList());

        // Liquidate the stocks that are not the most and least popular to release funds for higher expected return
trades.
        SetHoldings(targets, liquidateExistingHoldings: true);
    }

    private class VolumeShareFillModel : FillModel
    {
        private readonly QCAlgorithm _algorithm;
        private readonly decimal _maximumRatio;
        private readonly Dictionary<int, decimal> _absoluteRemainingByOrderId = new();

        public VolumeShareFillModel(QCAlgorithm algorithm, decimal maximumRatio = 0.3m)
            : base()
        {
            _algorithm = algorithm;
            _maximumRatio = maximumRatio;
        }

        public override OrderEvent MarketFill(Security asset, MarketOrder order)
        {
            decimal absoluteRemaining;
```

```
            decimal absoluteRemaining;
            if (!_absoluteRemainingByOrderId.TryGetValue(order.Id, out absoluteRemaining))
            {
                absoluteRemaining = order.AbsoluteQuantity;
            }

            // Create the object
            var fill = base.MarketFill(asset, order);

            // Set the fill amount
            fill.FillQuantity = Math.Sign(order.Quantity) * 10m;
            if (Math.Min(Math.Abs(fill.FillQuantity), absoluteRemaining) == absoluteRemaining)
            {
                fill.FillQuantity = Math.Sign(order.Quantity) * absoluteRemaining;
                fill.Status = OrderStatus.Filled;
                _absoluteRemainingByOrderId.Remove(order.Id);
            }
            else
            {
                fill.Status = OrderStatus.PartiallyFilled;
                _absoluteRemainingByOrderId[order.Id] = absoluteRemaining - Math.Abs(fill.FillQuantity);
                var price = fill.FillPrice;
                //_algorithm.Debug($"{_algorithm.Time} - Partial Fill - Remaining
{_absoluteRemainingByOrderId[order.Id]} Price - {price}");
            }
            return fill;
        }
    }
}
```

Equity Model

Introduction

The `EquityFillModel` is the default fill model if you trade Equity assets with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
C#
security.SetFillModel(new EquityFillModel());
```

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following sections explain the fill logic of each order given these factors.

For more information about this model, see the class reference and implementation .

Market Orders

The model fills buy market orders at the best effort ask price plus slippage and fills sell market orders at the best effort bid price minus slippage.

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

The model only fills market orders during regular trading hours.

Limit Orders

To fill limit orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `EndTime` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the fill condition and fill price of limit orders. The model only fills the order once the fill condition is met.

Order Direction	Fill Condition	Fill Price
Buy	low price < limit price	min(open price, limit price)
Sell	high price > limit price	max(open price, limit price)

The model only fills limit orders when the exchange is open.

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

To fill limit if touched orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `EndTime` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

After the model has a valid best effort `TradeBar` , it can check if the trigger price has been touched. The following table describes the trigger condition of limit if touched orders for each order direction:

Order Direction	Trigger Condition
Buy	low price <= trigger price
Sell	high price >= trigger price

Once the limit if touched order triggers, the model starts to check if it should fill the order. The following table shows the fill condition and fill price of limit if touched orders. The model only fills the order once the fill condition is met

Order Direction	Fill Condition	Fill Price
Buy	Best effort ask price <= limit price	min(best effort ask price, limit price)
Sell	Best effort bid price >= limit price	max(best effort bid price, limit price)

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

The model only fills limit orders when the exchange is open.

The model won't trigger or fill limit if touched orders with stale data .

Stop Market Orders

To fill stop market orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `EndTime` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the stop condition is met, the model fills the orders and sets the fill price.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the stop condition and fill price of stop market orders. The model only fills the order once the stop condition is met.

Order Direction	Fill Condition	Fill Price
Buy	high price >= stop price	max(open price, stop price) + slippage
Sell	low price <= stop price	min(open price, stop price) - slippage

The model only fills stop market orders during regular trading hours.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The fill logic of stop limit orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of stop limit orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

The following table describes how the fill model processes the order given the data format and order direction. Once the stop condition is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

The model only fills stop limit orders when the exchange is open.

Trailing Stop Orders

To fill trailing stop orders, the model first gets the best effort `TradeBar` . To get the best effort `TradeBar` , the model checks the resolution of your security subscription. If your subscription provies `Tick` data, it gets the most recent batch of trade ticks and consolidates them to build a `TradeBar` . If your subscription provies `TradeBar` data, it gets the most recent `TradeBar` . If the `EndTime` of the best effort `TradeBar` is less than or equal to the time you placed the order, the model waits until the next best effort `TradeBar` to fill the order.

Once the stop condition is met, the model fills the orders and sets the fill price.

Once the model has a valid best effort `TradeBar` , it can fill the order. The following table shows the stop condition and fill price of trailing stop orders. The model only fills the order once the stop condition is met.

Order Direction	Fill Condition	Fill Price
Buy	high price >= stop price	max(open price, stop price) + slippage
Sell	low price <= stop price	min(open price, stop price) - slippage

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Order Direction	Update Condition	Stop Price
Buy	stop price - low price <= trailing amount	low price + trailing amount
Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts:

Order Direction	Update Condition	Stop Price
Buy	stop price - low price <= low price * trailing amount	low price * (1 + trailing amount)
Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders during regular trading hours.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order direction:

Data Format	Order Direction	Fill Price
`Tick`	Buy	If the model receives the official opening auction price within one minute, the order fills at official open price + slippage. After one minute, the order fills at the most recent trade price + slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort ask price + slippage.
`Tick`	Sell	If the model receives the official opening auction price within one minute, the order fills at the official open price - slippage. After one minute, the order fills at the most recent trade price - slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort bid price - slippage.
`TradeBar`	Buy	Open price + slippage
`TradeBar`	Sell	Open price - slippage
`QuoteBar`	Buy	Best effort ask price + slippage
`QuoteBar`	Sell	Best effort bid price - slippage

The model checks the data format in the following order:

1. `Tick`

2. `TradeBar`
3. `QuoteBar`

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order direction:

Data Format	Order Direction	Fill Price
`Tick`	Buy	If the model receives the official closing auction price within one minute after the close, the order fills at official close price + slippage. After one minute, the order fills at the most recent trade price + slippage. If the security doesn't trade within the first two minutes, the order fills at the best effort ask price + slippage.
`Tick`	Sell	If the model receives the official closing auction price within one minute after the close, the order fills at the official close price - slippage. After one minute, the order fills at the most recent trade price - slippage. If the security doesn't trade within the first two minutes after the close, the order fills at the best effort bid price - slippage.
`TradeBar`	Buy	Open price + slippage
`TradeBar`	Sell	Open price - slippage
`QuoteBar`	Buy	Best effort ask price + slippage
`QuoteBar`	Sell	Best effort bid price - slippage

The model checks the data format in the following order:

1. `Tick`
2. `TradeBar`
3. `QuoteBar`

To get the best effort bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the best effort ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the best effort bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Combo Market Orders

The fill logic of combo market orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of combo market orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	Ask quote price + slippage
`Tick`	`Quote`	Sell	Bid quote price - slippage
`Tick`	`Trade`	Buy	Trade price + slippage
`Tick`	`Trade`	Sell	Trade price - slippage
`QuoteBar`		Buy	Ask close price + slippage
`QuoteBar`		Sell	Bid close price - slippage
`TradeBar`		Buy	Close price + slippage
`TradeBar`		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale

- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

The fill logic of combo limit orders depends on the data format of the security subscription and the order direction. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	`TickType`	Combo Order Direction	Leg Order Direction	Price
`Tick`	`Quote`	Buy or sell	Buy	Ask price
`Tick`	`Quote`	Buy or sell	Sell	Bid price
`Tick`	`Trade`	Buy or sell	Buy or sell	Trade price
`QuoteBar`		Buy	Buy	Ask low price
`QuoteBar`		Buy	Sell	Bid low price
`QuoteBar`		Sell	Buy	Ask high price
`QuoteBar`		Sell	Sell	Bid high price
`TradeBar`		Buy	Buy or sell	Low price
`TradeBar`		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The fill logic of combo leg limit orders depends on the data format of the security subscription and the order direction. The following table shows the fill price of combo leg limit orders given these factors. To determine the fill price of the order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Future Model

Introduction

The `FutureFillModel` is the default fill model if you trade Futures contracts with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
C#
security.SetFillModel(new FutureFillModel());
```

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides Tick data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides QuoteBar data, use the closing bid price of the most recent QuoteBar .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	`TickType`	Order Direction	Stop Condition	Fill Price
`Tick`	`Quote`	Buy	quote price > stop price	max(stop price, quote price + slippage)
`Tick`	`Quote`	Sell	quote price < stop price	min(stop price, quote price - slippage)
`Tick`	`Trade`	Buy	trade price > stop price	max(stop price, last trade price + slippage)
`Tick`	`Trade`	Sell	trade price < stop price	min(stop price, last trade price - slippage)
`QuoteBar`		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
`QuoteBar`		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
`TradeBar`		Buy	high price > stop price	max(stop price, close price + slippage)
`TradeBar`		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition

is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Future Option Model

Introduction

The `FutureOptionFillModel` is the default fill model if you trade Future Option contracts with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
C#
security.SetFillModel(new FutureOptionFillModel());
```

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition

is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Immediate Model

Introduction

The `ImmediateFillModel` is the default fill model if you trade non-Equity assets with the DefaultBrokerageModel . This fill model fills trades completely and immediately.

```
C#
security.SetFillModel(new ImmediateFillModel());
```

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If your security subscription doesn't provide quote data, the fill model checks the most recent `TradeBar` .

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	`TickType`	Order Direction	Stop Condition	Fill Price
`Tick`	`Quote`	Buy	quote price > stop price	max(stop price, quote price + slippage)
`Tick`	`Quote`	Sell	quote price < stop price	min(stop price, quote price - slippage)
`Tick`	`Trade`	Buy	trade price > stop price	max(stop price, last trade price + slippage)
`Tick`	`Trade`	Sell	trade price < stop price	min(stop price, last trade price - slippage)
`QuoteBar`		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
`QuoteBar`		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
`TradeBar`		Buy	high price > stop price	max(stop price, close price + slippage)
`TradeBar`		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition

is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Supported Models

Latest Price Model

Introduction

The `LatestPriceFillModel` fills trades completely and immediately.

```
security.SetFillModel(new LatestPriceFillModel());
```

The fill logic of each order depends on the order type, the data format of the security subscription, and the order direction. The following tables show the fill price of each order given these factors. To determine the fill price of an order, the fill model first checks the most recent tick for the security. If your security subscription doesn't provide tick data, the fill model checks the most recent `QuoteBar` . If there is no `QuoteBar` available, it uses the OHLC prices from the `Security` object. If there is a `QuoteBar` available, the fill model gets the most recent `TradeBar` . If the `TradeBar` is more recent, it uses the `TradeBar` data. Otherwise, it uses the `QuoteBar` data.

For more information about this model, see the class reference and implementation .

Market Orders

The following table describes the fill price of market orders for each data format and order direction:

Data Format	`TickType`	Order Direction	Fill Price
`Tick`	`Quote`	Buy	quote price + slippage
`Tick`	`Quote`	Sell	quote price - slippage
`Tick`	`Trade`	Buy	trade price + slippage
`Tick`	`Trade`	Sell	trade price - slippage
`QuoteBar`		Buy	ask close price + slippage
`QuoteBar`		Sell	bid close price - slippage
`TradeBar`		Buy	close price + slippage
`TradeBar`		Sell	close price - slippage

The model only fills market orders if the exchange is open and it immediately fills them. If your algorithm places a market order at 10 AM, it fills at 10 AM.

Limit Orders

The following table describes the fill logic of limit orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	low price < limit price	min(high price, limit price)
TradeBar		Sell	high price > limit price	max(low price, limit price)

The model won't fill limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Limit if Touched Orders

The model converts a limit if touched order to a limit order when the trigger condition is met. The following table describes the trigger condition of limit if touched orders for each data format and order direction:

Data Format	TickType	Order Direction	Trigger Condition
Tick	Quote	Buy	quote price <= trigger price
Tick	Quote	Sell	quote price >= trigger price
Tick	Trade	Buy	trade price <= trigger price
Tick	Trade	Sell	trade price >= trigger price
TradeBar		Buy	low price <= trigger price
TradeBar		Sell	high price >= trigger price

Once the limit if touched order triggers, to fill the order, the model checks the bid price for buy orders and the ask price for sell orders.

To get the bid price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a buy quote, use the bid price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing bid price of the most recent `QuoteBar` .

To get the ask price, the model uses the following procedure:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a sell quote, use the ask price of the most recent quote tick.
2. If the subscription provides `QuoteBar` data, use the closing ask price of the most recent `QuoteBar` .

If neither of the preceding procedures yield a result, the model uses the following procedure to get the bid or ask price:

1. If the subscription provides `Tick` data and the most recent batch of ticks contains a tick of type `TickType.Trade` , use the last trade price.
2. If the subscription provides `TradeBar` data, use the closing bid price of the most recent `QuoteBar` .

Buy orders fill when the bid price <= limit price and sell orders fill when the ask price >= limit price. The order fills at the limit price. The model won't trigger or fill limit if touched orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Market Orders

The following table describes the fill logic of stop market orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	`TickType`	Order Direction	Stop Condition	Fill Price
`Tick`	`Quote`	Buy	quote price > stop price	max(stop price, quote price + slippage)
`Tick`	`Quote`	Sell	quote price < stop price	min(stop price, quote price - slippage)
`Tick`	`Trade`	Buy	trade price > stop price	max(stop price, last trade price + slippage)
`Tick`	`Trade`	Sell	trade price < stop price	min(stop price, last trade price - slippage)
`QuoteBar`		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
`QuoteBar`		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
`TradeBar`		Buy	high price > stop price	max(stop price, close price + slippage)
`TradeBar`		Sell	low price < stop price	min(stop price, close price - slippage)

The model only fills stop market orders when the exchange is open.

The model won't fill stop market orders with stale data or data with the order timestamp to avoid look-ahead bias.

Stop Limit Orders

The following table describes the fill logic of stop limit orders for each data format and order direction. Once the stop condition

is met, the model starts to check the fill condition. Once the fill condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	quote price < limit price	min(quote price, limit price)
Tick	Quote	Sell	quote price < stop price	quote price > limit price	max(quote price, limit price)
Tick	Trade	Buy	trade price > stop price	trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	trade price < stop price	trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	ask high price > stop price	ask close price < limit price	min(ask high price, limit price)
QuoteBar		Sell	bid low price < stop price	bid close price > limit price	max(bid low price, limit price)
TradeBar		Buy	high price > stop price	close price < limit price	min(high price, limit price)
TradeBar		Sell	low price < stop price	close price > limit price	max(low price, limit price)

The model won't fill stop limit orders with stale data or data with the order timestamp to avoid look-ahead bias.

Trailing Stop Orders

The following table describes the fill logic of trailing stop orders for each data format and order direction. Once the stop condition is met, the model fills the orders and sets the fill price.

Data Format	TickType	Order Direction	Stop Condition	Fill Price
Tick	Quote	Buy	quote price > stop price	max(stop price, quote price + slippage)
Tick	Quote	Sell	quote price < stop price	min(stop price, quote price - slippage)
Tick	Trade	Buy	trade price > stop price	max(stop price, last trade price + slippage)
Tick	Trade	Sell	trade price < stop price	min(stop price, last trade price - slippage)
QuoteBar		Buy	ask high price > stop price	max(stop price, ask close price + slippage)
QuoteBar		Sell	bid low price < stop price	min(stop price, bid close price - slippage)
TradeBar		Buy	high price > stop price	max(stop price, close price + slippage)
TradeBar		Sell	low price < stop price	min(stop price, close price - slippage)

While the stop condition is not met, the model updates the stop price under certain conditions. The following table shows the update condition and stop price value for currency-based trailing amounts:

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= trailing amount	quote price + trailing amount
Tick	Quote	Sell	quote price - stop price <= trailing amount	quote price - trailing amount
Tick	Trade	Buy	stop price - trade price <= trailing amount	trade price + trailing amount
Tick	Trade	Sell	trade price - stop price <= trailing amount	trade price - trailing amount
QuoteBar		Buy	stop price - ask low price <= trailing amount	ask low price + trailing amount
QuoteBar		Sell	bid high price - stop price <= trailing amount	bid high price - trailing amount
TradeBar		Buy	stop price - low price <= trailing amount	low price + trailing amount
TradeBar		Sell	high price - stop price <= trailing amount	high price - trailing amount

The following table shows the update condition and stop price value for percentage-based trailing amounts.

Data Format	TickType	Order Direction	Update Condition	Stop Price
Tick	Quote	Buy	stop price - quote price <= quote price * trailing amount	quote price * (1 + trailing amount)
Tick	Quote	Sell	quote price - stop price <= quote price * trailing amount	quote price * (1 - trailing amount)
Tick	Trade	Buy	stop price - trade price <= trade price * trailing amount	trade price * (1 + trailing amount)
Tick	Trade	Sell	trade price - stop price <= trade price * trailing amount	trade price * (1 - trailing amount)
QuoteBar		Buy	stop price - ask low price <= ask low price * trailing amount	ask low price * (1 + trailing amount)
QuoteBar		Sell	bid high price - stop price <= bid high price * trailing amount	bid high price * (1 - trailing amount)
TradeBar		Buy	stop price - low price <= stop price * trailing amount	low price * (1 + trailing amount)
TradeBar		Sell	high price - stop price <= high price * trailing amount	high price * (1 - trailing amount)

The model only fills trailing stop orders when the exchange is open.

The model won't fill trailing stop orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Open Orders

The following table describes the fill price of market on open orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask open price + slippage
QuoteBar		Sell	bid open price - slippage
TradeBar		Buy	open price + slippage
TradeBar		Sell	open price - slippage

The model won't fill market on open orders during pre-market hours.

The model won't fill market on open orders with stale data or data with the order timestamp to avoid look-ahead bias.

Market on Close Orders

The following table describes the fill price of market on close orders for each data format and order side:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	quote price + slippage
Tick	Quote	Sell	quote price - slippage
Tick	Trade	Buy	trade price + slippage
Tick	Trade	Sell	trade price - slippage
QuoteBar		Buy	ask close price + slippage
QuoteBar		Sell	bid close price - slippage
TradeBar		Buy	close price + slippage
TradeBar		Sell	close price - slippage

The model won't fill market on close orders with stale data or data with the order timestamp to avoid look-ahead bias.

Combo Market Orders

The following table describes the fill price of combo market orders for each data format and order direction:

Data Format	TickType	Order Direction	Fill Price
Tick	Quote	Buy	Ask quote price + slippage
Tick	Quote	Sell	Bid quote price - slippage
Tick	Trade	Buy	Trade price + slippage
Tick	Trade	Sell	Trade price - slippage
QuoteBar		Buy	Ask close price + slippage
QuoteBar		Sell	Bid close price - slippage
TradeBar		Buy	Close price + slippage
TradeBar		Sell	Close price - slippage

The model only fills combo market orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity of each leg is the product of the leg order quantity and the combo market order quantity.

Combo Limit Orders

To fill combo limit orders, the fill model calculates the aggregate price of the combo order, which is the sum of prices for each security in the order legs. The price of each security is a function of the data format and order direction. Legs with a positive order quantity increase the aggregate price and legs with a negative quantity decrease the aggregate price. The following table shows how the fill model calculates the security prices.

Data Format	TickType	Combo Order Direction	Leg Order Direction	Price
Tick	Quote	Buy or sell	Buy	Ask price
Tick	Quote	Buy or sell	Sell	Bid price
Tick	Trade	Buy or sell	Buy or sell	Trade price
QuoteBar		Buy	Buy	Ask low price
QuoteBar		Buy	Sell	Bid low price
QuoteBar		Sell	Buy	Ask high price
QuoteBar		Sell	Sell	Bid high price
TradeBar		Buy	Buy or sell	Low price
TradeBar		Sell	Buy or sell	High price

After the fill model calculates the aggregate price of the combo order, it checks if it should fill the order. The following table describes the fill condition of the combo order and the fill price price of each leg:

Data Format	TickType	Combo Order Direction	Fill Condition	Leg Order Direction	Fill Price
Tick	Quote	Buy	Aggregate price < combo limit price	Buy or sell	Quote price
Tick	Quote	Sell	Aggregate price > combo limit price	Buy or sell	Quote price
Tick	Trade	Buy	Aggregate price < combo limit price	Buy or sell	Trade price
Tick	Trade	Sell	Aggregate price > combo limit price	Buy or sell	Trade price
QuoteBar		Buy	Aggregate price < combo limit price	Buy	Ask low price
QuoteBar		Buy	Aggregate price < combo limit price	Sell	Bid low price
QuoteBar		Sell	Aggregate price > combo limit price	Buy	Ask high price
QuoteBar		Sell	Aggregate price > combo limit price	Sell	Bid high price
TradeBar		Buy	Aggregate price < combo limit price	Buy or sell	Low price
TradeBar		Sell	Aggregate price > combo limit price	Buy or sell	High price

The model only fills combo limit orders if the data isn't stale and all the legs can fill in the same time step after the order time step. The fill quantity of each leg is the product of the leg order quantity and the combo order quantity.

Combo Leg Limit Orders

The following table describes the fill logic of combo leg limit orders for each data format and order direction. The order direction in the table represents the order direction of the order leg, not the order direction of the combo order.

Data Format	TickType	Order Direction	Fill Condition	Fill Price
Tick	Quote	Buy	Ask price < limit price	min(ask price, limit price)
Tick	Quote	Sell	Bid price > limit price	max(bid price, limit price)
Tick	Trade	Buy	Trade price < limit price	min(trade price, limit price)
Tick	Trade	Sell	Trade price > limit price	max(trade price, limit price)
QuoteBar		Buy	Ask low price < limit price	min(ask high price, limit price)
QuoteBar		Sell	Bid high price > limit price	max(bid low price, limit price)
TradeBar		Buy	Low price < limit price	min(high price, limit price)
TradeBar		Sell	High price > limit price	max(low price, limit price)

The model only fills combo leg limit orders if all the following conditions are met:

- The exchange is open
- The data isn't stale
- All the legs can fill in the same time step after the order time step

The fill quantity is the product of the leg order quantity and the combo order quantity.

Reality Modeling

Slippage

Slippage

Key Concepts

Introduction

Slippage is the difference between the fill price you expect to get for an order and the actual fill price. Since the price can move in the direction of your trade or against the direction of your trade while you wait for the order to fill, slippage can be positive or negative. Slippage models model slippage to make backtest results more realistic.

Factors Impacting Slippage

There are many factors that can impact slippage, including the trading engine, brokerage connection, and market dynamics.

Trading Engine

How long does it take from when you place an order to when it's sent to the brokerage? Longer delays lead to more slippage.

Brokerage Connection

How long does it take for your brokerage to receive an order that you send? Slow internet connections, long travel distances, and poor infrastructure lead to more slippage

Market Dynamics

How volatile is the current market environment? More volatility leads to more slippage.

Does the market consist of sophisticated microsecond arbitrageurs? If your order creates an arbitrage opportunity, it can cause more slippage.

Set Models

The brokerage model of your algorithm automatically sets the slippage model for each security, but you can override it. To manually set the slippage model of a security, call the `SetSlippageModel` method on the `Security` object.

C#

```
public override void Initialize()
{
    var security = AddEquity("SPY");
    // Set the slippage model for the requested security to backtest with the most realistic scenario
    // VolumeShareSlippageModel has slippage size affected by the volume of the order compared to the actual filled
volume of the bar
    // It is only valid for the security with a volume property, while being more accurate with denser resolution
    security.SetSlippageModel(new VolumeShareSlippageModel());
}
```

You can also set the slippage model in a security initializer . If your algorithm has a dynamic universe, use the security initializer

technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

```C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetSlippageModel(new VolumeShareSlippageModel());
    }
}
```

To view all the pre-built slippage models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the slippage model of each security. The default brokerage model is the `DefaultBrokerageModel` , which uses the NullSlippageModel to model zero slippage for all securities.

Model Structure

Slippage models should implement the `ISlippageModel` interface. Extensions of the `ISlippageModel` interface must implement the `GetSlippageApproximation` method, which calculates the slippage quantity.

```C#
public class CustomSlippageModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the custom slippage model for an added security to use the custom model
        var security = AddEquity("SPY");
        security.SetSlippageModel(new MySlippageModel());
    }
}

// Define the custom slippage model
public class MySlippageModel : ISlippageModel
{
    public decimal GetSlippageApproximation(Security asset, Order order)
    {
        return asset.Price*0.0001m*(decimal) Math.Log10(2*(double) order.AbsoluteQuantity);
    }
}
```

Examples

The following examples demonstrate some common practices for implementing a custom slippage model.

Example 1: Logarithmic Scaling

The following algorithm defines a custom slippage model where the slippage increases logarithmically with order size, scaled by 0.01% of the asset price, modeling realistic market impact where larger orders have diminishing marginal price impact.

```C#
public class CustomSlippageModelAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var security = AddEquity("SPY", Resolution.Daily);
        security.SetSlippageModel(new MySlippageModel());
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }
}

public class MySlippageModel : ISlippageModel
{
    public decimal GetSlippageApproximation(Security asset, Order order)
    {
        return asset.Price*0.0001m*(decimal) Math.Log10(2*(double) order.AbsoluteQuantity);
    }
}
```

Example 2: Volume Ratio Capped Slippage Model

The following algorithm trades the microeconomic demand popularity gap between the top 10 and bottom 10 liquid constituents of QQQ. A custom slippage model simulates the slippage on less liquid stock fills. The slippage percent is set to be 2% multiplied by the ratio of the order quantity to the previous minute bar's volume, maximized at 2%.

C#

```
public class RealityModelingSlippageAlgorithm : QCAlgorithm
{
    private List<Symbol> _longs = new();
    private List<Symbol> _shorts = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =>
        {
            // To set the slippage model to the custom one for all stocks entering the universe.
            security.SetSlippageModel(new CustomSlippageModel());
        });

        // Request extended market hour QQQ data for trading.
        var qqq = AddEquity("QQQ").Symbol;

        // Weekly portfolio updating to allow time to capitalize on the popularity gap.
        UniverseSettings.Schedule.On(DateRules.WeekStart());
        // Add universe to trade on the most and least liquid stocks among QQQ constituents.
        AddUniverse(
            // First, we select all QQQ constituents for the next filter on liquidity.
            Universe.ETF(qqq, Market.USA, UniverseSettings, (constituents) => constituents.Select(c => c.Symbol)),
            FundamentalSelection
        );

        // Set a scheduled event to rebalance the portfolio at the start of every week.
        Schedule.On(
            DateRules.WeekStart(qqq),
            TimeRules.AfterMarketOpen(qqq),
            Rebalance
        );
    }

    private IEnumerable<Symbol> FundamentalSelection(IEnumerable<Fundamental> fundamentals)
    {
        var sortedByDollarVolume = fundamentals.OrderBy(x => x.DollarVolume).ToList();
        // Add the 10 most liquid stocks to the universe to long later.
        _longs = sortedByDollarVolume.TakeLast(10)
            .Select(x => x.Symbol)
            .ToList();
        // Add the 10 least liquid stocks to the universe to short later.
        _shorts = sortedByDollarVolume.Take(10)
            .Select(x => x.Symbol)
            .ToList();

        return _longs.Union(_shorts);
    }

    private void Rebalance()
    {
        // Equally invest in the selected stocks to dissipate capital risk evenly.
        // Dollar neutral of long and short stocks to eliminate systematic risk, only capitalize the popularity gap.
        var targets = _longs.Select(symbol => new PortfolioTarget(symbol, 0.05m)).ToList();
        targets.AddRange(_shorts.Select(symbol => new PortfolioTarget(symbol, -0.05m)).ToList());

        // Liquidate the stocks that are not the most and least popular to release funds for trades with higher
expected returns.
        SetHoldings(targets, liquidateExistingHoldings: true);
    }

    internal class CustomSlippageModel : ISlippageModel
    {
        public decimal GetSlippageApproximation(Security asset, Order order)
        {
            // We set a maximum 2% slippage that is linearly linked to the ratio of the order size versus the
previous bar's volume.
            return asset.Price * 0.02m * Math.Min(1m, order.AbsoluteQuantity / asset.Volume);
        }
    }
}
```

Other Examples

Demonstration Algorithms
CustomModelsAlgorithm.cs C#

Slippage

Supported Models

Introduction

This page describes the pre-built slippage models in LEAN. If none of these models perform exactly how you want, create a custom slippage model .

Null Model

The `NullSlippageModel` sets the slippage of each order to zero. It's the default slippage model of the DefaultBrokerageModel .

```
C#
security.SetSlippageModel(NullSlippageModel.Instance);
```

For more information about this model, see the class reference and implementation .

Constant Model

The `ConstantSlippageModel` applies a constant percentage of slippage to each order.

```
C#
security.SetSlippageModel(new ConstantSlippageModel(0.01m));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`slippagePercent`	`decimal`	The slippage percent for each order. The value must be in the interval (0, 1).	

For more information about this model, see the class reference and implementation .

Volume Share Model

The `VolumeShareSlippageModel` calculates the slippage of each order by multiplying the price impact constant by the square of the ratio of the order to the total volume. If the volume of the current bar is zero, the slippage percent is

$$volumeLimit^2 * priceImpact$$

where volumeLimit and priceImpact are custom input variables. If the volume of the current bar is positive, the slippage percent is

$$\min(\frac{|orderQuantity|}{barVolume}, volumeLimit)^2 * priceImpact$$

where orderQuantity is the quantity of the order and barVolume is the volume of the current bar. If the security subscription provides `TradeBar` data, the barVolume is the volume of the current bar. If the security subscription provides `QuoteBar` data, the barVolume is the bid or ask size of the current bar. CFD, Forex, and Crypto data often doesn't include volume. If there is no

volume reported for these asset classes, the model returns zero slippage.

```
C#
security.SetSlippageModel(new VolumeShareSlippageModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`volumeLimit`	`decimal`	Maximum percent of historical volume that can fill in each bar. 0.5 means 50% of historical volume. 1.0 means 100%.	0.025
`priceImpact`	`decimal`	Scaling coefficient for price impact. Larger values will result in more simulated price impact. Smaller values will result in less simulated price impact.	0.1

For more information about this model, see the class reference and implementation .

Market Impact Model

The `MarketImpactSlippageModel` calculates the slippage with perspective to the market impact created by an order, which mimics the consumption of the order book and disruption of the supply-demand relationship at the microeconomic scale. The model is divided into distinct parts, the market impact estimation and the slippage that results from it.

Factors to Consider

The model includes factors that create market impact. Almgren, Thum, Hauptmann & Li (2005) suggested the following factors:

1. Execution Time

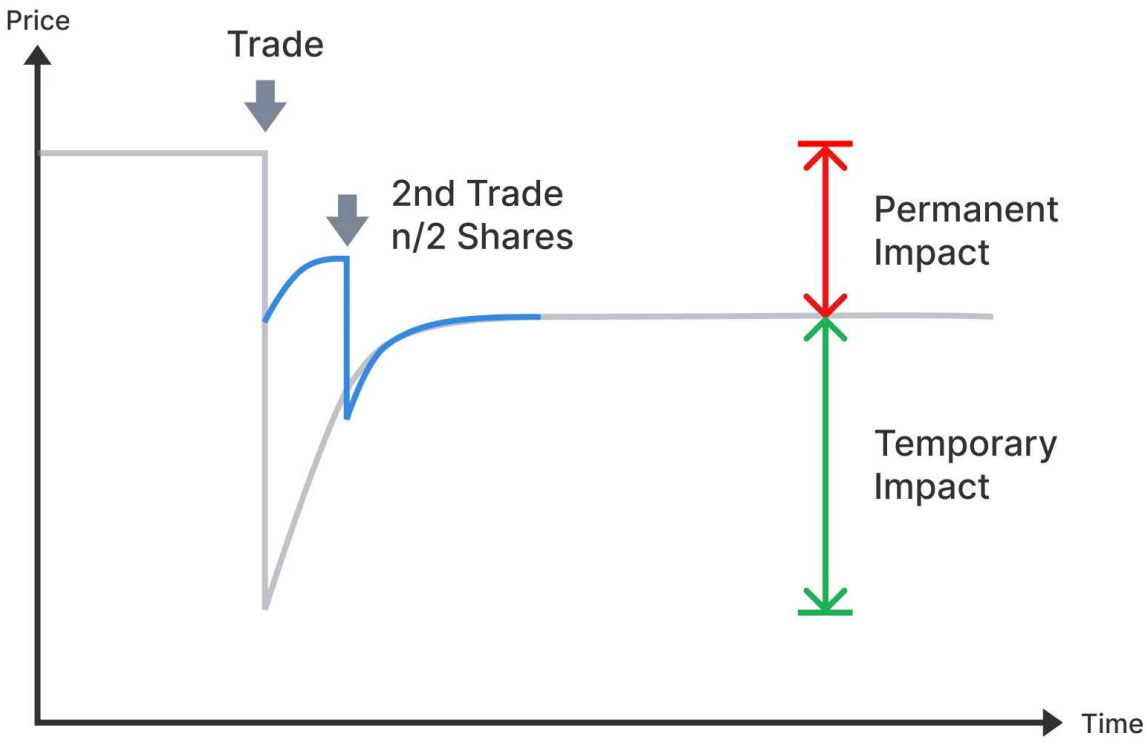
   Asset price time series is usually considered as Random walk (with/without drift) $S_t = S_{t-1} + f(S, t) + \epsilon$ or Brownian Motion $S_t = S_0 + exp((\mu-\frac{1}{2}\sigma^2)t + \sigma W_t)$ In either model, the variance of predictions increases over time ($Var(S)=\sigma\sqrt{t}$). In fact, this happens to most stock price models. Thus, time uncertainty should also apply to the concept of slippage. The longer it takes to go from order submission to execution, the further the fill price will be from the price at order submission.

2. Volatility of the Underlying Securities

   Like (1), the volatility also contributes to the uncertainty of the next price ($Var(S)=\sigma\sqrt{t}$). In most cases, volatility has a one-sided impact since the market's volatility is often introduced by overbuying or overselling from positive or negative sentiments.

3. Liquidity

   Liquidity plays a crucial role in the supply-demand resilience. When a stock is liquid, an order usually only takes a small fraction of the market depth. Hence, the gap between the bid and ask price can be refilled quickly due to high market participation and a small gap. However, when a stock is illiquid, a single order might already take the top few layers of the order book, creating a wide gap between the bid and ask price and volume, which makes a bigger shift in the equilibrium price. This will create an impact which is permanent in nature.

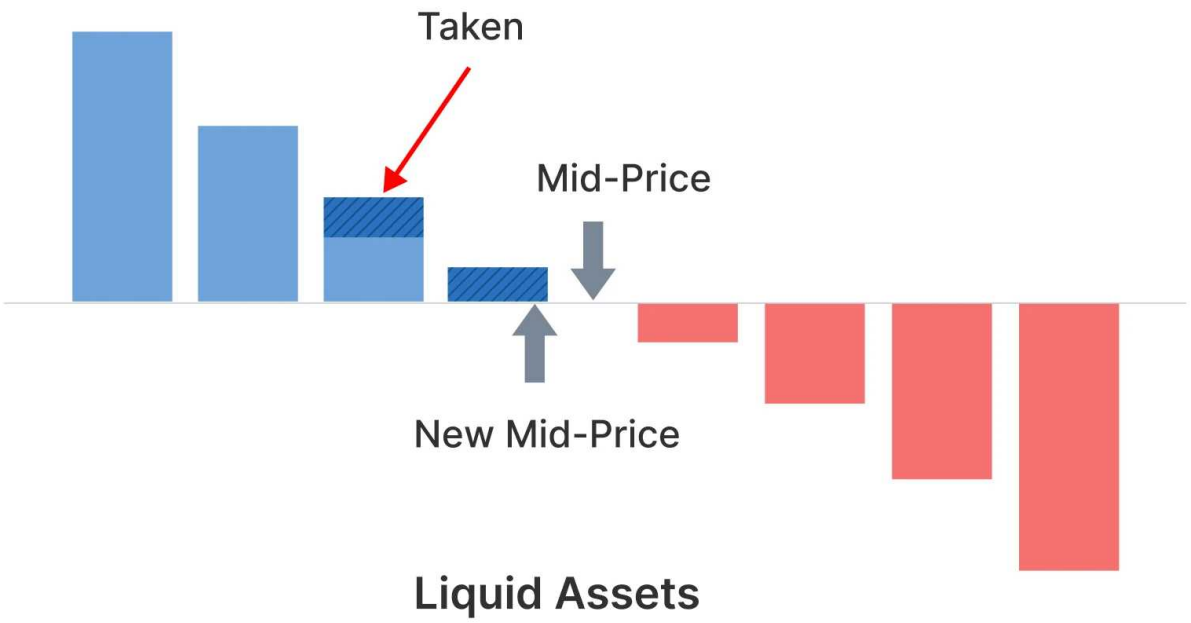


4. Order Size

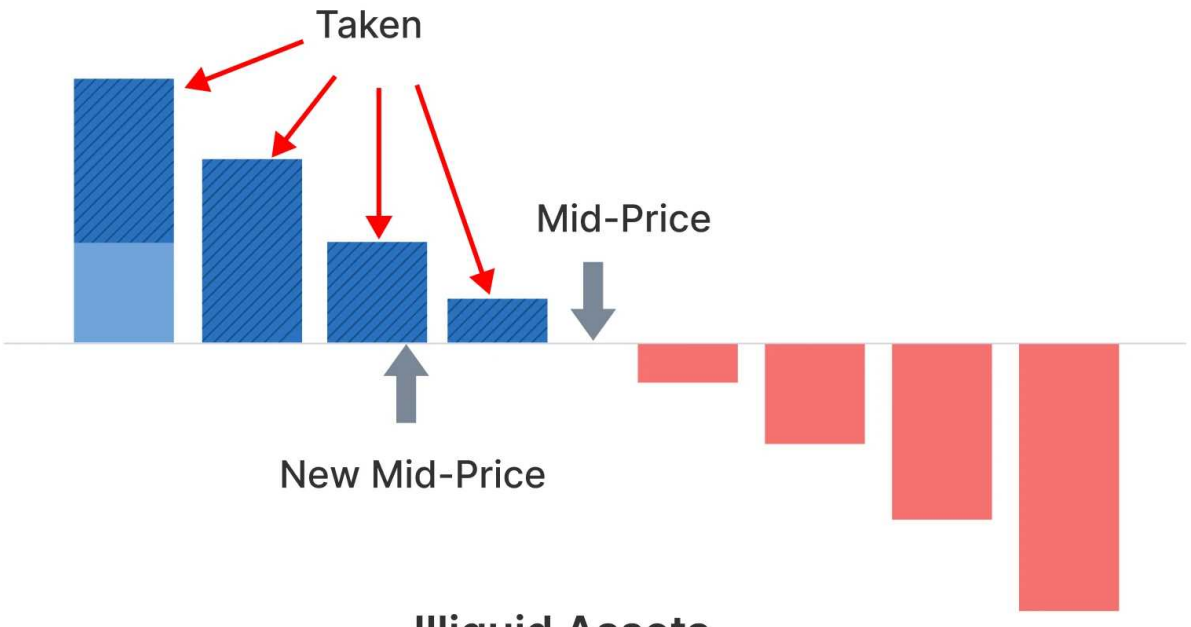
   Last but not least, the order size directly affects the proportion of the order book/liquidity that the order consumes. Moreover, the larger the order is, the longer it takes to fill since the market might not have sufficient depth. This has interaction effects with the preceding factors.

Market Impact Decomposition

In the book "A Signal Processing Perspective on Financial Engineering", Feng & Palomer (2015) generalized scholars' opinions that market impact can be broken down into "permanent" and "temporary" components, with noise. The permanent impact of a trade refers to the price differences between equilibrium prices before and after the trade and the resilience of the order book. In contrast, temporary impact refers to the price difference between the instant price drop after a trade and the post-trade equilibrium.



Liquid Assets



Illiquid Assets

The model incorporates the preceding factors and estimates both the permanent and temporary impact components with two diffusion models as a function of $\nu=\frac{X}{VT}$, which is the normalized order size:

$G\left(\nu\right)=\pm\gamma\left|\nu\right|^\alpha+\text{noise}$ $H\left(\nu\right)=\pm\eta\left|\nu\right|^\beta+\text{noise}$

where X is the order quantity, V is the average daily volume, and T is the time difference between order submission and filling (execution time). The other symbols are parameters that are calibrated from historical trade data. Together with the execution time, daily volatility σ, and liquidity factor δ, the complete models are as follows: $I=\sigma T \gamma\left|\frac{X}$

{VT}\right|^\alpha\left(\frac{\Theta}{V}\right)^\delta+\sigma\sqrt{T_{\text{post}}}\epsilon J=\sigma T \eta\left|\frac{X}{VT}\right|^\beta+\sigma\sqrt{T_{\text{post}}}\epsilon where \Theta is the share outstanding, T_{post} is the time difference between order submission and the new equilibrium established, I is the permanent market impact, and J is the temporary market impact. The inverse of the turnover rate \frac{\Theta}{V} contributes to the permanent impact. This relationship is reasonable since higher turnover means more market participants are in the market, so the order book depth is deeper.

Implementation

```C#
security.SetSlippageModel(new MarketImpactSlippageModel(self));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`algorithm`	`IAlgorithm`	The algorithm instance	
`nonNegative`	`bool`	Indicator whether only non-negative slippage allowed.	`true`
`latency`	`double`	Seconds between order submission and order fill	0.075
`impactTime`	`double`	Seconds between order fill and the establishment of the new equilibrium	1800
`alpha`	`double`	Exponent of the permanent impact function	0.891
`beta`	`double`	Exponent of the temporary impact function	0.600
`gamma`	`double`	Coefficient of the permanent impact function	0.314
`eta`	`double`	Coefficient of the temporary impact function	0.142
`delta`	`double`	Liquidity scaling factor for permanent impact	0.267
`randomSeed`	`int`	Random seed for generating gaussian noise	50

The default parameters of the `MarketImpactSlippageModel` are the parameters that the authors calibrated and shared. However, you may want to reference the original paper and recalibrate the parameters because of the following reasons:

- The default parameters are calibrated around 2 decades ago
- The trading time effect is not accounted (volume near market open/close is larger)
- The market environment does not have many market makers at that time

For more information about this model, see the class reference and implementation .

Reality Modeling

Transaction Fees

Transaction Fees

Key Concepts

Introduction

Your orders incur a transaction fee when a brokerage fills them in the market. LEAN uses transaction fee models in backtesting to model the live trading fees you would incur with the strategy. Transaction fee models make backtest results more realistic. To give your backtests the most accurate fees, LEAN contains transaction fee models that model the fee structure of many popular brokerages.

Set Models

The brokerage model of your algorithm automatically sets the fee model for each security, but you can override it. To manually set the fee model of a security, call the `SetFeeModel` method on the `Security` object.

C#

```
public override Initialize()
{
    var security = AddEquity("SPY");
    // Set the fee model for the requested security to backtest with the most realistic scenario
    // Constant fee model of 0 dollar is accurate for the commission-free brokerage
    security.SetFeeModel(new ConstantFeeModel(0));
}
```

You can also set the fee model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

C#

```
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetFeeModel(new ConstantFeeModel(0));
    }
}
```

In live trading, the `SetFeeModel` method isn't ignored. If we use order helper methods like `SetHoldings` , the fee model helps to calculate the order quantity. However, the algorithm doesn't update the cash book with the fee from the fee model. The algorithm uses the actual fee from the brokerage to update the cash book.

To view all the pre-built fee models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the fill model for each security. The default brokerage model is the `DefaultBrokerageModel` , which set the ConstantFeeModel with no fees for Forex, CFD, and Crypto assets and sets the InteractiveBrokersFeeModel for the remaining asset classes.

Model Structure

Fee models should extend the `FeeModel` class. Extensions of the `FeeModel` class must implement the `GetOrderFee` method, which receives `OrderFeeParameters` and returns an `OrderFee` that represents a cash amount in a currency.

```
C#

public class CustomFeeModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the custom fee model for an added security to use the custom model
        var security = AddEquity("SPY");
        security.SetFeeModel(new MyFeeModel());
    }
}

// Define the custom fee model
public class MyFeeModel : FeeModel
{
    public override OrderFee GetOrderFee(OrderFeeParameters parameters)
    {
        return new OrderFee(new CashAmount(0.5m, "USD"));
    }
}
```

The `OrderFeeParameters` object has the following members:

Zero Transaction Fees

To model zero transaction fees, use the ConstantFeeModel with zero as `fee` and specify the `currency` .

```
C#

public override Initialize()
{
    var security = AddEquity("SPY");
    security.SetFeeModel(new ConstantFeeModel(fee: 0m, currency: "USD"));
}
```

Negative Transaction Fees

If you short a security and receive interest payments, they are negative transaction fees.

Examples

The following examples demonstrate common practices for implementing a custom fee model.

Example 1: Fixed Fees

The following algorithm incurs a $0.50 fee for each order.

```
C#
public class CustomFeeModelAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        var security = AddEquity("SPY", Resolution.Daily);
        security.SetFeeModel(new MyFeeModel());
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }
}

public class MyFeeModel : FeeModel
{
    public override OrderFee GetOrderFee(OrderFeeParameters parameters)
    {
        return new OrderFee(new CashAmount(0.5m, "USD"));
    }
}
```

Transaction Fees

Supported Models

Introduction

This page describes some of the pre-built fee models in LEAN. For more brokerage-specific fee models, see the brokerage model documentation . If none of these models perform exactly how you want, create a custom fee model .

Constant Model

The `ConstantFeeModel` applies the absolute value of a constant fee to each order. It's the default fee model of the DefaultBrokerageModel if you trade Forex, CFD, or Crypto assets. Use this model to set zero transaction fees .

```
C#
security.SetFeeModel(new ConstantFeeModel(0.05m));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`fee`	`decimal`	The order fee quantity	
`currency`	`string`	The order fee currency	"USD"

For more information about this model, see the class reference and implementation .

Alpaca Model

The `AlpacaFeeModel` models the fees of Alpaca .

```
C#
security.SetFeeModel(new AlpacaFeeModel());
```

The `AlpacaFeeModel` charges zero fees for Equity and Equity Options trading. For Crypto trades, it charges a 0.15% maker and 0.25% taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Alpaca adjusts your fees based on your 30-day trading volume, but we don't currently model these metrics to adjust fees.

The `AlpacaFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Binance Model

The `BinanceFeeModel` models the fees of spot trades on Binance and Binance US .

```
C#
security.SetFeeModel(new BinanceFeeModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`mFee`	`decimal`	Maker fee value	0.001
`tFee`	`decimal`	Taker fee value	0.001

The `BinanceFeeModel` charges the order fees of Binance and Binance US at the VIP 0 level, which is a 0.1% maker and taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Binance Futures Model

The `BinanceFuturesFeeModel` models the Binance Futures live trading fees .

```
C#
security.SetFeeModel(new BinanceFuturesFeeModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`mUsdtFee`	`decimal`	Maker fee value for USDT pair contracts	0.0002
`tUsdtFee`	`decimal`	Taker fee value for USDT pair contracts	0.0004
`mBusdFee`	`decimal`	Maker fee value for BUSD pair contracts	0.00012
`tBusdFee`	`decimal`	Taker fee value for BUSD pair contracts	0.00036

By default, the `BinanceFuturesFeeModel` charges the order fees of Binance Futures at the Regular User level. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceFuturesFeeModel` charges fees in the currency you receive from a trade. For example, if you buy BTCUSD, you pay fees in BTC. If you sell BTCUSD, you pay fees in USD.

For more information about this model, see the class reference and implementation .

Binance Coin Futures Model

The `BinanceCoinFuturesFeeModel` models the Binance Coin Futures live trading fees .

```
security.SetFeeModel(new BinanceCoinFuturesFeeModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`mFee`	`decimal`	Maker fee value	0.0001
`tFee`	`decimal`	Taker fee value	0.0005

By default, the `BinanceCoinFuturesFeeModel` charges the order fees of Binance Coin Futures at the Regular User level. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Binance adjusts your fees based on your 30-day trading volume and BNB balance, but we don't currently model these metrics to adjust fees.

The `BinanceCoinFuturesFeeModel` charges fees in the currency you receive from a trade. For example, if you buy BTCUSDT, you pay fees in BTC. If you sell BTCUSDT, you pay fees in USDT.

For more information about this model, see the class reference and implementation .

Bitfinex Model

The `BitfinexFeeModel` models the Bitfinex live trading fees .

```
security.SetFeeModel(new BitfinexFeeModel());
```

The `BitfinexFeeModel` charges a 0.1% maker fee and a 0.2% taker fee. If you place a limit order that hits a hidden order or you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you place a hidden order or you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Bitfinex adjusts your fees based on your 30-day trading volume and LEO balance, but we don't currently model these metrics to adjust fees.

The `BitfinexFeeModel` charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Bybit Model

The `BybitFeeModel` models the Bybit live trading fees .

```
security.SetFeeModel(new BybitFeeModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
mFee	decimal	Maker fee value	0.001
tFee	decimal	Taker fee value	0.001

The BybitFeeModel charges the order fees of Bybit at the VIP 0 level, which is a 0.1% maker and taker fee for spot trades. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Bybit adjusts your fees based on your 30-day trading volume, net borrowings, or asset balance, but we don't currently model these metrics to adjust fees. Bybit also charges different fees for fiat-Crypto pairs, (for example, USDT/EUR), but the BybitFeeModel charges the same fee rate for all pairs.

The BybitFeeModel charges fees in the currency you receive from a trade. For example, if you buy ETHBTC, you pay fees in ETH. If you sell ETHBTC, you pay fees in BTC.

For more information about this model, see the class reference and implementation .

Bybit Futures Model

The BybitFuturesFeeModel models the Bybit live trading fees .

```
C#
security.SetFeeModel(new BybitFuturesFeeModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
makerFee	decimal	Maker fee value	0.0002
takerFee	decimal	Taker fee value	0.00055

The BybitFuturesFeeModel charges the order fees of Bybit at the VIP 0 level, which is a 0.02% maker and a 0.055% taker fee for Crypto Futures trades. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Bybit adjusts your fees based on your 30-day trading volume, net borrowings, or asset balance, but we don't currently model these metrics to adjust fees.

The BybitFuturesFeeModel charges fees in the currency you receive from a trade. For example, if you buy BTCUSDT, you pay fees in BTC. If you sell BTCUSDT, you pay fees in USDT.

For more information about this model, see the class reference and implementation .

Charles Schwab Model

The CharlesSchwabFeeModel models the fees of Charles Schwab .

```
C#
security.SetFeeModel(new CharlesSchwabFeeModel());
```

The CharlesSchwabFeeModel charges $0 USD for Equity trades.

For more information about this model, see the class reference and implementation .

Coinbase Model

The `CoinbaseFeeModel` models the Coinbase live trading fees .

```
C#
security.SetFeeModel(new CoinbaseFeeModel());
```

The `CoinbaseFeeModel` models the order fees of Coinbase at the $50K-100K pricing tier for all Crypto pairs, so it charges a 0.6% maker and a 0.8% taker fee for most pairs. The following table shows the Coinbase Stable Pairs, which charge a 0% maker fee and a 0.001% taker fee:

Stable Pairs			
DAIUSDC	DAIUSD	GYENUSD	PAXUSD
PAXUSDT	MUSDUSD	USDCEUR	USDCGBP
USDTEUR	USDTGBP	USDTUSD	USDTUSDC
USTEUR	USTUSD	USTUSDT	WBTCBTC

If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. Coinbase adjusts your fees based on your 30-day trading volume, but we don't currently model trading volume to adjust fees.

The `CoinbaseFeeModel` models the adjustments Coinbase has made to their fees over time. The following table shows the fees for each time period:

Time Period (UTC)	**Maker Fee (%)**	**Taker Fee (%)**	**Stable Coin**
Time < 3/23/2019 1:30AM	0	0.3	
3/23/2019 1:30AM <= Time < 10/8/2019 12:30AM	0.15	0.25	
10/8/2019 12:30AM <= Time	0.5	0.5	
Time < 6/1/2022 3/23/2019 12:00AM	0	0.1%	✓

The `CoinbaseFeeModel` charges fees in the quote currency .

For more information about this model, see the class reference and implementation .

dYdX Model

The `dYdXFeeModel` models the dYdX live trading fees .

```
C#
security.SetFeeModel(new dYdXFeeModel());
```

The `dYdXFeeModel` models the order fees of dYdX at the lowest pricing tier for all Cryptofuture pairs, so it charges a 0.01% maker and a 0.05% taker fee.

If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. dYdX adjusts your fees based on your 30-day trading volume, but we don't currently model trading volume to adjust fees.

The `dYdXFeeModel` charges fees in the quote currency .

For more information about this model, see the class reference and implementation .

Interactive Brokers Model

The `InteractiveBrokersFeeModel` models the fees of Interactive Brokers .

```
C#
security.SetFeeModel(new InteractiveBrokersFeeModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`monthlyForexTradeAmountInUSDollars`	`decimal`	Monthly Forex dollar volume traded	0
`monthlyOptionsTradeAmountInContracts`	`decimal`	Monthly Option contracts traded	0

The following table describes which currency the `InteractiveBrokersFeeModel` charges fees in for each asset class:

Asset Class	Fee Currency
US Equity	USD
India Equity	INR
Equity Options	USD
Forex	USD
US Futures	USD
Hong Kong Futures	The contract quote currency (CNH, HKD, or USD)
US Future Options	USD
Hong Kong Future Options	The contract quote currency (CNH, HKD, or USD)
Index Options	USD
CFD	The contract quote currency

The following sections describe the trading fees of each asset class.

For more information about this model, see the class reference and implementation .

US Equities

US Equity trades cost 0.005/share with a 1 minimum fee and a 0.5% maximum fee.

Equity Options and Index Options

Equity Options and Index Options fees are a function of your monthly volume and the premium of the contract you trade. The following table shows the fees for each volume tier:

Monthly Volume (Contacts)	Premium ($)	Fee per Contract ($)
<= 10,000	< 0.05	0.25
<= 10,000	0.05 <= premium < 0.10	0.50
<= 10,000	>= 0.10	0.70
10,000 < volume <= 50,000	< 0.05	0.25
10,000 < volume <= 50,000	>= 0.05	0.50
50,000 < volume <= 100,000	Any	0.25
> 100,000	Any	0.15

By default, LEAN models your fees at the tier with the lowest monthly volume. To adjust the fee tier, manually set the fee model and provide a `monthlyOptionsTradeAmountInContracts` argument.

The following table shows how the model determines the premium for each order type and direction:

Order Type	Buy Order Premium	Sell Order Premium
Market	Bid price	Ask price
Limit	Limit price	Limit price
Limit if touched	Limit price	Limit price
Stop market	Stop price	Stop price
Stop limit	Limit price	Limit price
Trailing stop	Stop price	Stop price
Market on open	Bid price	Ask price
Market on close	Bid price	Ask price
Combo market	Bid price	Ask price
Combo limit	Limit price	Limit price
Combo leg limit	Limit price	Limit price

There is no fee to exercise Option contracts.

Forex

Forex fees are a function of your monthly Forex trading volume. The following table shows the fee tiers:

Monthly Volume (USD)	Commission Rate (%)	Minimum Fee ($)
<= 1B	0.002	2
1B < volume <= 2B	0.0015	1.5
2B < volume <= 5B	0.001	1.25
> 5B	0.0008	1

By default, LEAN models your fees at the tier with the lowest monthly volume. To adjust the fee tier, manually set the fee model and provide a `monthlyForexTradeAmountInUSDollars` argument.

US Futures

US Futures fees depend on the contracts you trade. The following table shows the base fee per contract for each Future:

Contract Symbol	Market	Name	Base Fee Per Contract ($)	Exchange Fee Per Contract ($)
E-mini Futures				
ES	CME	E-mini S&P 500 Futures	0.85	1.28
NQ	CME	E-mini Nasdaq-100 Futures	0.85	1.28
YM	CBOT	E-mini Dow ($5) Futures	0.85	1.28
RTY	CME	E-mini Russell 2000 Index Futures	0.85	1.28
EMD	CME	E-mini S&P MidCap 400 Futures	0.85	1.28
Micro E-mini Futures				
MYM	CBOT	Micro E-mini Dow Jones Industrial Average Index Futures	0.25	0.3
M2K	CME	Micro E-mini Russell 2000 Index Futures	0.25	0.3
MES	CME	Micro E-mini Standard and Poor's 500 Stock Price Index Futures	0.25	0.3
MNQ	CME	Micro E-mini Nasdaq-100 Index Futures	0.25	0.3

2YY	CBOT	Micro 2-Year Yield Futures	0.25	0.3
5YY	CBOT	Micro 5-Year Yield Futures	0.25	0.3
10Y	CBOT	Micro 10-Year Yield Futures	0.25	0.3
30Y	CBOT	Micro 30-Year Yield Futures	0.25	0.3
MCL	NYMEX	Micro WTI Crude Oil Futures	0.25	0.3
MGC	COMEX	Micro Gold Futures	0.25	0.3
SIL	COMEX	Micro Silver Futures	0.25	0.3
Cryptocurrency Futures				
BTC	CME	Bitcoin Futures	5	6
MIB	CME	BTIC on Micro Bitcoin Futures	2.25	2.5
MBT	CME	Micro Bitcoin Futures	2.25	2.5
MET	CME	Micro Ether Futures	0.2	0.2
MRB	CME	BTIC on Micro Ether Futures	0.2	0.2
E-mini FX Futures				
E7	CME	E-mini Euro FX Futures	0.5	0.85
J7	CME	E-mini Japanese Yen Futures	0.5	0.85
Micro E-mini FX Futures				
M6E	CME	Micro Euro/U.S. Dollar (EUR/USD) Futures	0.15	0.24
M6A	CME	Micro Australian Dollar/U.S. Dollar (AUD/USD) Futures	0.15	0.24
M6B	CME	Micro British Pound Sterling/U.S. Dollar (GBP/USD) Futures	0.15	0.24
MCD	CME	Micro Canadian Dollar/U.S.Dollar(CAD/USD) Futures	0.15	0.24

MJY	CME	Micro Japanese Yen/U.S. Dollar (JPY/USD) Futures	0.15	0.24
MSF	CME	Micro Swiss Franc/U.S. Dollar (CHF/USD) Futures	0.15	0.24
M6J	CME	Micro USD/JPY Futures	0.15	0.24
MIR	CME	Micro INR/USD Futures	0.15	0.24
M6C	CME	Micro USD/CAD Futures	0.15	0.24
M6S	CME	Micro USD/CHF Futures	0.15	0.24
MNH	CME	Micro USD/CNH Futures	0.15	0.24

If you trade a contract that's not in the preceding table, the base fee is 0.85/contract and the exchange fee is 1.60/contract.

In addition to the base fee and exchange fee, there is a $0.02/contract regulatory fee.

Futures Options

Futures Options fees depend on the contracts you trade. The following table shows the base fee per contract for each Future:

Contract Symbol	**Market**	**Underlying Futures Name**	**Base Fee Per Contract ($)**	**Exchange Fee Per Contract ($)**
E-mini Futures Options				
ES	CME	E-mini S&P 500 Futures	0.85	0.55
NQ	CME	E-mini Nasdaq-100 Futures	0.85	0.55
YM	CBOT	E-mini Dow ($5) Futures	0.85	0.55
RTY	CME	E-mini Russell 2000 Index Futures	0.85	0.55
EMD	CME	E-mini S&P MidCap 400 Futures	0.85	0.55
Micro E-mini Futures Options				
MYM	CBOT	Micro E-mini Dow Jones Industrial Average Index Futures	0.25	0.2
M2K	CME	Micro E-mini Russell 2000 Index Futures	0.25	0.2

MES	CME	Micro E-mini Standard and Poor's 500 Stock Price Index Futures	0.25	0.2
MNQ	CME	Micro E-mini Nasdaq-100 Index Futures	0.25	0.2
2YY	CBOT	Micro 2-Year Yield Futures	0.25	0.2
5YY	CBOT	Micro 5-Year Yield Futures	0.25	0.2
10Y	CBOT	Micro 10-Year Yield Futures	0.25	0.2
30Y	CBOT	Micro 30-Year Yield Futures	0.25	0.2
MCL	NYMEX	Micro WTI Crude Oil Futures	0.25	0.2
MGC	COMEX	Micro Gold Futures	0.25	0.2
SIL	COMEX	Micro Silver Futures	0.25	0.2
Cryptocurrency Futures Options				
BTC	CME	Bitcoin Futures	5	5
MIB	CME	BTIC on Micro Bitcoin Futures	1.25	2.5
MBT	CME	Micro Bitcoin Futures	1.25	2.5
MET	CME	Micro Ether Futures	0.1	0.2
MRB	CME	BTIC on Micro Ether Futures	0.1	0.2

If you trade a contract that's not in the preceding table, the base fee is 0.85/contract and the exchange fee is 1.60/contract.

In addition to the base fee and exchange fee, there is a $0.02/contract regulatory fee.

CFD

CFD trades cost 0.002% of the trade value. The following table shows the minimum fee for each quote currency:

Quote Currency	**Fee**
JPY	¥40
MKD	HK$10
Other	1

CFD trading fees are denominated in the quote currency of the CFD product.

Kraken Model

The `KrakenFeeModel` models the fees of Kraken .

```
C#
security.SetFeeModel(new KrakenFeeModel());
```

The `KrakenFeeModel` model the order fees of Kraken. For trading pairs that contain only Crypto assets, this fee model models the lowest tier in Kraken's tiered fee structure, which is a 0.16% maker fee and a 0.26% taker fee. If you add liquidity to the order book by placing a limit order that doesn't cross the spread, you pay maker fees. If you remove liquidity from the order book by placing an order that crosses the spread, you pay taker fees. For trading pairs that have any of the following currencies as the base currency in the pair, the fee is 0.2%:

- CAD
- EUR
- GBP
- JPY
- USD
- USDT
- DAI
- USDC

The `KrakenFeeModel` charges fees in the quote currency for buy orders and in the base currency for sell orders. To override these settings, define the `KrakenOrderProperties` .

```
C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new KrakenOrderProperties()
    {
        FeeInBase = true,
        FeeInQuote = false
    };
}

public override void OnData(Slice slice)
{
    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new KrakenOrderProperties
               {
                   FeeInQuote = true,
                   FeeInBase = false
               });
}
```

Kraken adjusts your fees based on your 30-day trading volume, but the `KrakenFeeModel` don't currently model trading volume to adjust fees.

For more information about this model, see the class reference and implementation .

Samco Model

The `SamcoFeeModel` models the fees of Samco .

```
security.SetFeeModel(new SamcoFeeModel());
```

The `SamcoFeeModel` models the order fees of Samco by its Equity Intraday fee structure. The following table shows the fees:

Charge Item	Fee
Brokerage Fee	₹20 per trade or 0.02% (whichever is lower)
Exchange Transaction Charge	0.00345%
Securities Transaction Tax	0.025%
Goods and Services Tax	18%
SEBI Charges	0.0001%
Stamp Duty	0.003%

The `SamcoFeeModel` charges fees in INR.

For more information about this model, see the class reference and implementation .

Tastytrade Model

The `TastytradeFeeModel` models the fees of Tastytrade .

```
security.SetFeeModel(new TastytradeFeeModel());
```

The following sections describe the trading fees of each asset class.

For more information about this model, see the class reference and implementation .

US Equities

US Equity trades are free.

Equity Options

Equity Option trades cost $1 USD per contract to open a position, free to close.

Index Options

Index Option trades cost $1 USD per contract to open a position, free to close.

Futures

Futures trades cost $1.25 USD per contract.

Future Options

Future Option trades cost $2.5 USD per contract to open a position, free to close.

TradeStation Model

The `TradeStationFeeModel` models the fees of TradeStation .

```
security.SetFeeModel(new TradeStationFeeModel());
```

The following sections describe the trading fees of each asset class.

For more information about this model, see the class reference and implementation .

US Equities

US Equity trades are free for US residents. For non-US residents, they cost $5 USD per order.

Equity Options

Equity Option trades cost 0.60 USD per contract. For non-US residents, they cost an extra 5 USD per order.

Index Options

Index Option trades cost 1.00 USD per contract. For non-US residents, they cost an extra 5 USD per order.

Futures

Futures trades cost $1.50 USD per contract.

Wolverine Model

The `WolverineFeeModel` models the fees of Wolverine Execution Services.

```
security.SetFeeModel(new WolverineFeeModel());
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`feesPerShare`	`decimal?`	The fees per share to apply. If `null` , it uses 0.005.	`null`

The `WolverineFeeModel` charges fees in USD.

For more information about this model, see the class reference and implementation .

Zerodha Model

The `ZerodhaFeeModel` models the fees of Zerodha .

```
security.SetFeeModel(new ZerodhaFeeModel());
```

The `ZerodhaFeeModel` models the order fees of Zerodha with its Equity Intraday fee structure. The following table shows the fees:

Charge Item	Fee
Brokerage Fee	₹20 per trade or 0.03% (whichever is lower)
Exchange Transaction Charge	0.00345%
Securities Transaction Tax	0.025%
Goods and Services Tax	18%
SEBI Charges	0.0001%
Stamp Duty	0.003%

The `ZerodhaFeeModel` charges fees in INR.

For more information about this model, see the class reference and implementation .

Reality Modeling

Brokerages

Brokerages

Key Concepts

Introduction

Brokerages provide you with a connection to the market so you can fill trades. Brokerage models simulate the live behavior of a real brokerage. To avoid sending invalid orders for execution in live trading, the brokerage model validates your orders before LEAN sends them to the real brokerage. Brokerage models combine together all of the models relevant for a brokerage. If you set the appropriate brokerage model, the supported order types, default markets, and some of the security-level models are appropriately set in your algorithm.

Set Models

To set a brokerage model, in the `Initialize` method, call the `SetBrokerageModel` method with a `BrokerageName` and an `AccountType` . If you set a brokerage model, it overrides any security level models you manually set in your algorithm.

```
C#
public override void Initialize()
{
 // Set the brokerage model to backtest with the most realistic scenario to handle the order validity, margin rate
and transaction fee
 SetBrokerageModel(BrokerageName.OandaBrokerage); // Defaults to margin account
 SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin); // Overrides the default account type, which is
AccountType.Cash
}
```

In live trading, LEAN doesn't ignore your `SetBrokerageModel` method calls. LEAN uses some of the brokerage model rules to catch invalid orders before they reach your real brokerage.

To view all the pre-built brokerage models, see Supported Models .

Default Behavior

The default brokerage model is the `DefaultBrokerageModel` , but LEAN has many other brokerage models you can use in your algorithms. For more information about the `DefaultBrokerageModel` , see QuantConnect Paper Trading .

Modeled Properties

Brokerage models model that following properties:

- Transaction fees
- Supported asset classes
- Account types
- Support for extended market hours

- Leverage for assets
- Trade settlement rules
- Order properties and updates

Model Structure

Brokerage models should extend the `DefaultBrokerageModel` class. Extensions of the `DefaultBrokerageModel` class should implement the following methods:

```
C#
public class CustomBrokerageModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the custom brokerage model
        SetBrokerageModel(new MyBrokerageModel());
    }
}

// Define the custom brokerage model outside of the algorithm
class MyBrokerageModel : DefaultBrokerageModel
{
    public override decimal RequiredFreeBuyingPowerPercent { get; }

    public new IReadOnlyDictionary<SecurityType, string> DefaultMarkets  = new Dictionary<SecurityType, string>
    {
        {SecurityType.Equity, Market.USA}
    }.ToReadOnlyDictionary();

    public MyBrokerageModel(AccountType accountType = AccountType.Margin)
        : base(accountType)
    {

    }

    public override bool CanSubmitOrder(Security security, Order order,
        out BrokerageMessageEvent message)
    {
        return base.CanSubmitOrder(security, order, out message);
    }

    public override bool CanUpdateOrder(Security security, Order order,
        UpdateOrderRequest request, out BrokerageMessageEvent message)
    {
        return base.CanUpdateOrder(security, order, request, out message);
    }

    public override bool CanExecuteOrder(Security security, Order order)
    {
        return base.CanExecuteOrder(security, order);
    }

    public override void ApplySplit(List<OrderTicket> tickets, Split split)
    {
        base.ApplySplit(tickets, split);
    }

    public override decimal GetLeverage(Security security)
    {
        return base.GetLeverage(security);
    }

    public override IBenchmark GetBenchmark(SecurityManager securities)
    {
        return base.GetBenchmark(securities);
    }

    public override IFillModel GetFillModel(Security security)
    {
        return base.GetFillModel(security);
    }

    public override IFeeModel GetFeeModel(Security security)
    {
        return base.GetFeeModel(security);
    }
```

```
    public override ISlippageModel GetSlippageModel(Security security)
    {
        return base.GetSlippageModel(security);
    }

    public override ISettlementModel GetSettlementModel(Security security)
    {
        return base.GetSettlementModel(security);
    }

    public override IBuyingPowerModel GetBuyingPowerModel(Security security)
    {
        return base.GetBuyingPowerModel(security);
    }

    public override IMarginInterestRateModel GetMarginInterestRateModel(Security security)
    {
        return base.GetMarginInterestRateModel(security);
    }

    public override IShortableProvider GetShortableProvider(Security security)
    {
        return base.GetShortableProvider(security);
    }
}
```

Custom brokerage models give you enormous control over your algorithm behavior and allow you to model virtually any brokerage in the world.

Examples

The following examples demonstrate common practices for implementing a custom brokerage model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the `DefaultBrokerageModel` and overrides the built-in members so you can easily customize the parts you need.

C#

```
public class CustomBrokerageModelAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        SetBrokerageModel(new MyBrokerageModel());
        AddEquity("SPY", Resolution.Daily);
    }

    /// OnData event is the primary entry point for your algorithm. Each new data point will be pumped in here.
    /// Slice object keyed by symbol containing the stock data
    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }

}

class MyBrokerageModel : DefaultBrokerageModel
{
    public override decimal RequiredFreeBuyingPowerPercent { get; }

    public new IReadOnlyDictionary<SecurityType, string> DefaultMarkets  = new Dictionary<SecurityType, string>
    {
        {SecurityType.Equity, Market.USA}
    }.ToReadOnlyDictionary();

    public MyBrokerageModel(AccountType accountType = AccountType.Margin)
```

```
        : base(accountType)
    {

    }

    public override bool CanSubmitOrder(Security security, Order order,
        out BrokerageMessageEvent message)
    {
        return base.CanSubmitOrder(security, order, out message);
    }

    public override bool CanUpdateOrder(Security security, Order order,
        UpdateOrderRequest request, out BrokerageMessageEvent message)
    {
        return base.CanUpdateOrder(security, order, request, out message);
    }

    public override bool CanExecuteOrder(Security security, Order order)
    {
        return base.CanExecuteOrder(security, order);
    }

    public override void ApplySplit(List<OrderTicket> tickets, Split split)
    {
        base.ApplySplit(tickets, split);
    }

    public override decimal GetLeverage(Security security)
    {
        return base.GetLeverage(security);
    }

    public override IBenchmark GetBenchmark(SecurityManager securities)
    {
        return base.GetBenchmark(securities);
    }

    public override IFillModel GetFillModel(Security security)
    {
        return base.GetFillModel(security);
    }

    public override IFeeModel GetFeeModel(Security security)
    {
        return base.GetFeeModel(security);
    }

    public override ISlippageModel GetSlippageModel(Security security)
    {
        return base.GetSlippageModel(security);
    }

    public override ISettlementModel GetSettlementModel(Security security)
    {
        return base.GetSettlementModel(security);
    }

    public override IBuyingPowerModel GetBuyingPowerModel(Security security)
    {
        return base.GetBuyingPowerModel(security);
    }

    public override IMarginInterestRateModel GetMarginInterestRateModel(Security security)
    {
        return base.GetMarginInterestRateModel(security);
    }

    public override IShortableProvider GetShortableProvider(Security security)
    {
        return base.GetShortableProvider(security);
    }
}
```

Other Examples

For more examples, see the following algorithms:

Brokerages

Supported Models

Brokerage models combine together all of the models relevant for a brokerage. The following brokerage models are available:

QuantConnect Paper Trading

Interactive Brokers

TradeStation

Tastytrade

Alpaca

Charles Schwab

Binance

Bybit

Tradier

Kraken

Coinbase

Bitfinex

dYdX

Terminal Link

SSC Eze

Trading Technologies

Wolverine

Oanda

See Also

Live Trading Brokerages

Supported Models

QuantConnect Paper Trading

Introduction

This page explains the `DefaultBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
C#

SetBrokerageModel(BrokerageName.QuantConnectBrokerage, AccountType.Cash);
SetBrokerageModel(BrokerageName.QuantConnectBrokerage, AccountType.Margin); // Overrides the default account type
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `DefaultBrokerageModel` supports trading for all asset classes .

Orders

The following sections describe how the `DefaultBrokerageModel` handles orders.

Order Types

The following table describes the available order types for each asset class that the `DefaultBrokerageModel` supports:

Order Type	US Equity	Equity Options	Crypto	Crypto Futures	Forex	CFD	Futures	Futures Options	Index Options
Market	✓	✓	✓	✓	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓	✓	✓	✓	✓
Limit if touched	✓	✓	✓	✓	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓	✓	✓	✓	✓	✓
Market on open	✓	✓	✓		✓	✓			✓
Market on close	✓	✓	✓		✓	✓	✓	✓	✓
Combo market		✓						✓	✓
Combo limit		✓						✓	✓
Combo leg limit		✓						✓	✓
Exercise Option		✓ Not supported for cash-settled Options						✓	

In live trading, Option orders require a third-party data provider that supports Options. To view the data providers that support Options, see their respective documentation in Cloud Platform , Local Platform , or the CLI .

Time In Force

The `DefaultBrokerageModel` supports the following TimeInForce instructions:

- `Day`
- `GoodTilCanceled`
- `GoodTilDate`

Updates

The `DefaultBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `DefaultBrokerageModel` uses for each `SecurityType` :

`SecurityType`	**Fill Model**
`Equity`	EquityFillModel
`Future`	FutureFillModel
`FutureOption`	FutureOptionFillModel
Remaining `SecurityType` values	ImmediateFillModel

Slippage

The `DefaultBrokerageModel` uses the NullSlippageModel .

Fees

The `DefaultBrokerageModel` uses the ConstantFeeModel with no fees for Forex, CFD, Crypto, and Crypto Future assets and the InteractiveBrokersFeeModel for the remaining asset classes.

```
C#
// For Forex, CFD, Crypto, and Crypto Future assets:
security.SetFeeModel(new ConstantFeeModel(0.0m));

// For the remaining asset classes:
security.SetFeeModel(new InteractiveBrokersFeeModel());
```

Buying Power

The `DefaultBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`
Future Options	`FuturesOptionsMarginModel`
Index Options	`OptionMarginModel`
Crypto	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`
Forex	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
Other	`SecurityMarginModel`

If you have a margin account, the `DefaultBrokerageModel` allows 2x leverage for Equities, 50x leverage for Forex and CFDs, and 1x leverage for the remaining asset classes.

Settlement

The following table shows which settlement model the `DefaultBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `DefaultBrokerageModel` uses the ImmediateSettlementModel .

```C#
// For US Equities with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For Equity Options with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Option.DefaultSettlementDays, Option.DefaultSettlementTime));

// For Futures
security.SetSettlementModel(new FutureSettlementModel());

// For remaining cases:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `DefaultBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `DefaultBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA
Forex	Oanda
Cfd	Oanda
Crypto	Coinbase
CryptoFuture	Binance

Account Currency

The `DefaultBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Interactive Brokers

Introduction

This page explains the `InteractiveBrokersBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```C#
SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Cash);
SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `InteractiveBrokersBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Forex
- Futures
- Future Options
- Indices
- Index Options
- CFD

Orders

The `InteractiveBrokersBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the order types that the `InteractiveBrokersBrokerageModel` supports: supports. For specific details about each order type, refer to the IB documentation.

Order Type	IB Documentation Page
Market	Market Orders
Limit	Limit Orders
Limit if touched	Limit if Touched Orders
Stop market	Stop Orders
Stop limit	Stop-Limit Orders
Trailing stop	Trailing Stop Orders
Market on open	Market-on-Open (MOO) Orders
Market on close	Market-on-Close (MOC) Orders
Combo market	Spread Orders
Combo limit	Spread Orders
Combo leg limit	Spread Orders
Exercise Option	Options Exercise

The following table describes the available order types for each asset class that the `InteractiveBrokersBrokerageModel` supports:

Order Type	US Equity	Equity Options	Forex	Futures	Futures Options	Index Options	CFD
Market	✓	✓	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓	✓	✓
Limit if touched	✓	✓	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓	✓	✓
Stopl imit	✓	✓	✓	✓	✓	✓	✓
Trailing stop	✓	✓	✓	✓	✓	✓	✓
Market on open	✓	✓			✓	✓	✓
Market on close	✓			✓			✓
Combo market		✓			✓	✓	
Combo limit		✓			✓	✓	
Combo leg limit		✓			✓	✓	
Exercise Option		✓ Not supported for cash-settled Options			✓		

Order Properties

The `InteractiveBrokersBrokerageModel` supports custom order properties. The following table describes the members of the `InteractiveBrokersOrderProperties` object that you can set to customize order execution. The table does not include the methods for FA accounts .

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`OutsideRegularTradingHours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`false`

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new InteractiveBrokersOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        OutsideRegularTradingHours = false
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new InteractiveBrokersOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   OutsideRegularTradingHours = false
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new InteractiveBrokersOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day)),
                   OutsideRegularTradingHours = true
               });
}
```

Updates

The `InteractiveBrokersBrokerageModel` supports order updates .

Financial Advisor Group Orders

To place FA group orders, see Financial Advisors .

Fractional Trading

The `InteractiveBrokersBrokerageModel` doesn't support fractional trading .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity

- Limit price
- Stop price
- Trigger price

Order Size Limits

The `InteractiveBrokersBrokerageModel` enforces the Spot Currency Minimum/Maximum Order Sizes from the IB website.

Fills

The following table shows the fill model that the `InteractiveBrokersBrokerageModel` uses for each `SecurityType` :

`SecurityType`	**Fill Model**
`Equity`	EquityFillModel
`Future`	FutureFillModel
`FutureOption`	FutureOptionFillModel
Remaining `SecurityType` values	ImmediateFillModel

Slippage

The `InteractiveBrokersBrokerageModel` uses the NullSlippageModel .

Fees

The `InteractiveBrokersBrokerageModel` uses the InteractiveBrokersFeeModel with the default argument values. We model current Interactive Brokers fees on all assets.

Buying Power

The `InteractiveBrokersBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	**Model**
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`
Future Options	`FuturesOptionsMarginModel`
Index Options	`OptionMarginModel`
Crypto	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`
Forex	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
Other	`SecurityMarginModel`

If you have a margin account, the `InteractiveBrokersBrokerageModel` allows 2x leverage for Equities, 50x leverage for Forex, 10x leverage for CFDs, and 1x leverage for the remaining asset classes.

Settlement

The `InteractiveBrokersBrokerageModel` uses the ImmediateSettlementModel in most cases. If you trade US Equities or Equity Options with a cash account, it uses the DelayedSettlementModel with the default settlement rules .

The following table shows which settlement model the `InteractiveBrokersBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `InteractiveBrokersBrokerageModel` uses the ImmediateSettlementModel .

```C#
// For US Equities with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For Equity Options with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Option.DefaultSettlementDays, Option.DefaultSettlementTime));

// For remaining cases:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Interactive Brokers doesn't provide information on which assets aren't settled, so we assume each live trading session starts with its cash fully settled.

Margin Interest Rate

The `InteractiveBrokersBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `InteractiveBrokersBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA
Forex	Oanda
Cfd	InteractiveBrokers

Financial Advisors

IB supports FA accounts for Trading Firm and Institution organizations. FA accounts enable certified professionals to use a single trading algorithm to manage several client accounts.

To place trades using a subset of client accounts, create Account Groups in Trader Workstation and then define the `InteractiveBrokersOrderProperties` when you create orders.

```
C#
DefaultOrderProperties = new InteractiveBrokersOrderProperties
{
    FaGroup = "TestGroupEQ",
    FaMethod = "Equal",
    Account = "DU123456"
};
```

SecurityHolding objects aggregate your positions across all the account groups. If you have two groups where group A has 10 shares of SPY and group B has -10 shares of SPY, then `Portfolio["SPY"].Quantity` is zero.

LEAN supports several allocation methods for FA group orders. If you intend to use the same group allocation method for every order, set the `DefaultOrderProperties` of your algorithm, which sets the order properties for all of your orders.

```
C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new InteractiveBrokersOrderProperties()
    {
        FaGroup = "TestGroupEQ",
        FaMethod = "Equal",
        Account = "DU123456"
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);
}
```

To adjust the order properties of an order, change the `DefaultOrderProperties` or pass an order properties object to the order

method . The following sections explain the FA group allocation methods.

Equal

This group allocation method distributes shares equally between all accounts in the group. When you use this method, you need to specify an order quantity.

For example, say your Account Group includes four accounts and you place an order to buy 400 shares of a stock. In this case, each account receives 100 shares. If your Account Group includes six accounts, each account receives 66 shares, and then 1 share is allocated to each account until all are distributed. After you submit the order, your algorithm receives order events to track the order progress. When all the shares are bought, the order status is `OrderStatus.Filled` . If one of the accounts in the group can't afford 10 of the shares it needs to buy, 10 shares are cancelled and you'll only end up buying 390 shares in total.

```C#
LimitOrder(
    _symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "Equal"
    }
);
```

Net Liquidation Value

This group allocation method distributes shares based on the net liquidation value of each account. The system calculates ratios based on the net liquidation value in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with Net Liquidation values of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```C#
LimitOrder(_symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "NetLiq"
    }
);
```

Available Equity

This group allocation method distributes shares based on the amount of available equity in each account. The system calculates ratios based on the available equity in each account and allocates shares based on these ratios. When you use this method, you need to specify an order quantity.

For example, say your account group includes three accounts, A, B and C with available equity of 25,000, 50,000 and $100,000, respectively. In this case, the system calculates a ratio of 1:2:4. If you place an order for 700 shares of a stock, it allocates 100 shares to Client A, 200 shares to Client B, and 400 shares to Client C.

```C#
LimitOrder(_symbol, quantity, limitPrice,
    orderProperties: new InteractiveBrokersOrderProperties
    {
        FaMethod = "AvailableEquity"
    }
);
```

Account Currency

The `InteractiveBrokersBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

TradeStation

Introduction

This page explains the `TradeStationBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```C#
SetBrokerageModel(BrokerageName.TradeStation, AccountType.Cash);
SetBrokerageModel(BrokerageName.TradeStation, AccountType.Margin);
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `TradeStationBrokerageModel` supports trading the following asset classes:

- US Equities
- Equity Options
- Futures
- Index
- Index Options

Orders

The `TradeStationBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TradeStationBrokerageModel` supports:

Order Type	Equity	Equity Options	Index Options	Futures
Market	✓	✓	✓	✓
Limit	✓	✓	✓	✓
Stop market	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓
Trailing stop	✓	✓	✓	✓
Market on Open	✓			
Market on Close	✓			
Combo market	✓	✓	✓	✓
Combo limit	✓	✓	✓	✓

Order Properties

The `TradeStationBrokerageModel` supports custom order properties. The following table describes the members of the `TradeStationOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`OutsideRegularTradingHours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`false`
`PostOnly`	`bool`	This flag will ensure the limit order executes only as a maker (no fee) order. If part of the order results in taking liquidity rather than providing, it will be rejected and no part of the order will execute. Equities only.	`false`

C#

```
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new TradeStationOrderProperties
    {
        OutsideRegularTradingHours = false,
        TimeInForce = TimeInForce.GoodTilCanceled
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new TradeStationOrderProperties
               {
                   PostOnly = true,
                   TimeInForce = TimeInForce.Day
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new TradeStationOrderProperties
               {
                   OutsideRegularTradingHours = true,
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day))
               });
}
```

Updates

The `TradeStationBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `TradeStationBrokerageModel` uses for each `SecurityType` :

`SecurityType`	**Fill Model**
`Equity`	EquityFillModel
`Option`	ImmediateFillModel
`Future`	FutureFillModel

Slippage

The `TradeStationBrokerageModel` uses the NullSlippageModel .

Fees

The `TradeStationBrokersBrokerageModel` uses the TradeStationFeeModel with the default argument values. We model current TradeStation fees on all assets.

Buying Power

The `TradeStationBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	**Model**
Equities	`SecurityMarginModel`
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`

If you have a margin account, the `TradeStationBrokerageModel` allows 2x leverage for Equities and and 1x leverage for Equity Options and Futures.

Settlement

The following table shows which settlement model the `TradeStationBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `TradeStationBrokerageModel` uses the ImmediateSettlementModel .

```C#
// For US Equities with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For Equity Options with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Option.DefaultSettlementDays, Option.DefaultSettlementTime));

// For Futures
security.SetSettlementModel(new FutureSettlementModel());

// For remaining cases:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `TradeStationBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `TradeStationBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME

Account Currency

The `TradeStationBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Tastytrade

Introduction

This page explains the `TastytradeBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
SetBrokerageModel(BrokerageName.Tastytrade, AccountType.Cash);
SetBrokerageModel(BrokerageName.Tastytrade, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `TastytradeBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Futures
- Future Options
- Indices
- Index Options

Orders

The `TastytradeBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TastytradeBrokerageModel` supports:

Order Type	Equity	Equity Options	Futures	Future Options	Index Options
Market	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓	✓
Combo limit	✓	✓	✓	✓	✓

Order Properties

The `TastytradeBrokerageModel` supports custom order properties. The following table describes the members of the `TastytradeOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`

```
C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new TastytradeOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new TastytradeOrderProperties
               {
                   TimeInForce = TimeInForce.Day
               });
}
```

Updates

The `TastytradeBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `TastytradeBrokerageModel` uses for each `SecurityType` :

SecurityType	Fill Model
Equity	EquityFillModel
Future	FutureFillModel
FutureOption	FutureOptionFillModel
Remaining SecurityType values	ImmediateFillModel

Slippage

The TastytradeBrokerageModel uses the NullSlippageModel .

Fees

The TastytradeBrokersBrokerageModel uses the TastytradeFeeModel with the default argument values. We model current Tastytrade fees on all assets.

Buying Power

The TastytradeBrokerageModel sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equities	SecurityMarginModel
Futures	FutureMarginModel
All Options Types	OptionMarginModel

If you have a margin account, the TastytradeBrokerageModel allows 2x leverage for Equities. The remaining asset classes are derivatives.

Settlement

The following table shows which settlement model the TastytradeBrokerageModel uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the TastytradeBrokerageModel uses the ImmediateSettlementModel .

```C#
// For US Equities with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For Equity Options with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Option.DefaultSettlementDays, Option.DefaultSettlementTime));

// For Futures
security.SetSettlementModel(new FutureSettlementModel());

// For remaining cases:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `TastytradeBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `TastytradeBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA

Supported Models

Alpaca

Introduction

This page explains the `AlpacaBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
SetBrokerageModel(BrokerageName.Alpaca, AccountType.Cash);
SetBrokerageModel(BrokerageName.Alpaca, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `AlpacaBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Crypto

Orders

The `AlpacaBrokerageModel` supports several order types, order properties, and most order updates.

Order Types

The following table describes the available order types for each asset class that the `AlpacaBrokerageModel` supports:

Order Type	Equity	Equity Options	Crypto
Market	✓	✓	✓
Limit	✓	✓	✓
Stop market	✓	✓	✓
Stop limit	✓	✓	✓
Market on Open	✓		
Market on Close	✓		

Order Properties

The `AlpacaBrokerageModel` supports custom order properties. The following table describes the members of the `AlpacaOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`OutsideRegularTradingHours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`false`

```
C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new AlpacaOrderProperties
    {
        OutsideRegularTradingHours = false,
        TimeInForce = TimeInForce.GoodTilCanceled
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new AlpacaOrderProperties
               {
                   TimeInForce = TimeInForce.Day
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new AlpacaOrderProperties
               {
                   OutsideRegularTradingHours = true,
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day))
               });
}
```

Updates

The `AlpacaBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The `AlpacaBrokerageModel` uses the EquityFillModel for Equity trades and the ImmediateFillModel for Option and Crypto trades.

Slippage

The `AlpacaBrokerageModel` uses the NullSlippageModel .

Fees

The `AlpacaBrokerageModel` uses the AlpacaFeeModel with the default argument values. We model current Alpaca fees on all assets.

Buying Power

The `AlpacaBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts, the `SecurityMarginModel` for margin accounts, and the `OptionMarginModel` for Option trades.

If you have a margin account, the `AlpacaBrokerageModel` allows 2x leverage for Equities and 3x leverage for Crypto.

Settlement

The `AlpacaBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts with Equity and Equity Options.

```C#
// For US Equities with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For Equity Options with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Option.DefaultSettlementDays, Option.DefaultSettlementTime));

// For remaining cases:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `AlpacaBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `AlpacaBrokerageModel` is `Market.USA` for Equity and Equity Options. It's `Market.Coinbase` for Crypto.

Account Currency

The `AlpacaBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Charles Schwab

Introduction

This page explains the `CharlesSchwabBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```C#
SetBrokerageModel(BrokerageName.CharlesSchwab, AccountType.Cash);
SetBrokerageModel(BrokerageName.CharlesSchwab, AccountType.Margin);
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `CharlesSchwabBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Index
- Index Options

Orders

The `CharlesSchwabBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `CharlesSchwabBrokerageModel` supports:

Order Type	Equity	Equity Options	Index Options
Market	✓	✓	✓
Limit	✓	✓	✓
Stop market	✓	✓	
Market on open	✓		
Market on close	✓		
Combo market	✓	✓	✓
Combo limit	✓	✓	✓

Order Properties

The `CharlesSchwabBrokerageModel` supports custom order properties. The following table describes the members of the `CharlesSchwabOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`ExtendedRegularTradingHours`	`bool`	If set to true, allows orders to also trigger or fill outside of regular trading hours.	`false`

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled;
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new CharlesSchwabOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   ExtendedRegularTradingHours = false
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new CharlesSchwabOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day))
               });
}
```

Updates

The `CharlesSchwabBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Fills

The `CharlesSchwabBrokerageModel` uses the EquityFillModel for Equity trades and the ImmediateFillModel for Equity and Index Options trades.

Slippage

The `CharlesSchwabBrokerageModel` uses the NullSlippageModel .

Fees

The `CharlesSchwabBrokerageModel` uses the CharlesSchwabFeeModel .

Buying Power

The `CharlesSchwabBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `CharlesSchwabBrokerageModel` allows up to 2x leverage.

Settlement

The `CharlesSchwabBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
C#
// For cash accounts:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For margin accounts:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `CharlesSchwabBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `CharlesSchwabBrokerageModel` is `Market.USA` .

Account Currency

The `CharlesSchwabBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Binance

Introduction

This page explains the Binance brokerage models, including the asset classes they supports, their default security-level models , and their default markets.

```
C#

// Binance Spot
SetBrokerageModel(BrokerageName.Binance, AccountType.Cash);
SetBrokerageModel(BrokerageName.Binance, AccountType.Margin);

// Binance Futures
SetBrokerageModel(BrokerageName.BinanceFutures, AccountType.Margin);
SetBrokerageModel(BrokerageName.BinanceCoinFutures, AccountType.Margin);

// Binance US Spot
SetBrokerageModel(BrokerageName.BinanceUS, AccountType.Cash);
```

For more information about these models, see their respective class reference and implementation.

Model	Class Reference	Implementation
BinanceBrokerageModel		
BinanceFuturesBrokerageModel		
BinanceCoinFuturesBrokerageModel		
BinanceUSBrokerageModel		

Asset Classes

The Binance brokerage models support trading Crypto and Crypto Futures .

```
C#

AddCrypto("BTCUSDT", Resolution.Minute, Market.Binance);
AddCryptoFuture("BTCUSD", Resolution.Minute, Market.Binance);
AddCrypto("BTCUSDT", Resolution.Minute, Market.BinanceUS);
```

The Binance US brokerage model supports trading Crypto .

```
C#

AddCrypto("BTCUSDT", Resolution.Minute, Market.BinanceUS);
```

Orders

The Binance and Binance US brokerage models support several order types and order properties, but don't support order updates.

Order Types

The following table describes the available order types for each asset class that the Binance and Binance US brokerage models support:

Order Type	Crypto	Crypto Futures
Market	✓	✓
Limit	✓	✓
Stop Market		✓
Stop limit	✓	✓

Order Properties

The Binance and Binance US brokerage models supports custom order properties. The following table describes the members of the `BinanceOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`PostOnly`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new BinanceOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        PostOnly = false
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new BinanceOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   PostOnly = false
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new BinanceOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day)),
                   PostOnly = true
               });
}
```

Updates

The Binance and Binance US brokerage models don't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The Binance brokerage models use the ImmediateFillModel .

Slippage

The Binance brokerage models use the NullSlippageModel .

Fees

The following table shows the fee model that each Binance brokerage model uses:

Brokerage Model	Fee Model
`BinanceBrokerageModel`	BinanceFeeModel
`BinanceFuturesBrokerageModel`	BinanceFuturesFeeModel
`BinanceCoinFuturesBrokerageModel`	BinanceCoinFuturesFeeModel
`BinanceUSBrokerageModel`	BinanceFeeModel

The Binance brokerage models use the default argument values for each fee model so that it models the current Binance fee schedule.

Buying Power

The Binance brokerage models use the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

The following table shows the maximum leverage each brokerage model allows for margin accounts:

Brokerage Model	Maximum Leverage
`BinanceBrokerageModel`	3
`BinanceFuturesBrokerageModel`	25
`BinanceCoinFuturesBrokerageModel`	25

The `BinanceUSBrokerageModel` doesn't currently support margin trading.

Settlement

The Binance brokerage models use the ImmediateSettlementModel .

Margin Interest Rate

The following table shows the margin interest rate model that the Binance brokerages use:

Brokerage Model	Margin Interest Rate Model
`BinanceBrokerageModel`	NullMarginInterestRateModel
`BinanceFuturesBrokerageModel`	BinanceFutureMarginInterestRateModel for Crypto Perpetual Futures and NullMarginInterestRateModel for other assets
`BinanceCoinFuturesBrokerageModel`	BinanceFutureMarginInterestRateModel for Crypto Perpetual Futures and NullMarginInterestRateModel for other assets
`BinanceUSBrokerageModel`	NullMarginInterestRateModel

Default Markets

The following table shows the default market of the Binance brokerage models:

Brokerage Model	Market
`BinanceBrokerageModel`	`Market.Binance`
`BinanceFuturesBrokerageModel`	`Market.Binance`
`BinanceCoinFuturesBrokerageModel`	`Market.Binance`
`BinanceUSBrokerageModel`	`Market.BinanceUS`

Account Currency

Most of the Binance brokerage models support fiat currencies like USD, but the `BinanceBrokerageModel` doesn't. When you use this brokerage model, set the account currency to USDT or another Cryptocurrency that Binance supports .

Supported Models

Bybit

Introduction

This page explains the `BybitBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```C#
SetBrokerageModel(BrokerageName.Bybit, AccountType.Cash);
SetBrokerageModel(BrokerageName.Bybit, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `BybitBrokerageModel` supports trading Crypto and Crypto Futures .

Orders

The `BybitBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `BybitBrokerageModel` supports:

Order Type	Crypto	Crypto Futures
Market	✓	✓
Limit	✓	✓
Stop market	✓	✓
Stop limit	✓	✓

Order Properties

The `BybitBrokerageModel` supports custom order properties. The following table describes the members of the `BybitBrokerageModel` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`PostOnly`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled. This order property is only available for limit orders.	
`ReduceOnly`	`bool?`	A flag to signal that the order must only reduce your current position size. For more information about this order property, see Reduce-Only Order on the Bybit website.	

C#

```
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new BybitOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        PostOnly = false,
        ReduceOnly = false
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new BybitOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   PostOnly = true,
                   ReduceOnly = false
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new BybitOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day)),
                   PostOnly = false,
                   ReduceOnly = true
               });
}
```

Updates

The BybitBrokerageModel supports order updates for Crypto Future assets that have one of the following order states :

- OrderStatus.New
- OrderStatus.PartiallyFilled
- OrderStatus.Submitted
- OrderStatus.UpdateSubmitted

In cases where you can't update an order, you can cancel the existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The BybitBrokerageModel uses the ImmediateFillModel .

Slippage

The BybitBrokerageModel uses the NullSlippageModel .

Fees

The BybitBrokerageModel uses the BybitFeeModel for Crypto trades and the BybitFuturesFeeModel for Crypto Future trades. In both cases, the brokerage model uses the default argument values that models the Bybit fee schedule for VIP Level 0.

Buying Power

The BybitBrokerageModel sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Crypto	CashBuyingPowerModel for cash accounts or SecurityMarginModel for margin accounts
CryptoFuture	CryptoFutureMarginModel

If you have a margin account, the BybitBrokerageModel allows 10x leverage.

Settlement

The BybitBrokerageModel uses the ImmediateSettlementModel .

Margin Interest Rate

The BybitBrokerageModel uses the BybitFutureMarginInterestRateModel for perpetual Futures and the NullMarginInterestRateModel for every other asset.

Default Markets

The default market of the BybitBrokerageModel is Market.Bybit .

Account Currency

The BybitBrokerageModel doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Tradier

Introduction

This page explains the `TradierBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```C#
SetBrokerageModel(BrokerageName.TradierBrokerage, AccountType.Cash);
SetBrokerageModel(BrokerageName.TradierBrokerage, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `TradierBrokerageModel` supports trading US Equities and Equity Options .

Orders

The `TradierBrokerageModel` supports several order types, order properties, and most order updates.

Order Types

The following table describes the available order types for each asset class that the `TradierBrokerageModel` supports:

Order Type	Equity	Equity Options
Market	✓	✓
Limit	✓	✓
Stop market	✓	✓
Stop limit	✓	✓

Order Properties

The `TradierBrokerageModel` supports custom order properties. The following table describes the members of the `TradierOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`OutsideRegularTradingHours`	`bool`	A flag to signal that the order may be triggered and filled outside of regular trading hours.	`false`

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new TradierOrderProperties
    {
        OutsideRegularTradingHours = false,
        TimeInForce = TimeInForce.GoodTilCanceled
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new TradierOrderProperties
               {
                   TimeInForce = TimeInForce.Day
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new TradierOrderProperties
               {
                   OutsideRegularTradingHours = true,
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day))
               });
}
```

Updates

The `TradierBrokerageModel` supports most order updates . To update the quantity of an order, cancel the order and then submit a new order with the desired quantity. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Extended Market Hours

The `TradierBrokerageModel` doesn't support extended market hours trading. If you place an order outside of regular trading hours, the order will be processed at market open.

Automatic Cancellations

If you have open orders for a security when it performs a reverse split, the `TradierBrokerageModel` automatically cancels your orders.

Errors

To view the order-related error codes from Tradier, see Error Responses in their documentation.

The `TradierBrokerageModel` validates your orders for the following errors before sending them to Tradier:

Error	Description
`ShortOrderIsGtc`	You can't short sell with the `GoodTilCanceled` time in force
`SellShortOrderLastPriceBelow5`	You can't short sell stocks below $5
`IncorrectOrderQuantity`	The order quantity must be between 1 and 10,000,000 shares

Fills

The `TradierBrokerageModel` uses the EquityFillModel for Equity trades and the ImmediateFillModel for Option trades.

Slippage

The `TradierBrokerageModel` uses the NullSlippageModel .

Fees

The `TradierBrokerageModel` uses the ConstantFeeModel with zero fees.

```
C#
security.SetFeeModel(new ConstantFeeModel(0.0m));
```

Buying Power

The `TradierBrokerageModel` uses the `OptionMarginModel` for Option trades and the `SecurityMarginModel` for Equity trades.

If you have a margin account, the `TradierBrokerageModel` allows 2x leverage for Equities.

Settlement

The `TradierBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
C#
// For US Equities with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For Equity Options with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Option.DefaultSettlementDays, Option.DefaultSettlementTime));

// For remaining cases:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `TradierBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `TradierBrokerageModel` is `Market.USA` .

Account Currency

The `TradierBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Kraken

Introduction

This page explains the `KrakenBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
C#
SetBrokerageModel(BrokerageName.Kraken, AccountType.Cash);
SetBrokerageModel(BrokerageName.Kraken, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `KrakenBrokerageModel` supports trading Crypto .

Orders

The `KrakenBrokerageModel` supports several order types and order properties, but it doesn't support order updates.

Order Types

The following table describes the available order types for each asset class that the `KrakenBrokerageModel` supports:

Order Type	Crypto
Market	✓
Limit	✓
Limit if touched	✓
Stop market	✓
Stop limit	✓

Order Properties

The `KrakenBrokerageModel` supports custom order properties. The following table describes the members of the `KrakenOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`PostOnly`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	
`FeeInBase`	`bool`	A flag to signal that the order fees should be paid in the base currency, which is the default behavior when selling. This flag must be the opposite of the `FeeInQuote` flag.	
`FeeInQuote`	`bool`	A flag to signal that the order fees should be paid in the quote currency, which is the default behavior when buying. This flag must be the opposite of the `FeeInBase` flag.	
`NoMarketPriceProtection`	`bool`	A flag to signal that no Market Price Protection should be used.	
`ConditionalOrder`	`Order`	An `Order` that's submitted when the primary order is executed. The `ConditionalOrder` quantity must match the primary order quantity and the `ConditionalOrder` direction must be the opposite of the primary order direction. This order property is only available for live algorithms.	

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new KrakenOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        PostOnly = false,
        FeeInBase = true,
        FeeInQuote = false,
        NoMarketPriceProtection = true
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new KrakenOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   PostOnly = true,
                   FeeInBase = false,
                   FeeInQuote = true,
                   NoMarketPriceProtection = true
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new KrakenOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day)),
                   PostOnly = false,
                   FeeInBase = true,
                   FeeInQuote = false,
                   NoMarketPriceProtection = false,
                   ConditionalOrder = StopLimitOrder(_symbol, -quantity, stopLimitPrice, stopPrice)
               });
}
```

Updates

The `KrakenBrokerageModel` doesn't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `KrakenBrokerageModel` uses the ImmediateFillModel .

Slippage

The `KrakenBrokerageModel` uses the NullSlippageModel .

Fees

The `KrakenBrokerageModel` uses the KrakenFeeModel .

Buying Power

The `KrakenBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

If you have a margin account, the `KrakenBrokerageModel` allows 1x leverage for most Crypto pairs. The following table shows pairs that have additional leverage available:

Quote Currency	Base Currencies	Leverage
ADA	BTC, ETH, USD, EUR	3
BCH	BTC, USD, EUR	2
BTC	USD, EUR	5
DASH	BTC, USD, EUR	3
EOS	BTC, ETH, USD, EUR	3
ETH	BTC, USD, EUR	5
LINK	BTC, ETH, USD, EUR	3
LTC	BTC, USD, EUR	3
REP	BTC, ETH, USD, EUR	2
TRX	BTC, ETH, USD, EUR	3
USDC	USD, EUR	3
USDT	USD, EUR	2
XMR	BTC, USD, EUR	2
XRP	BTC, USD, EUR	3
XTZ	BTC, ETH, USD, EUR	2

Settlement

The `KrakenBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `KrakenBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `KrakenBrokerageModel` is `Market.Kraken` .

Account Currency

The `KrakenBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Coinbase

Introduction

This page explains the `CoinbaseBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```C#
SetBrokerageModel(BrokerageName.Coinbase, AccountType.Cash);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `CoinbaseBrokerageModel` supports trading Crypto .

Orders

The `CoinbaseBrokerageModel` supports several order types and order properties, but it doesn't support order updates.

Order Types

The following table describes the available order types for each asset class that the `CoinbaseBrokerageModel` supports:

Order Type	Crypto
Market	✓
Limit	✓
Stop market	✓ Supported before 2019-03-23 in backtests. For reference, see the Coinbase Market Structure Update on the Coinbase website.
Stop limit	✓

Order Properties

The `CoinbaseBrokerageModel` supports custom order properties. The following table describes the members of the `CoinbaseOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The `GoodTilCanceled` `GOOD_TIL_CANCELED` `TimeInForce` is supported.	`TimeInForce.GoodTilCanceled`
`PostOnly`	`bool`	A flag that signals the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	
`SelfTradePreventionId`	`bool`	A flag that signals self-trade prevention is enabled for this order. Self-trade prevention helps prevent an order from crossing against the same user, reducing the risk of unintentional trades within the same account.	

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new CoinbaseOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        PostOnly = false
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new CoinbaseOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilCanceled,
                   PostOnly = true
               });
}
```

Updates

The `CoinbaseBrokerageModel` doesn't support limit order updates, but you can cancel an existing limit order and then create a new limit order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `CoinbaseBrokerageModel` uses the ImmediateFillModel .

Slippage

The `CoinbaseBrokerageModel` uses the NullSlippageModel .

Fees

The `CoinbaseBrokerageModel` uses the CoinbaseFeeModel .

Buying Power

The `CoinbaseBrokerageModel` uses the `CashBuyingPowerModel` . The brokerage model doesn't currently support margin trading.

Settlement

The `CoinbaseBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `CoinbaseBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `CoinbaseBrokerageModel` is `Market.Coinbase` .

Account Currency

The `CoinbaseBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Bitfinex

Introduction

This page explains the `BitfinexBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```C#
SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Cash);
SetBrokerageModel(BrokerageName.Bitfinex, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `BitfinexBrokerageModel` supports trading Crypto .

Orders

The `BitfinexBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `BitfinexBrokerageModel` supports:

Order Type	Crypto
Market	✓
Limit	✓
Stop market	✓
Stop limit	✓

Order Properties

The `BitfinexBrokerageModel` supports custom order properties. The following table describes the members of the `BitfinexOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`Hidden`	`bool`	A flag to signal that the order should be hidden. Hidden orders do not appear in the order book, so they do not influence other market participants. Hidden orders incur the taker fee.	
`PostOnly`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled.	

C#

```
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new BitfinexOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        Hidden = false,
        PostOnly = false
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new BitfinexOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   Hidden = true,
                   PostOnly = false
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new BitfinexOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day)),
                   Hidden = false,
                   PostOnly = true
               });
}
```

Updates

The `BitfinexBrokerageModel` supports order updates .

Fills

The `BitfinexBrokerageModel` uses the ImmediateFillModel .

Slippage

The `BitfinexBrokerageModel` uses the NullSlippageModel .

Fees

The `BitfinexBrokerageModel` uses the BitfinexFeeModel with the default argument values that models the current Bitfinex fee schedule.

Buying Power

The `BitfinexBrokerageModel` uses the `CashBuyingPowerModel` for cash accounts and the `SecurityMarginModel` for margin accounts.

If you have a margin account, the `BitfinexBrokerageModel` allows 3.3x leverage.

Settlement

The `BitfinexBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `BitfinexBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `BitfinexBrokerageModel` is `Market.Bitfinex` .

Account Currency

The `BitfinexBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

dYdX

Introduction

This page explains the `dYdXBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
SetBrokerageModel(BrokerageName.dYdX, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `dYdXBrokerageModel` supports trading Crypto futures .

Orders

The `dYdXBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `dYdXBrokerageModel` supports:

Order Type	Crypto Future
Market	✓
Limit	✓
Stop market	✓
Stop limit	✓

Order Properties

The `dYdXBrokerageModel` supports custom order properties. The following table describes the members of the `dYdXOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`GasLimit`	`ulong`	The maximum amount of gas to use for the order.	1_000_000
`GoodTilBlockOffset`	`ulong`	The block height at which the order expires.	20
`PostOnly`	`bool`	A flag to signal that the order must only add liquidity to the order book and not take liquidity from the order book. If part of the order results in taking liquidity rather than providing liquidity, the order is rejected without any part of it being filled. This order property is only available for limit orders.	
`ReduceOnly`	`bool?`	A flag to signal that the order must only reduce your current position size. For more information about this order property, see Reduce-Only Order on the dYdX website.	

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new dYdXOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        ReduceOnly = false,
        PostOnly = false
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new dYdXOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   ReduceOnly = true,
                   PostOnly = false
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new dYdXOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day)),
                   ReduceOnly = false,
                   PostOnly = true
               });
}
```

Updates

The `dYdXBrokerageModel` doesn't support order updates, but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Fills

The `dYdXBrokerageModel` uses the ImmediateFillModel .

Slippage

The `dYdXBrokerageModel` uses the NullSlippageModel .

Fees

The `dYdXBrokerageModel` uses the dYdXFeeModel with the default argument values that models the current dYdX fee schedule.

Buying Power

The `dYdXBrokerageModel` uses the `SecurityMarginModel` and allows 3.3x leverage.

Settlement

The `dYdXBrokerageModel` uses the ImmediateSettlementModel .

Margin Interest Rate

The `dYdXBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `dYdXBrokerageModel` is `Market.dYdX` .

Account Currency

The `dYdXBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Terminal Link

Introduction

This page explains the Terminal Link brokerage, including the asset classes it supports, its default security-level models , and its default markets.

Asset Classes

Terminal Link supports trading the following asset classes:

- Equities
- Equity Options
- Futures
- Index Options

Orders

Terminal Link enables you to create and manage Bloomberg™ orders.

Order Types

The following table describes the available order types for each asset class that Terminal Link supports:

Order Type	Equity	Equity Options	Futures	Index Options
Market	✓	✓	✓	✓
Limit	✓	✓	✓	✓
Stop market	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓

Order Properties

We model custom order properties from the Bloomberg EMSX API. The following table describes the members of the `TerminalLinkOrderProperties` object that you can set to customize order execution:

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`

`Notes`	`string`	The free form instructions that may be sent to the broker.	
`HandlingInstruction`	`string`	The instructions for handling the order or route. The values can be preconfigured or a value customized by the broker.	
`CustomNotes1`	`string`	Custom user order notes 1. For more information about custom order notes, see Custom Notes & Free Text Fields in the EMSX API documentation	
`CustomNotes2`	`string`	Custom user order notes 2.	
`CustomNotes3`	`string`	Custom user order notes 3.	
`CustomNotes4`	`string`	Custom user order notes 4.	
`CustomNotes5`	`string`	Custom user order notes 5.	
`Account`	`string`	The EMSX account.	
`Broker`	`string`	The EMSX broker code.	
`Strategy`	`StrategyParameters`	An object that represents the EMSX order strategy details. You must append strategy parameters in the order that the EMSX API expects. The following strategy names are supported: "DMA", "DESK", "VWAP", "TWAP", "FLOAT", "HIDDEN", "VOLUMEINLINE", "CUSTOM", "TAP", "CUSTOM2", "WORKSTRIKE", "TAPNOW", "TIMED", "LIMITTICK", "STRIKE"	
`ExecutionInstruction`	`string`	The execution instruction field.	
`AutomaticPositionSides`	`bool`	A flag that determines whether to automatically include the position side in the order direction (buy-to-open, sell-to-close, etc.) instead of the default (buy, sell).	

PositionSide	OrderPosition?	An OrderPosition object that specifies the position side in the order direction (buy-to-open, sell-to-close, etc.) instead of the default (buy, sell). This member has precedence over AutomaticPositionSides .	
Exchange	Exchange	Defines the exchange name for sending the order to.	

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new TerminalLinkOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        Strategy = new TerminalLinkOrderProperties.StrategyParameters(
            "VWAP",
            new List<TerminalLinkOrderProperties.StrategyField>
            {
                new("09:30:00"),
                new("10:30:00"),
                new(),
                new()
            }
        )
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new TerminalLinkOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   Account = "account1"
               });
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new TerminalLinkOrderProperties
               {
                   TimeInForce = TimeInForce.GoodTilDate(new DateTime(year, month, day)),
                   Account = "account2"
               });
}
```

For more information about the format that the Bloomberg EMSX API expects, see Create Order and Route Extended Request in the EMSX API documentation and the createOrderAndRouteWithStrat documentation on the MathWorks website.

Get Open Orders

Terminal Link lets you access open orders .

Monitor Fills

Terminal Link allows you to monitor orders as they fill through order events .

Updates

Terminal Link doesn't support order updates , but you can cancel an existing order and then create a new order with the desired arguments. For more information about this workaround, see the Workaround for Brokerages That Don't Support Updates .

Cancellations

Terminal Link enables you to cancel open orders .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity
- Limit price
- Stop price
- Trigger price

Brokerage-Side Orders

By default, your algorithm doesn't record orders that you submit to your account by third-parties instead of through LEAN. To accept these orders, create a custom brokerage message handler .

Fills

To view how we model fills in backtests, see Fills .

Slippage

To view how we model slippage in backtests, see Slippage .

Fees

To view how we model fees in backtests, see Fees .

Buying Power

To view how we model buying power in backtests, see Buying Power .

Settlement

To view how we model settlements in backtests, see Settlement .

Margin Interest Rate

To view how we model margin interest rates in backtests, see Margin Interest Rate .

Default Markets

To view the default markets of each asset class when you use Terminal Link, see Default Markets .

Account Currency

The Terminal Link brokerage doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

SSC Eze

Introduction

This page explains the `EzeBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
SetBrokerageModel(BrokerageName.Eze, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `EzeBrokerageModel` supports the following asset classes:

- US Equities
- Equity Options
- Futures
- Future Options
- Indices
- Index Options

Orders

The `EzeBrokerageModel` supports several order types, order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `EzeBrokerageModel` supports:

Order Type	Equity	Equity Options	Futures	Future Options	Index Options
Market	✓	✓	✓	✓	✓
Limit	✓	✓	✓	✓	✓
Stop market	✓	✓	✓	✓	✓
Stop limit	✓	✓	✓	✓	✓
Market on Open	✓				
Market on Close	✓				

Order Properties

The `EzeBrokerageModel` supports custom order properties. The following table describes the members of the `EzeOrderProperties` object that you can set to customize order execution.

Property	Data Type	Description	Default Value
`TimeInForce`	`TimeInForce`	A TimeInForce instruction to apply to the order. The following instructions are supported: • `Day` • `GoodTilCanceled` • `GoodTilDate`	`TimeInForce.GoodTilCanceled`
`Account`	`string`	Sets a semi-colon separated list of trade or neutral accounts the user has permission for, e.g., "TAL;TEST;USER1;TRADE" or "TAL;TEST;USER2;NEUTRAL".	
`AccountType`	`string`	Sets the account type for the order. E.g., **"119"** for margin orders in Eze EMS.	
`Notes`	`string`	Sets the user message or notes.	
`Route`	`string`	Sets the route name as shown in SS&C Eze EMS.	

C#

```
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new EzeOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        Notes = "Default order properties"
    };
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new EzeOrderProperties
               {
                   TimeInForce = TimeInForce.Day,
                   Notes = "Default order properties"
               });
}
```

Updates

The `EzeBrokerageModel` supports order updates .

Handling Splits

If you're using raw data normalization and you have active orders with a limit, stop, or trigger price in the market for a US Equity when a stock split occurs, the following properties of your orders automatically adjust to reflect the stock split:

- Quantity

- Limit price
- Stop price
- Trigger price

Fills

The following table shows the fill model that the `EzeBrokerageModel` uses for each `SecurityType` :

`SecurityType`	**Fill Model**
`Equity`	EquityFillModel
`Future`	FutureFillModel
`FutureOption`	FutureOptionFillModel
Remaining `SecurityType` values	ImmediateFillModel

Slippage

The `EzeBrokerageModel` uses the NullSlippageModel .

Fees

The `EzeBrokerageModel` uses the EzeFeeModel which extends the ConstantFeeModel with with zero as `fee` for all assets.

Buying Power

The `EzeBrokerageModel` sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	**Model**
Equities	`SecurityMarginModel`
Futures	`FutureMarginModel`
All Options Types	`OptionMarginModel`

If you have a margin account, the `EzeBrokerageModel` allows 2x leverage for Equities. The remaining asset classes are derivatives.

Settlement

The following table shows which settlement model the `EzeBrokerageModel` uses based on the security type and your account type:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `EzeBrokerageModel` uses the ImmediateSettlementModel .

```C#
// For US Equities with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For Equity Options with a cash account:
security.SetSettlementModel(new DelayedSettlementModel(Option.DefaultSettlementDays, Option.DefaultSettlementTime));

// For Futures
security.SetSettlementModel(new FutureSettlementModel());

// For remaining cases:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `EzeBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The following table describes the default markets of each `SecurityType` for the `EzeBrokerageModel` :

SecurityType	Market
Equity	USA
Option	USA
Future	CME
FutureOption	CME
Index	USA
IndexOption	USA

Supported Models

Trading Technologies

Introduction

This page explains the `TradingTechnologiesBrokerageModel`, including the asset classes it supports, its default security-level models, and its default markets.

```C#
SetBrokerageModel(BrokerageName.TradingTechnologies, AccountType.Cash);
SetBrokerageModel(BrokerageName.TradingTechnologies, AccountType.Margin);
```

For more information about this model, see the class reference and implementation.

Asset Classes

The `TradingTechnologiesBrokerageModel` supports trading Futures.

Orders

The `TradingTechnologiesBrokerageModel` supports several order types, some `TimeInForce` order properties, and order updates.

Order Types

The following table describes the available order types for each asset class that the `TradingTechnologiesBrokerageModel` supports:

Order Type	Futures
Market	✓
Limit	✓
Stop market	✓
Stop limit	✓

The `TradingTechnologiesBrokerageModel` enforces the following order rules:

- If you are buying (selling) with a `StopMarketOrder` or a `StopLimitOrder`, the stop price of the order must be greater (less) than the current security price.
- If you are buying (selling) with a `StopLimitOrder`, the limit price of the order must be greater (less) than the stop price.

Time In Force

The `TradingTechnologiesBrokerageModel` supports the `Day` and `GoodTilCanceled` TimeInForce order properties.

```
C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled;
}

public override void OnData(Slice slice)
{
    // Use default order order properties
    LimitOrder(_symbol, quantity, limitPrice);

    // Override the default order properties
    LimitOrder(_symbol, quantity, limitPrice,
               orderProperties: new OrderProperties
               {
                   TimeInForce = TimeInForce.Day
               });
}
```

Updates

The `TradingTechnologiesBrokerageModel` supports order updates .

Fills

The `TradingTechnologiesBrokerageModel` uses the FutureFillModel .

Slippage

The `TradingTechnologiesBrokerageModel` uses the NullSlippageModel .

Fees

The `TradingTechnologiesBrokerageModel` uses the ConstantFeeModel with zero fees.

```
C#
security.SetFeeModel(new ConstantFeeModel(0.0m));
```

Buying Power

The `TradingTechnologiesBrokerageModel` uses the `FutureMarginModel` .

Settlement

The `TradingTechnologiesBrokerageModel` uses the FutureSettlementModel .

Margin Interest Rate

The `TradingTechnologiesBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `TradierBrokerageModel` is `Market.CME` .

Account Currency

The `TradingTechnologiesBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Wolverine

Introduction

This page explains the `WolverineBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
C#

SetBrokerageModel(BrokerageName.Wolverine, AccountType.Cash);
SetBrokerageModel(BrokerageName.Wolverine, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `WolverineBrokerageModel` supports trading US Equities .

Orders

The `WolverineBrokerageModel` supports one order type, but doesn't support order updates or extended market hours trading.

Order Types

The `WolverineBrokerageModel` supports market orders .

Updates

The `WolverineBrokerageModel` doesn't support order updates.

Extended Market Hours

The `WolverineBrokerageModel` doesn't support extended market hours trading. If you place an order outside of regular trading hours, the order is invalid.

Order Properties

The `WolverineBrokerageModel` supports custom order properties. The following table describes the members of the `WolverineOrderProperties` object that you can set to customize order execution:

Property	Description

`TimeInForce`	`TimeInForce`

Exchange	Exchange

`ExchangePostFix`	`string`

```C#
public override void Initialize()
{
    // Set the default order properties
    DefaultOrderProperties = new WolverineOrderProperties
    {
        TimeInForce = TimeInForce.GoodTilCanceled,
        Exchange = Exchange.SMART,
        ExchangePostFix = "-INCA-TX"
    };
}
```

Fills

The `WolverineBrokerageModel` uses the EquityFillModel for Equity trades.

Slippage

The `WolverineBrokerageModel` uses the NullSlippageModel .

Fees

The `WolverineBrokerageModel` uses the WolverineFeeModel .

Buying Power

The `WolverineBrokerageModel` uses the `SecurityMarginModel` . If you have a margin account, the `WolverineBrokerageModel` allows up to 2x leverage.

Settlement

The `WolverineBrokerageModel` uses the ImmediateSettlementModel for margin accounts and the DelayedSettlementModel with the default settlement rules for cash accounts.

```
C#

// For cash accounts:
security.SetSettlementModel(new DelayedSettlementModel(Equity.DefaultSettlementDays, Equity.DefaultSettlementTime));

// For margin accounts:
security.SetSettlementModel(new ImmediateSettlementModel());
```

Margin Interest Rate

The `WolverineBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `WolverineBrokerageModel` is `Market.USA` .

Account Currency

The `WolverineBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Supported Models

Oanda

Introduction

This page explains the `OandaBrokerageModel` , including the asset classes it supports, its default security-level models , and its default markets.

```
SetBrokerageModel(BrokerageName.OandaBrokerage, AccountType.Margin);
```

For more information about this model, see the class reference and implementation .

Asset Classes

The `OANDABrokerageModel` supports trading Forex and CFDs .

Orders

The `OandaBrokerageModel` supports several order types, the `TimeInForce` order property, and order updates.

Order Types

The following table describes the available order types for each asset class that the `OANDABrokerageModel` supports:

Order Type	Forex	CFD
Market	✓	✓
Limit	✓	✓
Stop market	✓	✓
Stop limit	✓	✓

Time In Force

The `OANDABrokerageModel` the `GoodTilCanceled` TimeInForce .

```
DefaultOrderProperties.TimeInForce = TimeInForce.GoodTilCanceled;
LimitOrder(_symbol, quantity, limitPrice);
```

Updates

The `OANDABrokerageModel` supports order updates .

Fills

The `OandaBrokerageModel` uses the ImmediateFillModel .

Slippage

The `OandaBrokerageModel` uses the NullSlippageModel .

Fees

The `OandaBrokerageModel` uses the ConstantFeeModel with zero fees. OANDA offers "Spread" and "Core + Commission" pricing models. Our data is the spread dataset, so we model the spread pricing. To estimate OANDA Core+Commission data, use a custom fee model and a custom fill model .

```
C#
security.SetFeeModel(new ConstantFeeModel(0.0m));
```

Buying Power

The `OandaBrokerageModel` uses the `SecurityMarginModel` and allows up to 50x leverage.

Settlement

The `OandaBrokerageModel` uses the ImmediateSettlementModel for Forex trades and the AccountCurrencyImmediateSettlementModel for CFD trades.

Margin Interest Rate

The `OandaBrokerageModel` uses the NullMarginInterestRateModel .

Default Markets

The default market of the `OandaBrokerageModel` is `Market.Oanda` .

Account Currency

The `OandaBrokerageModel` doesn't set a default currency. To change the algorithm's currency from USD to a different currency, see Set Account Currency .

Reality Modeling

Brokerage Message Handler

Introduction

When your brokerage sends a message, you receive this information in the algorithm and can take any actions. When you place an order through your brokerage platform instead of placing it through LEAN, you can decide whether the transaction handler should process the order. By default, the transaction handler only process orders that you place through LEAN. Custom brokerage message handlers enable you to instruct the transaction handler to process orders that you create directly through your brokerage's platform.

Set Models

To set a brokerage message handler, in the `Initialize` method, call the `SetBrokerageMessageHandler` method.

```C#
public override void Initialize()
{
    // Set a custom brokerage message handler for the algorithm in Initialize method
    // It handles different type of returned message from the broker, helping you filter or abstract for the ones you
care about
    SetBrokerageMessageHandler(new MyBrokerageMessageHandler(this));
}
```

Default Behavior

The default brokerage message handler is the `DefaultBrokerageMessageHandler` . The following table describes how the `DefaultBrokerageMessageHandler` processes brokerage messages:

Brokerage Message Type	Action
`BrokerageMessageType. Information`	Sends a debug message for the algorithm.
`BrokerageMessageType. Warning`	Sends an error message for the algorithm.
`BrokerageMessageType. Error`	Sets the algorithm runtime error and stops it.
`BrokerageMessageType. Disconnect`	Stops the algorithm after 15 minutes if the market is open. Otherwise, it stops five minutes after market open.
`BrokerageMessageType. Reconnect`	Cancels the disconnection process.

The default brokerage message handler rejects orders you create through the brokerage. An example of this is when you place an order using the brokerage website or a third-party software.

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`algorithm`	`IAlgorithm`	The running algorithm.	
`initialDelay`	`TimeSpan?`	The amount of time LEAN will wait after a brokerage disconnection message for a reconnection message. If the reconnection message doesn't arrive before the time limit, LEAN stops running. If you don't provide a value, it uses `TimeSpan.FromMinutes(15)`.	`null`
`openThreshold`	`TimeSpan?`	Defines how long before market open to re-check for brokerage reconnect message. If you don't provide a value, it uses `TimeSpan.FromMinutes(5)`.	`null`

For more information about this model, see the class reference and implementation .

Model Structure

Brokerage message handlers extend the `DefaultBrokerageMessageHandler` class. Extensions of the `DefaultBrokerageMessageHandler` class should define the `HandleMessage` and `HandleOrder` methods.

The `HandleMessage` method processes the brokerage message event. It triggers any actions in the algorithm or notifications system required.

The `HandleOrder` method defines whether the transaction handler should process a new order you placed directly through the brokerage's website or third-party software.

```C#
public class CustomBrokerageMessageHandlerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the brokerage message handler
        SetBrokerageMessageHandler(new MyBrokerageMessageHandler(this));
    }
}

// Define the custom brokerage message handler
public class MyBrokerageMessageHandler : DefaultBrokerageMessageHandler
{
    private readonly IAlgorithm _algorithm;
    public MyBrokerageMessageHandler(IAlgorithm algorithm)
        : base(algorithm)
    {
        _algorithm = algorithm;
    }

    public void HandleMessage(BrokerageMessageEvent message)
    {
        _algorithm.Debug($"{_algorithm.Time.ToStringInvariant("o")} Event: {message.Message}");
    }

    public bool HandleOrder(NewBrokerageOrderNotificationEventArgs eventArgs)
    {
        return false;
    }
}
```

The `BrokerageMessageEvent` class has the following properties:

The `NewBrokerageOrderNotificationEventArgs` class has the following properties:

Brokerage Support

Most QuantConnect brokerage integrations don't support brokerage-side orders. If you create an order directly through your brokerage instead of through LEAN, your algorithm won't process the order because the return value of the `HandleOrder` method is ignored.

Terminal Link is the exception that can support brokerage-side orders. This algorithm demonstrates how to implement a custom brokerage handler that accepts orders with a target `TerminalLinkOrderProperties.CustomNotes1` value.

Examples

The following examples demonstrate common practices for implementing a custom brokerage message handler.

Example 1: Notification

The following algorithm buys and holds SPY. It implemented a custom brokerage message handler to send notifications to users through email and SMS in cases of disconnection, reconnections, and outside trades.

C#

```
public class CustomBrokerageMessageHandlerAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // To simulate the connection to IB brokerage.
        SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Margin);
        // Set the brokerage message handler to our custom model.
        SetBrokerageMessageHandler(new CustomBrokerageMessageHandler(this));

        // Request SPY data for trading.
        _spy = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Buy and hold SPY as a strategy.
        if (!Portfolio.Invested)
        {
            SetHoldings(_spy, 1m);
        }
    }
}

// Define the custom brokerage message handler.
public class CustomBrokerageMessageHandler : DefaultBrokerageMessageHandler
{
    private readonly IAlgorithm _algorithm;
    public CustomBrokerageMessageHandler(IAlgorithm algorithm)
        : base(algorithm)
    {
        _algorithm = algorithm;
    }

    public void HandleMessage(BrokerageMessageEvent message)
    {
        // Notify the user by SMS on disconnection of the algorithm instance from the brokerage.
        if (message.Type == BrokerageMessageType.Disconnect)
        {
            _algorithm.Notify.Sms(
                phoneNumber: "<YOUR_PHONE_NUMBER>",
                message: "Your QC Algorithm instance 'CustomBrokerageMessageHandlerAlgorithm' was disconnected from
the IB brokerage."
            );
        }
        // Notify the user by SMS on reconnection of the algorithm instance to the brokerage after disconnection.
        else if (message.Type == BrokerageMessageType.Reconnect)
        {
            _algorithm.Notify.Sms(
                phoneNumber: "<YOUR_PHONE_NUMBER>",
                message: "Your QC Algorithm instance 'CustomBrokerageMessageHandlerAlgorithm' was reconnected to the
IB brokerage."
            );
        }
    }

    public bool HandleOrder(NewBrokerageOrderNotificationEventArgs eventArgs)
    {
        // Notify the user by email on receiving an order from outside the algorithm.
        _algorithm.Notify.Email(
            address: "<YOUR_EMAIL_ADDRESS@example.com>",
            subject: "Outside Order",
            message: "Your QC Algorithm instance 'CustomBrokerageMessageHandlerAlgorithm' detected an outside order
from the IB brokerage; it has been processed to the algorithm."
        );
        // Process a new order placed through the brokerage's website or third-party software to handle it in the
algorithm instance.
        return true;
    }
}
```

Other Examples

For more examples, see the following algorithms:

Reality Modeling

Buying Power

Introduction

Buying power models (also known as margin models) control how much buying power or leverage your portfolio has to make trades. When you place an order, LEAN uses the buying power model to determine whether the order should be submitted so you avoid placing orders that would be rejected by the brokerage. Buying power calculations can be very complex and depend on many factors, including the brokerage or even the time of day. For example, the `PatternDayTradingMarginModel` lets you have 4x leverage during regular trading hours and 2x leverage during pre-market and post-market trading hours.

What is Buying Power?

Buying power is the total amount of money you can spend in your brokerage account. It depends on the security type and account type. On one hand, Option and Future contracts are leveraged securities with specific buying power rules. On the other hand, the buying power of cash accounts is just the cash in the account while the buying power of margin accounts is leveraged by the brokerage credit.

What is Margin?

Margin is a credit loan from your brokerage you receive after you deposit collateral into your margin account. You need margin to place short-biased trades and you can use margin to increase your buying power, but you incur interest fees. Margin is the dollar value of the loan that the brokerage gives you. A margin requirement of 25% means that to purchase 10,000 worth of securities, you need at least 2,500 worth of collateral in your brokerage account to open the trade and you can borrow the rest on margin. Maintenance margin is the minimum equity (equity = total portfolio value - borrowed funds) you must have in your brokerage account to stay in your positions. If the value of your portfolio falls below the maintenance margin, you receive a margin call . If you receive a margin call, you either need to add more capital to your brokerage account or the brokerage will liquidate some of your holdings to reduce your exposure and their risk.

Some securities have special margin rules. Derivatives are leveraged assets with a floating margin requirement. In particular, long Options have zero maintenance margin requirement and their initial margin requirement is only the premium that you pay upfront.

What is Leverage?

Leverage is using borrowed money to increase your buying power. Leverage has an inverse relationship with your margin requirement and maintenance margin. If you have a margin requirement of 50%, you can use up to 1 / 50% = 2 leverage. Trading with leverage can be risky. It can boost your returns on profitable trades but can make your losing trades more expensive. If you have 10,000 in your brokerage margin account and purchase 20,000 worth of securities, you are trading with 2x leverage. If the value of the securities in your portfolio drops by 50% when you have a 2x leverage position, you lose all of your equity.

What Are Position Groups?

A position group is the combination of holdings. It has lower margin requirement and maintenance margin than the sum of each position of the group. If you have a margin requirement of 29,150 to purchase an in-the-money call Option contract, and a margin requirement of 101,499 to sell an out-of-the money call Option contract, the total margin requirement is $130,649. However, these positions compose a bull call spread with a margin requirement of $0.

Set Models

The brokerage model of your algorithm automatically sets the buying power model for each security, but you can override it. To manually set the buying power model of a security, call the `SetBuyingPowerModel` method on the `Security` object.

```
C#
public override void Initialize()
{
    var security = AddEquity("SPY");
    // Use 3x leverage on the selected security, which mimic the actual buying power of your broker
    security.SetBuyingPowerModel(new SecurityMarginModel(3m));
}
```

You can also set the buying power model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

```
C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetBuyingPowerModel(new SecurityMarginModel(3m));
    }
}
```

You cannot change the position group buying power models.

Supported Models

The following buying power models are available:

- BuyingPowerModel
- CashBuyingPowerModel
- ConstantBuyingPowerModel
- CryptoFutureMarginModel
- NullBuyingPowerModel
- FutureMarginModel
- FuturesOptionsMarginModel
- SecurityMarginModel
- OptionMarginModel
- PatternDayTradingMarginModel

The following position group buying power models are available:

- SecurityPositionGroupBuyingPowerModel
- OptionStrategyPositionGroupBuyingPowerModel

Default Behavior

The brokerage model of your algorithm automatically sets the buying power model of each security. The default brokerage

model is the `DefaultBrokerageModel`, which sets the buying power model based on the asset class of the security. The following table shows the default buying power model of each asset class:

Asset Class	Model
Equity Options	`OptionMarginModel`
Futures	`FutureMarginModel`
Future Options	`FuturesOptionsMarginModel`
Index Options	`OptionMarginModel`
Crypto	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
CryptoFuture	`CryptoFutureMarginModel`
Forex	`CashBuyingPowerModel` for cash accounts or `SecurityMarginModel` for margin accounts
Other	`SecurityMarginModel`

Model Structure

Buying power models should extend the `BuyingPowerModel` class. Extensions of the `BuyingPowerModel` class should implement the following methods:

```C#
public class CustomBuyingPowerModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var security = AddEquity("SPY");
        // Set the custom buying power model of the selected security to mimic its actual buying power in your used
broker
        security.SetBuyingPowerModel(new MyBuyingPowerModel());
    }
}

// Define the custom buying power model
class MyBuyingPowerModel : BuyingPowerModel
{
    public MyBuyingPowerModel(
        decimal leverage = 2m,
        decimal requiredFreeBuyingPowerPercent = 0m)
        : base(leverage, requiredFreeBuyingPowerPercent)
    {
    }

    public override decimal GetLeverage(Security security)
    {
       return base.GetLeverage(security);
    }

    public override void SetLeverage(Security security, decimal leverage)
    {
        base.SetLeverage(security, leverage);
    }

    public override InitialMargin GetInitialMarginRequiredForOrder(
        InitialMarginRequiredForOrderParameters parameters)
    {
        return base.GetInitialMarginRequiredForOrder(parameters);
    }

    public override MaintenanceMargin GetMaintenanceMargin(
        MaintenanceMarginParameters parameters)
```

```
        MaintenanceMarginParameters parameters)
    {
        return base.GetMaintenanceMargin(parameters);
    }

    protected override decimal GetMarginRemaining(
        SecurityPortfolioManager portfolio,
        Security security,
        OrderDirection direction)
    {
        return base.GetMarginRemaining(portfolio, security, direction);
    }

    public override InitialMargin GetInitialMarginRequirement(
        InitialMarginParameters parameters)
    {
        return base.GetInitialMarginRequirement(parameters);
    }

    public override HasSufficientBuyingPowerForOrderResult
HasSufficientBuyingPowerForOrder(HasSufficientBuyingPowerForOrderParameters parameters)
    {
        return base.HasSufficientBuyingPowerForOrder(parameters);
    }

    public override GetMaximumOrderQuantityResult
GetMaximumOrderQuantityForDeltaBuyingPower(GetMaximumOrderQuantityForDeltaBuyingPowerParameters parameters)
    {
        return base.GetMaximumOrderQuantityForDeltaBuyingPower(parameters);
    }

    public override GetMaximumOrderQuantityResult
GetMaximumOrderQuantityForTargetBuyingPower(GetMaximumOrderQuantityForTargetBuyingPowerParameters parameters)
    {
        return base.GetMaximumOrderQuantityForTargetBuyingPower(parameters);
    }

    public override ReservedBuyingPowerForPosition GetReservedBuyingPowerForPosition(
        ReservedBuyingPowerForPositionParameters parameters)
    {
        return base.GetReservedBuyingPowerForPosition(parameters);
    }

    public override BuyingPower GetBuyingPower(BuyingPowerParameters parameters)
    {
        return base.GetBuyingPower(parameters);
    }
}
```

Disable Buying Power Models

You can disable order margin checks and opt to let your brokerage decide to accept or reject the trades. This is helpful in live trading if you have a more permissive brokerage margin allowance that what LEAN models. The default position group buying power models are helpful for Option trading strategies. However, it can be counterproductive if it's not a supported Option strategy . To disable the validations of the default position group buying power model, use the `NullSecurityPositionGroupModel` . To set the `NullSecurityPositionGroupModel` for the portfolio, during initialization , call the `SetPositions` method with the `SecurityPositionGroupModel. Null` argument.

```
C#
Portfolio.SetPositions(SecurityPositionGroupModel.Null);
```

To disable the validations of the default buying power model , use the `NullBuyingPowerModel` . To set the `NullBuyingPowerModel` for a security subscription, call the `SetBuyingPowerModel` method with the `BuyingPowerModel. Null` argument.

```
C#
public override void Initialize()
{
    var equity = AddEquity("SPY");
    // To disable any buying power of the selected security
    equity.SetBuyingPowerModel(BuyingPowerModel.Null);
    // Alias:
    // equity.SetMarginModel(SecurityMarginModel.Null);
}
```

You can also set the `NullBuyingPowerModel` in a security initializer . If your algorithm has a universe, use the security initializer technique. To set the buying power of securities in the security initializer, set the brokerage model , set the security initializer , and then create security subscriptions.

```
C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite the security buying power
        security.SetBuyingPowerModel(BuyingPowerModel.Null);
    }
}
```

Set Asset Leverage

The buying power model sets the leverage for each security in your algorithm, but you can override its leverage settings after the buying power model is set.

To set the leverage when you create a security subscription, pass in a `leverage` argument.

```
C#
public override void Initialize()
{
 // Set the leverage to 3x manually subjected to specific need
 AddEquity("SPY", leverage: 3);
}
```

You can also set the asset leverage in a security initializer. In order to set the leverage of securities in the security initializer, call `AddSecurityInitializer` before you create security subscriptions and after you call `SetBrokerageModel` . If you pass in a `leverage` argument when you create the security subscription, the `leverage` argument takes precedence over the `SetLeverage` call in the security initializer.

```C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite the security leverage
        security.SetLeverage(3);
    }
}
```

To set the leverage for all securities in a universe, set the `UniverseSettings.Leverage` property.

```C#
public override void Initialize()
{
 // Set the leverage to 3x to all securities, it should only be used for a very narrow spectrum of security universe
with the same leverage
 // E.g. US Equities universe composed of only primary stocks in NYSE exchange
 UniverseSettings.Leverage = 3;
}
```

In live trading, LEAN doesn't ignore the leverage you set. However, if you set a different leverage from what your brokerage provides, it creates a mismatch between the buying power in your algorithm and the buying power the brokerage gives you. In this case, orders can pass the validations in LEAN but your brokerage may reject them.

PDT Rule

If all of the following statements are true, you are classified as a pattern day trader:

- You reside in the United States.
- You trade in a margin account.
- You execute 4+ intraday US Equity trades within 5 business days.
- Your intraday US Equity trades represent more than 6% of your total trades.

Pattern day traders must maintain a minimum equity of $25,000 in their margin account to continue trading. For more information about pattern day trading, see Am I a Pattern Day Trader? on the FINRA website.

The `PatternDayTradingMarginModel` doesn't enforce minimum equity rules and doesn't limit your trades, but it adjusts your available leverage based on the market state. During regular market hours, you can use up to 4x leverage. During extended market hours, you can use up to 2x leverage.

```C#
security.MarginModel = new PatternDayTradingMarginModel();
```

Get Initial Margin Requirements

The following sections explain how to check if you have enough margin remaining to cover the initial margin requirements of various order types.

Check Requirements of Regular Orders

Follow these steps to check if you have enough margin remaining to cover the initial margin requirements of an order:

1. Create an `InitialMarginParameters` object with the security and quantity you want to trade.

```
C#

public override void OnData(Slice slice)
{
    var security = Securities["SPY"];
    var quantity = 100m;
    var parameter = new InitialMarginParameters(security, quantity);
```

2. Call the `GetInitialMarginRequirement` method of the security's buying power model with the `InitialMarginParameters` .

```
C#

    var initialMargin = security.BuyingPowerModel.GetInitialMarginRequirement(parameter);
```

   The `GetInitialMarginRequirement` method returns an `InitialMargin` object, which have the following properties:

3. Compare the margin you have remaining against the initial margin requirement of the order.

```
C#

    if (Portfolio.MarginRemaining >= initialMargin.Value)
    {
        MarketOrder(security.Symbol, quantity);
    }
    else
    {
        Debug("You don't have sufficient margin for this order.");
    }
}
```

Check Requirements of Option Strategy Orders

Follow these steps to check if you have enough margin remaining to cover the initial margin requirements of an Option strategy :

1. Create an `OptionStrategy` object with the strategy you want to trade and its buying power model.

   For example, create a Bull Put Spread strategy.

```
C#

private Symbol _symbol;

public override void Initialize()
{
    // Subscribe to option data and cache the canonical symbol to obtain the option data
    _symbol = AddOption("SPY").Symbol;
}

public override void OnData(Slice slice)
{
    // Trade on updated option chain data
    if (!slice.OptionChains.TryGetValue(_symbol, out var chain))
    {
        return;
    }

    var itmStrike = chain.Max(x => x.Strike);
    var otmStrike = chain.Min(x => x.Strike);
    var expiry = chain.Min(x => x.Expiry);

    var optionStrategy = OptionStrategies.BullPutSpread(_symbol, itmStrike, otmStrike, expiry);
```

2. Create an `OptionStrategyPositionGroupBuyingPowerModel` object of the strategy.

```
C#
var buyingPowerModel = new OptionStrategyPositionGroupBuyingPowerModel(optionStrategy);
```

3. Create a list of `Position` objects from the strategy legs.

```
C#
var positions = optionStrategy.OptionLegs.Select(leg =>
{
    var symbol = QuantConnect.Symbol.CreateOption(_symbol.Underlying, _symbol.ID.Market,
_symbol.ID.OptionStyle, leg.Right, leg.Strike, leg.Expiration);
    return new Position(symbol, leg.Quantity, 1);
});
```

4. Create a `PositionGroupInitialMarginParameters` objects with the portfolio and the position group.

```
C#
var positionGroup = new PositionGroup(buyingPowerModel, 1, positions.ToArray());
var parameters = new PositionGroupInitialMarginParameters(Portfolio, positionGroup);
```

5. Call the `GetInitialMarginRequirement` method of the strategy's buying power model with the `PositionGroupInitialMarginParameters`.

```
C#
var initialMargin = buyingPowerModel.GetInitialMarginRequirement(parameters);
```

   The `GetInitialMarginRequirement` method returns an `InitialMargin` object, which have the following properties:

6. Compare the margin you have remaining against the initial margin requirement of the order.

   In this case, the `initialMargin.Value` is the initial margin requirement for a trade size of 1. For different trade sizes, multiply the `initialMargin.Value` by the quantity.

```
C#
var strategyQuantity = 2;
if (Portfolio.MarginRemaining >= strategyQuantity * initialMargin.Value)
{
    Buy(optionStrategy, quantity);
}
else
{
    Debug("You don't have sufficient margin for this order.");
}
}
```

Examples

The following examples demonstrate some common practices for implementing a custom buying power model.

Example 1: Always Sufficient Buying Power

The following algorithm trades protective call strategy. Sometimes, the brokerage's margin requirement differs from the algorithm's default. To avoid errors on order submission at the algorithm level, we can use the `SecurityPositionGroupModel.Null` and `NullBuyingPowerModel` to disable buying power limitation so the order is sent directly to the broker.

```C#
using QuantConnect.Securities.Positions;

public class BuyingPowerModelAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =ggt;
        {
            // Do not allow buying power for options; only a hedging strategy with 0 margin is allowed.
            security.SetBuyingPowerModel(new NullBuyingPowerModel());
        });

        // Disable the validations of the default position group buying power model
        // that evaluates the buying power of multi-leg strategies
        Portfolio.SetPositions(SecurityPositionGroupModel.Null);

        // Request SPY data for trading. Set the data normalization mode to raw to allow for a fair comparison in
strike price.
        _spy = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;

        // Set a scheduled event to rebalance the protective put strategy.
        Schedule.On(
            DateRules.WeekStart(_spy),
            TimeRules.AfterMarketOpen(_spy, 0),
            Rebalance
        );
    }

    private void Rebalance()
    {
        // Select the weekend expiring ATM put for the protective put strategy.
        var atmPutContract = OptionChain(_spy)
            .Where(x => x.Right == OptionRight.Put && x.Expiry < Time.AddDays(6))
            .OrderByDescending(x => x.Expiry)
            .ThenBy(x => Math.Abs(x.Strike - x.UnderlyingLastPrice))
            .First();
        // Request the ATM put data for trading.
        var atmPut = AddOptionContract(atmPutContract).Symbol;

        if (Portfolio[_spy].Invested)
        {
            // If SPY is not assigned, we only need to buy the put.
            MarketOrder(atmPut, 1, tag: "Protective Put");
            return;
        }

        // Order the protective put strategy by combo order.
        ComboMarketOrder(
            new List<Leg> () {
                Leg.Create(_spy, 100),
                Leg.Create(atmPut, 1)
            },
            1,
            tag: "Protective Put"
        );
    }
}
```

Example 2: Default Model Wrapper

The following algorithm defines a subclass of the default `BuyingPowerModel` and overrides its built-in members so you can easily customize the parts you need.

```C#
public class CustomBuyingPowerModelAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
```

```
        SetStartDate(2024, 7, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var security = AddEquity("SPY", Resolution.Daily);
        security.SetBuyingPowerModel(new MyBuyingPowerModel());
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }
}

class MyBuyingPowerModel : BuyingPowerModel
{
    public MyBuyingPowerModel(
        decimal leverage = 2m,
        decimal requiredFreeBuyingPowerPercent = 0m)
        : base(leverage, requiredFreeBuyingPowerPercent)
    {
    }

    public override decimal GetLeverage(Security security)
    {
    return base.GetLeverage(security);
    }

    public override void SetLeverage(Security security, decimal leverage)
    {
        base.SetLeverage(security, leverage);
    }

    public override InitialMargin GetInitialMarginRequiredForOrder(
        InitialMarginRequiredForOrderParameters parameters)
    {
        return base.GetInitialMarginRequiredForOrder(parameters);
    }

    public override MaintenanceMargin GetMaintenanceMargin(
        MaintenanceMarginParameters parameters)
    {
        return base.GetMaintenanceMargin(parameters);
    }

    protected override decimal GetMarginRemaining(
        SecurityPortfolioManager portfolio,
        Security security,
        OrderDirection direction)
    {
        return base.GetMarginRemaining(portfolio, security, direction);
    }

    public override InitialMargin GetInitialMarginRequirement(
        InitialMarginParameters parameters)
    {
        return base.GetInitialMarginRequirement(parameters);
    }

    public override HasSufficientBuyingPowerForOrderResult
HasSufficientBuyingPowerForOrder(HasSufficientBuyingPowerForOrderParameters parameters)
    {
        return base.HasSufficientBuyingPowerForOrder(parameters);
    }

    public override GetMaximumOrderQuantityResult
GetMaximumOrderQuantityForDeltaBuyingPower(GetMaximumOrderQuantityForDeltaBuyingPowerParameters parameters)
    {
        return base.GetMaximumOrderQuantityForDeltaBuyingPower(parameters);
    }

    public override GetMaximumOrderQuantityResult
GetMaximumOrderQuantityForTargetBuyingPower(GetMaximumOrderQuantityForTargetBuyingPowerParameters parameters)
    {
        return base.GetMaximumOrderQuantityForTargetBuyingPower(parameters);
    }

    public override ReservedBuyingPowerForPosition GetReservedBuyingPowerForPosition(
        ReservedBuyingPowerForPositionParameters parameters)
```

```
        ReservedBuyingPowerForPositionParameters parameters)
    {
        return base.GetReservedBuyingPowerForPosition(parameters);
    }

    public override BuyingPower GetBuyingPower(BuyingPowerParameters parameters)
    {
        return base.GetBuyingPower(parameters);
    }
}
```

Reality Modeling

Settlement

Settlement

Key Concepts

Introduction

After you trade an asset, the brokerage needs to settle the funds in your account. The most common type of settlement is immediate, where the funds are immediately available for trading after the transaction. In some cases, you may have delayed settlement, where you sell an asset and need to wait a few days to spend the cash you receive from the sale. A settlement model simulates these settlement rules.

Set Models

The brokerage model of your algorithm automatically sets the settlement model for each security, but you can override it. To manually set the settlement model of a security, call the `SetSettlementModel` method on the `Security` object.

C#

```
public override void Initialize()
{
    var security = AddEquity("SPY");
    // Set a delayed settlement model that settles 7 days after the trade at 8 AM
    // This can better mimic actual settlement of some brokerage, providing more realistic fund and margin available
    security.SetSettlementModel(new DelayedSettlementModel(7, TimeSpan.FromHours(8)));
}
```

You can also set the settlement model in a security initializer . If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

C#

```
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetSettlementModel(new DelayedSettlementModel(7, TimeSpan.FromHours(8)));
    }
}
```

To view all the pre-built settlement models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the settlement model for each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the settlement model based on the security type and your account type. The following table shows how it sets the settlement models:

Security Type	Account Type	Settlement Model
Equity	Cash	DelayedSettlementModel with the default settlement rules
Option	Cash	DelayedSettlementModel with the default settlement rules
Future	Any	FutureSettlementModel

For all other cases, the `DefaultBrokerageModel` uses the ImmediateSettlementModel .

The default delayed settlement rule for US Equity trades is T+2 at 8 AM Eastern Time (ET). For example, if you sell on Monday, the trade settles on Wednesday at 8 AM. The default delayed settlement rule for Future and Option contracts is T+1 at 8 AM.

Model Structure

Settlement models must extend the `ISettlementModel` interface. Extensions of the `ISettlementModel` interface must implement the `Scan` and `ApplyFunds` methods. The `Scan` method is automatically called at the top of each hour and it receives a `ScanSettlementModelParameters` object. The `ApplyFunds` method receives an `ApplyFundsSettlementModelParameters` object and applies the settlement rules. The `ApplyFunds` method is also automatically called, but its frequency depends on the security type. The `ApplyFunds` method is automatically called when you fill an order for the following security types:

- Equity
- Equity Options
- Crypto
- Forex
- Future Options
- Index Options

The `ApplyFunds` method is automatically called when you close a position for the following security types:

- Futures
- Crypto Futures
- CFD

```C#
public class CustomSettlementModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var security = AddEquity("SPY");
        // Set the custom settlement model of the selected security to reflect actual scenario for more realistic
margin available
        security.SetSettlementModel(new MySettlementModel());
    }
}

// Define the custom settlement model outside of the algorithm
public class MySettlementModel : ISettlementModel
{
    public void ApplyFunds(ApplyFundsSettlementModelParameters applyFundsParameters)
    {
        var currency = applyFundsParameters.CashAmount.Currency;
        var amount = applyFundsParameters.CashAmount.Amount;
        applyFundsParameters.Portfolio.CashBook[currency].AddAmount(amount);
    }

    public void Scan(ScanSettlementModelParameters settlementParameters)
    {
    }

    public CashAmount GetUnsettledCash()
    {
        return new CashAmount(0, "USD");
    }
}
```

`ApplyFundsSettlementModelParameters` objects have the following properties:

`ScanSettlementModelParameters` objects have the following properties:

You likely don't need to create a custom settlement model because the supported models already implement immediate and delayed settlement rules.

Examples

The following examples demonstrate some common practices for implementing the settlement model.

Example 1: 2-day Settlement

The following algorithm simulates Interactive Brokers cash account. According to IB's website, cash positions will be settled in 48 hours. Thus, we can implement `DelayedSettlementModel` to mimic that. We hold the intra-day position of SPY to implement the settlement logic.

C#

```
public class SettlementModelAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Simulate a cash account of IB.
        SetBrokerageModel(BrokerageName.InteractiveBrokersBrokerage, AccountType.Cash);
        // We need to set the settlement model in the security initializer.
        SetSecurityInitializer(new CustomSecurityInitializer(BrokerageModel, SecuritySeeder.Null));

        // Request SPY data for trading.
        _spy = AddEquity("SPY").Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Trade based on updated data.
        if (slice.QuoteBars.TryGetValue(_spy, out var bar) && !Portfolio.Invested)
        {
            // Order based on the current available cash.
            var quantity = Math.Floor((Portfolio.Cash - Portfolio.UnsettledCash) / bar.Ask.Close);
            if (quantity > 0)
            {
                MarketOrder(_spy, quantity);
            }
        }

        // Exit position before market close; we only hold the intraday position.
        if (slice.Time.Hour == 15 && slice.Time.Minute == 45)
        {
            Liquidate();
        }
    }
}

class CustomSecurityInitializer : BrokerageModelSecurityInitializer
{
    public CustomSecurityInitializer(IBrokerageModel brokerageModel, ISecuritySeeder securitySeeder)
        : base(brokerageModel, securitySeeder)
    {

    }
    public override void Initialize(Security security)
    {
        base.Initialize(security);
        // IB settles cash in 48 hours.
        security.SetSettlementModel(new DelayedSettlementModel(2, new TimeSpan(0, 0, 0)));
    }
}
```

Example 2: No Unsettled Cash

The following algorithm implements a custom settlement model that states there is always $0 of unsettled cash.

C#

```
public class CustomSettlementModelAlgorithm : QCAlgorithm
{
    private bool _traded;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var security = AddEquity("SPY");
        security.SetSettlementModel(new MySettlementModel());

        Schedule.On(
            DateRules.EveryDay("SPY"),
            TimeRules.Every(TimeSpan.FromMinutes(30)),
            plotCash
        );

        _traded = false;
    }

    private void plotCash()
    {
        Plot("Settled Cash", "USD", Portfolio.CashBook["USD"].Amount);
        Plot("Unsettled Cash", "USD", Portfolio.UnsettledCashBook["USD"].Amount);
    }

    public override void OnData(Slice data)
    {
        if (_traded)
            return;

        MarketOrder("SPY", 1);
        MarketOrder("SPY", -1);
        _traded = true;
    }
}

public class MySettlementModel : ISettlementModel
{
    public void ApplyFunds(ApplyFundsSettlementModelParameters applyFundsParameters)
    {
        var currency = applyFundsParameters.CashAmount.Currency;
        var amount = applyFundsParameters.CashAmount.Amount;
        applyFundsParameters.Portfolio.CashBook[currency].AddAmount(amount);
    }

    public void Scan(ScanSettlementModelParameters settlementParameters)
    {
    }

    public CashAmount GetUnsettledCash()
    {
        return new CashAmount(0, "USD");
    }
}
```

Settlement

Supported Models

Introduction

This page describes all of the pre-built settlement models in LEAN. For more brokerage-specific settlement models, see the brokerage model documentation . If none of these models perform exactly how you want, create a custom settlement model .

Immediate Model

The `ImmediateSettlementModel` immediately adds or removes the cash from your portfolio when your transactions fill.

```
C#
security.SetSettlementModel(new ImmediateSettlementModel());
```

For more information about this model, see the class reference and implementation .

Delayed Model

The `DelayedSettlementModel` immediately removes the cash from your portfolio when your buy orders fill. When your sell orders fill, it adds the cash to your unsettled cash book . When the settlement period ends, the unsettled cash is added to your portfolio.

```
C#
security.SetSettlementModel(new DelayedSettlementModel(7, TimeSpan.FromHours(8)));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`numberOfDays`	`int`	The number of days required for settlement	
`timeOfDay`	`TimeSpan`	The time of day used for settlement	

For more information about this model, see the class reference and implementation .

Account Currency Immediate Model

The `AccountCurrencyImmediateSettlementModel` applies cash settlement immediately and automatically converts the settlement cash into the account currency.

```
C#
security.SetSettlementModel(new AccountCurrencyImmediateSettlementModel());
```

For more information about this model, see the class reference and implementation .

Future Model

The `FutureSettlementModel` settles the daily profit and loss at the start of each day.

```C#
security.SetSettlementModel(new FutureSettlementModel());
```

For more information about this model, see the class reference and implementation .

Reality Modeling

Options Models

Options Models

Pricing

Introduction

Option price models compute the theoretical price of Option contracts, their implied volatility (IV), and their Greek values. Theoretical prices can help you detect undervalued and overvalued contracts, IV can provide you insight into the upcoming volatility of the underlying security, and Greek values can help you hedge your portfolio.

Data Discrepancies

There are several ways for you to get the Greeks and IV values, but you may notice some discrepancies between them.

Greeks in Universe Selection

The Greeks and IV values in the universe filter function are the daily, pre-calculated values based on the end of the previous trading day. You can't customize the Greeks and IV values that the filter function receives.

Greeks in Chain Requests

The Greeks and IV values in the `OptionUniverse` objects that you get from calling the `OptionChain` method are the daily, pre-calculated values based on the end of the previous trading day. You can't customize the Greeks and IV values that you get from this method.

Greeks in Data Events

The Greeks and IV values in the Slice that you get in the `OnData` method are the values from the Option price model. To customize the Greeks and IV values in the `Slice` , set a different price model.

Set Models

To set the pricing model of an Option, set its `PriceModel` property.

If you have access to the `Option` object when you subscribe to the Option universe or contract, you can set the price model immediately after you create the subscription.

```C#
public override Initialize()
{
    UniverseSettings.Asynchronous = true;
    var option = AddOption("SPY");
    // SPY options are American Options, in which IV and greeks more accurately calculated using Binomial model
    option.PriceModel = OptionPriceModels.BinomialCoxRossRubinstein();
}
```

Otherwise, set the price model in a security initializer .

```C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite the price model
        if (security.Type == SecurityType.Option) // Option type
        {
            (security as Option).PriceModel = OptionPriceModels.BinomialCoxRossRubinstein();
        }
    }
}
```

Default Behavior

The default Option pricing model is the `BinomialCoxRossRubinstein` for American Options or `BlackScholes` for European Options.

Disable Pricing

To turn off the Option price model, use the `CurrentPriceOptionPriceModel` . This model sets the Greeks to 0, sets the IV to 0, and sets the theoretical price to the current price.

```C#
option.PriceModel = new CurrentPriceOptionPriceModel();
```

Supported Models

LEAN supports the following Option price models.

Model	American Style	European Style
`AdditiveEquiprobabilities`	✓	✓
`BaroneAdesiWhaley`	✓	
`BinomialCoxRossRubinstein`	✓	✓
`BinomialJarrowRudd`	✓	✓
`BinomialJoshi`	✓	✓
`BinomialLeisenReimer`	✓	✓
`BinomialTian`	✓	✓
`BinomialTrigeorgis`	✓	✓
`BjerksundStensland`	✓	
`BlackScholes`		✓
`CrankNicolsonFD`	✓	✓
`Integral`		✓

If you set the price model of an Option to a model with an incompatible style, LEAN throws an exception.

What are Greeks?

Option Greeks measure the exposure of Option price or Option delta to the movement of different factors such as the underlying price, time, and volatility. The Greeks are a function of implied volatility. For more information about them, see The Greek Letters .

LEAN also provides indicator implementations of Option Greeks. It provides higher flexibility on Option price model selection, volatility modeling , and allows IV smoothing through call-put pair. For details, see Option Indicators .

What Is Implied Volatility?

Implied volatility is the forecasted future volatility of a security. The Option price model uses the realized volatility to calculate the implied volatility. By default, it uses the formula from Brenner and Subrahmanyam (1988) as the initial guess for implied volatility.

$$\frac{P}{S} \sqrt{\frac{2\pi}{T}}$$

where P is the Option contract price, S is the underlying price, and T is the time until Option expiration.

If the volatility model of the underlying security is ready , the price model uses its value as the initial guess for implied volatility and as an input to calculate the theoretical contract prices.

LEAN also provides an indicator implementation of implied volatility. It provides higher flexibility on Option price model selection, volatility modeling , and allows IV smoothing through call-put pair. For details, see Implied Volatility .

What Is Volatility Smile?

The "volatility smile" is a term used in finance to describe a particular shape that can be observed when plotting IV against strike

prices for options that share the same expiration date. Typically, when you plot IVs against strike prices, the curve tends to be concave, resembling a smile. This means that options with strike prices significantly above or below the current market price of the underlying asset tend to have higher IV than options with strike prices closer to the current market price.

Several theories attempt to explain the existence of the volatility smile. One explanation is that it arises from adjustments to the classic Black-Scholes-Merton (BSM) model, which assumes that asset prices follow a log-normal distribution. The volatility smile suggests that the market anticipates a higher probability of extreme price movements (fat tails) than the BSM model predicts. Another explanation is related to market dynamics and the demand for hedging. During periods of heightened market volatility, the volatility smile tends to become steeper, indicating a greater disparity in implied volatilities across different strike prices. This means that options, particularly those with out-of-the-money strike prices, become more expensive as investors seek protection against potential market downturns or increased price fluctuations. As a result, the volatility smile can serve as a valuable tool for investors and traders to assess market sentiment and gauge the level of risk in their portfolios.

According to some volatility models, such as the Heston model, the IV smile/surface should exhibit a smooth pattern. Any deviations from this smoothness, such as non-smooth spikes or irregularities, may signal potential arbitrage opportunities for traders.

Volatility Smirk

However, in some cases, rather than a traditional U-shaped curve, traders may observe what's known as a "smirk." This smirk occurs when the implied volatilities for higher-strike options are lower than those for ATM and lower-strike options. This deviation from the typical volatility smile pattern indicates a market expectation of a significant downward movement in the underlying asset's price. Traders interpret this as a signal that investors are allocating funds towards options with higher probabilities of such downward movements, resulting in increased demand for lower-strike options.

What Is Volatility Smoothing?

Volatility smoothing refers to the creation of a smooth volatility smile/surface. Derivative like options are favorable for maket-making and arbitration trading, due to the existence of fair price modeling. In the contemporary domain of high-frequency trading, the efficiency of calculating IV and Greeks assumes paramount significance. Thus, the quest for swift and refined IV surface computation becomes an inevitable quest for traders. Rather than relying solely on conventional methods involving slow-paced sampling and continuous parameter recalibration, the adoption of approximation techniques and stationary state analyses gains traction, especially in the context of IV estimation.

Accuracy Consideration

The Law of One Price stipulates the existence of a singular fair price for any given underlying asset. Consequently, according to the principles of put-call parity, each strike price for European options at expiration should correspond to a unique IV value. Within the realm of the Black-Scholes-Merton (BSM) framework, for instance, the concept of put-call parity yields insights into the equivalence of IVs for call and put options at identical strike prices and expirations. This equivalence serves as the foundation for formulating objective function: $C(t,K) - P(t,K)=e^{(q-r)t} (S_T - K) \\\Rightarrow e^{(q-r)t} [S_T (\Phi(d_{+}^{call})+\Phi(-d_{+}^{put})) - K (\Phi(d_{-}^{call})+\Phi(-d_{-}^{put}))] = e^{(q-r)t} (S_T - K) \\\Rightarrow \Phi(d_{+}^{call})+\Phi(-d_{+}^{put}) = 1\ \text{and}\ \Phi(d_{-}^{call})+\Phi(-d_{-}^{put}) = 1 \\\Rightarrow d_{\pm}^{call}=d_{\pm}^{put}$ Thus, we can formulate an objective function of $C_{market} + P_{market} = C_{BSM} + P_{BSM}$.

Alternatively, certain schools of thought contend that the bulk of historical volatility information is encapsulated within at-the-money (ATM) options, with any residual volatility attributable to the extrinsic value of the option. Consequently, a strategy focused on out-of-the-money (OTM) options for IV calculations gains traction.

Speed Consideration

In the realm of high-frequency trading, where split-second decisions are the norm, the traditional process of sampling, evaluating, recalibrating, and deriving implied volatility expectations is simply unfeasible. In response, traders and analysts increasingly turn to polynomial regression techniques as a pragmatic solution for IV modeling.

For example, $IV_t = \beta_0 + \beta_1 M + \beta_2 M^2 + \beta_3 (T-t) + \beta_4 (T-t)^2 + \beta_5 M(T-t) \\\text{where} M = ln(S_t/K)$

Additionally, the utilization of advanced mathematical algorithms, such as the Fast Fourier Transform (FFT), enables the rapid computation of the entire Greek surface, enhancing speed and efficiency. While these approaches may entail minor trade-offs in terms of accuracy, the overarching objective remains the attainment of a seamlessly smooth implied volatility surface that fosters effective arbitrage strategies.

Options Models

Volatility

Volatility

Key Concepts

Introduction

Volatility models measure the historical volatility of an asset. They are mostly used to calculate the volatility of the underlying security of an Option because the implied volatility of an Option contract needs an initial guess. The historical volatility doesn't need to be the standard deviation of the asset prices. The various volatility models in LEAN each have a unique methodology to calculate volatility.

LEAN also provides an indicator implementation of implied volatility. It provides higher flexibility on Option price model selection, volatility modeling , and allows IV smoothing through call-put pair. For details, see Implied Volatility .

Set Models

To set the volatility model of the underlying security of an Option, set the `VolatilityModel` property of the `Security` object. The volatility model can have a different resolution than the underlying asset subscription.

```C#
public override void Initialize()
{
    var underlyingSecurity = AddEquity("SPY");
    // Usually, the historical and implied volatility is calculated using 30-day standard deviation of return
    underlyingSecurity.VolatilityModel = new StandardDeviationOfReturnsVolatilityModel(30);
}
```

You can also set the volatility model in a security initializer . If your algorithm has a universe of underlying assets, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

```C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite the volatility model
        if (security.Type == SecurityType.Equity)
        {
            security.VolatilityModel = new StandardDeviationOfReturnsVolatilityModel(30);
        }
    }
}
```

To view all the pre-built volatility models, see Supported Models .

Default Behavior

The default underlying volatility model for Equity Options and Index Options is the StandardDeviationOfReturnsVolatilityModel based on 30 days of daily resolution data. The default underlying volatility model for Future Options is the NullVolatilityModel .

Model Structure

Volatility models should extend the `BaseVolatilityModel` class. Extensions of the `BaseVolatilityModel` class must have `Update` and `GetHistoryRequirements` methods and a `Volatility` property. The `Update` method receives `Security` and `BaseData` objects and then updates the `Volatility` . The `GetHistoryRequirements` method receives `Security` and `DateTime` objects and then returns a list of `HistoryRequest` objects that represent the history requests to warm up the model. Volatility models receive data at each time step in the algorithm to update their state.

```C#
public class CustomVolatilityModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var underlyingSecurity = AddIndex("VIX");
        // Apply custom volatility model for specific underlyings, often they are synthetic products or with
different market calendar
        underlyingSecurity.VolatilityModel = new MyVolatilityModel();
    }
}

// Define the custom volatility model outside of the algorithm
public class MyVolatilityModel : BaseVolatilityModel
{
    public override decimal Volatility { get; }

    public override void SetSubscriptionDataConfigProvider(
        ISubscriptionDataConfigProvider subscriptionDataConfigProvider)
    {
        SubscriptionDataConfigProvider = subscriptionDataConfigProvider;
    }

    public override void Update(Security security, BaseData data)
    {
    }

    public override IEnumerable<HistoryRequest> GetHistoryRequirements(
        Security security,
        DateTime utcTime)
    {
        return base.GetHistoryRequirements(security, utcTime);
    }

    public new IEnumerable<HistoryRequest> GetHistoryRequirements(
        Security security,
        DateTime utcTime,
        Resolution? resolution,
        int barCount)
    {
        return base.GetHistoryRequirements(security, utcTime, resolution, barCount);
    }
}
```

Warm Up Models

To use your volatility model as the inital guess for the implied volatility , warm up the volatility model of the underlying security. If you subscribe to all the Options in the `Initialize` method, set a warm-up period to warm up their volatility models. The warm-up period should provide the volatility models with enough data to compute their values.

```C#
public override void Initialize()
{
    // For default 30-day SD of return as volatility, you need 30+1 trading day to warm up
    SetWarmUp(31, Resolution.Daily);
}

public override void OnData(Slice slice)
{
    // Only take the warmed-up volatility value into account for accuracy issue
    if (IsWarmingUp) return;
}
```

If you have a dynamic universe of underlying assets and add Option contracts to your algorithm with the `AddOptionContract` , `AddIndexOptionContract` , or `AddFutureOptionContract` methods, warm up the volatility model when the underlying asset enters your universe. We recommend you do this inside a security initializer .

```C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite and warm up the volatility model
        if (security.Type == SecurityType.Equity) // Underlying asset type
        {
            security.VolatilityModel = new StandardDeviationOfReturnsVolatilityModel(30);
            foreach (var tradeBar in History(security.Symbol, 30, Resolution.Daily))
            {
                security.VolatilityModel.Update(security, tradeBar);
            }
        }
    }
}
```

Examples

The following examples demonstrate common practices for implementing a custom volatility model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the `BaseVolatilityModel` and overrides its built-in members so you can easily customize the parts you need.

C#

```
public class CustomVolatilityModelAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        var security = AddEquity("SPY", Resolution.Daily);
        security.VolatilityModel = new MyVolatilityModel();
    }

    /// OnData event is the primary entry point for your algorithm. Each new data point will be pumped in here.
    /// Slice object keyed by symbol containing the stock data
    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }

}

public class MyVolatilityModel : BaseVolatilityModel
{
    public override decimal Volatility { get; }

    public override void SetSubscriptionDataConfigProvider(
        ISubscriptionDataConfigProvider subscriptionDataConfigProvider)
    {
        SubscriptionDataConfigProvider = subscriptionDataConfigProvider;
    }

    public override void Update(Security security, BaseData data)
    {
    }

    public override IEnumerable<HistoryRequest> GetHistoryRequirements(
        Security security,
        DateTime utcTime)
    {
        return base.GetHistoryRequirements(security, utcTime);
    }

    public new IEnumerable<HistoryRequest> GetHistoryRequirements(
        Security security,
        DateTime utcTime,
        Resolution? resolution,
        int barCount)
    {
        return base.GetHistoryRequirements(security, utcTime, resolution, barCount);
    }
}
```

CustomVolatilityModelAlgorithm.cs C#

Volatility

Supported Models

Introduction

This page describes all of the pre-built volatility models in LEAN. If none of these models perform exactly how you want, create a custom volatility model .

Null Model

The `NullVolatilityModel` sets the volatility of the security to zero. It's the default volatility model for the underlying asset of Future Options.

```
C#
underlyingSecurity.VolatilityModel = VolatilityModel.Null;
```

For more information about this model, see the class reference and implementation .

Standard Deviation of Returns Model

The `StandardDeviationOfReturnsVolatilityModel` sets the volatility of the security to the annualized sample standard deviation of trailing returns. It's the default volatility model for the underlying asset of Equity Options and Index Options.

```
C#
underlyingSecurity.VolatilityModel = new StandardDeviationOfReturnsVolatilityModel(30);
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`periods`	`int`	The max number of samples to use when calculating the standard deviation of returns. This value must be greater than two.	
`resolution`	`Resolution?`	The resolution of the price data used to calculate the standard deviation. This only has a material effect in live mode. For backtesting, this value does not cause any behavioral changes.	`null`
`updateFrequency`	`TimeSpan?`	The frequency at which new values are inserted into the rolling window for the standard deviation calculation. If the value is `null`, it defaults to the `TimeSpan` representation of `resolution`. If the value and `resolution` are `null`, it defaults to a `TimeSpan` of one day.	`null`

For more information about this model, see the class reference and implementation.

Relative Standard Deviation Model

The `RelativeStandardDeviationVolatilityModel` sets the volatility of the security to the relative standard deviation of its price. In symbols, the value is

$$\frac{|\mu|}{\sigma}$$

where μ is the average of the samples and σ is the standard deviation of the samples.

```C#
underlyingSecurity.VolatilityModel = new RelativeStandardDeviationVolatilityModel(TimeSpan.FromDays(1), 10);
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`periodSpan`	`TimeSpan`	The period of time to wait between each sample of the security price	
`periods`	`int`	The number of samples to use to calculate the volatility value	

For more information about this model, see the class reference and implementation.

Options Models

Exercise

Introduction

If you exercise a long Option position or are assigned on your short Option position, LEAN processes an Option exercise order. The Option exercise model converts the Option exercise order into an OrderEvent .

Set Models

To set the exercise model of an Option, call the `SetOptionExerciseModel` method of the `Option` object inside a security initializer .

```C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite the Option exercise model
        if (security.Type == SecurityType.Option) // Option type
        {
            (security as Option).SetOptionExerciseModel(new DefaultExerciseModel());
        }
    }
}
```

Default Behavior

The default Option exercise model is the `DefaultExerciseModel` . The `DefaultExerciseModel` fills exercise orders to the full quantity with zero fees and applies an order tag to represent if the order is an exercise or assignment.

For more information about this model, see the class reference and implementation .

Model Structure

Option exercise models should implement the `IOptionExerciseModel` interface. The `IOptionExerciseModel` interface must implement the `OptionExercise` method, which receives `Option` and `OptionExerciseOrder` objects and then returns a list of `OrderEvent` objects that contain the order fill information.

```C#
public class CustomOptionExerciseModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var security = AddOption("SPY");
        // Set custom option exercise model for mimicking specific Brokerage most realistic actions
        (security as Option).SetOptionExerciseModel(new MyOptionExerciseModel());
    }
}

// Define the custom Option exercise model outside of the algorithm
public class MyOptionExerciseModel : IOptionExerciseModel
{
    public IEnumerable<OrderEvent> OptionExercise(Option option, OptionExerciseOrder order)
    {
        var inTheMoney = option.IsAutoExercised(option.Underlying.Close);
        var isAssignment = inTheMoney && option.Holdings.IsShort;

        yield return new OrderEvent(
            order.Id,
            option.Symbol,
            option.LocalTime.ConvertToUtc(option.Exchange.TimeZone),
            OrderStatus.Filled,
            Extensions.GetOrderDirection(order.Quantity),
            0.0m,
            order.Quantity,
            OrderFee.Zero,
            "Tag"
        ) { IsAssignment = isAssignment };
    }
}
```

`OptionExerciseOrder` objects have the following properties:

The following table describes the arguments of the `OrderEvent` constructor:

Argument Details
Argument: `orderId` Id of the parent order Data Type: `int` | Default Value: `-`
Argument: `symbol` Asset Symbol Data Type: `Symbol` | Default Value: `-`
Argument: `utcTime` Date/time of this event Data Type: `DateTime` | Default Value: `-`

Argument: `direction` The direction of the order. The `OrderDirection` enumeration has the following members: Data Type: `OrderDirection` | Default Value: `Hold`
Argument: `fillPrice` Fill price information if applicable Data Type: `decimal` | Default Value: `0`
Argument: `fillQuantity` Fill quantity Data Type: `decimal` | Default Value: `0`
Argument: `orderFee` The order fee. You can use `OrderFee.Zero` or create an `OrderFee` object with a custom fee. `new OrderFee(new CashAmount(0.5m, "USD"));` Data Type: `OrderFee` | Default Value: `-`
Argument: `message` Message from the exchange Data Type: `string` | Default Value: `""`

`OrderEvent` objects have the following attributes:

Examples

The following examples demonstrate some common practices for implementing a custom Option exercise model.

Example 1: Cash Settlement

The following algorithm trades GOOG 30-day expiring straddle. Yet, instead of settling with the underlying stock, some brokerages will settle with cash for ITM options. To simulate this behavior, we can create a custom option exercise model.

C#

```
using static QuantConnect.Extensions;
public class OptionExerciseModelAlgorithm : QCAlgorithm
{
    private Symbol _goog;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Request GOOG option data for trading.
        var security = AddOption("GOOG");
        _goog = security.Symbol;
        // Filter for the 2 ATM contracts expiring in 30 days to form a straddle strategy.
        security.SetFilter((universe) => universe.IncludeWeeklys().Straddle(30));
        // Set custom option exercise model for disabling exercise through security initializer.
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =>
        {
            // Set the custom Option exercise model for Option securities
            if (security.Type == SecurityType.Option)
            {
                (security as Option).SetOptionExerciseModel(new MyOptionExerciseModel());
            }
        });
    }

    public override void OnData(Slice slice)
    {
        // Open position on updated option chain data.
        if (!Portfolio.Invested && slice.OptionChains.TryGetValue(_goog, out var chain))
        {
            // Only one strike and expiry for the straddle universe.
            var strike = chain.Min(x => x.Strike);
            var expiry = chain.Min(x => x.Expiry);
            // Open the straddle position.
            var optionStrategy = OptionStrategies.Straddle(_goog, strike, expiry);
            Buy(optionStrategy, 5);
        }
    }

    // Define the custom Option exercise model outside of the algorithm
    private class MyOptionExerciseModel : IOptionExerciseModel
    {
        public IEnumerable<OrderEvent> OptionExercise(Option option, OptionExerciseOrder order)
        {
            var underlying = option.Underlying;
            var utcTime = option.LocalTime.ConvertToUtc(option.Exchange.TimeZone);
            var inTheMoney = option.IsAutoExercised(underlying.Close);
            // Cash settle: using payoff.
            var payoff = option.GetIntrinsicValue(underlying.Close);

            // Only liquidate option positions, but do not add equity positions.
            yield return new OrderEvent(
                order.Id,
                option.Symbol,
                utcTime,
                OrderStatus.Filled,
                GetOrderDirection(order.Quantity),
                payoff,
                order.Quantity,
                OrderFee.Zero,
                "Option Settlement"
            )
            {
                IsInTheMoney = inTheMoney
            };
        }
    }
}
```

Example 2: Default Model Implementation

The following algorithm implements the `DefaultExerciseModel` so you can easily customize the parts you need.

C#

```
public class CustomExerciseModelAlgorithm : QCAlgorithm
{
    private Symbol _optionSymbol;
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        Settings.SeedInitialPrices = true;
        AddSecurityInitializer(security =>
        {
            // Set the custom Option exercise model for Option securities
            if (security.Type == SecurityType.Option)
            {
                (security as Option).SetOptionExerciseModel(new MyOptionExerciseModel(this));
            }
        });
        var option = AddOption("SPY");
        _optionSymbol = option.Symbol;
    }

    /// OnData event is the primary entry point for your algorithm. Each new data point will be pumped in here.
    /// Slice object keyed by symbol containing the stock data
    public override void OnData(Slice data)
    {
        if (Portfolio.Invested)
        {
            return;
        }
        if (data.OptionChains.TryGetValue(_optionSymbol, out var chain))
        {
            var contract = chain
                .Where(x => x.Right == OptionRight.Call)
                .OrderBy(x => x.Strike)
                .FirstOrDefault();

            MarketOrder(contract.Symbol, 1);
            ExerciseOption(contract.Symbol, 1);
            Quit();
        }
    }
}

public class MyOptionExerciseModel : IOptionExerciseModel
{
    private readonly QCAlgorithm _algorithm;
    public MyOptionExerciseModel(QCAlgorithm algorithm) => _algorithm = algorithm;

    public IEnumerable<OrderEvent> OptionExercise(Option option, OptionExerciseOrder order)
    {
        var underlying = option.Underlying;
        var utcTime = option.LocalTime.ConvertToUtc(option.Exchange.TimeZone);

        var inTheMoney = option.IsAutoExercised(underlying.Close);
        var isAssignment = inTheMoney && option.Holdings.IsShort;

        yield return new OrderEvent(
            order.Id,
            option.Symbol,
            utcTime,
            OrderStatus.Filled,
            GetOrderDirection(order.Quantity),
            0.0m,
            order.Quantity,
            OrderFee.Zero,
            Messages.DefaultExerciseModel.ContractHoldingsAdjustmentFillTag(inTheMoney, isAssignment, option)
        )
        {
            IsAssignment = isAssignment,
            IsInTheMoney = inTheMoney
        };

        if (inTheMoney && option.ExerciseSettlement == SettlementType.PhysicalDelivery)
        {
            var exerciseQuantity = option.GetExerciseQuantity(order.Quantity);

            yield return new OrderEvent(
                order.Id,
                underlying.Symbol,
                utcTime,
```

```
                    OrderStatus.Filled,
                    GetOrderDirection(exerciseQuantity),
                    option.StrikePrice,
                    exerciseQuantity,
                    OrderFee.Zero,
                    isAssignment ? Messages.DefaultExerciseModel.OptionAssignment :
Messages.DefaultExerciseModel.OptionExercise
                ) { IsInTheMoney = true };
            }
        }
    }
```

Demonstration Algorithms
CustomOptionExerciseModelRegressionAlgorithm.cs C#

Options Models

Assignment

Introduction

If you sell an Option in a backtest, an assignment model can simulate an Option exercise order on behalf of the buyer and assign you to complete the requirements of the contract.

Set Models

To set the assignment model of an Option, call the `SetOptionAssignmentModel` method of the `Option` object inside a security initializer .

```
C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite the assignment model
        if (security.Type == SecurityType.Option) // Option type
        {
            (security as Option).SetOptionAssignmentModel(new DefaultOptionAssignmentModel());
        }
    }
}
```

Default Behavior

The default Option assignment model is the `DefaultOptionAssignmentModel` . The `DefaultOptionAssignmentModel` scans your portfolio every hour. It considers exercising American-style Options if they are within 4 days of their expiration and it considers exercising European-style Options on their day of expiration. If you have sold an Option that's 5% in-the-money and the Option exercise order is profitable after the cost of fees, this model exercises the Option.

For more information about this model, see the class reference and implementation .

Model Structure

Option assignment models should implement the `IOptionAssignmentModel` interface. Extensions of the `IOptionAssignmentModel` interface must implement the `GetAssignment` method, which automatically fires at the top of each hour and returns the Option assignments to generate.

```C#
public class CustomOptionAssignmentModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var security = AddOption("SPY");
        // Set custom option assignment model for mimicking specific Brokerage most realistic actions
        (security as Option).SetOptionAssignmentModel(new MyOptionAssignmentModel());
    }
}

// Define the custom Option assignment model outside of the algorithm
public class MyOptionAssignmentModel : IOptionAssignmentModel
{
    public OptionAssignmentResult GetAssignment(OptionAssignmentParameters parameters)
    {
        var option = parameters.Option;
        // Check if the contract is ITM
        if ((option.Right == OptionRight.Call && option.Underlying.Price > option.StrikePrice) ||
            (option.Right == OptionRight.Put && option.Underlying.Price < option.StrikePrice))
        {
            return new OptionAssignmentResult(option.Holdings.AbsoluteQuantity, "MyTag");
        }
        return OptionAssignmentResult.Null;
    }
}
```

The `OptionAssignmentParameters` object has the following members:

To exercise the Option, return an `OptionAssignmentResult` with a positive quantity. Otherwise, return `OptionAssignmentResult.Null`. The `OptionAssignmentResult` constructor accepts the following arguments:

Argument	Data Type	Description	Default Value
`quantity`	`decimal`	The quantity to assign	
`tag`	`string`	The order tag to use	

Disable Assignments

To disable early Option assignments, set the Option assignment model to the `NullOptionAssignmentModel`.

```C#
(security as Option).SetOptionAssignmentModel(new NullOptionAssignmentModel());
```

Examples

The following examples demonstrate some common practices for handling Option assignment.

Example 1: Liquidate After Assignment

The following algorithm trades a short straddle strategy on ATM SPY Options that expire within seven days. To capitalize the cash profit, it liquidates the underlying assigned Equity position in the `OnAssignmentOrderEvent` `on_assignment_order_event` method.

```C#
public class OptionAssignmentAlgorithm : QCAlgorithm
{
    private Option _option;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Add SPY Options data for trading.
        _option = AddOption("SPY");
        // Filter for the 2 ATM contracts that expire in 7 days to form a straddle.
        _option.SetFilter((universe) => universe.IncludeWeeklys().Straddle(7));
    }

    public override void OnData(Slice slice)
    {
        // Get the current Option chain and open a new position if we're not already invested.
        if (!Portfolio.Invested && slice.OptionChains.TryGetValue(_option.Symbol, out var chain))
        {
            // Select the strike and expiry of the contracts.
            var strike = chain.Min(x => x.Strike);
            var expiry = chain.Min(x => x.Expiry);
            // Open the straddle position.
            var optionStrategy = OptionStrategies.ShortStraddle(_option.Symbol, strike, expiry);
            Buy(optionStrategy, 1);
        }
    }

    public override void OnAssignmentOrderEvent(OrderEvent assignmentEvent)
    {
        // Liquidate the assigned SPY position.
        MarketOrder(
            assignmentEvent.Symbol.Underlying,
            -assignmentEvent.Quantity * _option.SymbolProperties.ContractMultiplier
        );
    }
}
```

Example 2: Wheel Strategy

The following algorithm demonstrates a wheel Option strategy . The strategy is split into separate parts to generate consistent income: selling puts and selling covered call.

C#

```
public class WheelStrategyAlgorithm : QCAlgorithm
{
    // Define the OTM threshold. A greater value means lower risk of assignment but lower premiums to collect.
    private readonly decimal _otmThreshold = 0.05m;
    private Equity _equity;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Seed the initial price of the each new security so we can add and trade contracts in the same time step.
        Settings.SeedInitialPrices = true;
        // Add SPY data for trading. Use raw data normalization mode to enable fair strike price comparison.
        _equity = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw);
    }

    private Symbol GetTargetContract(OptionRight right, decimal targetPrice)
    {
        // Get the Option chain.
        var chain = OptionChain(_equity.Symbol);
        // Select the contracts that are first to expire after 30 days since they have greater premiums and theta
        // to collect.
        var expiry = chain.Where(x => x.Expiry > Time.AddDays(30))
            .Min(x => x.Expiry);
        // Select the OTM Option contract to start the wheel or covered call.
        Symbol symbol;
        if (right == OptionRight.Call)
        {
            symbol = chain.Where(x => x.Expiry == expiry && x.Right == right && x.Strike >= targetPrice)
                .OrderBy(x => x.Strike)
                .First();
        }
        else
        {
            symbol = chain.Where(x => x.Expiry == expiry && x.Right == right && x.Strike <= targetPrice)
                .OrderByDescending(x => x.Strike)
                .First();
        }
        // Add the Option contract to the algorithm.
        return AddOptionContract(symbol).Symbol;
    }

    public override void OnData(Slice slice)
    {
        // Start the wheel by selling the OTM put.
        if (!Portfolio.Invested && IsMarketOpen(_equity.Symbol))
        {
            var symbol = GetTargetContract(OptionRight.Put, _equity.Price * (1m - _otmThreshold));
            SetHoldings(symbol, -0.2m);
        }
    }

    public override void OnAssignmentOrderEvent(OrderEvent assignmentEvent)
    {
        // After the put is assigned, look for an OTM call to form a covered call with the assigned underlying
        // position.
        var symbol = GetTargetContract(OptionRight.Call, _equity.Price * (1m + _otmThreshold));
        MarketOrder(symbol, -_equity.Holdings.Quantity / 100m);
    }
}
```

Example 3: Assign ITM Contracts

The following algorithm assigns all in-the-money contracts at the top of each hour.

C#

```
public class CustomOptionAssignmentAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);
        AddSecurityInitializer(InitializeSecurity);
        var option = AddOption("GOOG");
        option.SetFilter(universe => universe.CallsOnly().Strikes(-65, 0).Expiration(0, 30));
    }

    private void InitializeSecurity(Security security)
    {
        // Overwrite the assignment model.
        if (security.Type == SecurityType.Option) // Option type
        {
            (security as Option).SetOptionAssignmentModel(new MyOptionAssignmentModel());
        }
    }

    public override void OnData(Slice data)
    {
        if (Portfolio.Invested) return;

        foreach (var kvp in data.OptionChains)
        {
            var chain = kvp.Value;
            var minExpiry = chain.Select(x => x.Expiry).Min();
            var contracts = chain.Where(x => x.Expiry == minExpiry).OrderBy(x => x.Strike).ToList();

            if (contracts.Any())
            {
                MarketOrder(contracts[0].Symbol, -1);
            }
        }
    }
}

public class MyOptionAssignmentModel : IOptionAssignmentModel
{
    public OptionAssignmentResult GetAssignment(OptionAssignmentParameters parameters)
    {
        var option = parameters.Option;
        // Check if the contract is ITM
        if ((option.Right == OptionRight.Call && option.Underlying.Price > option.StrikePrice) ||
            (option.Right == OptionRight.Put && option.Underlying.Price < option.StrikePrice))
        {
            return new OptionAssignmentResult(option.Holdings.AbsoluteQuantity, "MyTag");
        }

        return OptionAssignmentResult.Null;
    }
}
```

Reality Modeling

Risk Free Interest Rate

Risk Free Interest Rate

Key Concepts

Introduction

The risk free interest rate is the hurdle rate for investments. If investors can get a rate of return with virtually no risk, an investment needs to offer the potential for a greater return to attract capital from rational investors. The risk free interest rate also impacts some performance statistics , like Sharpe and Sortino ratios. Risk free interest rate models provide the interest rate data to your algorithms to enable these calculations.

Set Models

To set the risk free interest rate model, in the Initialize method, call the `SetRiskFreeInterestRateModel` method.

```C#
public overide void Initialize()
{
    // Set the interest rate model for accurate option IV/greeks and result metrics like Sharpe Ratio
    // You should set it according to the main currency of your trading Securities
    SetRiskFreeInterestRateModel(new ConstantRiskFreeRateInterestRateModel(0.02m));
}
```

To view all the pre-built risk free interest rate models, see Supported Models .

Default Behavior

The default risk free interest rate model is the InterestRateProvider , which provides the primary credit rate from the Federal Open Market Committee (FOMC).

Model Structure

Risk free interest rate models must extend the `IRiskFreeInterestRateModel` interface. Extensions of the `IRiskFreeInterestRateModel` interface must implement a `GetInterestRate` method. The `GetInterestRate` method returns the risk free interest rate for a given date.

```C#
public class CustomRiskFreeInterestRateModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // Set the interest rate model for accurate option IV/greeks and result metrics like Sharpe Ratio
        // You should set it according to the main currency of your trading Securities
        SetRiskFreeInterestRateModel(new MyRiskFreeInterestRateModel());
    }
}

// Define the custom risk free interest rate model
public class MyRiskFreeInterestRateModel : IRiskFreeInterestRateModel
{
    public decimal GetInterestRate(DateTime date)
    {
        return 0.02m;
    }
}
```

Disable Interest Rates

To disable the risk free interest rate, set the model to the `ConstantRiskFreeRateInterestRateModel` and set the risk free rate to zero.

```C#
SetRiskFreeInterestRateModel(new ConstantRiskFreeRateInterestRateModel(0));
```

Get Interest Rate

To get the risk free interest rate for a specific time, call the `GetInterestRate` method with the time.

```C#
public override void OnData(Slice slice)
{
 var riskFreeInterestRate = RiskFreeInterestRateModel.GetInterestRate(slice.Time);
}
```

To get the average risk free interest rate for a window of time, call the `GetRiskFreeRate` method with the start date and end date.

```C#
public override void OnData(Slice slice)
{
 var avgRiskFreeInterestRate = RiskFreeInterestRateModel.GetRiskFreeRate(Time.AddDays(-30), Time);
}
```

To get the average risk free interest rate for a set of dates, call the `GetAverageRiskFreeRate` method with the list of dates.

```C#
public override void OnData(Slice slice)
{
 var avgRiskFreeInterestRate = RiskFreeInterestRateModel.GetAverageRiskFreeRate(
  new [] {Time, Time.AddDays(-180), Time.AddDays(-365)}
 );
}
```

Examples

The following examples demonstrate common practices for implementing a custom risk free interest rate model.

Example 1: Fixed Rate

The following algorithm implements a custom risk free interest rate model with a fixed rate of 2%.

```C#
public class CustomFillModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        SetRiskFreeInterestRateModel(new MyRiskFreeInterestRateModel());
        AddEquity("SPY", Resolution.Daily);
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }
}

public class MyRiskFreeInterestRateModel : IRiskFreeInterestRateModel
{
    public decimal GetInterestRate(DateTime date)
    {
        return 0.02m;
    }
}
```

Risk Free Interest Rate

Supported Models

Introduction

This page describes all of the pre-built risk free interest rate models in LEAN. If none of these models perform exactly how you want, create a custom risk free interest rate model .

Constant Model

The `ConstantRiskFreeRateInterestRateModel` returns a constant rate across time. It's the default risk free interest rate model.

```
C#
SetRiskFreeInterestRateModel(new ConstantRiskFreeRateInterestRateModel(0.02m));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`riskFreeRate`	`decimal`	The risk free interest rate	

For more information about this model, see the class reference and implementation .

Function Model

The `FuncRiskFreeRateInterestRateModel` calls a function you provide to get the risk free interest rate. The function you pass to the constructor effectively replaces the GetInterestRate method.

```
C#
SetRiskFreeInterestRateModel(new FuncRiskFreeRateInterestRateModel(getInterestRateFunc));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`getInterestRateFunc`	`Func<DateTime, decimal>`	A function that returns the risk free interest rate for a given date	

For more information about this model, see the class reference and implementation .

Interest Rate Provider Model

The `InterestRateProvider` returns the primary credit rate from the Federal Open Market Committee (FOMC).

```
C#
SetRiskFreeInterestRateModel(new InterestRateProvider());
```

For more information about this model, see the class reference and implementation .

Reality Modeling

Dividend Yield

Dividend Yield

Key Concepts

Introduction

Dividends are periodic payments a company makes to its shareholders out of its earnings. The dividend yield refers to the rate of return an investor earns in the form of dividends from holding a stock.

In the context of Option pricing models , the dividend yield is a critical factor because it affects the value of the underlying stock. When calculating the theoretical price of an Option using these models, the dividend yield is factored into the equation.

Set Models

To set the dividend yield model for an Option indicator , pass a `DividendYieldProvider` as the `dividendYieldModel` parameter.

```C#
public override void Initialize()
{
    // Before creating the indicator, create the set dividend yield model, such that it will use it in default
    // Using DividendYieldProvider will calculate the continuous dividend yield using all dividend payoffs in 1 year
    var dividendYieldModel = new DividendYieldProvider(symbol.Underlying);
    _iv = new ImpliedVolatility(symbol, RiskFreeInterestRateModel, dividendYieldModel,
OptionPricingModelType.BlackScholes);
}
```

To view all the pre-built dividend yield models, see Supported Models .

Default Behavior

For US Equity Options, the default dividend yield model is the DividendYieldProvider , which provides the continuous yield calculated from all dividend payoffs from the underlying Equity over the previous 350 days.

For other Option types, the default dividend yield model is the `DividendYieldProvider` , but it calculates the yield from the dividends of the SPY ETF.

Model Structure

Dividend yield models must extend the `IDividendYieldModel` interface. Extensions of the `IDividendYieldModel` interface must implement a `GetDividendYield` method. The `GetDividendYield` method returns the dividend yield for a given date.

```C#
public class CustomDividendYieldModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        // Create the dividend yield model
        var dividendYieldModel = new MyDividendYieldModel();
        // Add the Option contracts.
        var underlying = AddEquity("SPY", dataNormalizationMode: DataNormalizationMode.Raw).Symbol;
        var strike = 595m;
        var expiry = new DateTime(2024, 12, 30);
        var option = AddContract(underlying, OptionRight.Put, strike, expiry);
        var mirror = AddContract(underlying, OptionRight.Call, strike, expiry);
        // Add the indicator.
        var iv = new ImpliedVolatility(option, RiskFreeInterestRateModel, dividendYieldModel, mirror);
    }

    private Symbol AddContract(Symbol underlyingSymbol, OptionRight right, decimal strike, DateTime expiry)
    {
        var contractSymbol = QuantConnect.Symbol.CreateOption(underlyingSymbol, Market.USA, OptionStyle.American,
right, strike, expiry);
        AddOptionContract(contractSymbol);
        return contractSymbol;
    }
}

// Define the custom dividend yield model
public class MyDividendYieldModel : IDividendYieldModel
{
    decimal _yield = 0.02m;
    public decimal GetDividendYield(DateTime date)
    {
        return _yield;
    }
    public decimal GetDividendYield(DateTime date, decimal price)
    {
        return _yield;
    }
}
```

Examples

The following examples demonstrate common practices for implementing a custom dividend yield model.

Example 1: Fixed Yield

The following algorithm implements a custom dividend yield model with a fixed yield of 2%.

C#

```
public class CustomDividendYieldModelAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Dictionary<Symbol, Delta> _deltas = new();
    private Dictionary<Symbol, MyDividendYieldModel> _dividendYieldModel = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var option = AddOption("MSFT");
        option.SetFilter(0,1,0,31);
        _symbol = option.Symbol;
        _dividendYieldModel[_symbol.Underlying] = new MyDividendYieldModel();
    }

    public override void OnData(Slice data)
    {
        if (!data.OptionChains.TryGetValue(_symbol, out var chain)) return;
        var expiry = chain.Min(x => x.Expiry);
        chain
            .Where(x => x.Expiry == expiry && x.Right == OptionRight.Call && !_deltas.ContainsKey(x.Symbol))
            .Select(x => x.Symbol)
            .DoForEach(x => _deltas[x] = CreateDeltaIndicator(x));
    }

    private Delta CreateDeltaIndicator(Symbol symbol)
    {
        var dividendYieldModel = _dividendYieldModel[symbol.Underlying];
        var delta = new Delta(symbol.Value, symbol, RiskFreeInterestRateModel, dividendYieldModel);
        RegisterIndicator(symbol, delta, Resolution.Minute);
        RegisterIndicator(symbol.Underlying, delta, Resolution.Minute);
        return delta;
    }

    public override void OnEndOfDay(Symbol symbol)
    {
        if (_deltas.TryGetValue(symbol, out var delta))
        {
            Plot("Delta", symbol.Value, delta.Current.Value);
        }
    }
}

public class MyDividendYieldModel : IDividendYieldModel
{
    public decimal GetDividendYield(DateTime date)
    {
        return 0.02m;
    }
}
```

Dividend Yield

Supported Models

Introduction

This page describes all of the pre-built dividend yield models in LEAN. If none of these models perform exactly how you want, create a custom dividend yield model .

Constant Model

The `ConstantDividendYieldModel` returns a constant yield across time. It's the default dividend yield model for securities that don't pay dividends.

```
C#
_dividendYieldModel = new ConstantDividendYieldModel(0.02m);
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`dividendYield`	`decimal`	The dividend yield	

For more information about this model, see the class reference and implementation .

Dividend Yield Provider Model

The `DividendYieldProvider` uses historical dividend payments to estimate the annualized continuous dividend yield for a given date.

```
C#
_dividendYieldModel = new DividendYieldProvider();
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`symbol`	`Symbol`	The symbol of a dividend-paying security. If you don't provide a value, it defaults to SPY.	

For more information about this model, see the class reference and implementation .

Reality Modeling

Margin Interest Rate

Margin Interest Rate

Key Concepts

Introduction

Margin interest is a cost associated with trading on margin. Margin interest rate models model margin interest cash flows by directly adding or removing cash from your portfolio.

Set Models

The brokerage model of your algorithm automatically sets the margin interest rate model for each security, but you can override it. To manually set the margin interest rate model of a security, assign a model to the `MarginInterestRateModel` property of the Security object.

```
C#
public override void Initialize()
{
    var security = AddEquity("SPY");
    // For US Equity, use the ShortMarginInterestRateModel with IB data
    security.SetShortableProvider(new InteractiveBrokersShortableProvider());
    security.MarginInterestRateModel = new ShortMarginInterestRateModel();
}
```

You can also set the margin interest rate model in a security initializer . If your algorithm has a dynamic universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

```
C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetShortableProvider(new InteractiveBrokersShortableProvider());
        security.MarginInterestRateModel = new ShortMarginInterestRateModel();

    }
}
```

To view all the pre-built margin interest rate models, see Supported Models .

Default Behavior

The brokerage model of your algorithm automatically sets the margin interest rate model of each security. The default brokerage model is the `DefaultBrokerageModel` , which sets the NullMarginInterestRateModel .

Model Structure

Margin interest rate models should implement the `IMarginInterestRateModel` interface. Extensions of the `IMarginInterestRateModel` interface must implement the `ApplyMarginInterestRate` method, which applies margin interest payments to the portfolio.

```
C#
public class CustomMarginInterestRateModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var security = AddEquity("SPY");
        // You should set it according to your broker information for the least actual-expected discrepancies
        security.SetMarginInterestRateModel(new MyMarginInterestRateModel());
    }
}

// Define the custom margin interest rate model
public class MyMarginInterestRateModel : IMarginInterestRateModel
{
    public void ApplyMarginInterestRate(MarginInterestRateParameters marginInterestRateParameters)
    {
        var holdings = marginInterestRateParameters.Security.Holdings;
        var positionValue = holdings.GetQuantityValue(holdings.Quantity);
        positionValue.Cash.AddAmount(-1);
    }
}
```

The `ApplyMarginInterestRate` method is automatically called at the top of each hour.

Examples

The following examples demonstrate some common practices for implementing a custom margin interest rate model.

Example 1: Based On Interest Rate

The following algorithm buys and holds SPY, with 2x leverage and holds 1.5x of portfolio value. Hence, funds will be borrowed from the broker and are susceptible to margin interest. We implement a custom margin interest rate model to simulate the Interactive Brokers margin interest deduction. While following daily accrual and monthly accounting of the margin interest, we simplify the rate from tiered to fixed at 1% above the current interest rate.

```
C#
public class MarginInterestRateModelAlgorithm : QCAlgorithm
{
    private Symbol _spy;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(1000000);

        // Request SPY data for trading.
        var equity = AddEquity("SPY");
        _spy = equity.Symbol;
        // Set custom margin interest rate model for the SPY security to mimic IB margin interest deduction.
        equity.SetMarginInterestRateModel(new MyMarginInterestRateModel(this, _spy));
    }

    public override void OnData(Slice slice)
    {
        if (!Portfolio.Invested)
        {
            // Place a position that exceeds available cash to buy with borrowed funds.
            SetHoldings(_spy, 1.5m);
```

```
        }
    }

    // Define the custom margin interest rate model
    public class MyMarginInterestRateModel : IMarginInterestRateModel
    {
        private QCAlgorithm _algorithm;
        private Dictionary<Cash, decimal> _accruedMarginInterest = new();

        public MyMarginInterestRateModel(QCAlgorithm algorithm, Symbol symbol)
            : base()
        {
            // Save the algorithm instance since we need to access the at-the-time interest rate to calculate the
margin rate.
            _algorithm = algorithm;
            // IBKR accrues interest daily and posts actual interest monthly on the third business day of the
following month.
            algorithm.Schedule.On(
                algorithm.DateRules.MonthStart(symbol, 3),
                algorithm.TimeRules.At(0, 0),
                MarginDeduction
            );
        }

        private void MarginDeduction()
        {
            foreach (var (cash, accruedInterest) in _accruedMarginInterest)
            {
                // Monthly deduction of cash position with accrued interests.
                cash.AddAmount(accruedInterest);
                // Reset the accrued interest accumulator.
                _accruedMarginInterest[cash] = 0m;
            }
        }

        public void ApplyMarginInterestRate(MarginInterestRateParameters marginInterestRateParameters)
        {
            // IBKR accrues interest daily for overnight positions only.
            if (_algorithm.Time.Hour == 16)
            {
                var holdings = marginInterestRateParameters.Security.Holdings;
                // Calculate the borrowed capital. The margin interest will only applied to the borrowed capital.
                var borrowedValue = holdings.UnleveredAbsoluteHoldingsCost - holdings.AbsoluteHoldingsCost;
                // Margin interest rate is 1% above the current risk-free interest rate.
                var marginRate = _algorithm.RiskFreeInterestRateModel.GetInterestRate(_algorithm.Time) + 0.01m;
                // Deduct the margin interest on the account cash position by the margin rate, multiplying the
borrowed sum.
                var cash = holdings.GetQuantityValue(holdings.Quantity).Cash;
                _accruedMarginInterest.TryAdd(cash, 0m);
                // Daily rate will be divided by 365.
                _accruedMarginInterest[cash] += borrowedValue * marginRate / 365m;

            }
        }
    }
}
```

Example 2: Fixed Dollar Rate

The following algorithm defines custom margin interest rate model that reduces your cash by $1 at the top of each hour.

C#

```
public class CustomFillModelAlgorithm : QCAlgorithm
{

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        var security = AddEquity("SPY", Resolution.Daily);
        security.SetMarginInterestRateModel(new MyMarginInterestRateModel());
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", 1);
        }
    }
}

public class MyMarginInterestRateModel : IMarginInterestRateModel
{
    public void ApplyMarginInterestRate(MarginInterestRateParameters marginInterestRateParameters)
    {
        var holdings = marginInterestRateParameters.Security.Holdings;
        var positionValue = holdings.GetQuantityValue(holdings.Quantity);
        positionValue.Cash.AddAmount(-1);
    }
}
```

Margin Interest Rate

Supported Models

Introduction

This page describes the pre-built margin interest rate models in LEAN. If none of these models perform exactly how you want, create a custom margin interest rate model .

Null Model

The `NullMarginInterestRateModel` doesn't charge any margin interest. It's the default margin interest rate of the DefaultBrokerageModel .

```
C#
security.margin_interest_rate_model = MarginInterestRateModel.NULL;
```

For more information about this model, see the class reference and implementation .

Short Equity Model

The `ShortMarginInterestRateModel` simulates the margin cost and payments of your Equity holdings. This model use the fee rate to compute the amount due to borrowing the asset to short, and the rebate rate to compute the amount due to lending the asset for shorting. For more information about these rates providers, see Short Availability .

```
C#
security.SetShortableProvider(new InteractiveBrokersShortableProvider());
security.MarginInterestRateModel = new ShortMarginInterestRateModel();
```

For more information about this model, see the class reference and implementation .

Binance Futures Model

The `BinanceFutureMarginInterestRateModel` simulates the margin cost and payments of your Crypto Future holdings. When the funding rate is positive, the price of the perpetual contract is higher than the mark price, so traders who are long pay for short positions. Conversely, a negative funding rate indicates that perpetual prices are below the mark price, so traders who are short pay for long positions. The interest amount is

$$Nominal \ Value \ of \ Positions * Funding \ Rate$$

The interest amount is periodically credited or debited from your currency holdings while you hold open positions. The interest amount is charged at 12 AM, 8 AM, 4 PM in your algorithm time zone .

```
C#
security.MarginInterestRateModel = new BinanceFutureMarginInterestRateModel();
```

For more information about this model, see the class reference and implementation .

Bybit Futures Model

The `BybitFutureMarginInterestRateModel` has the same behavior as the BinanceFutureMarginInterestRateModel .

```
security.MarginInterestRateModel = new BybitFutureMarginInterestRateModel();
```

C#

For more information about this model, see the class reference and implementation .

Reality Modeling

Margin Calls

Introduction

If the value of your portfolio falls below the maintenance margin, you receive a margin call. If you receive a margin call, you either need to add more capital to your brokerage account or the brokerage will liquidate some of your holdings to reduce your exposure and their risk. A margin call model monitors the margin levels of your portfolio, issues margin call warnings, and submits orders when margin calls occur.

Set Models

To set the margin call model, call the `SetMarginCallModel` method of the `Portfolio` object.

```
C#
public override void Initialize()
{
 // Set margin call model for the whole portfolio, better with reference to your broker information
 Portfolio.SetMarginCallModel(new DefaultMarginCallModel(Portfolio, DefaultOrderProperties));
}
```

Default Behavior

The brokerage model of your algorithm automatically sets the margin call model for the portfolio. The default brokerage model is the `DefaultBrokerageModel` , which sets the `DefaultMarginCallModel` . The `DefaultMarginCallModel` issues margin call warnings when the margin remaining in your portfolio is less than or equal to 5% of the total portfolio value. When your total margin used exceeds 10% of the total portfolio value, this model creates margin call orders. It sorts the generated margin call orders in ascending order by their unrealized profit and then synchronously executes each order until your portfolio is within the margin requirements.

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`portfolio`	`SecurityPortfolioManager`	The portfolio object to receive margin calls.	
`defaultOrderProperties`	`IOrderProperties`	The default order properties to be use in margin call orders.	
`marginBuffer`	`decimal`	The percent margin buffer to use when checking whether the total margin used is above the total portfolio value to generate margin call orders.	`0.10m` (10%)

For more information about this model, see the class reference and implementation .

Model Structure

Margin call models must extend the `DefaultMarginCallModel` class. Extensions of the `DefaultMarginCallModel` class can override the `GetMarginCallOrders` and `ExecuteMarginCall` methods.

The `GetMarginCallOrders` method scans the portfolio and the updated data for a potential margin call situation that may get the equity below zero. The method must return a list of `SubmitOrderRequest` objects that represent the margin call orders. To issue a margin call warning during this method, set the `issueMarginCallWarning` argument of the method to true.

The `ExecuteMarginCall` method receives the list of `SubmitOrderRequest` objects from the `GetMarginCallOrders` method, executes some of them, and returns a list of `OrderTicket` objects.

```
C#
public class CustomMarginCallModelExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // Set margin call model for the whole portfolio, better with reference to your broker information
        Portfolio.SetMarginCallModel(new MyMarginCallModel(Portfolio, DefaultOrderProperties));
    }
}

// Define the custom margin call model
public class MyMarginCallModel : DefaultMarginCallModel
{
    public MyMarginCallModel(
        SecurityPortfolioManager portfolio,
        IOrderProperties defaultOrderProperties)
        : base(portfolio, defaultOrderProperties)
    {
    }

    public override List<OrderTicket> ExecuteMarginCall(
        IEnumerable<SubmitOrderRequest> generatedMarginCallOrders)
    {
        return base.ExecuteMarginCall(generatedMarginCallOrders);
    }

    public List<SubmitOrderRequest> GetMarginCallOrders(out bool issueMarginCallWarning)
    {
        return base.GetMarginCallOrders(out issueMarginCallWarning);
    }
}
```

Disable Margin Calls

To disable margin calls, set the margin call model to the `NullMarginCallModel` .

```
C#
public override void Initialize()
{
 Portfolio.MarginCallModel = MarginCallModel.Null;
}
```

Monitor Margin Call Events

When the margin call model of your portfolio issues a margin call warning, we notify your algorithm through the `OnMarginCallWarning` event handler.

```
C#
public override void OnMarginCallWarning()
{
    Debug("Warning: Close to margin call");
}
```

Before we send the orders that the margin call model produces, we notify your algorithm through the `OnMarginCall` event

handler. This notification gives your algorithm a chance to liquidate some positions or modify the margin call orders. To modify the orders, adjust the list of `SubmitOrderRequest` objects the event handler receives.

```C#
public override void OnMarginCall(List<SubmitOrderRequest> requests)
{
    for (var i = 0; i < requests.Count; i++)
    {
        var order = requests[i];
        // liquidate an extra 10% each time you get a margin call to give yourself more padding
        var newQuantity = (int)(order.Quantity * 1.1m);
        requests[i] = new SubmitOrderRequest(order.OrderType, order.SecurityType,
                                             order.Symbol, newQuantity, order.StopPrice,
                                             order.LimitPrice, 0, Time, "OnMarginCall");
    }
}
```

Submit Order Request

If you receive a margin call or create a margin call model, you'll need to work with `SubmitOrderRequest` objects. These objects have the following properties:

The following table describes the arguments of the `SubmitOrderRequest` constructor:

Argument	Data Type	Description	Default Value
`orderType`	`OrderType`	The order type to be submitted	
`securityType`	`SecurityType`	The security type of the asset	
`symbol`	`Symbol`	The symbol to be traded	
`quantity`	`decimal`	The number of units to order	
`stopPrice`	`decimal`	The stop price for stop orders	
`limitPrice`	`decimal`	The limit price for limit orders	
`triggerPrice`	`decimal`	The trigger price for limit if touched orders	
`time`	`DateTime`	The time this request was created	
`tag`	`string`	A custom tag for this request	
`properties`	`IOrderProperties`	The order properties for this request	`null`

Examples

The following examples demonstrate common practices for implementing a custom margin call model.

Example 1: Default Model Wrapper

The following algorithm defines a subclass of the `DefaultMarginCallModel` and overrides its built-in members so you can easily customize the parts you need.

```C#
public class CustomFillModelAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        Portfolio.MarginCallModel = new MyMarginCallModel(Portfolio, DefaultOrderProperties);
        AddEquity("SPY", Resolution.Daily);
    }

    public override void OnData(Slice data)
    {
        if (!Portfolio.Invested)
        {
            SetHoldings("SPY", -2);
        }
    }
}

public class MyMarginCallModel : DefaultMarginCallModel
{
    public MyMarginCallModel(
        SecurityPortfolioManager portfolio,
        IOrderProperties defaultOrderProperties)
        : base(portfolio, defaultOrderProperties)
    {
    }

    public override List<OrderTicket> ExecuteMarginCall(
        IEnumerable<SubmitOrderRequest> generatedMarginCallOrders)
    {
        return base.ExecuteMarginCall(generatedMarginCallOrders);
    }

    public List<SubmitOrderRequest> GetMarginCallOrders(out bool issueMarginCallWarning)
    {
        return base.GetMarginCallOrders(out issueMarginCallWarning);
    }
}
```

Reality Modeling

Short Availability

Short Availability

Key Concepts

Introduction

To short a security, you need to borrow shares from another investor or organization that owns the shares. A shortable provider is a model that tracks the number of shares that are available for you to borrow. A shortable provider can make your backtest results more realistic because it doesn't let you place a short trade if there are no shares available for you to borrow.

Set Providers

The brokerage model of your algorithm automatically sets the settlement model for each security, but you can override it. To manually set the shortable provider of a security, call the `SetShortableProvider` method on the `Security` object.

C#

```
public override void Initialize()
{
    var security = AddEquity("SPY");
    // Get shortable stocks and quantity from local disk
    security.SetShortableProvider(new LocalDiskShortableProvider("axos"));
}
```

You can also set the shortable provider in a security initializer. If your algorithm has a universe, use the security initializer technique. In order to initialize single security subscriptions with the security initializer, call `AddSecurityInitializer` before you create the subscriptions.

C#

```
public override void Initialize()
{
    // Set the security initializer before requesting data to apply to all requested securities afterwards
    SetSecurityInitializer(CustomSecurityInitializer);
    AddEquity("SPY");
}

private void CustomSecurityInitializer(Security security)
{
    security.SetShortableProvider(new LocalDiskShortableProvider("axos"));
}
```

If you call the `SetSecurityInitializer` method, it overwrites the default security initializer. The default security initializer uses the security-level reality models of the brokerage model to set the following reality models of each security:

- Fill
- Slippage
- Fee

- Buying Power
- Settlement
- Short availability
- Margin Interest Rate

To extend upon the default security initializer instead of overwriting it, call `AddSecurityInitializer` before you create the subscriptions before you create the subscriptions.

```
C#
public class AddSecurityInitializerExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        // In the Initialize method, set the security initializer to set models of assets.
        AddSecurityInitializer(CustomSecurityInitializer);
    }

    private void CustomSecurityInitializer(Security security)
    {
        // Overwrite some of the reality models
        security.SetShortableProvider(new LocalDiskShortableProvider("axos"));
    }
}
```

To view all the pre-built shortable providers, see Supported Providers .

Default Behavior

The brokerage model of your algorithm automatically sets the shortable provider for each security. The default brokerage model is the `DefaultBrokerageModel` , which uses the NullShortableProvider .

Provider Structure

Shortable providers must implement the `IShortableProvider` interface. Shortable providers that implement the `IShortableProvider` interface must implement the `FeeRate` , `RebateRate` , and `ShortableQuantity` methods. These methods receives a Symbol and the local time of the algorithm. The `FeeRate` method returns the borrow fee rate. The `RebateRate` method returns the borrow rebate rate. The `ShortableQuantity` returns the shortable quantity.

```C#
public class CustomShortableProviderExampleAlgorithm : QCAlgorithm
{
    public override void Initialize()
    {
        var security = AddEquity("SPY");
        // Provide the selected security with your broker's shortable information
        security.SetShortableProvider(new MyShortableProvider());
    }
}

// Define the custom shortable provider
class MyShortableProvider : IShortableProvider
{
    public decimal FeeRate(Symbol symbol, DateTime localTime)
    {
        return 0.0025m;
    }

    public decimal RebateRate(Symbol symbol, DateTime localTime)
    {
        return 0.0507m;
    }

    public long? ShortableQuantity(Symbol symbol, DateTime localTime)
    {
        return 10000;
    }
}
```

Order Failures

If you place an order to short more shares than are available to borrow, LEAN rejects the order and applies the following tag: "Order exceeds maximum shortable quantity for Symbol ticker (requested short: quantity)".

Borrowing Costs

In live trading, your brokerage charges an interest fee when you borrow shares to short a security. In backtesting, use the ShortMarginInterestRateModel .

To get valid borrowing rates, use the InteractiveBrokersShortableProvider .

```C#
public override void Initialize()
{
    var security = AddEquity("SPY");
    // For US Equity, use the ShortMarginInterestRateModel with IB data
    security.SetShortableProvider(new InteractiveBrokersShortableProvider());
    security.MarginInterestRateModel = new ShortMarginInterestRateModel();
}
```

Examples

The following examples demonstrate common practices for using a shortable provider.

Example 1: Fixed Rates

The following algorithm defines a custom short availability model with fixed values for the fee rate, rebate rate, and shortable quantity.

```C#
public class CustomShortableProviderAlgorithm : QCAlgorithm
{
    private Equity _security;

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);
        SetCash(100000);

        _security = AddEquity("QQQ", Resolution.Daily);
        _security.SetShortableProvider(new MyShortableProvider());
    }

    public override void OnData(Slice data)
    {
        if (Portfolio.Invested) return;
        var shortableQuantity = _security.ShortableProvider.ShortableQuantity(_security.Symbol, Time);
        if (shortableQuantity == null) return;
        var feeRate = _security.ShortableProvider.FeeRate(_security.Symbol, Time);
        var rebateRate = _security.ShortableProvider.RebateRate(_security.Symbol, Time);
        SetHoldings(_security.Symbol, -0.05m, tag: $"Borrow fee rate {feeRate}. Borrow rebate rate {rebateRate}");
    }
}

class MyShortableProvider : IShortableProvider
{
    public decimal FeeRate(Symbol symbol, DateTime localTime)
    {
        return 0.0025m;
    }

    public decimal RebateRate(Symbol symbol, DateTime localTime)
    {
        return 0.0507m;
    }

    public long? ShortableQuantity(Symbol symbol, DateTime localTime)
    {
        return 10000;
    }
}
```

Example 2: Sizing By Shortable Quantity

The following algorithm trades arbitrage of class A and class C price divergence of Google stocks using cointegration analysis. However, the position sizing may be limited by the available quantity to be shorted by the brokerage, breaking the paired trade. Thus, we need to make use of the `ShortableQuantity` method of the shortable provider to calculate the quantity.

```C#
using Accord.Statistics;
using MathNet.Numerics.LinearRegression;
using QuantConnect.Data.Shortable;

public class ShortableProviderAlgorithm : QCAlgorithm
{
    private Symbol _goog1, _goog2;
    // The threshold that the spread/residual of the cointegrated series triggers a trade.
    private decimal _thresold;
    // Store the coefficient and intercept of the cointegrated series for calculating the spread of a new data point.
    private decimal[] _coefficients = new[] { 0m, 0m };
    // Store the price series of each symbol for cointegration calculation.
    private Dictionary<Symbol, RollingWindow<decimal>> _windows = new();

    public override void Initialize()
    {
        SetStartDate(2024, 9, 1);
        SetEndDate(2024, 12, 31);

        // Subscribe to 2 classes of Google stocks to trade their price divergence.
        var goog1 = AddEquity("GOOGL", Resolution.Daily);
        var goog2 = AddEquity("GOOG", Resolution.Daily);
        _goog1 = goog1.Symbol;          // Class A
        _goog2 = goog2.Symbol;          // Class C
```

```
        // Set the shortable providers to simulate the available shares to trade realistically.
        goog1.SetShortableProvider(new InteractiveBrokersShortableProvider());
        goog2.SetShortableProvider(new InteractiveBrokersShortableProvider());

        // Use rolling windows to save the price data for cointegration analysis.
        _windows[_goog1] = new(252);
        _windows[_goog2] = new(252);
        // Warm up the rolling windows.
        var history = History<TradeBar>(new[] { _goog1, _goog2 }, 252, Resolution.Daily);
        foreach (var bar in history)
        {
            _windows[_goog1].Add(bar[_goog1].Close);
            _windows[_goog2].Add(bar[_goog2].Close);
        }

        // Adjust the cointegration factor between the 2 classes' monthly price series.
        Schedule.On(
            DateRules.MonthStart(),
            TimeRules.At(0, 1),
            CalculateCointegration
        );

        CalculateCointegration();
    }

    public override void OnData(Slice slice)
    {
        if (slice.Bars.TryGetValue(_goog1, out var bar1) && slice.Bars.TryGetValue(_goog2, out var bar2))
        {
            // Update the rolling windows for cointegration analysis.
            _windows[_goog1].Add(bar1.Close);
            _windows[_goog2].Add(bar2.Close);

            // Calculate the current cointegrated series spread.
            var residual = _coefficients[0] * bar2.Close + _coefficients[1] - bar1.Close;

            var quantity = CalculateOrderQuantity(_goog1, 0.2m);
            // If the residual is lower than the negative threshold, it means class A price is much higher than what
it should be compared to class C.
            // We sell class A and buy class C to bet on their price convergence.
            if (residual < -_thresold && !Portfolio[_goog1].IsShort)
            {
                // Since it will be limited by shortable quantity, we max{shortable, 20% of portfolio value}.
                var shortableQuantity = Securities[_goog1].ShortableProvider.ShortableQuantity(_goog1, bar1.EndTime);
                quantity = Math.Min(quantity, Convert.ToDecimal(shortableQuantity));
                MarketOrder(_goog1, -quantity);
                MarketOrder(_goog2, quantity * _coefficients[0]);
            }
            // If the residual is higher than the threshold, it means class A price is much lower than what it should
be compared to class C.
            // We buy class A and sell class C to bet on their price convergence.
            else if (residual > _thresold && !Portfolio[_goog1].IsLong)
            {
                // Since it will be limited by shortable quantity, we max{shortable, 20% of portfolio value}.
                var shortableQuantity = Securities[_goog2].ShortableProvider.ShortableQuantity(_goog2, bar2.EndTime);
                quantity = Math.Min(quantity, Convert.ToDecimal(shortableQuantity));
                MarketOrder(_goog1, quantity);
                MarketOrder(_goog2, -quantity * _coefficients[0]);
            }
            // Close positions of the price are converged.
            else if ((Portfolio[_goog1].IsShort && residual > 0m) || (Portfolio[_goog1].IsLong && residual < 0m))
            {
                Liquidate();
            }
        }
    }

    private void CalculateCointegration()
    {
        // Lag direction is unimportant; it is just a sign flip in the linear regression, so we don't need to flip
the window order.
        var y = _windows[_goog1].Select(x => (double)x).ToArray();
        var x = _windows[_goog2].Select(x => (double)x).ToArray();

        // Perform Linear Regression on both price series to investigate their relationship.
        var regressionResult = SimpleRegression.Fit(x, y);
        var intercept = regressionResult.Item1;
        var slope = regressionResult.Item2;

        // Calculate the residuals series to check if it is stationary, meaning if the 2 price series move together.
        var residuals = new double[x.Length];
```

```
        for (int i = 0; i < x.Length; i++)
        {
            residuals[i] = y[i] - (intercept + slope * x[i]);
        }

        // Check if the residuals are stationary using the augmented Dickey-Fuller test.
        if (ADFTest(residuals))
        {
            // If cointegrated, update the positional sizing ratio and the spread threshold of the trade trigger.
            _coefficients = new[] { Convert.ToDecimal(slope), Convert.ToDecimal(intercept) };
            _thresold = 2m * Convert.ToDecimal(Measures.StandardDeviation(residuals));
        }
        else
        {
            // If not cointegrated, liquidate and set the size to zeros for no positions.
            Liquidate();
            _coefficients = new[] { 0m, 0m };
            _thresold = 100000000m;             // An arbitrarily large number that the class A price will never
reach.
        }
    }

    private static bool ADFTest(double[] series)
    {
        var n = series.Length;
        var lagged = new double[n - 1];
        var differences = new double[n - 1];

        // Fit linear regression for the residual series on unit root: ΔY_t = α + βY_{t-1} + ε_t.
        for (int i = 1; i < n; i++)
        {
            lagged[i - 1] = series[i - 1];
            differences[i - 1] = series[i] - series[i - 1];
        }

        var regressionResult = SimpleRegression.Fit(lagged, differences);
        var alpha = regressionResult.Item1;  // Intercept
        var beta = regressionResult.Item2;   // Coefficient of lagged term

        // Calculate the ADF statistic and check if the null hypothesis is rejected.
        var adfStatistic = beta / Measures.StandardError(differences);

        // Reject the null hypothesis of a unit root is present if test statistic <= -3.45 (approximate α=0.05 for
n=250)
        // This means no unit root exists for the difference series, and the residuals are stationary.
        return adfStatistic <= -3.45d;
    }
}
```

Other Examples

AllShortableSymbolsCoarseSelectionRegressionAlgorithm.cs C#

Short Availability

Supported Providers

Introduction

This page describes all of the pre-built shortable providers in LEAN. If none of these models perform exactly how you want, create a custom shortable provider .

Null Provider

The `NullShortableProvider` doesn't provide shortable data, so it allows you to infinitely short assets. It's the shortable provider of the `DefaultBrokerageModel` .

```
C#
security.SetShortableProvider(new NullShortableProvider());
```

For more information about this model, see the class reference and implementation .

Local Disk Provider

The `LocalDiskShortableProvider` sources short availability data from the local disk of a specific brokerage.

```
C#
security.SetShortableProvider(new LocalDiskShortableProvider("axos"));
```

The following table describes the arguments the model accepts:

Argument	Data Type	Description	Default Value
`brokerage`	`string`	Brokerage to read data	

For more information about this model, see the class reference and implementation .

Interactive Brokers Provider

The `InteractiveBrokersShortableProvider` sources short availability data from Interactive Brokers.

```
C#
security.SetShortableProvider(new InteractiveBrokersShortableProvider());
```

For more information about this model, see the class reference and implementation .

Scheduled Events

Introduction

Scheduled Events let you trigger code to run at specific times of day, regardless of your algorithm's data subscriptions. It's easier and more reliable to execute time-based events with Scheduled Events than checking the current algorithm time in the `OnData` event handler.

Create Scheduled Events

To create a Scheduled Event, call the `Schedule.On` method. The method expects a `DateRules` object, a `TimeRules` object, and a function to execute. The following examples demonstrate some common Scheduled Events.

Schedule Events Before Market Open

You may want to train a model or fetch historical data before the market opens. The following example demonstrates how to set a Scheduled Event for 10 minutes before the market opens.

```
C#
public override void Initialize()
{
    // Call the BeforeMarketOpen method 10 minutes before open every day SPY is trading.
    Schedule.On(
        DateRules.EveryDay("SPY"),
        TimeRules.BeforeMarketOpen("SPY", 10),
        BeforeMarketOpen
    );
}
```

Schedule Events on the Last Trading Day of the Week

You may want to rebalance your portfolio on the last trading day of each week and factor in market holidays. The following example demonstrates how to set a Scheduled Event for the last trading day of each week 30 minutes before the market closes.

```
C#
public override void Initialize()
{
    // Call the Rebalance method 30 minutes before the end of the SPY trading week.
    Schedule.On(
        DateRules.WeekEnd("SPY"),
        TimeRules.BeforeMarketClose("SPY", 30),
        Rebalance
    );
}
```

Schedule Events on Regular Intervals Throughout the Trading Day

You may want to perform some action on a regular interval through each trading day. The following example demonstrates how to set a Scheduled Event for every 30 minutes through the trading day for SPY.

```
C#
public override void Initialize()
{
    // Every day SPY is trading, call the 'SomeAction' method every 30 minutes.
    Schedule.On(
        DateRules.EveryDay("SPY"),
        TimeRules.Every(TimeSpan.FromMinutes(30)),
        SomeAction
    );
}
```

Date Rules

The following table describes the supported `DateRules` :

Member	Description
`DateRules.SetDefaultTimeZone(DateTimeZone timeZone);`	Sets the time zone for the `DateRules` object used in all methods in this table. The default time zone is the algorithm time zone .
`DateRules.On(int year, int month, int day)`	Trigger an event on a specific date.
`DateRules.On(params DateTime[] dates)`	Trigger an event on specific dates.
`DateRules.EveryDay()`	Trigger an event all seven days of the week.
`DateRules.EveryDay(Symbol symbol, bool extendedMarketHours = false)`	Trigger an event every day a specific symbol is trading.
`DateRules.Every(params DayOfWeek[] days)`	Trigger an event on specific days throughout the week. To view the `DayOfWeek` enum members, see DayOfWeek Enum in the .NET documentation.
`DateRules.MonthStart(int daysOffset = 0)`	Trigger an event on the first day of each month plus an offset.
`DateRules.MonthStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each month for a specific symbol plus an offset.
`DateRules.MonthEnd(int daysOffset = 0)`	Trigger an event on the last day of each month minus an offset.
`DateRules.MonthEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each month for a specific symbol minus an offset.
`DateRules.WeekStart(int daysOffset = 0)`	Trigger an event on the first day of each week plus an offset.
`DateRules.WeekStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each week for a specific symbol plus an offset.
`DateRules.WeekEnd(int daysOffset = 0)`	Trigger an event on the last day of each week minus an offset.
`DateRules.WeekEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each week for a specific symbol minus an offset.
`DateRules.YearStart(int daysOffset = 0)`	Trigger an event on the first day of each year plus an offset.
`DateRules.YearStart(Symbol symbol, int daysOffset = 0)`	Trigger an event on the first tradable date of each year for a specific symbol plus an offset.
`DateRules.YearEnd(int daysOffset = 0)`	Trigger an event on the last day of each year minus an offset.
`DateRules.YearEnd(Symbol symbol, int daysOffset = 0)`	Trigger an event on the last tradable date of each year for a specific symbol minus an offset.
`DateRules.Today`	Trigger an event once today.
`DateRules.Tomorrow`	Trigger an event once tomorrow.

To define custom date rules, create a `FuncDateRule` object. The `FuncDateRule` constructor expects a `name` argument of type `string` and a `getDatesFunction` argument of type `Func<DateTime, DateTime, IEnumerable<DateTime>>` . The `getDatesFunction` function receives the start and end dates of the algorithm and returns a list of dates for the date rule. In live trading, the end date is 12/31/2025. The following example demonstrates how to define a date rule that represents the 10th day of each month:

```
C#

// Create a date rule that specifies the 10th day of each month.
var dateRule = new FuncDateRule(
    name: "10th_day_of_the_month",
    getDatesFunction: (start, end) => Enumerable.Range(start.Year, end.Year - start.Year + 1)
        .SelectMany(year => Enumerable.Range(1, 12).Select(month => new DateTime(year, month, 10)))
);
```

Some date rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `DateRules.EveryDay("ES")` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```
C#

var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

Time Rules

The following table describes the supported `TimeRules` :

Member	Description
`TimeRules.SetDefaultTimeZone(DateTimeZone timeZone)`	Sets the time zone for the `TimeRules` object used in all methods in this table, except when a different time zone is given. The default time zone is the algorithm time zone .
`TimeRules.BeforeMarketOpen(Symbol symbol, double minutesBeforeOpen = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes before market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.AfterMarketOpen(Symbol symbol, double minutesAfterOpen = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes after market open for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.BeforeMarketClose(Symbol symbol, double minutesBeforeClose = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes before market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.AfterMarketClose(Symbol symbol, double minutesAfterClose = 0, bool extendedMarketOpen = false)`	Trigger an event a few minutes after market close for a specific symbol (default is 0). This rule doesn't work for Crypto securities or custom data.
`TimeRules.Every(TimeSpan interval)`	Trigger an event every period interval starting at midnight. This time rule triggers every period, regardless of whether or not the market is open.
`TimeRules.Now`	Trigger an event at the current time of day.
`TimeRules.Midnight`	Trigger an event at midnight.
`TimeRules.Noon`	Trigger an event at noon.
`TimeRules.At(int hour, int minute, int second = 0)`	Trigger an event at a specific time of day (e.g. 13:10).
`TimeRules.At(int hour, int minute, int second, DateTimeZone timeZone)`	Trigger an event at a specific time of day in the given time zone (e.g. 13:10 UTC).

To define custom time rules, create a `FuncTimeRule` object. The `FuncTimeRule` constructor expects a `name` argument of type `string` and a `createUtcEventTimesFunction` argument of type `Func<IEnumerable<DateTime>, IEnumerable<DateTime>>` . The function receives the list of dates from the date rule and then returns a list of `DateTime` that define the time rule.

```
C#
var timeRule = new FuncTimeRule(
    name: "CustomTimeRule",
    createUtcEventTimesFunction: dates => dates.Select(d => d.AddHours(10)));
```

Some time rules require a Symbol. However, they accept a string representation of the Symbol as well. If your algorithm doesn't add the security , it assumes the string refers to a US Equity Symbol. For example, if you use the `TimeRules.BeforeMarketOpen("ES", 15)` method, it assumes that 'ES' refers to a US Equity. To create a Symbol without adding a security to your algorithm, call the `QuantConnect.Symbol.Create` method.

```
C#
var symbol = QuantConnect.Symbol.Create("ES", SecurityType.Future, Market.CME);
```

Remove Scheduled Events

If you no longer need a Scheduled Event in your algorithm, remove it so your algorithm doesn't execute unnecessary functions. To remove a Scheduled Event, save a reference to the Scheduled Event when you create it and then call the `Remove` method to remove it.

```
C#
private ScheduledEvent _scheduledEvent;

public override void Initialize()
{
    // Remove a scheduled event by keeping a copy of the object on creation.
    _scheduledEvent = Schedule.On(
        DateRules.EveryDay("SPY"),
        TimeRules.AfterMarketOpen("SPY", 10),
        TenMinutesAfterOpen
    );
}

// Remove the scheduled event using the object reference in any method
Schedule.Remove(_scheduledEvent);
```

Common Errors

Common errors with Scheduled Events include stale fills and execution timeouts.

Stale Fills

A common error is to subscribe to daily resolution data and set a Scheduled Event intraday to place trades. If you trade intraday with daily data, you get stale fills.

Another common error is to set a Scheduled Event to trade immediately after the market open on illiquid securities. Illiquid securities can have no trades for the first few minutes after the market open. If you trade during this time, you get stale fills.

Execution Timeouts

If your Scheduled Event takes longer than 10 minutes to execute, your algorithm will timeout. To increase the amount of time that your Scheduled Event can run, replace your Scheduled Event with a training session .

Invoking the Callback Method

Make sure to not accidentally invote the event handler method by adding trailing braces `()` . Use `MyCallbackFunction` , not `MyCallbackFunction()` .

Execution Sequence

The algorithm manager calls events in the following order:

1. Scheduled Events
2. Consolidation event handlers
3. `OnData` event handler

This event flow is important to note. For instance, if your consolidation handlers or `OnData` event handler appends data to a `RollingWindow` and you use that `RollingWindow` in your Scheduled Event, when the Scheduled Event executes, the `RollingWindow` won't contain the most recent data.

Live Trading Considerations

In live trading, Scheduled Events execute in a parallel thread based on a real-time clock. If you set a Scheduled Event to fire at 10:00 AM, it executes at exactly 10:00 AM. In backtesting, Scheduled Events are part of the main algorithm manager loop, so they may not execute exactly when you set them. For example, if your algorithm subscribes to minute resolution US Equity data

with regular trading hours and you set a Scheduled Event to occur at 2:00 AM, your Scheduled Event will execute at 9:31 AM when the next bar is fed into your algorithm.

The difference between live trading and backtesting is important to note because it can affect your algorithm's behavior. There are two common scenarios to consider.

Execution Timing and Backtest Timeouts

Take the following scenario:

- You set Scheduled Events for 2:00 AM, 3:00 AM, and 4:00 AM each day.
- Each Scheduled Event takes eight minutes to execute.
- Your algorithm only subscribes to US Equity securities without extended market hours (9:30 AM - 4:00 PM).

In this scenario, the Scheduled Events each fire at the correct time and execute without error in live trading. In backtesting, all of the Scheduled Events execute at 9:31 AM when your algorithm receives the first bar of the trading day. Since all the Scheduled Events take eight minutes to execute, the algorithm tries to execute all the Scheduled Events but reaches the 10-minute timeout and the backtest stops execution.

Live Data Delays

In backtests, your algorithm receives data at perfect timing. If you request minute resolution data, your algorithm receives the bars at the top of each minute. In live trading, bars have a slight delay, so you may receive them milliseconds after the top of each minute. Take the following scenario:

- You subscribe to minute resolution data
- You set a Scheduled Event for 10:00 AM
- The Scheduled Event checks the current asset price

In live trading, the Scheduled Event executes at exactly 10:00 AM but your algorithm may receive the 9:59-10:00 AM bar at 10:00:00.01 AM. Therefore, when you check the price in the Scheduled Event, the price from the 9:58-9:59 AM bar is the latest price. In backtesting, the Scheduled Event gets the price from the 9:59-10:00 AM bar since your algorithm receives the bar at perfect timing.

Examples

C#

```
public override void Initialize()
{
    var symbol = QuantConnect.Symbol.Create("SPY", SecurityType.Equity, Market.USA);

    // Schedule an event to fire at a specific date/time using inline callback function.
    Schedule.On(DateRules.On(2013, 10, 7),
                TimeRules.At(13, 0),
                () => Log($"SpecificTime: Fired at : {Time}"));

    // Schedule an event to fire every trading day for a security
    // The time rule here tells it to fire at 13:00:00 UTC
    Schedule.On(DateRules.EveryDay("SPY"),
                TimeRules.At(13, 0, 0, TimeZones.Utc),
                () => Log($"EveryDay.SPY SpecificTime: Fired at: {Time}"));

    // Schedule an event to fire every trading day for a security
    // The time rule here tells it to fire 10 minutes before SPY's market open
    Schedule.On(DateRules.EveryDay("SPY"),
                TimeRules.BeforeMarketOpen("SPY", 10),
                () => Log($"EveryDay.SPY 10 min before open: Fired at: {Time}"));

    // Schedule an event to fire every trading day for a security
    // The time rule here tells it to fire 10 minutes after SPY's market open
    Schedule.On(DateRules.EveryDay("SPY"),
                TimeRules.AfterMarketOpen("SPY", 10),
                () => Log($"EveryDay.SPY 10 min after open: Fired at: {Time}"));
```

```
                () => Log($"EveryDay.SPY 10 min after open: Fired at: {Time}"));

    // Schedule an event to fire every trading day for a security
    // The time rule here tells it to fire 10 minutes before SPY's market close
    Schedule.On(DateRules.EveryDay("SPY"),
                TimeRules.BeforeMarketClose("SPY", 10),
                () => Log($"EveryDay.SPY 10 min before close: Fired at: {Time}"));

    // Schedule an event to fire every trading day for a security
    // The time rule here tells it to fire 10 minutes after SPY's market close
    Schedule.On(DateRules.EveryDay("SPY"),
                TimeRules.AfterMarketClose("SPY", 10),
                () => Log($"EveryDay.SPY 10 min after close: Fired at: {Time}"));

    // Schedule an event to fire on certain days of the week
    Schedule.On(DateRules.Every(DayOfWeek.Monday, DayOfWeek.Friday),
                TimeRules.At(12, 0),
                () => Log($"Mon/Fri at 12pm: Fired at: {Time}"));

    // Schedule an event to fire once today at when this method is called (now)
    Schedule.On(DateRules.Today,
                TimeRules.Now,
                () => Log($"Now: Fired at: {Time}"));

    // Schedule an event to fire once tomorrow at midnight
    Schedule.On(DateRules.Tomorrow,
                TimeRules.Midnight,
                () => Log($"Tomorrow at midnight: Fired at: {Time}"));

    // Schedule an event to fire once today at noon
    Schedule.On(DateRules.Today,
                TimeRules.Noon,
                () => Log($"Today at noon: Fired at: {Time}"));

    // The scheduling methods return the ScheduledEvent object which can be used
    // for other things here I set the event up to check the portfolio value every
    // 10 minutes, and liquidate if we have too many losses
    Schedule.On(DateRules.EveryDay(),
                TimeRules.Every(TimeSpan.FromMinutes(10)),
                LiquidateUnrealizedLosses);

    // Schedule an event to fire at the beginning of the month, the symbol is optional.
    // If specified, it will fire the first trading day for that symbol of the month.
    // Otherwise, it will fire on the first day of the month.
    Schedule.On(DateRules.MonthStart("SPY"),
                TimeRules.AfterMarketOpen("SPY"),
                RebalancingCode);

    // Schedule an event to fire at the end of the month, the symbol is optional.
    // If specified, it will fire the last trading day for that symbol of the month.
    // Otherwise, it will fire on the last day of the month.
    Schedule.On(DateRules.MonthEnd("SPY"),
                TimeRules.BeforeMarketClose("SPY"),
                RebalancingCode);

    // Schedule an event to fire at the beginning of the week, the symbol is optional.
    // If specified, it will fire the first trading day for that symbol of the week.
    // Otherwise, it will fire on the first day of the week.
    Schedule.On(DateRules.WeekStart("SPY"),
                TimeRules.AfterMarketOpen("SPY", 5),
                RebalancingCode);

    // Schedule an event to fire at the end of the week, the symbol is optional.
    // If specified, it will fire the last trading day for that symbol of the week.
    // Otherwise, it will fire on the first day of the week.
    Schedule.On(DateRules.WeekEnd("SPY"),
                TimeRules.BeforeMarketClose("SPY", 5),
                RebalancingCode);
    }

// The following methods are not defined in Initialize:
private void LiquidateUnrealizedLosses()
{
    // if we have over 1000 dollars in unrealized losses, liquidate
    if (Portfolio.TotalUnrealizedProfit < -1000)
    {
        Log($"Liquidated due to unrealized losses at: {Time}");
        Liquidate();
    }
}

private void RebalancingCode()
```

```
    private void RebalancingCode()
    {
        // Good spot for rebalancing code?
    }
```

Abandoned Baby

Introduction

Create a new Abandoned Baby candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using AbandonedBaby Indicator

To create an automatic indicator for `AbandonedBaby` , call the `AbandonedBaby` helper method from the `QCAlgorithm` class. The `AbandonedBaby` method creates a `AbandonedBaby` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class AbandonedBabyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AbandonedBaby _abandonedBaby;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _abandonedBaby = CandlestickPatterns.AbandonedBaby(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_abandonedBaby.IsReady)
        {
            // The current value of _abandonedBaby is represented by itself (_abandonedBaby)
            // or _abandonedBaby.Current.Value
            Plot("AbandonedBaby", "abandonedBaby", _abandonedBaby);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `AbandonedBaby` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AbandonedBabyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AbandonedBaby _abandonedBaby;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _abandonedBaby = new AbandonedBaby();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _abandonedBaby.Update(bar);

        if (_abandonedBaby.IsReady)
        {
            // The current value of _abandonedBaby is represented by itself (_abandonedBaby)
            // or _abandonedBaby.Current.Value
            Plot("AbandonedBaby", "abandonedBaby", _abandonedBaby);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AbandonedBaby` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class AbandonedBabyAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AbandonedBaby _abandonedBaby;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _abandonedBaby = CandlestickPatterns.AbandonedBaby(_symbol);

        var indicatorHistory = IndicatorHistory(_abandonedBaby, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_abandonedBaby, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_abandonedBaby, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Advance Block

Introduction

Create a new Advance Block candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using AdvanceBlock Indicator

To create an automatic indicator for `AdvanceBlock` , call the `AdvanceBlock` helper method from the `QCAlgorithm` class. The `AdvanceBlock` method creates a `AdvanceBlock` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class AdvanceBlockAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AdvanceBlock _advanceBlock;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _advanceBlock = CandlestickPatterns.AdvanceBlock(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_advanceBlock.IsReady)
        {
            // The current value of _advanceBlock is represented by itself (_advanceBlock)
            // or _advanceBlock.Current.Value
            Plot("AdvanceBlock", "advanceBlock", _advanceBlock);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `AdvanceBlock` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AdvanceBlockAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AdvanceBlock _advanceBlock;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _advanceBlock = new AdvanceBlock();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _advanceBlock.Update(bar);

        if (_advanceBlock.IsReady)
        {
            // The current value of _advanceBlock is represented by itself (_advanceBlock)
            // or _advanceBlock.Current.Value
            Plot("AdvanceBlock", "advanceBlock", _advanceBlock);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AdvanceBlock` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class AdvanceBlockAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AdvanceBlock _advanceBlock;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _advanceBlock = CandlestickPatterns.AdvanceBlock(_symbol);

        var indicatorHistory = IndicatorHistory(_advanceBlock, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_advanceBlock, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_advanceBlock, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Belt Hold

Introduction

Create a new Belt Hold candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using BeltHold Indicator

To create an automatic indicator for `BeltHold` , call the `BeltHold` helper method from the `QCAlgorithm` class. The `BeltHold` method creates a `BeltHold` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class BeltHoldAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BeltHold _beltHold;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _beltHold = CandlestickPatterns.BeltHold(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_beltHold.IsReady)
        {
            // The current value of _beltHold is represented by itself (_beltHold)
            // or _beltHold.Current.Value
            Plot("BeltHold", "beltHold", _beltHold);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `BeltHold` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class BeltHoldAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BeltHold _beltHold;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _beltHold = new BeltHold();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _beltHold.Update(bar);

        if (_beltHold.IsReady)
        {
            // The current value of _beltHold is represented by itself (_beltHold)
            // or _beltHold.Current.Value
            Plot("BeltHold", "beltHold", _beltHold);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `BeltHold` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class BeltHoldAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private BeltHold _beltHold;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _beltHold = CandlestickPatterns.BeltHold(_symbol);

        var indicatorHistory = IndicatorHistory(_beltHold, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_beltHold, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_beltHold, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Breakaway

Introduction

Create a new Breakaway candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Breakaway Indicator

To create an automatic indicator for `Breakaway` , call the `Breakaway` helper method from the `QCAlgorithm` class. The `Breakaway` method creates a `Breakaway` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class BreakawayAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Breakaway _breakaway;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _breakaway = CandlestickPatterns.Breakaway(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_breakaway.IsReady)
        {
            // The current value of _breakaway is represented by itself (_breakaway)
            // or _breakaway.Current.Value
            Plot("Breakaway", "breakaway", _breakaway);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Breakaway` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class BreakawayAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Breakaway _breakaway;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _breakaway = new Breakaway();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _breakaway.Update(bar);

        if (_breakaway.IsReady)
        {
            // The current value of _breakaway is represented by itself (_breakaway)
            // or _breakaway.Current.Value
            Plot("Breakaway", "breakaway", _breakaway);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Breakaway` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class BreakawayAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Breakaway _breakaway;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _breakaway = CandlestickPatterns.Breakaway(_symbol);

        var indicatorHistory = IndicatorHistory(_breakaway, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_breakaway, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_breakaway, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Closing Marubozu

Introduction

Create a new Closing Marubozu candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ClosingMarubozu Indicator

To create an automatic indicator for `ClosingMarubozu` , call the `ClosingMarubozu` helper method from the `QCAlgorithm` class. The `ClosingMarubozu` method creates a `ClosingMarubozu` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ClosingMarubozuAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ClosingMarubozu _closingMarubozu;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _closingMarubozu = CandlestickPatterns.ClosingMarubozu(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_closingMarubozu.IsReady)
        {
            // The current value of _closingMarubozu is represented by itself (_closingMarubozu)
            // or _closingMarubozu.Current.Value
            Plot("ClosingMarubozu", "closingMarubozu", _closingMarubozu);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ClosingMarubozu` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class ClosingMarubozuAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ClosingMarubozu _closingMarubozu;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _closingMarubozu = new ClosingMarubozu();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _closingMarubozu.Update(bar);

        if (_closingMarubozu.IsReady)
        {
            // The current value of _closingMarubozu is represented by itself (_closingMarubozu)
            // or _closingMarubozu.Current.Value
            Plot("ClosingMarubozu", "closingMarubozu", _closingMarubozu);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ClosingMarubozu` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class ClosingMarubozuAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ClosingMarubozu _closingMarubozu;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _closingMarubozu = CandlestickPatterns.ClosingMarubozu(_symbol);

        var indicatorHistory = IndicatorHistory(_closingMarubozu, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_closingMarubozu, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_closingMarubozu, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Concealed Baby Swallow

Introduction

Create a new Concealed Baby Swallow candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ConcealedBabySwallow Indicator

To create an automatic indicator for `ConcealedBabySwallow` , call the `ConcealedBabySwallow` helper method from the `QCAlgorithm` class. The `ConcealedBabySwallow` method creates a `ConcealedBabySwallow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ConcealedBabySwallowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ConcealedBabySwallow _concealedBabySwallow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _concealedBabySwallow = CandlestickPatterns.ConcealedBabySwallow(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_concealedBabySwallow.IsReady)
        {
            // The current value of _concealedBabySwallow is represented by itself (_concealedBabySwallow)
            // or _concealedBabySwallow.Current.Value
            Plot("ConcealedBabySwallow", "concealedBabySwallow", _concealedBabySwallow);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ConcealedBabySwallow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ConcealedBabySwallowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ConcealedBabySwallow _concealedBabySwallow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _concealedBabySwallow = new ConcealedBabySwallow();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _concealedBabySwallow.Update(bar);

        if (_concealedBabySwallow.IsReady)
        {
            // The current value of _concealedBabySwallow is represented by itself (_concealedBabySwallow)
            // or _concealedBabySwallow.Current.Value
            Plot("ConcealedBabySwallow", "concealedBabySwallow", _concealedBabySwallow);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ConcealedBabySwallow` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ConcealedBabySwallowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ConcealedBabySwallow _concealedBabySwallow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _concealedBabySwallow = CandlestickPatterns.ConcealedBabySwallow(_symbol);

        var indicatorHistory = IndicatorHistory(_concealedBabySwallow, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_concealedBabySwallow, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_concealedBabySwallow, _symbol, new DateTime(2024, 7, 1),
new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Counterattack

Introduction

Create a new Counterattack candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Counterattack Indicator

To create an automatic indicator for `Counterattack` , call the `Counterattack` helper method from the `QCAlgorithm` class. The `Counterattack` method creates a `Counterattack` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class CounterattackAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Counterattack _counterattack;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _counterattack = CandlestickPatterns.Counterattack(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_counterattack.IsReady)
        {
            // The current value of _counterattack is represented by itself (_counterattack)
            // or _counterattack.Current.Value
            Plot("Counterattack", "counterattack", _counterattack);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Counterattack` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class CounterattackAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Counterattack _counterattack;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _counterattack = new Counterattack();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _counterattack.Update(bar);

        if (_counterattack.IsReady)
        {
            // The current value of _counterattack is represented by itself (_counterattack)
            // or _counterattack.Current.Value
            Plot("Counterattack", "counterattack", _counterattack);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Counterattack` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class CounterattackAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Counterattack _counterattack;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _counterattack = CandlestickPatterns.Counterattack(_symbol);

        var indicatorHistory = IndicatorHistory(_counterattack, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_counterattack, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_counterattack, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Dark Cloud Cover

Introduction

Create a new Dark Cloud Cover candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using DarkCloudCover Indicator

To create an automatic indicator for `DarkCloudCover` , call the `DarkCloudCover` helper method from the `QCAlgorithm` class. The `DarkCloudCover` method creates a `DarkCloudCover` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class DarkCloudCoverAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DarkCloudCover _darkCloudCover;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _darkCloudCover = CandlestickPatterns.DarkCloudCover(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_darkCloudCover.IsReady)
        {
            // The current value of _darkCloudCover is represented by itself (_darkCloudCover)
            // or _darkCloudCover.Current.Value
            Plot("DarkCloudCover", "darkCloudCover", _darkCloudCover);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `DarkCloudCover` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class DarkCloudCoverAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DarkCloudCover _darkCloudCover;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _darkCloudCover = new DarkCloudCover();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _darkCloudCover.Update(bar);

        if (_darkCloudCover.IsReady)
        {
            // The current value of _darkCloudCover is represented by itself (_darkCloudCover)
            // or _darkCloudCover.Current.Value
            Plot("DarkCloudCover", "darkCloudCover", _darkCloudCover);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `DarkCloudCover` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class DarkCloudCoverAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DarkCloudCover _darkCloudCover;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _darkCloudCover = CandlestickPatterns.DarkCloudCover(_symbol);

        var indicatorHistory = IndicatorHistory(_darkCloudCover, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_darkCloudCover, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_darkCloudCover, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Doji

Introduction

Create a new Doji candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Doji Indicator

To create an automatic indicator for `Doji` , call the `Doji` helper method from the `QCAlgorithm` class. The `Doji` method creates a `Doji` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class DojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Doji _doji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _doji = CandlestickPatterns.Doji(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_doji.IsReady)
        {
            // The current value of _doji is represented by itself (_doji)
            // or _doji.Current.Value
            Plot("Doji", "doji", _doji);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Doji` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class DojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Doji _doji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _doji = new Doji();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _doji.Update(bar);

        if (_doji.IsReady)
        {
            // The current value of _doji is represented by itself (_doji)
            // or _doji.Current.Value
            Plot("Doji", "doji", _doji);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Doji` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class DojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Doji _doji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _doji = CandlestickPatterns.Doji(_symbol);

        var indicatorHistory = IndicatorHistory(_doji, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_doji, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_doji, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Doji Star

Introduction

Create a new Doji Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using DojiStar Indicator

To create an automatic indicator for `DojiStar` , call the `DojiStar` helper method from the `QCAlgorithm` class. The `DojiStar` method creates a `DojiStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class DojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DojiStar _dojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dojiStar = CandlestickPatterns.DojiStar(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_dojiStar.IsReady)
        {
            // The current value of _dojiStar is represented by itself (_dojiStar)
            // or _dojiStar.Current.Value
            Plot("DojiStar", "dojiStar", _dojiStar);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `DojiStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class DojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DojiStar _dojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dojiStar = new DojiStar();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _dojiStar.Update(bar);

        if (_dojiStar.IsReady)
        {
            // The current value of _dojiStar is represented by itself (_dojiStar)
            // or _dojiStar.Current.Value
            Plot("DojiStar", "dojiStar", _dojiStar);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `DojiStar` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class DojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DojiStar _dojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dojiStar = CandlestickPatterns.DojiStar(_symbol);

        var indicatorHistory = IndicatorHistory(_dojiStar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_dojiStar, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_dojiStar, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Dragonfly Doji

Introduction

Create a new Dragonfly Doji candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using DragonflyDoji Indicator

To create an automatic indicator for `DragonflyDoji` , call the `DragonflyDoji` helper method from the `QCAlgorithm` class. The `DragonflyDoji` method creates a `DragonflyDoji` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class DragonflyDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DragonflyDoji _dragonflyDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dragonflyDoji = CandlestickPatterns.DragonflyDoji(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_dragonflyDoji.IsReady)
        {
            // The current value of _dragonflyDoji is represented by itself (_dragonflyDoji)
            // or _dragonflyDoji.Current.Value
            Plot("DragonflyDoji", "dragonflyDoji", _dragonflyDoji);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `DragonflyDoji` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class DragonflyDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DragonflyDoji _dragonflyDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dragonflyDoji = new DragonflyDoji();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _dragonflyDoji.Update(bar);

        if (_dragonflyDoji.IsReady)
        {
            // The current value of _dragonflyDoji is represented by itself (_dragonflyDoji)
            // or _dragonflyDoji.Current.Value
            Plot("DragonflyDoji", "dragonflyDoji", _dragonflyDoji);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `DragonflyDoji` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class DragonflyDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private DragonflyDoji _dragonflyDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _dragonflyDoji = CandlestickPatterns.DragonflyDoji(_symbol);

        var indicatorHistory = IndicatorHistory(_dragonflyDoji, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_dragonflyDoji, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_dragonflyDoji, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Engulfing

Introduction

Create a new Engulfing candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Engulfing Indicator

To create an automatic indicator for `Engulfing` , call the `Engulfing` helper method from the `QCAlgorithm` class. The `Engulfing` method creates a `Engulfing` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class EngulfingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Engulfing _engulfing;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _engulfing = CandlestickPatterns.Engulfing(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_engulfing.IsReady)
        {
            // The current value of _engulfing is represented by itself (_engulfing)
            // or _engulfing.Current.Value
            Plot("Engulfing", "engulfing", _engulfing);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Engulfing` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class EngulfingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Engulfing _engulfing;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _engulfing = new Engulfing();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _engulfing.Update(bar);

        if (_engulfing.IsReady)
        {
            // The current value of _engulfing is represented by itself (_engulfing)
            // or _engulfing.Current.Value
            Plot("Engulfing", "engulfing", _engulfing);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Engulfing` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class EngulfingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Engulfing _engulfing;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _engulfing = CandlestickPatterns.Engulfing(_symbol);

        var indicatorHistory = IndicatorHistory(_engulfing, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_engulfing, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_engulfing, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Evening Doji Star

Introduction

Create a new Evening Doji Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using EveningDojiStar Indicator

To create an automatic indicator for `EveningDojiStar` , call the `EveningDojiStar` helper method from the `QCAlgorithm` class. The `EveningDojiStar` method creates a `EveningDojiStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class EveningDojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EveningDojiStar _eveningDojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _eveningDojiStar = CandlestickPatterns.EveningDojiStar(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_eveningDojiStar.IsReady)
        {
            // The current value of _eveningDojiStar is represented by itself (_eveningDojiStar)
            // or _eveningDojiStar.Current.Value
            Plot("EveningDojiStar", "eveningDojiStar", _eveningDojiStar);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `EveningDojiStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class EveningDojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EveningDojiStar _eveningDojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _eveningDojiStar = new EveningDojiStar();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _eveningDojiStar.Update(bar);

        if (_eveningDojiStar.IsReady)
        {
            // The current value of _eveningDojiStar is represented by itself (_eveningDojiStar)
            // or _eveningDojiStar.Current.Value
            Plot("EveningDojiStar", "eveningDojiStar", _eveningDojiStar);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `EveningDojiStar` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class EveningDojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EveningDojiStar _eveningDojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _eveningDojiStar = CandlestickPatterns.EveningDojiStar(_symbol);

        var indicatorHistory = IndicatorHistory(_eveningDojiStar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_eveningDojiStar, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_eveningDojiStar, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Evening Star

Introduction

Create a new Evening Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using EveningStar Indicator

To create an automatic indicator for `EveningStar` , call the `EveningStar` helper method from the `QCAlgorithm` class. The `EveningStar` method creates a `EveningStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class EveningStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EveningStar _eveningStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _eveningStar = CandlestickPatterns.EveningStar(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_eveningStar.IsReady)
        {
            // The current value of _eveningStar is represented by itself (_eveningStar)
            // or _eveningStar.Current.Value
            Plot("EveningStar", "eveningStar", _eveningStar);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `EveningStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class EveningStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EveningStar _eveningStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _eveningStar = new EveningStar();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _eveningStar.Update(bar);

        if (_eveningStar.IsReady)
        {
            // The current value of _eveningStar is represented by itself (_eveningStar)
            // or _eveningStar.Current.Value
            Plot("EveningStar", "eveningStar", _eveningStar);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `EveningStar` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class EveningStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private EveningStar _eveningStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _eveningStar = CandlestickPatterns.EveningStar(_symbol);

        var indicatorHistory = IndicatorHistory(_eveningStar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_eveningStar, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_eveningStar, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Gap Side By Side White

Introduction

Create a new Gap Side By Side White candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using GapSideBySideWhite Indicator

To create an automatic indicator for `GapSideBySideWhite` , call the `GapSideBySideWhite` helper method from the `QCAlgorithm` class. The `GapSideBySideWhite` method creates a `GapSideBySideWhite` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class GapSideBySideWhiteAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private GapSideBySideWhite _gapSideBySideWhite;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _gapSideBySideWhite = CandlestickPatterns.GapSideBySideWhite(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_gapSideBySideWhite.IsReady)
        {
            // The current value of _gapSideBySideWhite is represented by itself (_gapSideBySideWhite)
            // or _gapSideBySideWhite.Current.Value
            Plot("GapSideBySideWhite", "gapSideBySideWhite", _gapSideBySideWhite);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `GapSideBySideWhite` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class GapSideBySideWhiteAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private GapSideBySideWhite _gapSideBySideWhite;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _gapSideBySideWhite = new GapSideBySideWhite();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _gapSideBySideWhite.Update(bar);

        if (_gapSideBySideWhite.IsReady)
        {
            // The current value of _gapSideBySideWhite is represented by itself (_gapSideBySideWhite)
            // or _gapSideBySideWhite.Current.Value
            Plot("GapSideBySideWhite", "gapSideBySideWhite", _gapSideBySideWhite);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `GapSideBySideWhite` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class GapSideBySideWhiteAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private GapSideBySideWhite _gapSideBySideWhite;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _gapSideBySideWhite = CandlestickPatterns.GapSideBySideWhite(_symbol);

        var indicatorHistory = IndicatorHistory(_gapSideBySideWhite, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_gapSideBySideWhite, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_gapSideBySideWhite, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Gravestone Doji

Introduction

Create a new Gravestone Doji candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using GravestoneDoji Indicator

To create an automatic indicator for `GravestoneDoji` , call the `GravestoneDoji` helper method from the `QCAlgorithm` class. The `GravestoneDoji` method creates a `GravestoneDoji` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class GravestoneDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private GravestoneDoji _gravestoneDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _gravestoneDoji = CandlestickPatterns.GravestoneDoji(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_gravestoneDoji.IsReady)
        {
            // The current value of _gravestoneDoji is represented by itself (_gravestoneDoji)
            // or _gravestoneDoji.Current.Value
            Plot("GravestoneDoji", "gravestoneDoji", _gravestoneDoji);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `GravestoneDoji` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class GravestoneDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private GravestoneDoji _gravestoneDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _gravestoneDoji = new GravestoneDoji();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _gravestoneDoji.Update(bar);

        if (_gravestoneDoji.IsReady)
        {
            // The current value of _gravestoneDoji is represented by itself (_gravestoneDoji)
            // or _gravestoneDoji.Current.Value
            Plot("GravestoneDoji", "gravestoneDoji", _gravestoneDoji);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `GravestoneDoji` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class GravestoneDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private GravestoneDoji _gravestoneDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _gravestoneDoji = CandlestickPatterns.GravestoneDoji(_symbol);

        var indicatorHistory = IndicatorHistory(_gravestoneDoji, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_gravestoneDoji, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_gravestoneDoji, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Hammer

Introduction

Create a new Hammer candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Hammer Indicator

To create an automatic indicator for `Hammer` , call the `Hammer` helper method from the `QCAlgorithm` class. The `Hammer` method creates a `Hammer` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class HammerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Hammer _hammer;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hammer = CandlestickPatterns.Hammer(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_hammer.IsReady)
        {
            // The current value of _hammer is represented by itself (_hammer)
            // or _hammer.Current.Value
            Plot("Hammer", "hammer", _hammer);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Hammer` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class HammerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Hammer _hammer;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hammer = new Hammer();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _hammer.Update(bar);

        if (_hammer.IsReady)
        {
            // The current value of _hammer is represented by itself (_hammer)
            // or _hammer.Current.Value
            Plot("Hammer", "hammer", _hammer);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Hammer` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class HammerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Hammer _hammer;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hammer = CandlestickPatterns.Hammer(_symbol);

        var indicatorHistory = IndicatorHistory(_hammer, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_hammer, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_hammer, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Hanging Man

Introduction

Create a new Hanging Man candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HangingMan Indicator

To create an automatic indicator for `HangingMan` , call the `HangingMan` helper method from the `QCAlgorithm` class. The `HangingMan` method creates a `HangingMan` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class HangingManAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HangingMan _hangingMan;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hangingMan = CandlestickPatterns.HangingMan(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_hangingMan.IsReady)
        {
            // The current value of _hangingMan is represented by itself (_hangingMan)
            // or _hangingMan.Current.Value
            Plot("HangingMan", "hangingMan", _hangingMan);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HangingMan` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class HangingManAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HangingMan _hangingMan;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hangingMan = new HangingMan();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _hangingMan.Update(bar);

        if (_hangingMan.IsReady)
        {
            // The current value of _hangingMan is represented by itself (_hangingMan)
            // or _hangingMan.Current.Value
            Plot("HangingMan", "hangingMan", _hangingMan);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HangingMan` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class HangingManAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HangingMan _hangingMan;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hangingMan = CandlestickPatterns.HangingMan(_symbol);

        var indicatorHistory = IndicatorHistory(_hangingMan, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_hangingMan, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_hangingMan, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Harami

Introduction

Create a new Harami candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Harami Indicator

To create an automatic indicator for `Harami` , call the `Harami` helper method from the `QCAlgorithm` class. The `Harami` method creates a `Harami` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class HaramiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Harami _harami;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _harami = CandlestickPatterns.Harami(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_harami.IsReady)
        {
            // The current value of _harami is represented by itself (_harami)
            // or _harami.Current.Value
            Plot("Harami", "harami", _harami);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Harami` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class HaramiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Harami _harami;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _harami = new Harami();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _harami.Update(bar);

        if (_harami.IsReady)
        {
            // The current value of _harami is represented by itself (_harami)
            // or _harami.Current.Value
            Plot("Harami", "harami", _harami);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Harami` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class HaramiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Harami _harami;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _harami = CandlestickPatterns.Harami(_symbol);

        var indicatorHistory = IndicatorHistory(_harami, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_harami, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_harami, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Harami Cross

Introduction

Create a new Harami Cross candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HaramiCross Indicator

To create an automatic indicator for `HaramiCross` , call the `HaramiCross` helper method from the `QCAlgorithm` class. The `HaramiCross` method creates a `HaramiCross` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class HaramiCrossAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HaramiCross _haramiCross;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _haramiCross = CandlestickPatterns.HaramiCross(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_haramiCross.IsReady)
        {
            // The current value of _haramiCross is represented by itself (_haramiCross)
            // or _haramiCross.Current.Value
            Plot("HaramiCross", "haramiCross", _haramiCross);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HaramiCross` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class HaramiCrossAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HaramiCross _haramiCross;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _haramiCross = new HaramiCross();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _haramiCross.Update(bar);

        if (_haramiCross.IsReady)
        {
            // The current value of _haramiCross is represented by itself (_haramiCross)
            // or _haramiCross.Current.Value
            Plot("HaramiCross", "haramiCross", _haramiCross);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HaramiCross` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class HaramiCrossAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HaramiCross _haramiCross;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _haramiCross = CandlestickPatterns.HaramiCross(_symbol);

        var indicatorHistory = IndicatorHistory(_haramiCross, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_haramiCross, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_haramiCross, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

High Wave Candle

Introduction

Create a new High Wave Candle candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HighWaveCandle Indicator

To create an automatic indicator for `HighWaveCandle` , call the `HighWaveCandle` helper method from the `QCAlgorithm` class. The `HighWaveCandle` method creates a `HighWaveCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class HighWaveCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HighWaveCandle _highWaveCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _highWaveCandle = CandlestickPatterns.HighWaveCandle(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_highWaveCandle.IsReady)
        {
            // The current value of _highWaveCandle is represented by itself (_highWaveCandle)
            // or _highWaveCandle.Current.Value
            Plot("HighWaveCandle", "highWaveCandle", _highWaveCandle);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HighWaveCandle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class HighWaveCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HighWaveCandle _highWaveCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _highWaveCandle = new HighWaveCandle();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _highWaveCandle.Update(bar);

        if (_highWaveCandle.IsReady)
        {
            // The current value of _highWaveCandle is represented by itself (_highWaveCandle)
            // or _highWaveCandle.Current.Value
            Plot("HighWaveCandle", "highWaveCandle", _highWaveCandle);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HighWaveCandle` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class HighWaveCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HighWaveCandle _highWaveCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _highWaveCandle = CandlestickPatterns.HighWaveCandle(_symbol);

        var indicatorHistory = IndicatorHistory(_highWaveCandle, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_highWaveCandle, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_highWaveCandle, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Introduction

Create a new Hikkake candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Hikkake Indicator

To create an automatic indicator for `Hikkake` , call the `Hikkake` helper method from the `QCAlgorithm` class. The `Hikkake` method creates a `Hikkake` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class HikkakeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Hikkake _hikkake;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hikkake = CandlestickPatterns.Hikkake(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_hikkake.IsReady)
        {
            // The current value of _hikkake is represented by itself (_hikkake)
            // or _hikkake.Current.Value
            Plot("Hikkake", "hikkake", _hikkake);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Hikkake` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class HikkakeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Hikkake _hikkake;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hikkake = new Hikkake();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _hikkake.Update(bar);

        if (_hikkake.IsReady)
        {
            // The current value of _hikkake is represented by itself (_hikkake)
            // or _hikkake.Current.Value
            Plot("Hikkake", "hikkake", _hikkake);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Hikkake` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class HikkakeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Hikkake _hikkake;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hikkake = CandlestickPatterns.Hikkake(_symbol);

        var indicatorHistory = IndicatorHistory(_hikkake, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_hikkake, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_hikkake, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Hikkake Modified

Introduction

Create a new Hikkake Modified candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HikkakeModified Indicator

To create an automatic indicator for `HikkakeModified` , call the `HikkakeModified` helper method from the `QCAlgorithm` class. The `HikkakeModified` method creates a `HikkakeModified` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class HikkakeModifiedAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HikkakeModified _hikkakeModified;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hikkakeModified = CandlestickPatterns.HikkakeModified(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_hikkakeModified.IsReady)
        {
            // The current value of _hikkakeModified is represented by itself (_hikkakeModified)
            // or _hikkakeModified.Current.Value
            Plot("HikkakeModified", "hikkakeModified", _hikkakeModified);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HikkakeModified` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class HikkakeModifiedAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HikkakeModified _hikkakeModified;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hikkakeModified = new HikkakeModified();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _hikkakeModified.Update(bar);

        if (_hikkakeModified.IsReady)
        {
            // The current value of _hikkakeModified is represented by itself (_hikkakeModified)
            // or _hikkakeModified.Current.Value
            Plot("HikkakeModified", "hikkakeModified", _hikkakeModified);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HikkakeModified` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class HikkakeModifiedAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HikkakeModified _hikkakeModified;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _hikkakeModified = CandlestickPatterns.HikkakeModified(_symbol);

        var indicatorHistory = IndicatorHistory(_hikkakeModified, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_hikkakeModified, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_hikkakeModified, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Homing Pigeon

Introduction

Create a new Homing Pigeon candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using HomingPigeon Indicator

To create an automatic indicator for `HomingPigeon` , call the `HomingPigeon` helper method from the `QCAlgorithm` class. The `HomingPigeon` method creates a `HomingPigeon` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class HomingPigeonAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HomingPigeon _homingPigeon;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _homingPigeon = CandlestickPatterns.HomingPigeon(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_homingPigeon.IsReady)
        {
            // The current value of _homingPigeon is represented by itself (_homingPigeon)
            // or _homingPigeon.Current.Value
            Plot("HomingPigeon", "homingPigeon", _homingPigeon);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `HomingPigeon` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class HomingPigeonAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HomingPigeon _homingPigeon;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _homingPigeon = new HomingPigeon();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _homingPigeon.Update(bar);

        if (_homingPigeon.IsReady)
        {
            // The current value of _homingPigeon is represented by itself (_homingPigeon)
            // or _homingPigeon.Current.Value
            Plot("HomingPigeon", "homingPigeon", _homingPigeon);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `HomingPigeon` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class HomingPigeonAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private HomingPigeon _homingPigeon;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _homingPigeon = CandlestickPatterns.HomingPigeon(_symbol);

        var indicatorHistory = IndicatorHistory(_homingPigeon, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_homingPigeon, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_homingPigeon, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Identical Three Crows

Introduction

Create a new Identical Three Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using IdenticalThreeCrows Indicator

To create an automatic indicator for `IdenticalThreeCrows` , call the `IdenticalThreeCrows` helper method from the `QCAlgorithm` class. The `IdenticalThreeCrows` method creates a `IdenticalThreeCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class IdenticalThreeCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private IdenticalThreeCrows _identicalThreeCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _identicalThreeCrows = CandlestickPatterns.IdenticalThreeCrows(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_identicalThreeCrows.IsReady)
        {
            // The current value of _identicalThreeCrows is represented by itself (_identicalThreeCrows)
            // or _identicalThreeCrows.Current.Value
            Plot("IdenticalThreeCrows", "identicalThreeCrows", _identicalThreeCrows);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `IdenticalThreeCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class IdenticalThreeCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private IdenticalThreeCrows _identicalThreeCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _identicalThreeCrows = new IdenticalThreeCrows();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _identicalThreeCrows.Update(bar);

        if (_identicalThreeCrows.IsReady)
        {
            // The current value of _identicalThreeCrows is represented by itself (_identicalThreeCrows)
            // or _identicalThreeCrows.Current.Value
            Plot("IdenticalThreeCrows", "identicalThreeCrows", _identicalThreeCrows);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `IdenticalThreeCrows` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class IdenticalThreeCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private IdenticalThreeCrows _identicalThreeCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _identicalThreeCrows = CandlestickPatterns.IdenticalThreeCrows(_symbol);

        var indicatorHistory = IndicatorHistory(_identicalThreeCrows, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_identicalThreeCrows, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_identicalThreeCrows, _symbol, new DateTime(2024, 7, 1),
new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

In Neck

Introduction

Create a new In Neck candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using InNeck Indicator

To create an automatic indicator for `InNeck` , call the `InNeck` helper method from the `QCAlgorithm` class. The `InNeck` method creates a `InNeck` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class InNeckAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InNeck _inNeck;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _inNeck = CandlestickPatterns.InNeck(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_inNeck.IsReady)
        {
            // The current value of _inNeck is represented by itself (_inNeck)
            // or _inNeck.Current.Value
            Plot("InNeck", "inNeck", _inNeck);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `InNeck` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class InNeckAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InNeck _inNeck;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _inNeck = new InNeck();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _inNeck.Update(bar);

        if (_inNeck.IsReady)
        {
            // The current value of _inNeck is represented by itself (_inNeck)
            // or _inNeck.Current.Value
            Plot("InNeck", "inNeck", _inNeck);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `InNeck` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class InNeckAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InNeck _inNeck;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _inNeck = CandlestickPatterns.InNeck(_symbol);

        var indicatorHistory = IndicatorHistory(_inNeck, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_inNeck, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_inNeck, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Inverted Hammer

Introduction

Create a new Inverted Hammer candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using InvertedHammer Indicator

To create an automatic indicator for `InvertedHammer` , call the `InvertedHammer` helper method from the `QCAlgorithm` class. The `InvertedHammer` method creates a `InvertedHammer` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class InvertedHammerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InvertedHammer _invertedHammer;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _invertedHammer = CandlestickPatterns.InvertedHammer(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_invertedHammer.IsReady)
        {
            // The current value of _invertedHammer is represented by itself (_invertedHammer)
            // or _invertedHammer.Current.Value
            Plot("InvertedHammer", "invertedHammer", _invertedHammer);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `InvertedHammer` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class InvertedHammerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InvertedHammer _invertedHammer;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _invertedHammer = new InvertedHammer();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _invertedHammer.Update(bar);

        if (_invertedHammer.IsReady)
        {
            // The current value of _invertedHammer is represented by itself (_invertedHammer)
            // or _invertedHammer.Current.Value
            Plot("InvertedHammer", "invertedHammer", _invertedHammer);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `InvertedHammer` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class InvertedHammerAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private InvertedHammer _invertedHammer;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _invertedHammer = CandlestickPatterns.InvertedHammer(_symbol);

        var indicatorHistory = IndicatorHistory(_invertedHammer, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_invertedHammer, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_invertedHammer, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Kicking

Introduction

Create a new Kicking candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Kicking Indicator

To create an automatic indicator for `Kicking` , call the `Kicking` helper method from the `QCAlgorithm` class. The `Kicking` method creates a `Kicking` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class KickingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Kicking _kicking;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kicking = CandlestickPatterns.Kicking(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_kicking.IsReady)
        {
            // The current value of _kicking is represented by itself (_kicking)
            // or _kicking.Current.Value
            Plot("Kicking", "kicking", _kicking);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Kicking` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class KickingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Kicking _kicking;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kicking = new Kicking();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _kicking.Update(bar);

        if (_kicking.IsReady)
        {
            // The current value of _kicking is represented by itself (_kicking)
            // or _kicking.Current.Value
            Plot("Kicking", "kicking", _kicking);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Kicking` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class KickingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Kicking _kicking;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kicking = CandlestickPatterns.Kicking(_symbol);

        var indicatorHistory = IndicatorHistory(_kicking, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_kicking, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_kicking, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Kicking By Length

Introduction

Create a new Kicking By Length candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using KickingByLength Indicator

To create an automatic indicator for `KickingByLength` , call the `KickingByLength` helper method from the `QCAlgorithm` class. The `KickingByLength` method creates a `KickingByLength` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class KickingByLengthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KickingByLength _kickingByLength;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kickingByLength = CandlestickPatterns.KickingByLength(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_kickingByLength.IsReady)
        {
            // The current value of _kickingByLength is represented by itself (_kickingByLength)
            // or _kickingByLength.Current.Value
            Plot("KickingByLength", "kickingByLength", _kickingByLength);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `KickingByLength` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class KickingByLengthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KickingByLength _kickingByLength;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kickingByLength = new KickingByLength();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _kickingByLength.Update(bar);

        if (_kickingByLength.IsReady)
        {
            // The current value of _kickingByLength is represented by itself (_kickingByLength)
            // or _kickingByLength.Current.Value
            Plot("KickingByLength", "kickingByLength", _kickingByLength);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `KickingByLength` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class KickingByLengthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private KickingByLength _kickingByLength;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _kickingByLength = CandlestickPatterns.KickingByLength(_symbol);

        var indicatorHistory = IndicatorHistory(_kickingByLength, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_kickingByLength, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_kickingByLength, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Ladder Bottom

Introduction

Create a new Ladder Bottom candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using LadderBottom Indicator

To create an automatic indicator for `LadderBottom` , call the `LadderBottom` helper method from the `QCAlgorithm` class. The `LadderBottom` method creates a `LadderBottom` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class LadderBottomAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LadderBottom _ladderBottom;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ladderBottom = CandlestickPatterns.LadderBottom(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_ladderBottom.IsReady)
        {
            // The current value of _ladderBottom is represented by itself (_ladderBottom)
            // or _ladderBottom.Current.Value
            Plot("LadderBottom", "ladderBottom", _ladderBottom);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `LadderBottom` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class LadderBottomAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LadderBottom _ladderBottom;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ladderBottom = new LadderBottom();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _ladderBottom.Update(bar);

        if (_ladderBottom.IsReady)
        {
            // The current value of _ladderBottom is represented by itself (_ladderBottom)
            // or _ladderBottom.Current.Value
            Plot("LadderBottom", "ladderBottom", _ladderBottom);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `LadderBottom` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class LadderBottomAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LadderBottom _ladderBottom;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ladderBottom = CandlestickPatterns.LadderBottom(_symbol);

        var indicatorHistory = IndicatorHistory(_ladderBottom, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_ladderBottom, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_ladderBottom, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Long Legged Doji

Introduction

Create a new Long Legged Doji candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using LongLeggedDoji Indicator

To create an automatic indicator for `LongLeggedDoji` , call the `LongLeggedDoji` helper method from the `QCAlgorithm` class. The `LongLeggedDoji` method creates a `LongLeggedDoji` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class LongLeggedDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LongLeggedDoji _longLeggedDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _longLeggedDoji = CandlestickPatterns.LongLeggedDoji(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_longLeggedDoji.IsReady)
        {
            // The current value of _longLeggedDoji is represented by itself (_longLeggedDoji)
            // or _longLeggedDoji.Current.Value
            Plot("LongLeggedDoji", "longLeggedDoji", _longLeggedDoji);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `LongLeggedDoji` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class LongLeggedDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LongLeggedDoji _longLeggedDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _longLeggedDoji = new LongLeggedDoji();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _longLeggedDoji.Update(bar);

        if (_longLeggedDoji.IsReady)
        {
            // The current value of _longLeggedDoji is represented by itself (_longLeggedDoji)
            // or _longLeggedDoji.Current.Value
            Plot("LongLeggedDoji", "longLeggedDoji", _longLeggedDoji);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `LongLeggedDoji` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class LongLeggedDojiAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LongLeggedDoji _longLeggedDoji;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _longLeggedDoji = CandlestickPatterns.LongLeggedDoji(_symbol);

        var indicatorHistory = IndicatorHistory(_longLeggedDoji, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_longLeggedDoji, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_longLeggedDoji, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Long Line Candle

Introduction

Create a new Long Line Candle candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using LongLineCandle Indicator

To create an automatic indicator for `LongLineCandle` , call the `LongLineCandle` helper method from the `QCAlgorithm` class. The `LongLineCandle` method creates a `LongLineCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class LongLineCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LongLineCandle _longLineCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _longLineCandle = CandlestickPatterns.LongLineCandle(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_longLineCandle.IsReady)
        {
            // The current value of _longLineCandle is represented by itself (_longLineCandle)
            // or _longLineCandle.Current.Value
            Plot("LongLineCandle", "longLineCandle", _longLineCandle);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `LongLineCandle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class LongLineCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LongLineCandle _longLineCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _longLineCandle = new LongLineCandle();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _longLineCandle.Update(bar);

        if (_longLineCandle.IsReady)
        {
            // The current value of _longLineCandle is represented by itself (_longLineCandle)
            // or _longLineCandle.Current.Value
            Plot("LongLineCandle", "longLineCandle", _longLineCandle);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `LongLineCandle` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class LongLineCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private LongLineCandle _longLineCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _longLineCandle = CandlestickPatterns.LongLineCandle(_symbol);

        var indicatorHistory = IndicatorHistory(_longLineCandle, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_longLineCandle, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_longLineCandle, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Marubozu

Introduction

Create a new Marubozu candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Marubozu Indicator

To create an automatic indicator for `Marubozu` , call the `Marubozu` helper method from the `QCAlgorithm` class. The `Marubozu` method creates a `Marubozu` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MarubozuAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Marubozu _marubozu;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _marubozu = CandlestickPatterns.Marubozu(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_marubozu.IsReady)
        {
            // The current value of _marubozu is represented by itself (_marubozu)
            // or _marubozu.Current.Value
            Plot("Marubozu", "marubozu", _marubozu);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Marubozu` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class MarubozuAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Marubozu _marubozu;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _marubozu = new Marubozu();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _marubozu.Update(bar);

        if (_marubozu.IsReady)
        {
            // The current value of _marubozu is represented by itself (_marubozu)
            // or _marubozu.Current.Value
            Plot("Marubozu", "marubozu", _marubozu);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Marubozu` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class MarubozuAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Marubozu _marubozu;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _marubozu = CandlestickPatterns.Marubozu(_symbol);

        var indicatorHistory = IndicatorHistory(_marubozu, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_marubozu, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_marubozu, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Mat Hold

Introduction

Create a new Mat Hold candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MatHold Indicator

To create an automatic indicator for `MatHold` , call the `MatHold` helper method from the `QCAlgorithm` class. The `MatHold` method creates a `MatHold` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MatHoldAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MatHold _matHold;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _matHold = CandlestickPatterns.MatHold(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_matHold.IsReady)
        {
            // The current value of _matHold is represented by itself (_matHold)
            // or _matHold.Current.Value
            Plot("MatHold", "matHold", _matHold);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MatHold` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class MatHoldAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MatHold _matHold;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _matHold = new MatHold();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _matHold.Update(bar);

        if (_matHold.IsReady)
        {
            // The current value of _matHold is represented by itself (_matHold)
            // or _matHold.Current.Value
            Plot("MatHold", "matHold", _matHold);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MatHold` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class MatHoldAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MatHold _matHold;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _matHold = CandlestickPatterns.MatHold(_symbol);

        var indicatorHistory = IndicatorHistory(_matHold, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_matHold, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_matHold, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Matching Low

Introduction

Create a new Matching Low candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MatchingLow Indicator

To create an automatic indicator for `MatchingLow` , call the `MatchingLow` helper method from the `QCAlgorithm` class. The `MatchingLow` method creates a `MatchingLow` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MatchingLowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MatchingLow _matchingLow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _matchingLow = CandlestickPatterns.MatchingLow(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_matchingLow.IsReady)
        {
            // The current value of _matchingLow is represented by itself (_matchingLow)
            // or _matchingLow.Current.Value
            Plot("MatchingLow", "matchingLow", _matchingLow);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MatchingLow` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class MatchingLowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MatchingLow _matchingLow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _matchingLow = new MatchingLow();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _matchingLow.Update(bar);

        if (_matchingLow.IsReady)
        {
            // The current value of _matchingLow is represented by itself (_matchingLow)
            // or _matchingLow.Current.Value
            Plot("MatchingLow", "matchingLow", _matchingLow);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MatchingLow` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class MatchingLowAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MatchingLow _matchingLow;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _matchingLow = CandlestickPatterns.MatchingLow(_symbol);

        var indicatorHistory = IndicatorHistory(_matchingLow, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_matchingLow, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_matchingLow, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Morning Doji Star

Introduction

Create a new Morning Doji Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MorningDojiStar Indicator

To create an automatic indicator for `MorningDojiStar` , call the `MorningDojiStar` helper method from the `QCAlgorithm` class. The `MorningDojiStar` method creates a `MorningDojiStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class MorningDojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MorningDojiStar _morningDojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _morningDojiStar = CandlestickPatterns.MorningDojiStar(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_morningDojiStar.IsReady)
        {
            // The current value of _morningDojiStar is represented by itself (_morningDojiStar)
            // or _morningDojiStar.Current.Value
            Plot("MorningDojiStar", "morningDojiStar", _morningDojiStar);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MorningDojiStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class MorningDojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MorningDojiStar _morningDojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _morningDojiStar = new MorningDojiStar();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _morningDojiStar.Update(bar);

        if (_morningDojiStar.IsReady)
        {
            // The current value of _morningDojiStar is represented by itself (_morningDojiStar)
            // or _morningDojiStar.Current.Value
            Plot("MorningDojiStar", "morningDojiStar", _morningDojiStar);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MorningDojiStar` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class MorningDojiStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MorningDojiStar _morningDojiStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _morningDojiStar = CandlestickPatterns.MorningDojiStar(_symbol);

        var indicatorHistory = IndicatorHistory(_morningDojiStar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_morningDojiStar, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_morningDojiStar, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Morning Star

Introduction

Create a new Morning Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using MorningStar Indicator

To create an automatic indicator for `MorningStar` , call the `MorningStar` helper method from the `QCAlgorithm` class. The `MorningStar` method creates a `MorningStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class MorningStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MorningStar _morningStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _morningStar = CandlestickPatterns.MorningStar(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_morningStar.IsReady)
        {
            // The current value of _morningStar is represented by itself (_morningStar)
            // or _morningStar.Current.Value
            Plot("MorningStar", "morningStar", _morningStar);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `MorningStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class MorningStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MorningStar _morningStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _morningStar = new MorningStar();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _morningStar.Update(bar);

        if (_morningStar.IsReady)
        {
            // The current value of _morningStar is represented by itself (_morningStar)
            // or _morningStar.Current.Value
            Plot("MorningStar", "morningStar", _morningStar);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `MorningStar` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class MorningStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private MorningStar _morningStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _morningStar = CandlestickPatterns.MorningStar(_symbol);

        var indicatorHistory = IndicatorHistory(_morningStar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_morningStar, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_morningStar, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

On Neck

Introduction

Create a new On Neck candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using OnNeck Indicator

To create an automatic indicator for `OnNeck` , call the `OnNeck` helper method from the `QCAlgorithm` class. The `OnNeck` method creates a `OnNeck` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class OnNeckAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private OnNeck _onNeck;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _onNeck = CandlestickPatterns.OnNeck(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_onNeck.IsReady)
        {
            // The current value of _onNeck is represented by itself (_onNeck)
            // or _onNeck.Current.Value
            Plot("OnNeck", "onNeck", _onNeck);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `OnNeck` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class OnNeckAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private OnNeck _onNeck;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _onNeck = new OnNeck();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _onNeck.Update(bar);

        if (_onNeck.IsReady)
        {
            // The current value of _onNeck is represented by itself (_onNeck)
            // or _onNeck.Current.Value
            Plot("OnNeck", "onNeck", _onNeck);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `OnNeck` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class OnNeckAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private OnNeck _onNeck;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _onNeck = CandlestickPatterns.OnNeck(_symbol);

        var indicatorHistory = IndicatorHistory(_onNeck, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_onNeck, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_onNeck, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Piercing

Introduction

Create a new Piercing candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Piercing Indicator

To create an automatic indicator for `Piercing` , call the `Piercing` helper method from the `QCAlgorithm` class. The `Piercing` method creates a `Piercing` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class PiercingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Piercing _piercing;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _piercing = CandlestickPatterns.Piercing(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_piercing.IsReady)
        {
            // The current value of _piercing is represented by itself (_piercing)
            // or _piercing.Current.Value
            Plot("Piercing", "piercing", _piercing);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Piercing` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class PiercingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Piercing _piercing;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _piercing = new Piercing();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _piercing.Update(bar);

        if (_piercing.IsReady)
        {
            // The current value of _piercing is represented by itself (_piercing)
            // or _piercing.Current.Value
            Plot("Piercing", "piercing", _piercing);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Piercing` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class PiercingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Piercing _piercing;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _piercing = CandlestickPatterns.Piercing(_symbol);

        var indicatorHistory = IndicatorHistory(_piercing, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_piercing, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_piercing, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Rickshaw Man

Introduction

Create a new Rickshaw Man candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using RickshawMan Indicator

To create an automatic indicator for `RickshawMan` , call the `RickshawMan` helper method from the `QCAlgorithm` class. The `RickshawMan` method creates a `RickshawMan` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class RickshawManAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RickshawMan _rickshawMan;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rickshawMan = CandlestickPatterns.RickshawMan(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_rickshawMan.IsReady)
        {
            // The current value of _rickshawMan is represented by itself (_rickshawMan)
            // or _rickshawMan.Current.Value
            Plot("RickshawMan", "rickshawMan", _rickshawMan);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `RickshawMan` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class RickshawManAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RickshawMan _rickshawMan;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rickshawMan = new RickshawMan();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _rickshawMan.Update(bar);

        if (_rickshawMan.IsReady)
        {
            // The current value of _rickshawMan is represented by itself (_rickshawMan)
            // or _rickshawMan.Current.Value
            Plot("RickshawMan", "rickshawMan", _rickshawMan);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `RickshawMan` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class RickshawManAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RickshawMan _rickshawMan;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _rickshawMan = CandlestickPatterns.RickshawMan(_symbol);

        var indicatorHistory = IndicatorHistory(_rickshawMan, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_rickshawMan, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_rickshawMan, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Rise Fall Three Methods

Introduction

Create a new Rise Fall Three Methods candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using RiseFallThreeMethods Indicator

To create an automatic indicator for `RiseFallThreeMethods` , call the `RiseFallThreeMethods` helper method from the `QCAlgorithm` class. The `RiseFallThreeMethods` method creates a `RiseFallThreeMethods` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class RiseFallThreeMethodsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RiseFallThreeMethods _riseFallThreeMethods;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _riseFallThreeMethods = CandlestickPatterns.RiseFallThreeMethods(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_riseFallThreeMethods.IsReady)
        {
            // The current value of _riseFallThreeMethods is represented by itself (_riseFallThreeMethods)
            // or _riseFallThreeMethods.Current.Value
            Plot("RiseFallThreeMethods", "riseFallThreeMethods", _riseFallThreeMethods);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `RiseFallThreeMethods` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class RiseFallThreeMethodsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RiseFallThreeMethods _riseFallThreeMethods;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _riseFallThreeMethods = new RiseFallThreeMethods();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _riseFallThreeMethods.Update(bar);

        if (_riseFallThreeMethods.IsReady)
        {
            // The current value of _riseFallThreeMethods is represented by itself (_riseFallThreeMethods)
            // or _riseFallThreeMethods.Current.Value
            Plot("RiseFallThreeMethods", "riseFallThreeMethods", _riseFallThreeMethods);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `RiseFallThreeMethods` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class RiseFallThreeMethodsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private RiseFallThreeMethods _riseFallThreeMethods;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _riseFallThreeMethods = CandlestickPatterns.RiseFallThreeMethods(_symbol);

        var indicatorHistory = IndicatorHistory(_riseFallThreeMethods, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_riseFallThreeMethods, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_riseFallThreeMethods, _symbol, new DateTime(2024, 7, 1),
new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Separating Lines

Introduction

Create a new Separating Lines candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using SeparatingLines Indicator

To create an automatic indicator for `SeparatingLines` , call the `SeparatingLines` helper method from the `QCAlgorithm` class. The `SeparatingLines` method creates a `SeparatingLines` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class SeparatingLinesAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SeparatingLines _separatingLines;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _separatingLines = CandlestickPatterns.SeparatingLines(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_separatingLines.IsReady)
        {
            // The current value of _separatingLines is represented by itself (_separatingLines)
            // or _separatingLines.Current.Value
            Plot("SeparatingLines", "separatingLines", _separatingLines);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `SeparatingLines` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class SeparatingLinesAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SeparatingLines _separatingLines;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _separatingLines = new SeparatingLines();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _separatingLines.Update(bar);

        if (_separatingLines.IsReady)
        {
            // The current value of _separatingLines is represented by itself (_separatingLines)
            // or _separatingLines.Current.Value
            Plot("SeparatingLines", "separatingLines", _separatingLines);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `SeparatingLines` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class SeparatingLinesAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SeparatingLines _separatingLines;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _separatingLines = CandlestickPatterns.SeparatingLines(_symbol);

        var indicatorHistory = IndicatorHistory(_separatingLines, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_separatingLines, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_separatingLines, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Shooting Star

Introduction

Create a new Shooting Star candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ShootingStar Indicator

To create an automatic indicator for `ShootingStar` , call the `ShootingStar` helper method from the `QCAlgorithm` class. The `ShootingStar` method creates a `ShootingStar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ShootingStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ShootingStar _shootingStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _shootingStar = CandlestickPatterns.ShootingStar(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_shootingStar.IsReady)
        {
            // The current value of _shootingStar is represented by itself (_shootingStar)
            // or _shootingStar.Current.Value
            Plot("ShootingStar", "shootingStar", _shootingStar);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ShootingStar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ShootingStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ShootingStar _shootingStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _shootingStar = new ShootingStar();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _shootingStar.Update(bar);

        if (_shootingStar.IsReady)
        {
            // The current value of _shootingStar is represented by itself (_shootingStar)
            // or _shootingStar.Current.Value
            Plot("ShootingStar", "shootingStar", _shootingStar);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ShootingStar` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ShootingStarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ShootingStar _shootingStar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _shootingStar = CandlestickPatterns.ShootingStar(_symbol);

        var indicatorHistory = IndicatorHistory(_shootingStar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_shootingStar, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_shootingStar, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Short Line Candle

Introduction

Create a new Short Line Candle candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ShortLineCandle Indicator

To create an automatic indicator for `ShortLineCandle` , call the `ShortLineCandle` helper method from the `QCAlgorithm` class. The `ShortLineCandle` method creates a `ShortLineCandle` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ShortLineCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ShortLineCandle _shortLineCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _shortLineCandle = CandlestickPatterns.ShortLineCandle(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_shortLineCandle.IsReady)
        {
            // The current value of _shortLineCandle is represented by itself (_shortLineCandle)
            // or _shortLineCandle.Current.Value
            Plot("ShortLineCandle", "shortLineCandle", _shortLineCandle);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ShortLineCandle` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ShortLineCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ShortLineCandle _shortLineCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _shortLineCandle = new ShortLineCandle();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _shortLineCandle.Update(bar);

        if (_shortLineCandle.IsReady)
        {
            // The current value of _shortLineCandle is represented by itself (_shortLineCandle)
            // or _shortLineCandle.Current.Value
            Plot("ShortLineCandle", "shortLineCandle", _shortLineCandle);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ShortLineCandle` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ShortLineCandleAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ShortLineCandle _shortLineCandle;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _shortLineCandle = CandlestickPatterns.ShortLineCandle(_symbol);

        var indicatorHistory = IndicatorHistory(_shortLineCandle, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_shortLineCandle, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_shortLineCandle, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Spinning Top

Introduction

Create a new Spinning Top candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using SpinningTop Indicator

To create an automatic indicator for `SpinningTop` , call the `SpinningTop` helper method from the `QCAlgorithm` class. The `SpinningTop` method creates a `SpinningTop` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class SpinningTopAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SpinningTop _spinningTop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _spinningTop = CandlestickPatterns.SpinningTop(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_spinningTop.IsReady)
        {
            // The current value of _spinningTop is represented by itself (_spinningTop)
            // or _spinningTop.Current.Value
            Plot("SpinningTop", "spinningTop", _spinningTop);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `SpinningTop` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class SpinningTopAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SpinningTop _spinningTop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _spinningTop = new SpinningTop();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _spinningTop.Update(bar);

        if (_spinningTop.IsReady)
        {
            // The current value of _spinningTop is represented by itself (_spinningTop)
            // or _spinningTop.Current.Value
            Plot("SpinningTop", "spinningTop", _spinningTop);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `SpinningTop` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class SpinningTopAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private SpinningTop _spinningTop;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _spinningTop = CandlestickPatterns.SpinningTop(_symbol);

        var indicatorHistory = IndicatorHistory(_spinningTop, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_spinningTop, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_spinningTop, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Stalled Pattern

Introduction

Create a new Stalled Pattern candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using StalledPattern Indicator

To create an automatic indicator for `StalledPattern` , call the `StalledPattern` helper method from the `QCAlgorithm` class. The `StalledPattern` method creates a `StalledPattern` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class StalledPatternAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StalledPattern _stalledPattern;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stalledPattern = CandlestickPatterns.StalledPattern(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_stalledPattern.IsReady)
        {
            // The current value of _stalledPattern is represented by itself (_stalledPattern)
            // or _stalledPattern.Current.Value
            Plot("StalledPattern", "stalledPattern", _stalledPattern);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `StalledPattern` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class StalledPatternAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StalledPattern _stalledPattern;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stalledPattern = new StalledPattern();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _stalledPattern.Update(bar);

        if (_stalledPattern.IsReady)
        {
            // The current value of _stalledPattern is represented by itself (_stalledPattern)
            // or _stalledPattern.Current.Value
            Plot("StalledPattern", "stalledPattern", _stalledPattern);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `StalledPattern` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class StalledPatternAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StalledPattern _stalledPattern;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stalledPattern = CandlestickPatterns.StalledPattern(_symbol);

        var indicatorHistory = IndicatorHistory(_stalledPattern, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_stalledPattern, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_stalledPattern, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Stick Sandwich

Introduction

Create a new Stick Sandwich candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using StickSandwich Indicator

To create an automatic indicator for `StickSandwich` , call the `StickSandwich` helper method from the `QCAlgorithm` class. The `StickSandwich` method creates a `StickSandwich` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class StickSandwichAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StickSandwich _stickSandwich;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stickSandwich = CandlestickPatterns.StickSandwich(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_stickSandwich.IsReady)
        {
            // The current value of _stickSandwich is represented by itself (_stickSandwich)
            // or _stickSandwich.Current.Value
            Plot("StickSandwich", "stickSandwich", _stickSandwich);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `StickSandwich` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class StickSandwichAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StickSandwich _stickSandwich;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stickSandwich = new StickSandwich();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _stickSandwich.Update(bar);

        if (_stickSandwich.IsReady)
        {
            // The current value of _stickSandwich is represented by itself (_stickSandwich)
            // or _stickSandwich.Current.Value
            Plot("StickSandwich", "stickSandwich", _stickSandwich);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `StickSandwich` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class StickSandwichAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private StickSandwich _stickSandwich;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _stickSandwich = CandlestickPatterns.StickSandwich(_symbol);

        var indicatorHistory = IndicatorHistory(_stickSandwich, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_stickSandwich, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_stickSandwich, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Takuri

Introduction

Create a new Takuri candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Takuri Indicator

To create an automatic indicator for `Takuri` , call the `Takuri` helper method from the `QCAlgorithm` class. The `Takuri` method creates a `Takuri` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class TakuriAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Takuri _takuri;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _takuri = CandlestickPatterns.Takuri(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_takuri.IsReady)
        {
            // The current value of _takuri is represented by itself (_takuri)
            // or _takuri.Current.Value
            Plot("Takuri", "takuri", _takuri);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Takuri` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TakuriAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Takuri _takuri;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _takuri = new Takuri();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _takuri.Update(bar);

        if (_takuri.IsReady)
        {
            // The current value of _takuri is represented by itself (_takuri)
            // or _takuri.Current.Value
            Plot("Takuri", "takuri", _takuri);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Takuri` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class TakuriAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Takuri _takuri;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _takuri = CandlestickPatterns.Takuri(_symbol);

        var indicatorHistory = IndicatorHistory(_takuri, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_takuri, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_takuri, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Tasuki Gap

Introduction

Create a new Tasuki Gap candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using TasukiGap Indicator

To create an automatic indicator for `TasukiGap` , call the `TasukiGap` helper method from the `QCAlgorithm` class. The `TasukiGap` method creates a `TasukiGap` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class TasukiGapAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TasukiGap _tasukiGap;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tasukiGap = CandlestickPatterns.TasukiGap(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_tasukiGap.IsReady)
        {
            // The current value of _tasukiGap is represented by itself (_tasukiGap)
            // or _tasukiGap.Current.Value
            Plot("TasukiGap", "tasukiGap", _tasukiGap);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `TasukiGap` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TasukiGapAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TasukiGap _tasukiGap;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tasukiGap = new TasukiGap();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _tasukiGap.Update(bar);

        if (_tasukiGap.IsReady)
        {
            // The current value of _tasukiGap is represented by itself (_tasukiGap)
            // or _tasukiGap.Current.Value
            Plot("TasukiGap", "tasukiGap", _tasukiGap);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `TasukiGap` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class TasukiGapAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TasukiGap _tasukiGap;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tasukiGap = CandlestickPatterns.TasukiGap(_symbol);

        var indicatorHistory = IndicatorHistory(_tasukiGap, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_tasukiGap, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_tasukiGap, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Three Black Crows

Introduction

Create a new Three Black Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeBlackCrows Indicator

To create an automatic indicator for `ThreeBlackCrows` , call the `ThreeBlackCrows` helper method from the `QCAlgorithm` class. The `ThreeBlackCrows` method creates a `ThreeBlackCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ThreeBlackCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeBlackCrows _threeBlackCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeBlackCrows = CandlestickPatterns.ThreeBlackCrows(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_threeBlackCrows.IsReady)
        {
            // The current value of _threeBlackCrows is represented by itself (_threeBlackCrows)
            // or _threeBlackCrows.Current.Value
            Plot("ThreeBlackCrows", "threeBlackCrows", _threeBlackCrows);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeBlackCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ThreeBlackCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeBlackCrows _threeBlackCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeBlackCrows = new ThreeBlackCrows();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _threeBlackCrows.Update(bar);

        if (_threeBlackCrows.IsReady)
        {
            // The current value of _threeBlackCrows is represented by itself (_threeBlackCrows)
            // or _threeBlackCrows.Current.Value
            Plot("ThreeBlackCrows", "threeBlackCrows", _threeBlackCrows);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeBlackCrows` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ThreeBlackCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeBlackCrows _threeBlackCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeBlackCrows = CandlestickPatterns.ThreeBlackCrows(_symbol);

        var indicatorHistory = IndicatorHistory(_threeBlackCrows, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_threeBlackCrows, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_threeBlackCrows, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Three Inside

Introduction

Create a new Three Inside candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeInside Indicator

To create an automatic indicator for `ThreeInside` , call the `ThreeInside` helper method from the `QCAlgorithm` class. The `ThreeInside` method creates a `ThreeInside` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ThreeInsideAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeInside _threeInside;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeInside = CandlestickPatterns.ThreeInside(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_threeInside.IsReady)
        {
            // The current value of _threeInside is represented by itself (_threeInside)
            // or _threeInside.Current.Value
            Plot("ThreeInside", "threeInside", _threeInside);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeInside` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class ThreeInsideAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeInside _threeInside;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeInside = new ThreeInside();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _threeInside.Update(bar);

        if (_threeInside.IsReady)
        {
            // The current value of _threeInside is represented by itself (_threeInside)
            // or _threeInside.Current.Value
            Plot("ThreeInside", "threeInside", _threeInside);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeInside` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class ThreeInsideAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeInside _threeInside;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeInside = CandlestickPatterns.ThreeInside(_symbol);

        var indicatorHistory = IndicatorHistory(_threeInside, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_threeInside, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_threeInside, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Three Line Strike

Introduction

Create a new Three Line Strike candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeLineStrike Indicator

To create an automatic indicator for `ThreeLineStrike` , call the `ThreeLineStrike` helper method from the `QCAlgorithm` class. The `ThreeLineStrike` method creates a `ThreeLineStrike` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ThreeLineStrikeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeLineStrike _threeLineStrike;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeLineStrike = CandlestickPatterns.ThreeLineStrike(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_threeLineStrike.IsReady)
        {
            // The current value of _threeLineStrike is represented by itself (_threeLineStrike)
            // or _threeLineStrike.Current.Value
            Plot("ThreeLineStrike", "threeLineStrike", _threeLineStrike);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeLineStrike` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ThreeLineStrikeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeLineStrike _threeLineStrike;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeLineStrike = new ThreeLineStrike();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _threeLineStrike.Update(bar);

        if (_threeLineStrike.IsReady)
        {
            // The current value of _threeLineStrike is represented by itself (_threeLineStrike)
            // or _threeLineStrike.Current.Value
            Plot("ThreeLineStrike", "threeLineStrike", _threeLineStrike);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeLineStrike` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ThreeLineStrikeAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeLineStrike _threeLineStrike;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeLineStrike = CandlestickPatterns.ThreeLineStrike(_symbol);

        var indicatorHistory = IndicatorHistory(_threeLineStrike, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_threeLineStrike, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_threeLineStrike, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Three Outside

Introduction

Create a new Three Outside candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeOutside Indicator

To create an automatic indicator for `ThreeOutside` , call the `ThreeOutside` helper method from the `QCAlgorithm` class. The `ThreeOutside` method creates a `ThreeOutside` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ThreeOutsideAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeOutside _threeOutside;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeOutside = CandlestickPatterns.ThreeOutside(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_threeOutside.IsReady)
        {
            // The current value of _threeOutside is represented by itself (_threeOutside)
            // or _threeOutside.Current.Value
            Plot("ThreeOutside", "threeOutside", _threeOutside);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeOutside` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ThreeOutsideAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeOutside _threeOutside;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeOutside = new ThreeOutside();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _threeOutside.Update(bar);

        if (_threeOutside.IsReady)
        {
            // The current value of _threeOutside is represented by itself (_threeOutside)
            // or _threeOutside.Current.Value
            Plot("ThreeOutside", "threeOutside", _threeOutside);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeOutside` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ThreeOutsideAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeOutside _threeOutside;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeOutside = CandlestickPatterns.ThreeOutside(_symbol);

        var indicatorHistory = IndicatorHistory(_threeOutside, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_threeOutside, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_threeOutside, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Three Stars In South

Introduction

Create a new Three Stars In South candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeStarsInSouth Indicator

To create an automatic indicator for `ThreeStarsInSouth` , call the `ThreeStarsInSouth` helper method from the `QCAlgorithm` class. The `ThreeStarsInSouth` method creates a `ThreeStarsInSouth` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ThreeStarsInSouthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeStarsInSouth _threeStarsInSouth;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeStarsInSouth = CandlestickPatterns.ThreeStarsInSouth(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_threeStarsInSouth.IsReady)
        {
            // The current value of _threeStarsInSouth is represented by itself (_threeStarsInSouth)
            // or _threeStarsInSouth.Current.Value
            Plot("ThreeStarsInSouth", "threeStarsInSouth", _threeStarsInSouth);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeStarsInSouth` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ThreeStarsInSouthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeStarsInSouth _threeStarsInSouth;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeStarsInSouth = new ThreeStarsInSouth();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _threeStarsInSouth.Update(bar);

        if (_threeStarsInSouth.IsReady)
        {
            // The current value of _threeStarsInSouth is represented by itself (_threeStarsInSouth)
            // or _threeStarsInSouth.Current.Value
            Plot("ThreeStarsInSouth", "threeStarsInSouth", _threeStarsInSouth);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeStarsInSouth` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ThreeStarsInSouthAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeStarsInSouth _threeStarsInSouth;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeStarsInSouth = CandlestickPatterns.ThreeStarsInSouth(_symbol);

        var indicatorHistory = IndicatorHistory(_threeStarsInSouth, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_threeStarsInSouth, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_threeStarsInSouth, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Three White Soldiers

Introduction

Create a new Three White Soldiers candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using ThreeWhiteSoldiers Indicator

To create an automatic indicator for `ThreeWhiteSoldiers` , call the `ThreeWhiteSoldiers` helper method from the `QCAlgorithm` class. The `ThreeWhiteSoldiers` method creates a `ThreeWhiteSoldiers` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class ThreeWhiteSoldiersAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeWhiteSoldiers _threeWhiteSoldiers;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeWhiteSoldiers = CandlestickPatterns.ThreeWhiteSoldiers(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_threeWhiteSoldiers.IsReady)
        {
            // The current value of _threeWhiteSoldiers is represented by itself (_threeWhiteSoldiers)
            // or _threeWhiteSoldiers.Current.Value
            Plot("ThreeWhiteSoldiers", "threeWhiteSoldiers", _threeWhiteSoldiers);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `ThreeWhiteSoldiers` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ThreeWhiteSoldiersAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeWhiteSoldiers _threeWhiteSoldiers;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeWhiteSoldiers = new ThreeWhiteSoldiers();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _threeWhiteSoldiers.Update(bar);

        if (_threeWhiteSoldiers.IsReady)
        {
            // The current value of _threeWhiteSoldiers is represented by itself (_threeWhiteSoldiers)
            // or _threeWhiteSoldiers.Current.Value
            Plot("ThreeWhiteSoldiers", "threeWhiteSoldiers", _threeWhiteSoldiers);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `ThreeWhiteSoldiers` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class ThreeWhiteSoldiersAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ThreeWhiteSoldiers _threeWhiteSoldiers;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _threeWhiteSoldiers = CandlestickPatterns.ThreeWhiteSoldiers(_symbol);

        var indicatorHistory = IndicatorHistory(_threeWhiteSoldiers, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_threeWhiteSoldiers, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_threeWhiteSoldiers, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Thrusting

Introduction

Create a new Thrusting candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Thrusting Indicator

To create an automatic indicator for `Thrusting` , call the `Thrusting` helper method from the `QCAlgorithm` class. The `Thrusting` method creates a `Thrusting` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class ThrustingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Thrusting _thrusting;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _thrusting = CandlestickPatterns.Thrusting(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_thrusting.IsReady)
        {
            // The current value of _thrusting is represented by itself (_thrusting)
            // or _thrusting.Current.Value
            Plot("Thrusting", "thrusting", _thrusting);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Thrusting` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class ThrustingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Thrusting _thrusting;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _thrusting = new Thrusting();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _thrusting.Update(bar);

        if (_thrusting.IsReady)
        {
            // The current value of _thrusting is represented by itself (_thrusting)
            // or _thrusting.Current.Value
            Plot("Thrusting", "thrusting", _thrusting);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Thrusting` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class ThrustingAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Thrusting _thrusting;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _thrusting = CandlestickPatterns.Thrusting(_symbol);

        var indicatorHistory = IndicatorHistory(_thrusting, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_thrusting, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_thrusting, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Tristar

Introduction

Create a new Tristar candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using Tristar Indicator

To create an automatic indicator for `Tristar` , call the `Tristar` helper method from the `QCAlgorithm` class. The `Tristar` method creates a `Tristar` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class TristarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Tristar _tristar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tristar = CandlestickPatterns.Tristar(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_tristar.IsReady)
        {
            // The current value of _tristar is represented by itself (_tristar)
            // or _tristar.Current.Value
            Plot("Tristar", "tristar", _tristar);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `Tristar` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TristarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Tristar _tristar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tristar = new Tristar();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _tristar.Update(bar);

        if (_tristar.IsReady)
        {
            // The current value of _tristar is represented by itself (_tristar)
            // or _tristar.Current.Value
            Plot("Tristar", "tristar", _tristar);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `Tristar` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class TristarAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private Tristar _tristar;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _tristar = CandlestickPatterns.Tristar(_symbol);

        var indicatorHistory = IndicatorHistory(_tristar, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_tristar, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_tristar, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Two Crows

Introduction

Create a new Two Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using TwoCrows Indicator

To create an automatic indicator for `TwoCrows` , call the `TwoCrows` helper method from the `QCAlgorithm` class. The `TwoCrows` method creates a `TwoCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class TwoCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TwoCrows _twoCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _twoCrows = CandlestickPatterns.TwoCrows(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_twoCrows.IsReady)
        {
            // The current value of _twoCrows is represented by itself (_twoCrows)
            // or _twoCrows.Current.Value
            Plot("TwoCrows", "twoCrows", _twoCrows);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `TwoCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class TwoCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TwoCrows _twoCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _twoCrows = new TwoCrows();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _twoCrows.Update(bar);

        if (_twoCrows.IsReady)
        {
            // The current value of _twoCrows is represented by itself (_twoCrows)
            // or _twoCrows.Current.Value
            Plot("TwoCrows", "twoCrows", _twoCrows);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `TwoCrows` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class TwoCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private TwoCrows _twoCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _twoCrows = CandlestickPatterns.TwoCrows(_symbol);

        var indicatorHistory = IndicatorHistory(_twoCrows, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_twoCrows, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_twoCrows, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Unique Three River

Introduction

Create a new Unique Three River candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UniqueThreeRiver Indicator

To create an automatic indicator for `UniqueThreeRiver` , call the `UniqueThreeRiver` helper method from the `QCAlgorithm` class. The `UniqueThreeRiver` method creates a `UniqueThreeRiver` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class UniqueThreeRiverAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UniqueThreeRiver _uniqueThreeRiver;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _uniqueThreeRiver = CandlestickPatterns.UniqueThreeRiver(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_uniqueThreeRiver.IsReady)
        {
            // The current value of _uniqueThreeRiver is represented by itself (_uniqueThreeRiver)
            // or _uniqueThreeRiver.Current.Value
            Plot("UniqueThreeRiver", "uniqueThreeRiver", _uniqueThreeRiver);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `UniqueThreeRiver` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class UniqueThreeRiverAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UniqueThreeRiver _uniqueThreeRiver;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _uniqueThreeRiver = new UniqueThreeRiver();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _uniqueThreeRiver.Update(bar);

        if (_uniqueThreeRiver.IsReady)
        {
            // The current value of _uniqueThreeRiver is represented by itself (_uniqueThreeRiver)
            // or _uniqueThreeRiver.Current.Value
            Plot("UniqueThreeRiver", "uniqueThreeRiver", _uniqueThreeRiver);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `UniqueThreeRiver` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class UniqueThreeRiverAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UniqueThreeRiver _uniqueThreeRiver;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _uniqueThreeRiver = CandlestickPatterns.UniqueThreeRiver(_symbol);

        var indicatorHistory = IndicatorHistory(_uniqueThreeRiver, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_uniqueThreeRiver, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_uniqueThreeRiver, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Up Down Gap Three Methods

Introduction

Create a new Up Down Gap Three Methods candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UpDownGapThreeMethods Indicator

To create an automatic indicator for `UpDownGapThreeMethods` , call the `UpDownGapThreeMethods` helper method from the `QCAlgorithm` class. The `UpDownGapThreeMethods` method creates a `UpDownGapThreeMethods` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class UpDownGapThreeMethodsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UpDownGapThreeMethods _upDownGapThreeMethods;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _upDownGapThreeMethods = CandlestickPatterns.UpDownGapThreeMethods(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_upDownGapThreeMethods.IsReady)
        {
            // The current value of _upDownGapThreeMethods is represented by itself (_upDownGapThreeMethods)
            // or _upDownGapThreeMethods.Current.Value
            Plot("UpDownGapThreeMethods", "upDownGapThreeMethods", _upDownGapThreeMethods);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `UpDownGapThreeMethods` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class UpDownGapThreeMethodsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UpDownGapThreeMethods _upDownGapThreeMethods;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _upDownGapThreeMethods = new UpDownGapThreeMethods();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _upDownGapThreeMethods.Update(bar);

        if (_upDownGapThreeMethods.IsReady)
        {
            // The current value of _upDownGapThreeMethods is represented by itself (_upDownGapThreeMethods)
            // or _upDownGapThreeMethods.Current.Value
            Plot("UpDownGapThreeMethods", "upDownGapThreeMethods", _upDownGapThreeMethods);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `UpDownGapThreeMethods` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class UpDownGapThreeMethodsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UpDownGapThreeMethods _upDownGapThreeMethods;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _upDownGapThreeMethods = CandlestickPatterns.UpDownGapThreeMethods(_symbol);

        var indicatorHistory = IndicatorHistory(_upDownGapThreeMethods, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_upDownGapThreeMethods, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_upDownGapThreeMethods, _symbol, new DateTime(2024, 7, 1),
new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Upside Gap Two Crows

Introduction

Create a new Upside Gap Two Crows candlestick pattern to indicate the pattern's presence.

To view the implementation of this candlestick pattern, see the LEAN GitHub repository .

Using UpsideGapTwoCrows Indicator

To create an automatic indicator for `UpsideGapTwoCrows` , call the `UpsideGapTwoCrows` helper method from the `QCAlgorithm` class. The `UpsideGapTwoCrows` method creates a `UpsideGapTwoCrows` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class UpsideGapTwoCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UpsideGapTwoCrows _upsideGapTwoCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _upsideGapTwoCrows = CandlestickPatterns.UpsideGapTwoCrows(_symbol);
    }

    public override void OnData(Slice data)
    {
        if (_upsideGapTwoCrows.IsReady)
        {
            // The current value of _upsideGapTwoCrows is represented by itself (_upsideGapTwoCrows)
            // or _upsideGapTwoCrows.Current.Value
            Plot("UpsideGapTwoCrows", "upsideGapTwoCrows", _upsideGapTwoCrows);
        }
    }
}
```

For more information about this method, see the CandlestickPatterns class .

You can manually create a `UpsideGapTwoCrows` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class UpsideGapTwoCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UpsideGapTwoCrows _upsideGapTwoCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _upsideGapTwoCrows = new UpsideGapTwoCrows();
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _upsideGapTwoCrows.Update(bar);

        if (_upsideGapTwoCrows.IsReady)
        {
            // The current value of _upsideGapTwoCrows is represented by itself (_upsideGapTwoCrows)
            // or _upsideGapTwoCrows.Current.Value
            Plot("UpsideGapTwoCrows", "upsideGapTwoCrows", _upsideGapTwoCrows);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `UpsideGapTwoCrows` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class UpsideGapTwoCrowsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private UpsideGapTwoCrows _upsideGapTwoCrows;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _upsideGapTwoCrows = CandlestickPatterns.UpsideGapTwoCrows(_symbol);

        var indicatorHistory = IndicatorHistory(_upsideGapTwoCrows, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_upsideGapTwoCrows, _symbol, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_upsideGapTwoCrows, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Absolute Price Oscillator

Introduction

This indicator computes the Absolute Price Oscillator (APO) The Absolute Price Oscillator is calculated using the following formula: APO[i] = FastMA[i] - SlowMA[i]

To view the implementation of this indicator, see the LEAN GitHub repository .

Using APO Indicator

To create an automatic indicator for `AbsolutePriceOscillator` , call the `APO` helper method from the `QCAlgorithm` class. The `APO` method creates a `AbsolutePriceOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AbsolutePriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AbsolutePriceOscillator _apo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _apo = APO(_symbol, 10, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_apo.IsReady)
        {
            // The current value of _apo is represented by itself (_apo)
            // or _apo.Current.Value
            Plot("AbsolutePriceOscillator", "apo", _apo);
            // Plot all properties of abands
            Plot("AbsolutePriceOscillator", "fast", _apo.Fast);
            Plot("AbsolutePriceOscillator", "slow", _apo.Slow);
            Plot("AbsolutePriceOscillator", "signal", _apo.Signal);
            Plot("AbsolutePriceOscillator", "histogram", _apo.Histogram);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AbsolutePriceOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```
C#
public class AbsolutePriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AbsolutePriceOscillator _absolutepriceoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _absolutepriceoscillator = new AbsolutePriceOscillator(10, 20, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _absolutepriceoscillator.Update(bar.EndTime, bar.Close);

        if (_absolutepriceoscillator.IsReady)
        {
            // The current value of _absolutepriceoscillator is represented by itself (_absolutepriceoscillator)
            // or _absolutepriceoscillator.Current.Value
            Plot("AbsolutePriceOscillator", "absolutepriceoscillator", _absolutepriceoscillator);
            // Plot all properties of abands
            Plot("AbsolutePriceOscillator", "fast", _absolutepriceoscillator.Fast);
            Plot("AbsolutePriceOscillator", "slow", _absolutepriceoscillator.Slow);
            Plot("AbsolutePriceOscillator", "signal", _absolutepriceoscillator.Signal);
            Plot("AbsolutePriceOscillator", "histogram", _absolutepriceoscillator.Histogram);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AbsolutePriceOscillator` indicator properties:

Indicator History

To get the historical data of the `AbsolutePriceOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security

subscription.

```C#
public class AbsolutePriceOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AbsolutePriceOscillator _apo;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _apo = APO(_symbol, 10, 20, MovingAverageType.Simple);

        var indicatorHistory = IndicatorHistory(_apo, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_apo, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_apo, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var fast = indicatorHistory.Select(x => ((dynamic)x).Fast).ToList();
        var slow = indicatorHistory.Select(x => ((dynamic)x).Slow).ToList();
        var signal = indicatorHistory.Select(x => ((dynamic)x).Signal).ToList();
        var histogram = indicatorHistory.Select(x => ((dynamic)x).Histogram).ToList();
    }
}
```

Supported Indicators

Acceleration Bands

Introduction

The Acceleration Bands created by Price Headley plots upper and lower envelope bands around a moving average.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ABANDS Indicator

To create an automatic indicator for `AccelerationBands` , call the `ABANDS` helper method from the `QCAlgorithm` class. The `ABANDS` method creates a `AccelerationBands` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class AccelerationBandsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccelerationBands _abands;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _abands = ABANDS(_symbol, 10, 4m, MovingAverageType.Simple);
    }

    public override void OnData(Slice data)
    {

        if (_abands.IsReady)
        {
            // The current value of _abands is represented by itself (_abands)
            // or _abands.Current.Value
            Plot("AccelerationBands", "abands", _abands);
            // Plot all properties of abands
            Plot("AccelerationBands", "middleband", _abands.MiddleBand);
            Plot("AccelerationBands", "upperband", _abands.UpperBand);
            Plot("AccelerationBands", "lowerband", _abands.LowerBand);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AccelerationBands` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AccelerationBandsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccelerationBands _accelerationbands;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _accelerationbands = new AccelerationBands(10, 4m, MovingAverageType.Simple);
    }

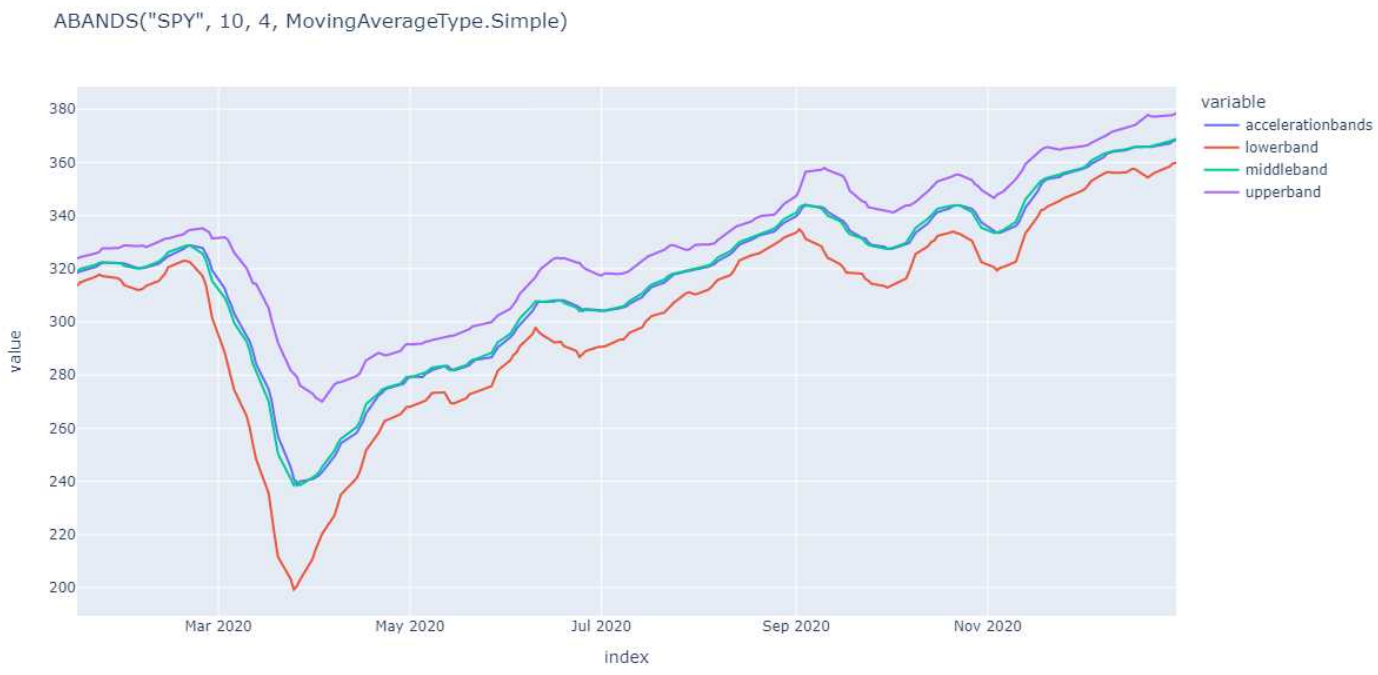
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _accelerationbands.Update(bar);

        if (_accelerationbands.IsReady)
        {
            // The current value of _accelerationbands is represented by itself (_accelerationbands)
            // or _accelerationbands.Current.Value
            Plot("AccelerationBands", "accelerationbands", _accelerationbands);
            // Plot all properties of abands
            Plot("AccelerationBands", "middleband", _accelerationbands.MiddleBand);
            Plot("AccelerationBands", "upperband", _accelerationbands.UpperBand);
            Plot("AccelerationBands", "lowerband", _accelerationbands.LowerBand);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AccelerationBands` indicator properties:



Indicator History

To get the historical data of the `AccelerationBands` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AccelerationBandsAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccelerationBands _abands;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _abands = ABANDS(_symbol, 10, 4m, MovingAverageType.Simple);

        var indicatorHistory = IndicatorHistory(_abands, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_abands, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_abands, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var middleBand = indicatorHistory.Select(x => ((dynamic)x).MiddleBand).ToList();
        var upperBand = indicatorHistory.Select(x => ((dynamic)x).UpperBand).ToList();
        var lowerBand = indicatorHistory.Select(x => ((dynamic)x).LowerBand).ToList();
    }
}
```

Supported Indicators

Accumulation Distribution

Introduction

This indicator computes the Accumulation/Distribution (AD) The Accumulation/Distribution is calculated using the following formula: AD = AD + ((Close - Low) - (High - Close)) / (High - Low) * Volume

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AD Indicator

To create an automatic indicator for `AccumulationDistribution` , call the `AD` helper method from the `QCAlgorithm` class. The `AD` method creates a `AccumulationDistribution` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class AccumulationDistributionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccumulationDistribution _ad;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ad = AD(_symbol);
    }

    public override void OnData(Slice data)
    {

        if (_ad.IsReady)
        {
            // The current value of _ad is represented by itself (_ad)
            // or _ad.Current.Value
            Plot("AccumulationDistribution", "ad", _ad);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AccumulationDistribution` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AccumulationDistributionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccumulationDistribution _accumulationdistribution;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _accumulationdistribution = new AccumulationDistribution();
    }

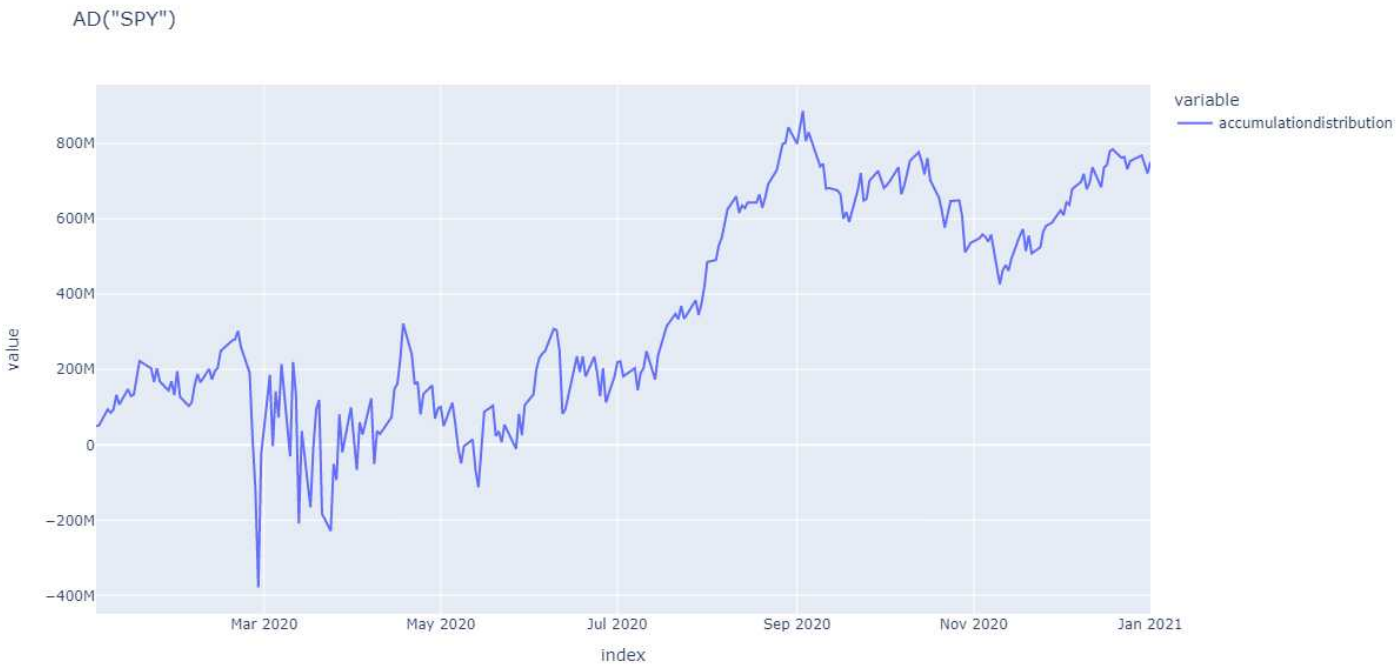
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _accumulationdistribution.Update(bar);

        if (_accumulationdistribution.IsReady)
        {
            // The current value of _accumulationdistribution is represented by itself (_accumulationdistribution)
            // or _accumulationdistribution.Current.Value
            Plot("AccumulationDistribution", "accumulationdistribution", _accumulationdistribution);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AccumulationDistribution` indicator properties:



Indicator History

To get the historical data of the `AccumulationDistribution` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AccumulationDistributionAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccumulationDistribution _ad;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _ad = AD(_symbol);

        var indicatorHistory = IndicatorHistory(_ad, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_ad, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_ad, _symbol, new DateTime(2024, 7, 1), new DateTime(2024,
7, 5), Resolution.Minute);
    }
}
```

Accumulation Distribution Oscillator

Introduction

This indicator computes the Accumulation/Distribution Oscillator (ADOSC) The Accumulation/Distribution Oscillator is calculated using the following formula: ADOSC = EMA(fast,AD) - EMA(slow,AD)

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADOSC Indicator

To create an automatic indicator for `AccumulationDistributionOscillator` , call the `ADOSC` helper method from the `QCAlgorithm` class. The `ADOSC` method creates a `AccumulationDistributionOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AccumulationDistributionOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccumulationDistributionOscillator _adosc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _adosc = ADOSC(_symbol, 10, 20);
    }

    public override void OnData(Slice data)
    {

        if (_adosc.IsReady)
        {
            // The current value of _adosc is represented by itself (_adosc)
            // or _adosc.Current.Value
            Plot("AccumulationDistributionOscillator", "adosc", _adosc);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AccumulationDistributionOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AccumulationDistributionOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccumulationDistributionOscillator _accumulationdistributionoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _accumulationdistributionoscillator = new AccumulationDistributionOscillator(10, 20);
    }

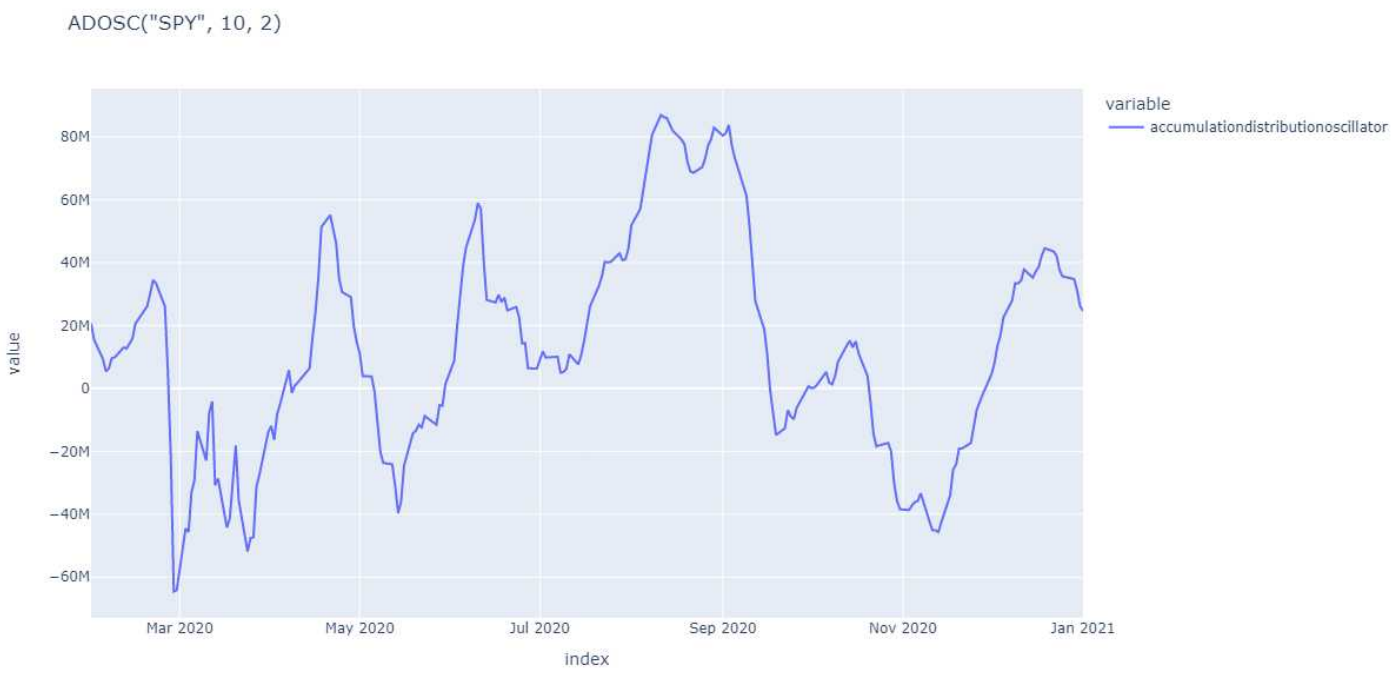
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _accumulationdistributionoscillator.Update(bar);

        if (_accumulationdistributionoscillator.IsReady)
        {
            // The current value of _accumulationdistributionoscillator is represented by itself
(_accumulationdistributionoscillator)
            // or _accumulationdistributionoscillator.Current.Value
            Plot("AccumulationDistributionOscillator", "accumulationdistributionoscillator",
_accumulationdistributionoscillator);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AccumulationDistributionOscillator` indicator properties:



Indicator History

To get the historical data of the `AccumulationDistributionOscillator` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AccumulationDistributionOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AccumulationDistributionOscillator _adosc;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _adosc = ADOSC(_symbol, 10, 20);

        var indicatorHistory = IndicatorHistory(_adosc, _symbol, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_adosc, _symbol, TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_adosc, _symbol, new DateTime(2024, 7, 1), new
DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Advance Decline Difference

Introduction

The Advance Decline Difference compute the difference between the number of stocks that closed higher and the number of stocks that closed lower than their previous day's closing prices.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADDIFF Indicator

To create an automatic indicator for `AdvanceDeclineDifference` , call the `ADDIFF` helper method from the `QCAlgorithm` class. The `ADDIFF` method creates a `AdvanceDeclineDifference` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class AdvanceDeclineDifferenceAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineDifference _addiff;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _addiff = ADDIFF([_symbol, _reference]);
    }

    public override void OnData(Slice data)
    {

        if (_addiff.IsReady)
        {
            // The current value of _addiff is represented by itself (_addiff)
            // or _addiff.Current.Value
            Plot("AdvanceDeclineDifference", "addiff", _addiff);
        }
    }
}
```

To create an automatic indicator for `AdvanceDeclineDifference` using universe constituents, call the `ADDIFF` helper method from the `QCAlgorithm` class. The `ADDIFF` method creates a `AdvanceDeclineDifference` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class AdvanceDeclineDifferenceAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private AdvanceDeclineDifference _addiff;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _addiff = ADDIFF(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_addiff.IsReady)
        {
            // The current value of _addiff is represented by itself (_addiff)
            // or _addiff.Current.Value
            Plot("AdvanceDeclineDifference", "addiff", _addiff);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AdvanceDeclineDifference` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AdvanceDeclineDifferenceAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineDifference _advancedeclinedifference;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _advancedeclinedifference = new AdvanceDeclineDifference();
        _advancedeclinedifference.Add(_symbol);
        _advancedeclinedifference.Add(_reference);
    }

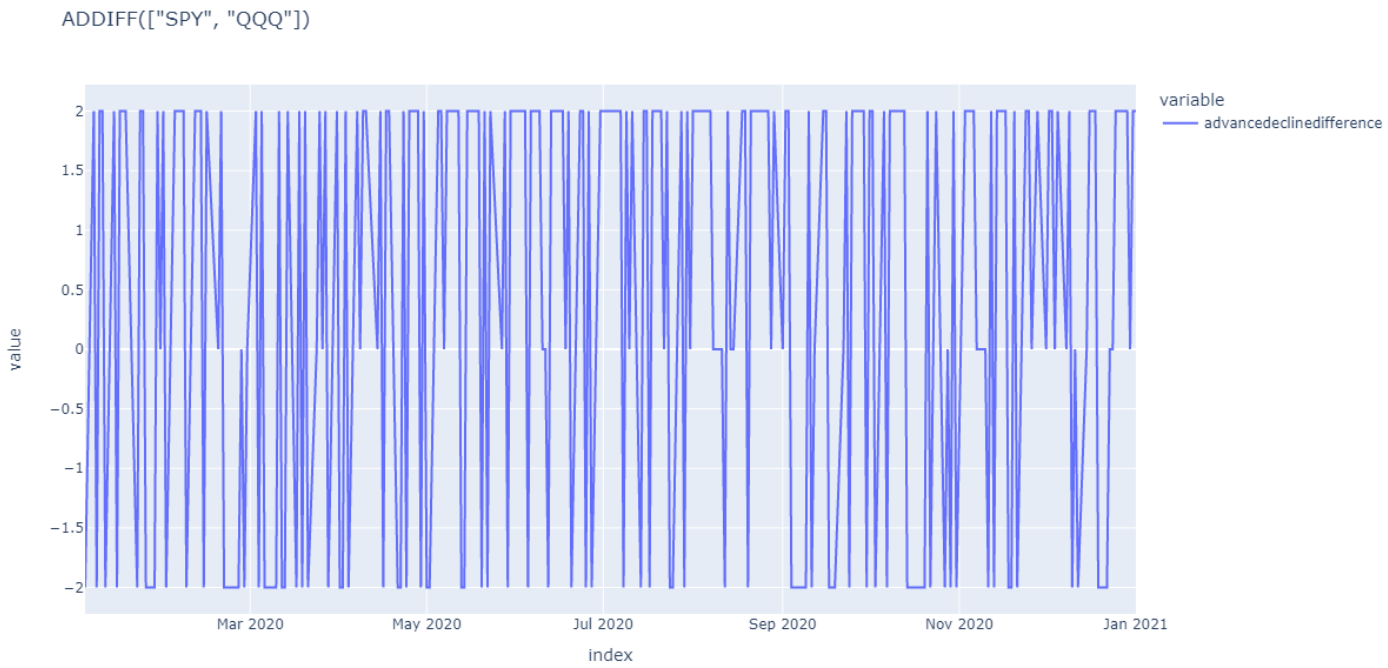
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _advancedeclinedifference.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _advancedeclinedifference.Update(bar);

        if (_advancedeclinedifference.IsReady)
        {
            // The current value of _advancedeclinedifference is represented by itself (_advancedeclinedifference)
            // or _advancedeclinedifference.Current.Value
            Plot("AdvanceDeclineDifference", "advancedeclinedifference", _advancedeclinedifference);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AdvanceDeclineDifference` indicator properties:



Indicator History

To get the historical data of the `AdvanceDeclineDifference` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AdvanceDeclineDifferenceAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineDifference _addiff;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _addiff = ADDIFF([_symbol, _reference]);

        var indicatorHistory = IndicatorHistory(_addiff, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_addiff, new[] { _symbol, _reference },
TimeSpan.FromDays(10), Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_addiff, new[] { _symbol, _reference }, new DateTime(2024,
7, 1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Advance Decline Ratio

Introduction

The advance-decline ratio (ADR) compares the number of stocks that closed higher against the number of stocks that closed lower than their previous day's closing prices.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADR Indicator

To create an automatic indicator for `AdvanceDeclineRatio` , call the `ADR` helper method from the `QCAlgorithm` class. The `ADR` method creates a `AdvanceDeclineRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class AdvanceDeclineRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineRatio _adr;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _adr = ADR(_symbol, _reference);
    }

    public override void OnData(Slice data)
    {

        if (_adr.IsReady)
        {
            // The current value of _adr is represented by itself (_adr)
            // or _adr.Current.Value
            Plot("AdvanceDeclineRatio", "adr", _adr);
        }
    }
}
```

To create an automatic indicator for `AdvanceDeclineRatio` using universe constituents, call the `ADR` helper method from the `QCAlgorithm` class. The `ADR` method creates a `AdvanceDeclineRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class AdvanceDeclineRatioAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private AdvanceDeclineRatio _adr;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _adr = ADR(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_adr.IsReady)
        {
            // The current value of _adr is represented by itself (_adr)
            // or _adr.Current.Value
            Plot("AdvanceDeclineRatio", "adr", _adr);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AdvanceDeclineRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AdvanceDeclineRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineRatio _advancedeclineratio;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _advancedeclineratio = new AdvanceDeclineRatio();
        _advancedeclineratio.Add(_symbol);
        _advancedeclineratio.Add(_reference);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _advancedeclineratio.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _advancedeclineratio.Update(bar);

        if (_advancedeclineratio.IsReady)
        {
            // The current value of _advancedeclineratio is represented by itself (_advancedeclineratio)
            // or _advancedeclineratio.Current.Value
            Plot("AdvanceDeclineRatio", "advancedeclineratio", _advancedeclineratio);
        }
    }
}
```

For more information about this indicator, see its reference .

Indicator History

To get the historical data of the `AdvanceDeclineRatio` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class AdvanceDeclineRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineRatio _adr;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _adr = ADR([_symbol, _reference]);

        var indicatorHistory = IndicatorHistory(_adr, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_adr, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_adr, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Advance Decline Volume Ratio

Introduction

The Advance Decline Volume Ratio is a Breadth indicator calculated as ratio of summary volume of advancing stocks to summary volume of declining stocks. AD Volume Ratio is used in technical analysis to see where the main trading activity is focused.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ADVR Indicator

To create an automatic indicator for `AdvanceDeclineVolumeRatio` , call the `ADVR` helper method from the `QCAlgorithm` class. The `ADVR` method creates a `AdvanceDeclineVolumeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class AdvanceDeclineVolumeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineVolumeRatio _advr;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _advr = ADVR([_symbol, _reference]);
    }

    public override void OnData(Slice data)
    {

        if (_advr.IsReady)
        {
            // The current value of _advr is represented by itself (_advr)
            // or _advr.Current.Value
            Plot("AdvanceDeclineVolumeRatio", "advr", _advr);
        }
    }
}
```

To create an automatic indicator for `AdvanceDeclineVolumeRatio` using universe constituents, call the `ADVR` helper method from the `QCAlgorithm` class. The `ADVR` method creates a `AdvanceDeclineVolumeRatio` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class AdvanceDeclineVolumeRatioAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private AdvanceDeclineVolumeRatio _advr;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _advr = ADVR(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_advr.IsReady)
        {
            // The current value of _advr is represented by itself (_advr)
            // or _advr.Current.Value
            Plot("AdvanceDeclineVolumeRatio", "advr", _advr);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AdvanceDeclineVolumeRatio` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AdvanceDeclineVolumeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineVolumeRatio _advancedeclinevolumeratio;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _advancedeclinevolumeratio = new AdvanceDeclineVolumeRatio();
        _advancedeclinevolumeratio.Add(_symbol);
        _advancedeclinevolumeratio.Add(_reference);
    }

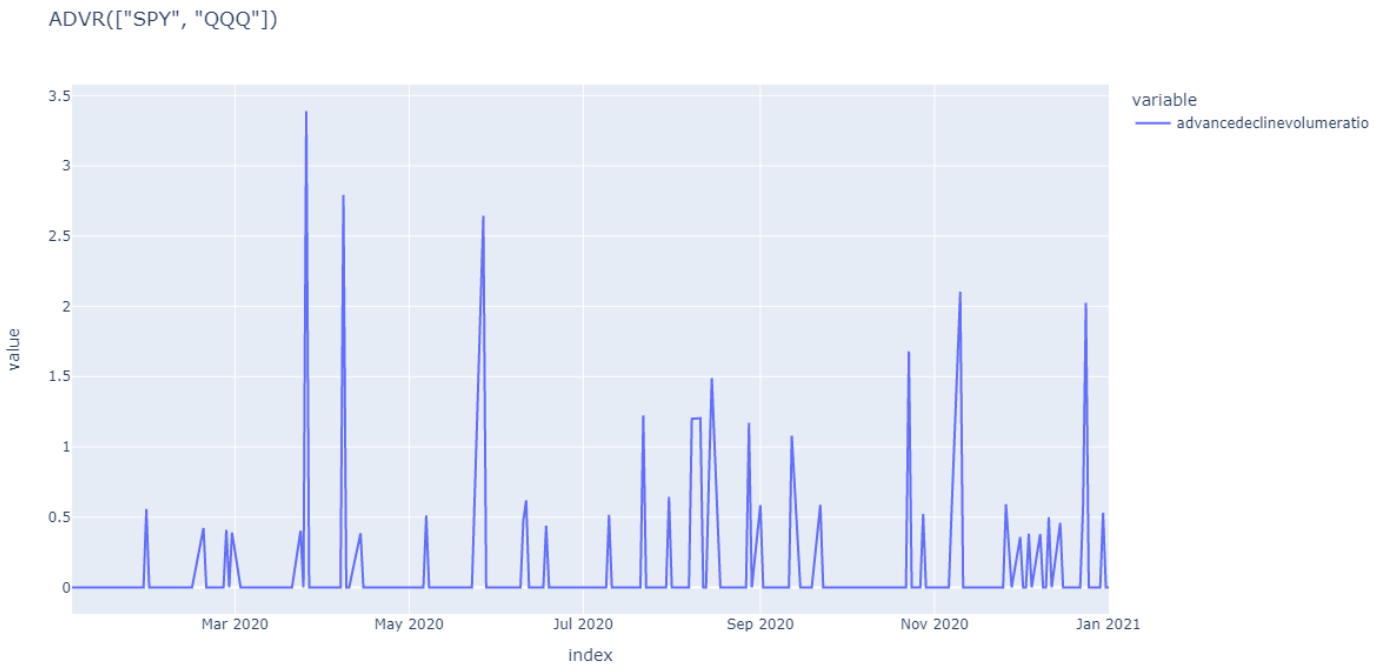
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _advancedeclinevolumeratio.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _advancedeclinevolumeratio.Update(bar);

        if (_advancedeclinevolumeratio.IsReady)
        {
            // The current value of _advancedeclinevolumeratio is represented by itself (_advancedeclinevolumeratio)
            // or _advancedeclinevolumeratio.Current.Value
            Plot("AdvanceDeclineVolumeRatio", "advancedeclinevolumeratio", _advancedeclinevolumeratio);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `AdvanceDeclineVolumeRatio` indicator properties:



Indicator History

To get the historical data of the `AdvanceDeclineVolumeRatio` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```C#
public class AdvanceDeclineVolumeRatioAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private AdvanceDeclineVolumeRatio _advr;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _advr = ADVR([_symbol, _reference]);

        var indicatorHistory = IndicatorHistory(_advr, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_advr, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_advr, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Alpha

Introduction

In financial analysis, the Alpha indicator is used to measure the performance of an investment (such as a stock or ETF) relative to a benchmark index, often representing the broader market. Alpha indicates the excess return of the investment compared to the return of the benchmark index. The S P 500 index is frequently used as a benchmark in Alpha calculations to represent the overall market performance. Alpha is an essential tool for investors to understand the idiosyncratic returns of their investment that aren't caused by movement in the underlying benchmark.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using A Indicator

To create an automatic indicator for `Alpha` , call the `A` helper method from the `QCAlgorithm` class. The `A` method creates a `Alpha` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AlphaAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Alpha _a;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _a = A(_symbol, _reference, 20);
    }

    public override void OnData(Slice data)
    {

        if (_a.IsReady)
        {
            // The current value of _a is represented by itself (_a)
            // or _a.Current.Value
            Plot("Alpha", "a", _a);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `Alpha` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AlphaAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Alpha _alpha;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _alpha = new Alpha(_symbol, _reference, 20);
    }

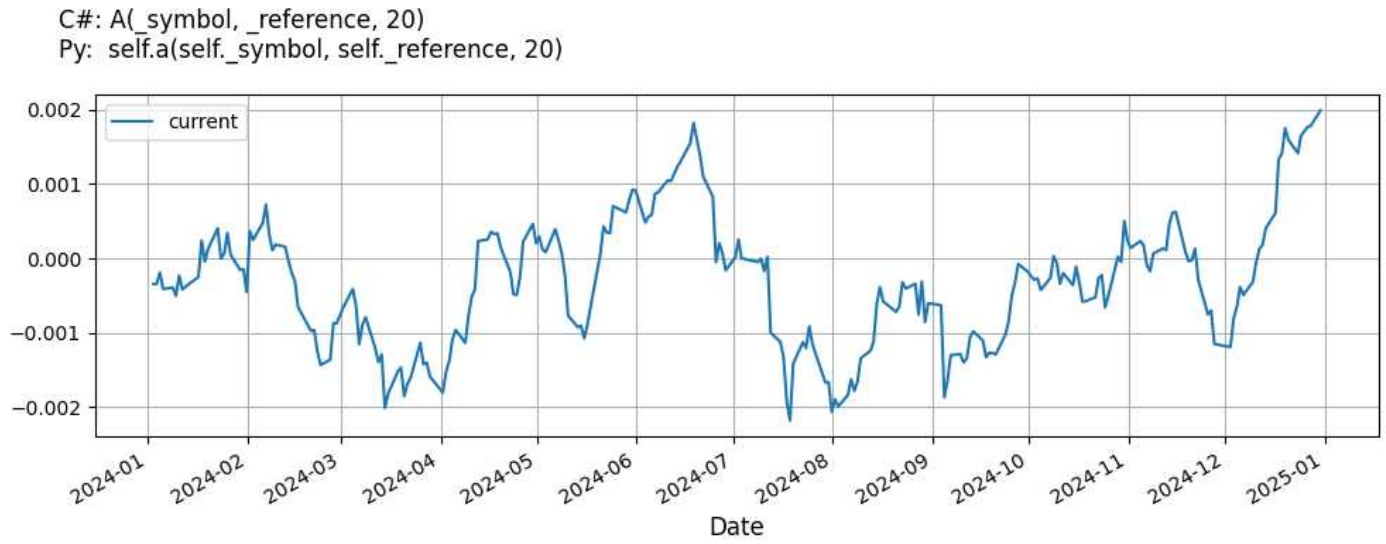
    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _alpha.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _alpha.Update(bar);

        if (_alpha.IsReady)
        {
            // The current value of _alpha is represented by itself (_alpha)
            // or _alpha.Current.Value
            Plot("Alpha", "alpha", _alpha);
        }
    }
}
```

For more information about this indicator, see its reference .

Visualization

The following plot shows values for some of the `Alpha` indicator properties:



Indicator History

To get the historical data of the `Alpha` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the `IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

C#

```
public class AlphaAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private Alpha _a;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _a = A(_symbol, _reference, 20);

        var indicatorHistory = IndicatorHistory(_a, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_a, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_a, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);
    }
}
```

Supported Indicators

Arms Index

Introduction

The Arms Index, also called the Short-Term Trading Index (TRIN) is a technical analysis indicator that compares the number of advancing and declining stocks (AD Ratio) to advancing and declining volume (AD volume).

To view the implementation of this indicator, see the LEAN GitHub repository .

Using TRIN Indicator

To create an automatic indicator for `ArmsIndex` , call the `TRIN` helper method from the `QCAlgorithm` class. The `TRIN` method creates a `ArmsIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```
C#
public class ArmsIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private ArmsIndex _trin;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _trin = TRIN([_symbol, _reference]);
    }

    public override void OnData(Slice data)
    {

        if (_trin.IsReady)
        {
            // The current value of _trin is represented by itself (_trin)
            // or _trin.Current.Value
            Plot("ArmsIndex", "trin", _trin);
            // Plot all properties of abands
            Plot("ArmsIndex", "adratio", _trin.ADRatio);
            Plot("ArmsIndex", "advratio", _trin.ADVRatio);
        }
    }
}
```

To create an automatic indicator for `ArmsIndex` using universe constituents, call the `TRIN` helper method from the `QCAlgorithm` class. The `TRIN` method creates a `ArmsIndex` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In this case, you should call the helper method in the `OnSecuritiesChanged` method.

```C#
public class ArmsIndexAlgorithm : QCAlgorithm
{
    private Universe _universe;
    private ArmsIndex _trin;

    public override void Initialize()
    {
        SetStartDate(2024,1,1);
        SetEndDate(2024,12,31);
        UniverseSettings.Resolution = Resolution.Daily;
        UniverseSettings.Schedule.On(DateRules.MonthStart());
        _universe = AddUniverse(Universe.ETF("SPY"));
    }

    public override void OnSecuritiesChanged(SecurityChanges changes)
    {
        _trin = TRIN(_universe.Selected);
    }

    public override void OnData(Slice data)
    {

        if (_trin.IsReady)
        {
            // The current value of _trin is represented by itself (_trin)
            // or _trin.Current.Value
            Plot("ArmsIndex", "trin", _trin);
            // Plot all properties of abands
            Plot("ArmsIndex", "adratio", _trin.ADRatio);
            Plot("ArmsIndex", "advratio", _trin.ADVRatio);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ArmsIndex` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ArmsIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private ArmsIndex _armsindex;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _armsindex = new ArmsIndex();
        _armsindex.Add(_symbol);
        _armsindex.Add(_reference);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _armsindex.Update(bar);
        if (data.Bars.TryGetValue(_reference, out bar))
            _armsindex.Update(bar);

        if (_armsindex.IsReady)
        {
            // The current value of _armsindex is represented by itself (_armsindex)
            // or _armsindex.Current.Value
            Plot("ArmsIndex", "armsindex", _armsindex);
            // Plot all properties of abands
            Plot("ArmsIndex", "adratio", _armsindex.ADRatio);
            Plot("ArmsIndex", "advratio", _armsindex.ADVRatio);
        }
    }
}
```

For more information about this indicator, see its reference .

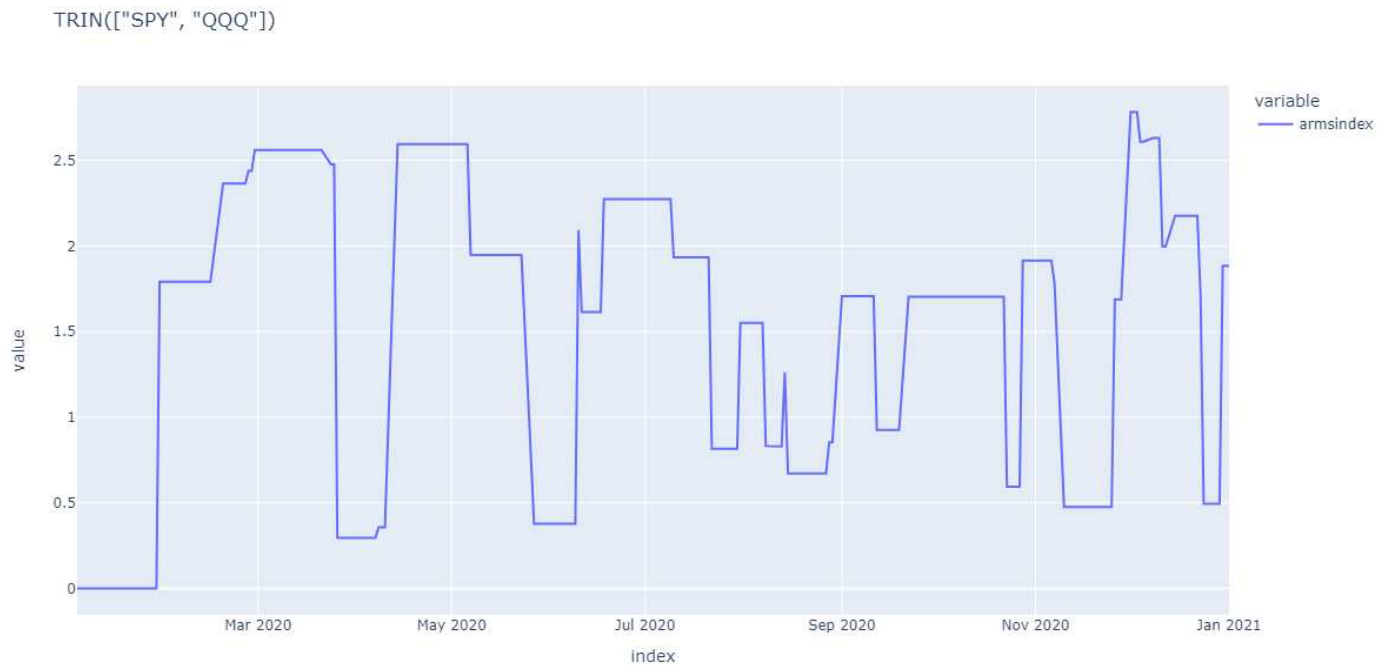
The following plot shows values for some of the `ArmsIndex` indicator properties:



Indicator History

To get the historical data of the `ArmsIndex` indicator, call the `IndicatorHistory` method. This method resets your indicator, makes a history request , and updates the indicator with the historical data. Just like with regular history requests, the

`IndicatorHistory` method supports time periods based on a trailing number of bars, a trailing period of time, or a defined period of time. If you don't provide a `resolution` argument, it defaults to match the resolution of the security subscription.

```
C#
public class ArmsIndexAlgorithm : QCAlgorithm
{
    private Symbol _symbol,_reference;
    private ArmsIndex _trin;

    public override void Initialize()
    {
        _symbol = AddEquity("QQQ", Resolution.Daily).Symbol;
        _reference = AddEquity("SPY", Resolution.Daily).Symbol;
        _trin = TRIN([_symbol, _reference]);

        var indicatorHistory = IndicatorHistory(_trin, new[] { _symbol, _reference }, 100, Resolution.Minute);
        var timeSpanIndicatorHistory = IndicatorHistory(_trin, new[] { _symbol, _reference }, TimeSpan.FromDays(10),
Resolution.Minute);
        var timePeriodIndicatorHistory = IndicatorHistory(_trin, new[] { _symbol, _reference }, new DateTime(2024, 7,
1), new DateTime(2024, 7, 5), Resolution.Minute);

        // Access all attributes of indicatorHistory
        var aDRatio = indicatorHistory.Select(x => ((dynamic)x).ADRatio).ToList();
        var aDVRatio = indicatorHistory.Select(x => ((dynamic)x).ADVRatio).ToList();
    }
}
```

Supported Indicators

Arnaud Legoux Moving Average

Introduction

Smooth and high sensitive moving Average. This moving average reduce lag of the information but still being smooth to reduce noises. Is a weighted moving average, which weights have a Normal shape; the parameters Sigma and Offset affect the kurtosis and skewness of the weights respectively. source

To view the implementation of this indicator, see the LEAN GitHub repository .

Using ALMA Indicator

To create an automatic indicator for `ArnaudLegouxMovingAverage` , call the `ALMA` helper method from the `QCAlgorithm` class. The `ALMA` method creates a `ArnaudLegouxMovingAverage` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

C#

```
public class ArnaudLegouxMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ArnaudLegouxMovingAverage _alma;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _alma = ALMA(_symbol, 10, 6, 0.85m);
    }

    public override void OnData(Slice data)
    {

        if (_alma.IsReady)
        {
            // The current value of _alma is represented by itself (_alma)
            // or _alma.Current.Value
            Plot("ArnaudLegouxMovingAverage", "alma", _alma);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `ArnaudLegouxMovingAverage` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class ArnaudLegouxMovingAverageAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private ArnaudLegouxMovingAverage _arnaudlegouxmovingaverage;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _arnaudlegouxmovingaverage = new ArnaudLegouxMovingAverage(10, 6, 0.85m);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _arnaudlegouxmovingaverage.Update(bar.EndTime, bar.Close);

        if (_arnaudlegouxmovingaverage.IsReady)
        {
            // The current value of _arnaudlegouxmovingaverage is represented by itself (_arnaudlegouxmovingaverage)
            // or _arnaudlegouxmovingaverage.Current.Value
            Plot("ArnaudLegouxMovingAverage", "arnaudlegouxmovingaverage", _arnaudlegouxmovingaverage);
        }
    }
}
```

For more information about this indicator, see its reference .

Supported Indicators

Aroon Oscillator

Introduction

The Aroon Oscillator is the difference between AroonUp and AroonDown. The value of this indicator fluctuates between -100 and +100. An upward trend bias is present when the oscillator is positive, and a negative trend bias is present when the oscillator is negative. AroonUp/Down values over 75 identify strong trends in their respective direction.

To view the implementation of this indicator, see the LEAN GitHub repository .

Using AROON Indicator

To create an automatic indicator for `AroonOscillator` , call the `AROON` helper method from the `QCAlgorithm` class. The `AROON` method creates a `AroonOscillator` object, hooks it up for automatic updates, and returns it so you can used it in your algorithm. In most cases, you should call the helper method in the `Initialize` method.

```C#
public class AroonOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AroonOscillator _aroon;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _aroon = AROON(_symbol, 10, 20);
    }

    public override void OnData(Slice data)
    {

        if (_aroon.IsReady)
        {
            // The current value of _aroon is represented by itself (_aroon)
            // or _aroon.Current.Value
            Plot("AroonOscillator", "aroon", _aroon);
            // Plot all properties of abands
            Plot("AroonOscillator", "aroonup", _aroon.AroonUp);
            Plot("AroonOscillator", "aroondown", _aroon.AroonDown);
        }
    }
}
```

For more information about this method, see the QCAlgorithm class .

You can manually create a `AroonOscillator` indicator, so it doesn't automatically update. Manual indicators let you update their values with any data you choose.

Updating your indicator manually enables you to control when the indicator is updated and what data you use to update it. To manually update the indicator, call the `Update` method. The indicator will only be ready after you prime it with enough data.

```C#
public class AroonOscillatorAlgorithm : QCAlgorithm
{
    private Symbol _symbol;
    private AroonOscillator _aroonoscillator;

    public override void Initialize()
    {
        _symbol = AddEquity("SPY", Resolution.Daily).Symbol;
        _aroonoscillator = new AroonOscillator(10, 20);
    }

    public override void OnData(Slice data)
    {
        if (data.Bars.TryGetValue(_symbol, out var bar))
            _aroonoscillator.Update(bar);

        if (_aroonoscillator.IsReady)
        {
            // The current value of _aroonoscillator is represented by itself (_aroonoscillator)
            // or _aroonoscillator.Current.Value
            Plot("AroonOscillator", "aroonoscillator", _aroonoscillator);
            // Plot all properties of abands
            Plot("AroonOscillator", "aroonup", _aroonoscillator.AroonUp);
            Plot("AroonOscillator", "aroondown", _aroonoscillator.AroonDown);
        }
    }
}
```

For more information about this indicator, see its reference .
